2) Whiteboard function: The purpose of using this function is to provide a collaborative environment for students and teachers. They can write messages in text format and draw lines on a shared whiteboard environment in real time. When they want a message or line, they must select tools by dragging and dropping them on the whiteboard. They can also delete objects by pressing the delete key on the keyboard. Students can write or erase any items at any time they want. Students and teachers have equal authority in this classroom.

3) Presentation function: This function allows creating a presentation in SWF format. This function contains two modes. The first mode is the teacher mode. The teacher can fully control the presentation. Students can see the same presentation frame simultaneously. The second mode is the student mode. Students can navigate the presentation by using next and back buttons in order to view the presentation. They are not allowed to control the presentation that the teacher is using. The presentation function requires an SWF presentation file.

4) Chat function: This function supports teacher and students for chatting in regular text format. They can send message to their friends in the same classroom. Text can be selected in different styles.

5) List of learners: This function displays teacher and student names that are logged into the classroom. All usernames appear on the list in the classroom and are used to identify who they are.

6) Audio/Video presentation function: This is very important function for providing face to face communication. A VDO camera and microphone are essential for this function. The teacher and his/her students can send and receive audio and video within the same classroom. If someone is sending audio or video or both, the other people in the classroom can see and hear it.

D. *Web-Based Collaborative Work*

The web-based collaborative application was developed using a wiki-style, WikkaWiki [11]. It provides several features such as a workspace, comment tool, chat room, and e-mail. Teachers and students can communicate with each other by editing text messages in the workspace. Teachers can assign tasks in the teacher's workspace and students can put the solutions to such tasks in their own workspace. Teachers can post a comment to the students or students can communicate with teacher or their colleagues using the comment tool. A chat room is also provided for them to communicate with each other in real-time. An e-mail system is provided to them for sending and receiving e-mails more smoothly and conveniently.

IV. Supporting Technologies

A. *Overview for Flash Media Server Architecture*

The Macromedia Flash Media Server (FMS) platform consists of two parts: the server, which provides the means of communication, and the Macromedia Flash Player. Applications consist of a client Macromedia Flash Movie (SWF file) that is run by the Flash Player. Server components are shared with all clients. The server component minimally consists of an application folder that we have created on the server side running the Flash Media Server. This folder can optionally contain Server-Side Communication ActionScript (ASC) files and other resource files used by the communication application. The server and the Flash client application communicate over a persistent connection using the Real-Time Message Protocol (RTMP). In a typical scenario, the Flash client is delivered to the Flash Player by a web server over HTTP. The Flash client then establishes a persistent connection to the Flash Media Server using RTMP, allowing for an uninterrupted data stream to flow between the client and the server [9], [22]. The RTMP protocol of communication for Streaming media is shown in Fig. 3.

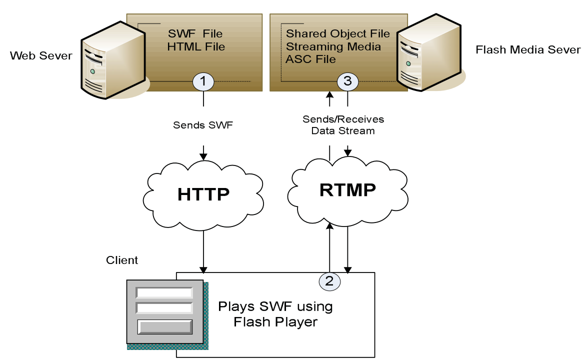

Figure 3. Flash media server provides a RTMP protocol of communication for Streaming media for client.

B. *RTMP*

The Real-Time Messaging Protocol (RTMP) is a protocol for client-server communication. It is a proprietary protocol developed by Adobe Systems (formerly developed by Macromedia) that is primarily used with the Macromedia Flash Media Server to stream audio and video over the internet to the Flash Player client, but can also be used for general remote procedure calls (RPC). RTMP is basically a TCP/IP protocol designed for high-performance transmission of audio, video, and data messages [14].

C. *Client-Server Connection Flow*

When the client connects to the server, the server calls the application start method to run. Next, the server-side will make and hold the connection. The logic in this method determines whether to accept or reject the connection. Back on the client side, the "on status" handler is called to report whether the connection was accepted or rejected. When the client closes the connection, the server-side disconnects and closes the session [1]. The connection flow between clients the server is shown in Fig. 4.

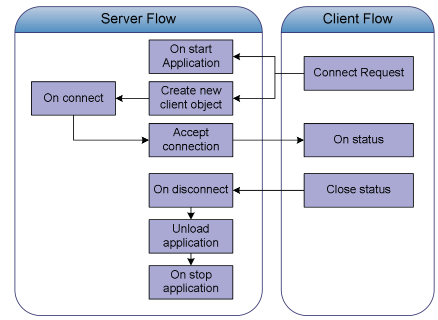

Figure 4. Connection flow between clients and server using RTMP protocol.

D. *Shared Objects*

Remote shared objects are managed by the Flash Media Server. The server provides messaging, data synchronization, and data storage services. Flash clients connect or subscribe to a remote shared object and receive updates whenever a change is made to that shared object. Also, messages can be sent to all clients connected to a remote shared object. A remote shared object can persist across application sessions, or be temporary [1]. The shared objects provide data storage and synchronization services for clients are shown in fig. 5.

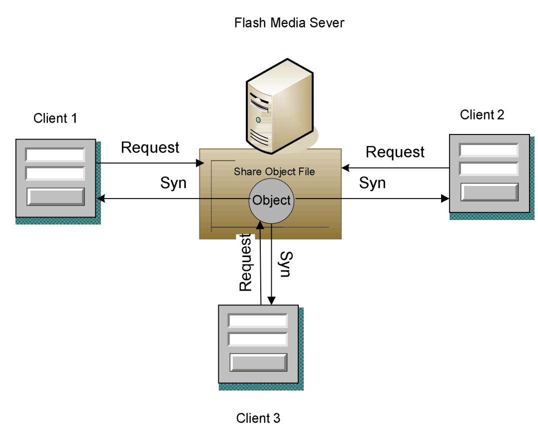

Figure 5. Shared objects provide data storage and synchronization services for clients.

E. *A Lightweight Wiki Engine*

The web-based collaborative application was developed using a wiki-style, WikkaWiki[11]. WikkaWiki is a lightweight wiki engine written in PHP, which uses MySQL to store pages. It can be easily extended or adapted for many different uses. By setting the appropriate access privileges and using appropriate actions, the user can turn WikkaWiki into different applications, tailored to user needs. The traditional idea behind the concept of a wiki is to create a digital blackboard on which any user, either registered or anonymous, can write modifications and add comments. WikkaWiki can be used as a public wiki, discussion forum, blog, invisible backend for a personal website, intranet CMS, personal organizer and memory support, presentation framework, community-maintained user manual, and etc.

V. IMPLEMENTATION

A. Participants

Thirty undergraduate students who registered in the multimedia course in the computer engineering department at Siam University were recruited to participate in the virtual classroom on the Internet application for a semester which lasts for four months. The teacher and students use a virtual interactive classroom on the Internet instead of using a traditional classroom for learning and teaching.

B. Virtual Interactive Classroom and Web-based Collaborative Work

1) A Virtual Interactive Classroom: We installed the virtual classroom as an Internet application on a streaming web server. A Flash media server and IIS must also be installed on the server. We tested the application and corrected the bugs in the application for two months before it was ready. The client side must contain the flash player application in order to display flash movies correctly. The experiment is set up and run on a windows platform. Fig. 6 shows a screenshot of a user login web page. A student and teacher must login with the correct username and password to enter virtual classroom. In the classroom, they are allowed to use shared objects or resources. Fig. 7 shows a screenshot of a virtual interactive classroom. The classroom has four main portions: 1) the picture screens for the teacher and students, 2) a workspace, 3) a list of people screen, and 4) a real-time chat screen. In this virtual classroom, the teacher has the full authority to control all kinds of things such as a white board, presentation, chat, and audio/video presence by clicking on a menu item above the workspace. For example, the teacher can just click on the presentation button to control the powerpoint slideshows. The students cannot edit any contents of the slideshows. Next, the teacher clicks on the whiteboard button to change the workspace to a shared whiteboard. This feature allows anyone in the classroom to edit text messages or draw a picture on the whiteboard. The VDO feature is used in two aspects. First, the teacher clicks on the VDO button to select the VDO file in the computer and play it. Second, the students click on the VDO button to record what their teacher is teaching. Moreover, the teacher can talk to the students and/or the students can also talk to their friends in the classroom through a microphone. The teacher can mute the voice of any students by clicking on the mute button. Using a web camera, they have access to a large amount of information about one another. The students can observe how their friends feel physically and emotionally. Both teacher and students can enter a web-based collaborative work by clicking on the Collabwork button. Fig. 8 shows a screenshot of a whiteboard function.

Figure 6. A screenshot of a user login web page.

Figure 7. A screenshot of a virtual interactive classroom application.

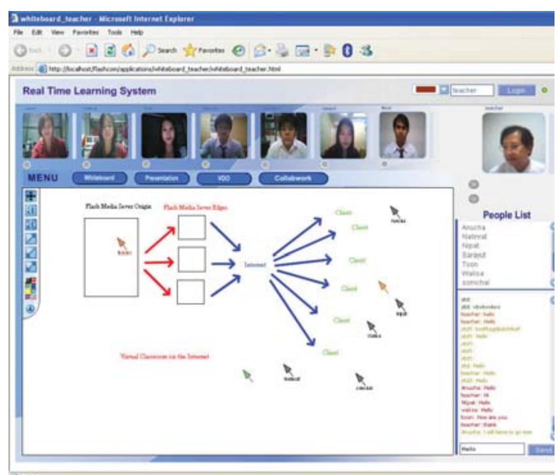

Figure 8. A screenshot of a whiteboard function.

2) A Web-based Collaborative Work: A web-based collaborative work capability was installed on a web server. It was created for a teacher who taught a multimedia course and used it for managing tasks or assignments for the students. The teacher posted a task every week on a teacher's workspace.

The students were arranged into teams to solve the given task. Using a web-based collaborative application, the students can collaborate or help each other to solve the given task, share the resources and materials, and generate additional ideas through the student's workspace and in the comment area. In addition to the task assignment and problem solving, the teacher can use this tool to monitor the progress of the given task and the student's behavior during an online collaborative work. The screenshots of the web-based collaborative work application are shown in fig. 9, 10, and 11.

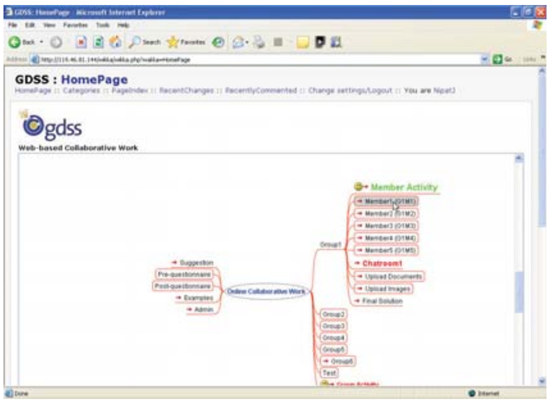

Figure 9. A screenshot of a web-based collaborative work homepage.

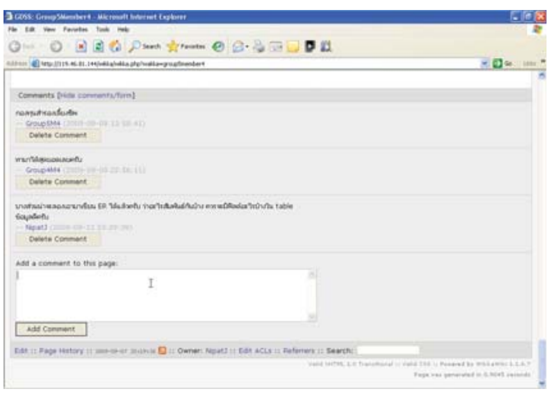

Figure 10 A screenshot of a comment tool in a web-based collaborative application.

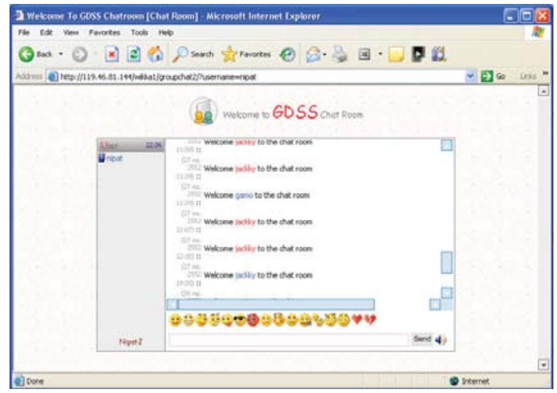

Figure 11 A screenshot of achat room in a web-based collaborative application.

VI. Conclusion and Future Work

This article presents the potential of integrating two concepts, namely those of a virtual interactive classroom and a web-based collaborative work application in order to enhance teaching and learning performance in distance learning. In addition to the concepts, the framework has been designed and implemented. The virtual interactive classrooms and the web-based collaborative work application work well according to their predefined functions. They can work as a substitute for any classroom in the school. With the use of computers and information technologies, the barriers of space and time can be eliminated. This virtual interactive classroom is an opportunity for a number of students in rural areas with homes that are far away from a school. They have a chance to study and communicate with the teacher and other students. We do not mean to imply that by using this virtual interactive classroom on the internet that it is better than the real classroom in the school but it is a choice in order to move schools closer to students who lack of the opportunity of physically attending a school. We want the virtual interactive classrooms on the internet to be one standard feature of several possible features for e-learning or distance learning.

In future research, based on this study, we intend to summarize the feedback received from teachers and students and take the results and recommendations obtained from the experiment into the consideration for improving the quality of the virtual interactive classroom and web-based collaborative work application in the future.

How Can Apache Help to Teach And Learn Automatic Control?

Teresa Alvarez, David Herrero, Jesús Francisco, David Madrigal
Dpt. Automatic Control
University of Valladolid
Valladolid, Spain
tere@autom.uva.es

Abstract— **Searching for examples to encourage and motivate students in a subject is not a trivial task. Future Computer Science and Telecommunications Engineers tend to look at Automatic Control reluctantly. They do not relate their working life to it. But, if we blend examples from two areas: telecommunications and control, maybe we can change their minds. These engineers work with web servers: systems that deal with a lot of requests and must give fast and reliable service to users. CPU and memory usage could improve their performance if automatic control techniques are applied. Apache is one of the most well known web servers and it is at this point where Apache can help us.**

Web server; Apache; Automatic Control; Internet server; PID; predictive control.

I. Introduction

Automatic control combines concepts and ideas from Mathematics and Engineering. There are many different techniques that allow real systems to be controlled. For instance, we can apply control techniques to ensure that a reactor does not reach a critical point, or we can control an airplane velocity or altitude.

Future Computer Science and Telecommunications Engineers (in Spain) learn about Communications Networks and Internet and they also learn automatic control techniques. It is sometimes difficult to find systems that appeal to them from both sides: communications and control. Most control books present electrical or mechanical examples. Rerefence [1] is the only textbook that gives examples of computing systems and how control techniques can improve their performance.

Apache ([2]) is a web server developed and maintained by the contributors to the Apache Software Foundation. There are variables that are critical for the right performance. As presented in [3], we can apply automatic control techniques to achieve better server performance. It should be decided which variables will act as inputs or manipulated variables and which variables will be the outputs or controlled variables. The work in [3] is used as reference. We aimed to design a tool that could be used in the classroom and act as a pool of control techniques to experiment and compare results.

CONAPA (CONtrolling APAche) is the user's tool. It has been developed taking into account that it should be easy to use. There are different working options:

- Monitoring tool: the user watches the system's evolution.
- Simulation tool: the user can simulate the system under different situations.
- Real-time control: the user defines the controller parameters and the real web server works following the controller calculations.

It works both as an online and as a virtual laboratory. Data can be saved and loaded in different programs to analyze results. This application manages the data capture for identification purposes, the simulation environment and the control of the real system.

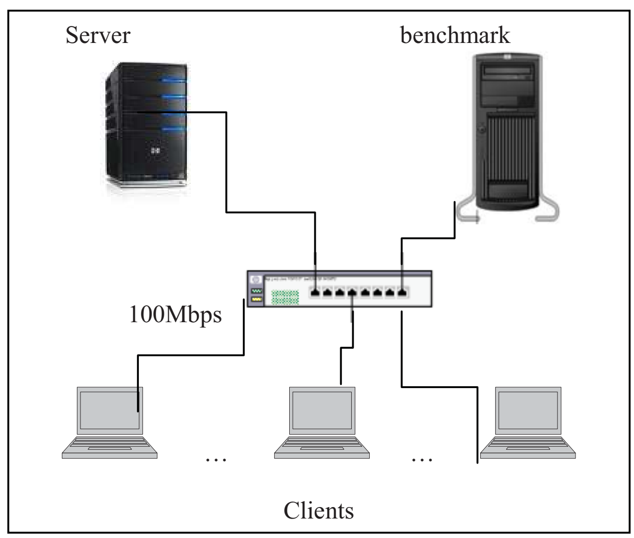

Figure 1. Working environment

The following sections describe our work. We have followed a top down approach, from general to particular. So Section II describes the system's architecture. Then the relevant variables are explained as well as how they are read and calculated from the server in Section III. Section IV

This work was supported in part by the Junta de Castilla y León under Grant VA037A08 and by the CICYT under grant DPI2007-66718-C04-02

describes the new module included in Apache. Then, a brief description of the type of controllers that are implemented is given in Section V. CONAPA is presented from the user's point of view (Section VI) and finally some conclusions and future work are outlined.

II. System's Architecture

The working environment () consists of a server running the modified Apache connected through a 100 Mbps LAN to a machine running a synthetic workload generator. Thus, we can work under different traffic conditions. The server is a Pentium IV Mobile 1.8 MHz (2GB RAM memory). The benchmark runs on an Intel dual core 2.24 MHz (4GB RAM memory). Both machines run under Ubuntu (www.ubuntu.com).

The clients' machines will connect to CONAPA's web page. From there, they could work with the different options that will be explained in Section VI.

The benchmark is Curl-Loader ([4]). This tool is open-source and written in C. It simulates the application load and behavior of HTTP/HTTPS and FTP/FTPS clients. Information about each virtual client can be statistically analyzed.

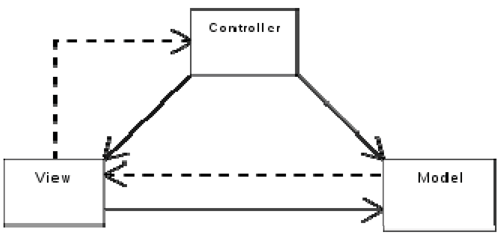

Figure 2. MVC architecture

Our application has been developed using the LAMP (Linux, Apache, Mysql and Php) architecture ([5]). The software architecture, i.e., how the system is organized inside, follows the Model-View-Controller (MVC, Figure 2) architecture (first described in [6]).

III. System's variables

Choosing manipulated and controlled variables is directly related with how and what we want to do. It is advisable to choose variables that have a real importance in the system and that can be easily modified and interpreted. There are several key variables in an Apache web server.

From the administrator's point of view, it is very important to keep the CPU and memory use within a desired band (from now on, these variables will be denoted CPU and MEM). If high values are reached, the system could overload or there might be a slow response to bursts in workload. CPU and MEM cannot be read directly and should be calculated (see the following subsection). These two variables are our system's outputs.

The controlled variables change their value as the result of a change in the manipulated variables. If we want CPU and MEM to follow a reference, i.e., to reach and stay around a value, we need to find which variables could affect them, and more importantly, we need these input variables to change their value dynamically.

Apache's KeepAliveTimeout (KA, [2]) directive is the number of seconds the server will wait for a subsequent request before closing a connection. The higher the value, the more server processes will be kept occupied waiting for idle clients. So, CPU and MEM are underused. If KA is very low, connections could be terminated too early. So KA should be given values that neither overload nor underload the server.

The maximum number of clients (MaxClients, MC for short) that can connect to the Apache server directly influences the use of the CPU and MEM. The more clients are connected, the higher the usage.

MC and KA cannot be modified in standard Apache. If we want to change their value dynamically, the Apache source code has to be modified (Section IV).

A. *How to calculate MEM and CPU utilization on line*

There are tools in Linux that calculate the use of MEM and CPU, but they group consumptions together by processes and not by application. So a script was written in Python ([10]).

The script in Figure 3 looks for information from each process that has been created. Linux stores these records in the directory /proc.

```
Cpu.py
#! /usr/bin/python
import sys
import time
import os
import pwd
import math
class PStat:
   def __init__(self, pid):
        fd = open("/proc/%d/stat" % pid)
        l = fd.readline().split()
        fd.close()
        self.pid = pid
        self.comm = l[1][1:-1]
        self.utime = int(l[13])
        self.stime = int(l[14])
    def get_time(self):
        return self.utime + self.stime
class SStat:
   def __init__(self):
        fd = open("/proc/stat")
        l = fd.readline().split()
        fd.close()
        self.uptime = int(l[4])
def get_pids():
    r = []
    for d in os.listdir("/proc"):
       try:
           r.append(int(d))
       except ValueError:
           pass
    return r
def get_pstats():
    r={}
    for pid in get_pids():
        r[pid] = PStat(pid)
    return r
def get_rss_mem(pid):
    """Return the process RSS in MB"""
    fd = open("/proc/%d/statm" % pid)
```

```
    l = fd.readline().split()[1]
    fd.close()
    return int(l) * os.sysconf('SC_PAGE_SIZE') / 
1024.0 / 1024.0
total = 0
memoria = 0
tab = get_pstats()
sstat = SStat()
time.sleep(1)
tab1 = get_pstats()
sstat1 = SStat()
for pid in tab1:
    if tab1[pid].comm=="httpd":
        #load = 100.0 * tab1[pid].get_time() / 
sstat1.uptime
        load = 100.0 * (tab1[pid].get_time() - 
tab[pid].get_time()) / \
            (sstat1.uptime - sstat.uptime)
        memoria = memoria +get_rss_mem(pid)
        total = total + load
total=('%5.3f' % total)
memoria= ('%5.3f' % memoria)
   print str(total) + '\t' + str(memoria)
```

Figure 3. Memory and CPU utilization

IV. APACHE WEB SERVER

This section explains Apache's architecture at a basic level. Session flow and conceptual architecture are described first. Then, the necessary changes in Apache and how to program them are explained.

A. Apache's architecture: session flow

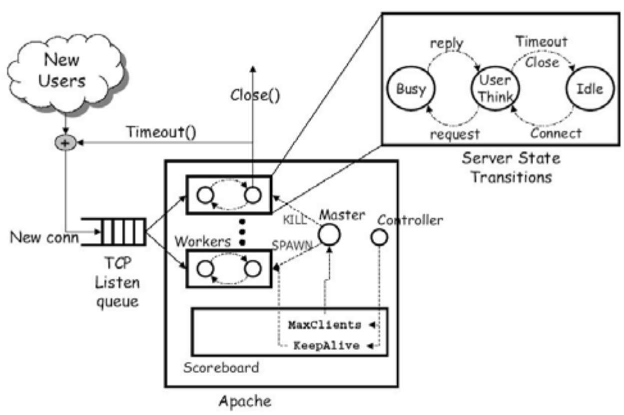

Figure 4. Apache's session flow

Although there are later versions, we are working with Apache 1.3 on Linux. This version is structured as a pool of 'worker' processes, monitorized and controlled by a master process (Figure 4). Worker processes manage the communication with the Web clients. At any time, a worker process can only deal with one connection and it is its responsibility until the connection ends. Thus, the worker process is inactive between successive petitions during the connection with the client.

MaxClients (MC, Section III) limits the size of the pool of the worker processes. KeepALive Timeout (KA, Section III) fixes the maximum time a worker process can be in the 'user think' state before the client's TCP connection is finished. If KA is too big, CPU and memory are underused. Decreasing its value, worker processes spend less time in the 'user think' state and the CPU usage increases. But, if the value is very small, TCP connections will finish before time and the benefits of persistent connections are lost.

B. Apache's conceptual architecture

Apache has a modular architecture ([6], [7], [8]) that makes it possible to increase its functionalities and customize it to our own purposes. Apache's core component defines the basic operations of a web server. The modules implement how to serve clients' requests, but the core calls the handlers in modules in a certain order that can be changed using the adequate directives.

The conceptual architecture is summarized in Figure 5. The PHP module is available to download, but it is not included in the standard installation. The mod_control.c is a new module we have written. Its main purpose is to create a socket that reads/writes KA and MC. Thus their values are updated each sampling time. More details in subsections C and D.

C. Changes in Apache source code

Configuration parameters are saved in the http.conf file. When Apache is launched, these values are read and cannot be modified until a restart of the server happens. So, MC and KA have default values that will be active all the time and cannot be changed during running time, i.e., dynamically every sampling period (the controller will calculate new values at certain time instants, sampling time and send to the Apache web server).

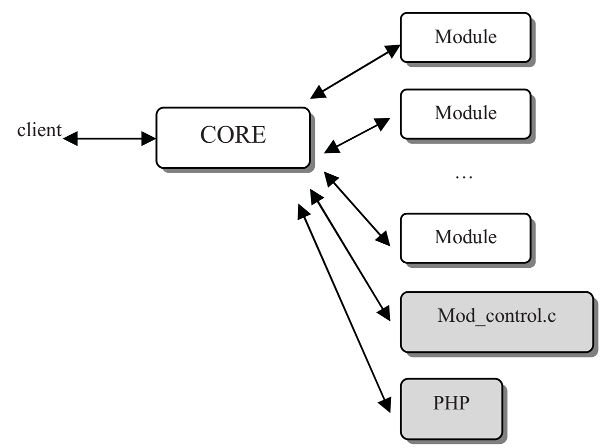

Figure 5. Apache's conceptual architecture

The first idea was to change the http.conf every sampling time and then carry out a 'graceful restart'. Thus, the parent process tells the child processes to terminate once they finish what they are doing. The new configuration file is read and the new child processes follow the new configuration. However, this approach is not very convenient because Apache is restarted every sampling time (about every 2 seconds) and only two parameters need new values. So, it was a computationally demanding approach.

The approach followed was to modify Apache's source code. Thus, MC and KA are no longer parameters, but variables. Two new modules were written. This new source code manages the variables and the interaction with the user's interface. The following sub-sections describe these topics.

D. MC and KA as variables

MC is called ap_daemons_limit and KA is called keep_alive_timeout in Apache's source code. Their declaration was changed from integer to integer pointers. Thus, the process receiving the petitions could change their value.

Changes regarding MC:

a. include/http_conf_global.h. The variable is declared as a pointer: extern API_VAR_EXPORT int * ap_daemons_limit;

b. main/http_conf.c. Shared memory is reserved:

```
Clave = ftok("/bin/ls",33);
         if (Clave==-1)
               exit(0);
         Id_Memoria          =          shmget
(Clave,sizeof(int),0777| IPC_CREAT);
         if (Id_Memoria == -1)
                 exit(0);
          ap_daemons_limit        =        (int
*)shmat(Id_Memoria,(char *)0,0);
         if (ap_daemons_limit == NULL)
                 exit(0);
```

c. main/http_main.c. The variable is declared as a pointer:

d. Other files: the variable should be addressed as the pointer's content.

Changes regarding KA:

a. Include/http.h. Pointer declaration: int *keep_alive_timeout.

b. Main/http_config.c. Shared memory is reserved:

```
Clave = ftok("/bin/ln",33);
        if (Clave==-1)
            exit(0);
      Id_Memoria = shmget (Clave,sizeof(int),0777 |
IPC_CREAT);
        if (Id_Memoria == -1)
            exit(0);
      s->keep_alive_timeout = (int *)shmat(Id_Memoria,(char
          *)0,0);
      if (s->keep_alive_timeout == NULL)
          exit(0);
```

When the new MC was smaller than the old one, Apache did not kill the excess of child processes once they had finished their job. So we wrote a method in Apache that runs periodically. It checks whether the MC (ap_daemons_limit) is smaller than its previous value (ap_maxclients_ant). If it is, the remaining processes are destroyed. This source code is in the method static void perform_idle_maintenance(void) in http_main.c (Figure 6).

```
if(*ap_daemons_limit<ap_maxclients_ant)
     {
for(j=*ap_daemons_limit;j<ap_maxclients_ant;j++)
                {
                     int status;
             if(j>=max_daemons_limit)
                break;
             ss = &ap_scoreboard_image-
>servers[j];
             status = ss->status;
             if (ss->timeout_len)
               {
               parent_score *ps =
&ap_scoreboard_image->parent[j];
               kill(ps->pid,SIGKILL);

ap_update_child_status(j,SERVER_DEAD,(request_rec
*)NULL);
             }
          }
      ap_maxclients_ant = *ap_daemons_limit;
  }
else if(*ap_daemons_limit>ap_maxclients_ant)
  {ap_maxclients_ant = *ap_daemons_limit;}
```

Figure 6. static void perform_idle_maintenance(void)

E. Apache new module

The changes explained in the previous sub-section allow the two input variables to be modified dynamically, but we need a way to send the information in and out of Apache.

A new Apache module (mod_control.c, see pseudocode in and source code in http://www.isa.cie.uva.es/~tere/) has been written. Basically, this code opens a socket on the server side and 'tells' Apache which internal parameters can be modified dynamically.

```
MODULE mod_control
 include <libreries>
 define CONSTANTS
 var variables
 PROC open_server
   IF process_can_be_created THEN
     EXECUTE  open_connection
   END IF
 END//open_server
 PROC abrir_conexion
 IF socket_cannot_be_created THEN
    ERROR
    EXIT
 END IF
 IF not_poss_to_send_inf_kernel_about_socket
THEN
    ERROR
    EXIT
 END IF

Figure 7. Simplified mod_control.c pseudocode

F. *php module*

The php module is installed as an Apache module, so when Apache starts, php also starts. As it is installed as shared, all the advantages of the dynamic linking/loading of *Dynamic Shared Objects* (DSO) will be available. This mechanism provides a way to build a piece of program code in a special format for loading it at run-time into the address space of an executable program ([11]).

The php application will be saved in Apache's *htdocs* directory. It is composed of:

a. User's interface. Html code that will be accessed via the client's web browser.

b. Simulation code. Scripts in php

c. Control of the web server. A collection of php scripts. The client's socket is programmed here (Figure 8 and pseudocode). This part sends requests to mod_control.c when KA and MC are needed to calculate the next control signals.

d. Access to the mysql database: queries, save data, retrieve information, …

```
<HTML>
<BODY>
<FORM METHOD="post" ACTION="socket.php">
<p>MaxClientes <input type="text" name="mc"
size="30" value=""></p>
<p>KeepAlive <input type="text" name="ka"
size="30" value=""></p>
<p><input type="submit" value="Enviar datos"
name="enviar">
</FORM>
</BODY>
<HTML>
socket.php
<?php
        // Create the socket
        if(($sockd = @socket_create(AF_INET,
SOCK_STREAM,SOL_TCP))<1)
                die("Unable to create
socket:" .
socket_strerror(socket_last_error()));
if(@socket_connect($sockd,"127.0.0.1", 3490)
== FALSE)
                die("Unable to connect:" .
socket_strerror(socket_last_error()));
        $buffer =
$_POST['mc'].";".$_POST['ka'];
        if(@socket_write($sockd, $buffer) <
strlen($buffer))
                die("Unable to connect:" .
socket_strerror(socket_last_error()));
        unset($buffer);
        if(($buffer = socket_read($sockd,
100)) == FALSE)
                die("Unable to read from
socket:" .
socket_strerror(socket_last_error()));
        socket_close($sockd);
        echo $buffer;
?>
```

Figure 8. php socket

V. CONTROLLERS

This section briefly describes the controllers that students can use to test their knowledge. We have included PIDs and a predictive controller (GPC).

The system we propose here is a MIMO. There are two inputs and two outputs, although the coupling between variables is not very strong. The reasons for choosing these two methods are: PID is the most widespread controller and students of every Engineering degree learn it. Predictive control is an advanced control methodology with a relatively important influence in industry and the MIMO formulation is inherent to the controllers. So, students can compare what happens when working with a MIMO system, but considered as two SISO ones or working with the MIMO system itself.

```
SOCKET.PHP
Create socket
If error then print('error')
Connect
If error then print('error')
Collect variables
Write variables in socket
If error then print('error')
Read variables
If error then print('error'
Close socket
```

Figure 9. php pseudocode

A. *PID*

The PID [13] is the most common form of feedback. Its continuous formulation can be described by (8):

$$u(t)=K_p\left(e(t)+\frac{1}{T_i}\int_0^t e(\tau)d\tau+T_d\frac{de(t)}{dt}\right) \qquad (1)$$

The PID implemented in the computer follows the guidelines in [13].

B. *Predictive control*

Model Based Predictive Control (MBPC) ([14]) is a control strategy based on the explicit use of a model to predict the process output over a long-range time period. A receding control horizon technique is used: only the first control signal is applied (so all the changes that take place between two control signal calculations are considered). A cost function is minimized at each sampling time. It is usually defined as a linear combination of the tracking error and the manipulated variables (the most common formulation being a quadratic cost function).

Although a non-linear model can be used for prediction, computational and robustness considerations makes the use of a linear model more adequate. Following the Generalized Predictive Controller (GPC) described in [14], a MIMO controller is described here. Considering a process with M inputs, N outputs and R measurable disturbances represented by the model:

$$A_i\left(q^{-1}\right)y_i(t) = \sum_{j=1}^{N} B_{ij}\left(q^{-1}\right)u_j(t) + \sum_{j=1}^{R} D_{ij}\left(q^{-1}\right)v_j(t) + \frac{T_i}{\Delta}\xi_i(t) \tag{2}$$

where: $i = 1, ..., M$ and A_i, B_{ij}, D_{ij} and T_i are polynomials in the q^{-1} operator, $\Delta=1-q^{-1}$ and ξ_i is white noise. The predicted future values of the controlled variables are:

$$\hat{y}_i(t+j) = \sum_{j=1}^{M}\sum_{k=1}^{j}\sigma_j g_{ij_k}\Delta u_j(t-k+j) + p_i(t+j), i = 1,\ldots,N \tag{3}$$

where g_{ij} is the step response between y_i and u_j and p_i is the free response of y_i. The coefficients σ and η take the value 1 if the corresponding input is included in the predicted output and 0 if it is not.

The control algorithm objective is the calculation of the sequence of (optimal) changes of the control variables in a control horizon Nu: $\Delta u_i(t+j)$, $j=0,..., Nu_i-1$ so that the predicted outputs $\hat{y}_i$ are as close as possible to the internal reference $r_i(t+j)$. This is translated into an optimization problem where a quadratic cost function of the tracking error and the manipulated variables is minimized, taking into account constraints on **Δu**, **u**, **y** and any other constrained variable that depends on **Δu**. This optimization problem can be stated as:

$$J = \sum_{i=1}^{N}\sum_{j=N1i}^{N2i}\eta_i\left(\gamma_i\left(\hat{y}_i(t+j)-r_i(t+j)\right)^2\right) +, \sum_{i=1}^{M}\sum_{j=0}^{Nu_i-1}\sigma\left(\beta\Delta u_i(t+j)\right)^2 \tag{4}$$

$$D_{m_i} \le \Delta u_i(t+j) \le D_{M_i}, j = 0,\ldots,N_{u_i}-1$$

$$U_{m_i} \le u_i(t+j) = u_i(t-1) + \sum_{i=0}^{j}\Delta u_i(t+j) \le U_{M_i}$$

$$L_{m_i} \le \hat{y}_i(t+j) \le L_{M_i}, j = N3_i,\ldots,N4_i \tag{5}$$

where the coefficients γ and β give the relative weight of every prediction error or change in the control variables, while the coefficients σ and η taking the value 1 or 0 allow a variable to be included in the index or excluded from it. When no constraints are considered, there exists an explicit solution of (4).

VI. CONAPA

Previous sections have described the architecture and the internal description of the system. Now, the user's interface is presented.

The tool is open; everyone can use it, although there are sections that require a password (Figure 10). There is only one web server, so only one student at a time can change the parameters of the controller that calculates MC and KA. The data acquisition area is also protected because the real system can only be accessed one user at a time.

The following subsections will describe CONAPA's capabilities and basic software engineering:

a. Data acquisition.
b. Simulation of the web server.
c. Control of the web server online.
d. Comparison of simulation and real system.
e. Setting the benchmark traffic generator parameters.

A. *Data acquisition*

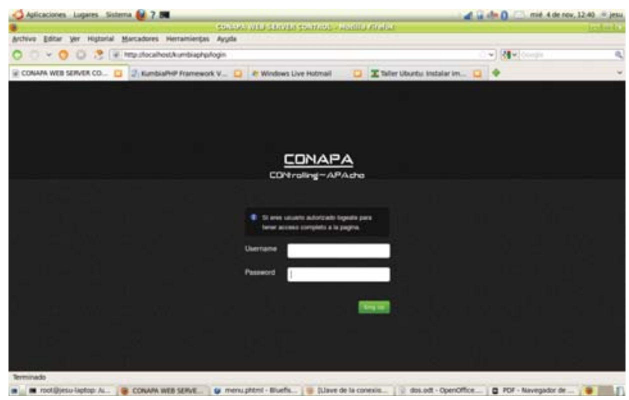

Figure 10. CONAPA's login screenshot

The user can collect data that allows the identification of a model that reflects how the real system works. As we have two inputs and two outputs, we keep constant one input and the other changes between the max and minimum value where the step duration decreases over time until 0 is reached. The procedure is repeated for the input that remained constant. This data can later be analyzed in other software such as Matlab. The period and max/min values are introduced by the user (Figure 11).

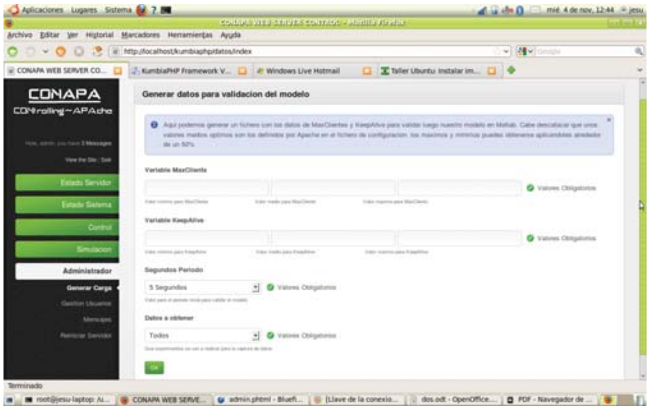

Figure 11. Setting parameters for data acquisition

Figure 12 shows the input variables (upper graphs) and the corresponding values for the outputs (lower graphs). A simple sequence diagram showing the main steps involved in the process is shown in Figure 13.

B. *Web server's simulation*

This area is open to all users. The type of controller can be selected and then the parameters (for instance, proportional, derivative and integral terms of the PID) should be entered. Each type of control has its own screen and parameters.

C. *Web server's control*

The available controllers are the same as in the previous sub-section. But, only one user can work with the real system. Each sampling time, KA, MC, MEM and CPU are read (using the socket described in Section IV) and sent to the controller.

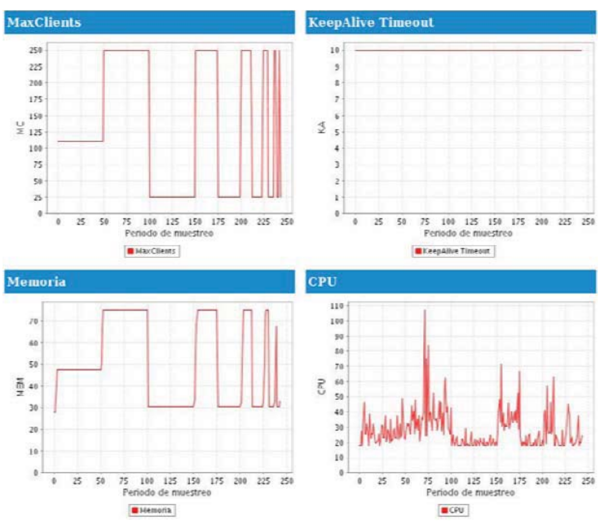

Figure 12. Data to export for identification

New values for MC and KA are calculated and sent to the server. Figure 14 shows the results of an experiment where the reference for the CPU was 5% and MEM was 40%. The controller was a PID.

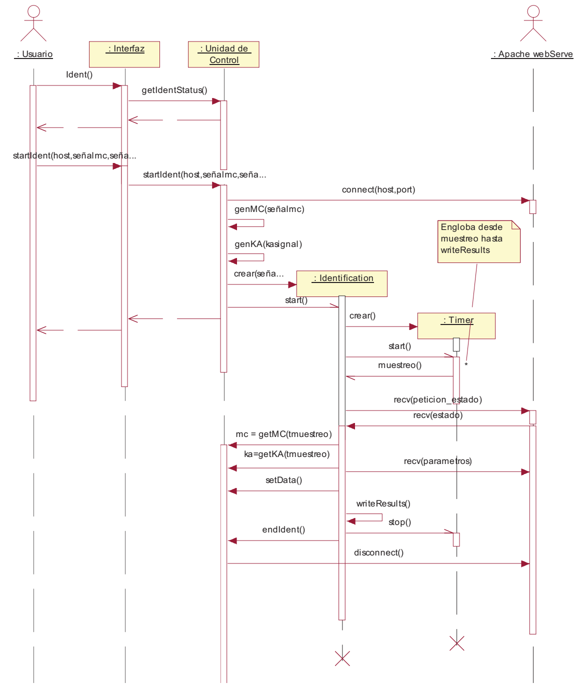

Figure 13. Sequence diagram, data acquisition

Figure 14. Real control

D. *Comparison of simulated and real system*

When this option is chosen, the real system is controlled and we apply the same tuning parameters to the simulation model. Thus, we compare whether the model and the real system have the same trends. This is quite useful if we are teaching our students the differences between simulation and the real world.

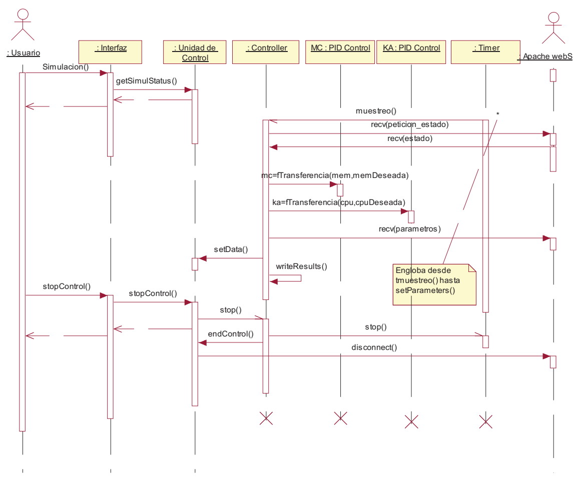

Figure 15. Simulation versus real system

Figure 15 shows the sequence diagram for this case when the controller is a PID.

E. *Setting the benchmark traffic generator parameters*

Different traffic conditions cause the behavior of the Apache web server to change. The tuning of the controller can be good for a traffic situation but not so adequate for another.

If we can define different scenarios, we can check the goodness of the controllers and the range they work in within acceptable performance.

This option is rather interesting for students because they can learn to think as a web administrator and deal with day to day situations. So, if they work administering networks in the future, they can be prepared to respond under pressure and changing network traffic loads.

VII. WHY IS CONAPA USEFUL?

It cannot be argued that there are many tools that present different components and characteristics of automatic control. There are virtual laboratories, online laboratories, add-ons to existing software: they are useful and have been developed for certain students and requirements.

CONAPA was built for students who follow courses where automatic control is not traditionally the main objective. But, if they are going to be good engineers they need a basic formation/knowledge and understanding of fundamental control ideas. If anyone studies Telecommunications or Computer Science, it is clear that they prefer networks and computers to a conventional mechanical system. It is at this point where problems arise. As stated in the introduction, most control books and applications deal with classic examples: electrical, mechanical, … So, we thought it would be interesting to present a system which these future engineers felt close to and that the tool could provide them with notions and knowledge in other valuable fields. CONAPA can be used for:

- Learning basic identification methods.
- Linear simulation.
- Controlling the Apache web server in simulation.
- Controlling the REAL Apache web server.
- Setting different traffic conditions and visualizing results: congestion, underutilization, overexploitation …

It is also useful for understanding Apache itself, how it works and how it can be modified to fulfill our necessities.

VIII. CONCLUSIONS

The paper has presented a tool that works both as a virtual and an online laboratory. The real system is a web server. Students can freely work with the simulation area, check their controllers and compare their tunings with the one that is being applied to the real system. The control of the web server is restricted because only one person at a time can change the parameters: we only have one plant and many potential users.

CONAPA is useful for those students whose degrees are not closely related to mechanical or traditional process control environments. They can see that automatic control can be applied to plants that have the same problems as these more conventional systems, but they feel more related to them.

The paper has given details on how to modify Apache's source code because there is little information about it and this was the hardest part of the work. In the future, we plan to migrate to a Windows operating system and to a higher Apache release.

***Abstract*— Changing economic and technological conditions require that talented and experienced engineers adapt and update their engineering skills. Communities support education and retraining in order to retain the human talent. This paper describes an innovative approach to helping engineers overcome barriers to career transitions, which incorporates career and personal development, an engineering skills refresher, a semester-long course at a top-tier engineering school, and an internship at a company in a high-growth sector.**

We describe the motivation for embarking on a career re-engineering program. A large percentage of the engineering population in the Austin community is engaged in semiconductor design and manufacturing, an industry in decline. In order to harness the collective skills and talents of engineers in the semiconductor industry and to redirect those skills, the Center for Lifelong Engineering Education provides training to help engineers to re-tool their skills for growth industries.

We describe success factors for a career re-engineering program, including (1) the engagement with multiple stakeholders: a university engineering faculty, community development organizations such as workforce commissions, companies in high-growth sectors, the university career counseling center, and governmental agencies; (2) the acquisition of funding to help support engineers as they embark on a retraining curriculum; and (3) the application process and selection criteria.

We describe the curriculum, including an initial orientation and assessment program; the selection of appropriate and available fall-semester engineering classes in fields such as biotechnology, nanotechnology, and environmental sciences; monthly workshops designed to improve communication, presentation, adaptability, and networking skills; weekly small-team meetings designed to keep participants accountable; regular meetings with individual mentors; and a spring-semester internship with a firm in a high-growth sector.

Programs to help retrain engineers and to retain engineering talent within a society are critical to community sustainability and growth.

Keywords- engineering professional development; continuing education; retraining; community development.

I. INTRODUCTION

Economic sustainability requires communities to adapt to changing environmental conditions. At both the macro-level and the micro-level, communities that fail to adapt to environmental changes decline. Programs to help retrain engineers and to retain engineering talent within a society are critical to community sustainability and growth.

II. HISTORICAL PERSPECTIVE

History provides us with examples of communities, both broadly and narrowly defined, in which engineering expertise provided the basis for economic growth, and in which the failure of the community to adapt to changing conditions and build new technological expertise led to economic decline.

A. Portugal

Navigational technology enabled Portugal to become a world power. In the early fourteenth century shipbuilders moved from a heavy shipbuilding technology, using overlapped wooden planks to keep water out of the vessel, to a lighter construction with a simple skeleton and caulking, the caravel construction. The caravels were larger, lighter, cheaper to sail and more seaworthy than their predecessors [1]. Mathematicians developed techniques for estimating distances from port to port, dead reckoning. Navigators developed port books or "*portolanos*" which allowed them to plot their voyages. By the fourteenth century, the compass was in use in Mediterranean allowing sailors to navigate even in cloudy weather [2].

In the fifteenth century, Prince Henry of Portugal (Henry the Navigator) launched several expeditions, apparently for both religious crusades and commercial reasons [3][4]. Henry the Navigator's nautical school helped prepare Vasco de Gama, who, at the close of the fifteenth century and early sixteenth century, rounded Africa and sailed to India, establishing Portuguese colonies around the coast of Africa, and creating important trade routes.

Portuguese navigational skills made the Portuguese rise to world power possible. When navigational skills became commonplace and less of a competitive advantage, Portugal did not sustain its dominant position. By the seventeenth century, the skill giving competitive advantage was the ability to manage far-flung empires, new forms of legal and financial risk-sharing (early insurance companies) and commercial trading companies.

And finally the competitive advantage afforded by the Industrial Revolution in the nineteenth century was slow to take hold in Portugal [5], giving a competitive advantage to England and France. Portugal fell from its position of world domination and suffered economic decline.

B. The Steel Industry

The United States turned to steel manufacturing during the depression of the 1890s. The industry flourished, and steel was the archetype and innovator of American commerce, dominating all competitors, nationally and internationally. Used for soup cans, automobiles, the cabling for the Golden Gate Bridge, steel production provided jobs for thousands of Americans. Early engineering advances fell aside to the later short-sightedness of upper management. Even as late as the 1990s leaders at Bethlehem Steel refused to adapt their traditional methods despite advances from "mini-mill" steel companies as well as the resurgence and development of alternative materials (aluminum and plastics) [6].

This failure by upper management to respond proactively to the influx of cheaper, foreign steel and remain entrenched in historical methodologies led to the loss of thousands of jobs and dramatically impacted a way of life for many Americans.

C. Digital Equipment Corporation

At the micro-level, the level of an individual company, the story of the rise and fall of Digital Equipment Corporation, is telling. DEC's engineering strength, culture of innovation and its dominance in the mini-computer market allowed it to rise to be second only to IBM in the computer industry, with annual revenues of $14 billion. DEC's decline, however, was precipitous, falling from market dominance to its demise in less than ten years.

The reasons for DEC's failure involve a complex array of issues. The obvious one is that DEC failed to adapt to the shift in the market, away from minicomputers to personal computers. Less apparent but equally powerful reasons involve the DEC culture and its focus on innovation and consensus. When the market shifted to one with far lower profit margins, the engineering skill that bestowed competitive advantage changed from expertise in innovation to capability in efficiency, cost controls and managing to very tight budgets.

Microsoft, Dell and Intel have de-bunked the myth that the best technology "wins." At different intervals, DEC had the best computer, best processor, and best search engine. DEC missed the market window by being too late (processor) or too early (search engine). Management's inability to seriously consider the threat of competition and develop an agile response led to the company's ultimate downfall. [7]

According to [8], "dealing with the business problems requires switching from the 'fun' of innovation and growth to the 'hard work' of creating a business strategy process, of becoming cost conscious, of changing organizational routines toward efficiency…, of modifying the basic processes in engineering and manufacturing to respond to changing technology."

The story of DEC is a chronicle of a failure to adapt to a changed environment.

III. Changes in the Semiconductor Industry

The global electronics industry suffered a significant decline in 2009, and the Austin technology community has suffered a 24% decline in employment [9]. Industry observers do not expect that the region will regain these jobs. Dell, Spansion, AMD, Freescale Semiconductor, Samsung and Applied Materials have reduced their manufacturing employment from approximately 40,000 to approximately 20,000. Table 1 illustrates the decline in the manufacturing industry in Austin.

The decline in technology jobs in the Austin region disrupts the careers of engineers, reduces the value of manufacturing plants, reduces the property tax revenue, and disrupts the ecosystem of suppliers and service companies that provided parts and services to the semiconductor companies.

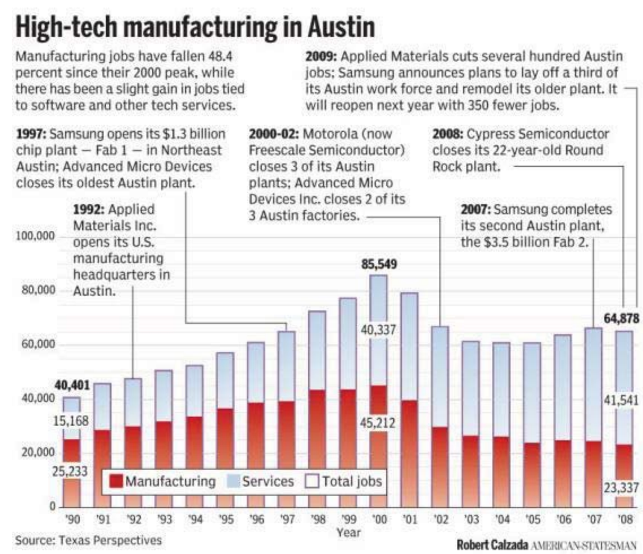
IV. Possible Scenarios

Given the loss of employment in the semiconductor manufacturing industry, what are some of the possible scenarios for the community?

A. Brain drain

In one scenario, engineers leave to work in other communities where their skills are still valued. However, given that the semiconductor manufacturing industry jobs are now primarily in Asia, the opportunity for relocating is small.

Table 1: High Tech Manufacturing in Austin [9]



B. Community decline

In a second scenario, engineers take positions which do not utilize their problem-solving and engineering skills or they remain unemployed. This is the primary current situation. Engineers are currently receiving unemployment benefits while looking for new employment.

C. Revitalization

In a third scenario, engineers receive training in a growth area and help to build new industries, applying their problem-solving skills to new problem domains. With training in entrepreneurial skills, they are able to build new firms and revitalize the economy.

This scenario happens at the individual level with great regularity. Engineers acquire certain skills in their college training, but within a few years, those skills are stale; technology has advanced. Many engineers recognize the need for regular skill enhancement and seek out training opportunities, either through their firms or on their own. Typically, these are technical skills. Engineers who want sustainable careers see the need for frequent skill enhancement.

But faced with a massive industry decline, technical skill acquisition alone is inadequate. In order to help rebuild an economy, the engineers' problem-solving and engineering skills need to be supplemented with leadership, communication, and negotiation skills.

V. Responding to a Changed Environment

How can a community, whether it is a nation, a region, a city or a firm, respond to a change in its technical and economic environment?

First, that community must recognize that if it fails to support the re-tooling of its talent, it will go into certain decline.

Second, it must recognize that it needs to support retraining its engineers to acquire skills in areas of potential growth and skills in leadership in order to help build new industries. Such retraining is necessary in order to retain the engineering talent within the community.

Applied Materials, a leading capital equipment producer serving the semiconductor industry and based in the Silicon Valley, recognizes the risks to its business and is attempting to move into the growth industry of manufacturing solar equipment. This is the sort of adaptability that can revitalize a community, in this case the community of one firm. So far, however, Applied Materials has not found adequate demand for solar equipment in the United States [10].

The Center for Lifelong Engineering Education at the University of Texas at Austin's Cockrell School of Engineering currently offers training to engineers in Aerospace Engineering, Biomedical Engineering, Chemical Engineering, Civil Engineering, Electrical and Computer Engineering, Energy and Environmental Engineering, Engineering Ethics, Engineering Finance, Engineering Leadership, Mechanical Engineering, Petroleum Engineering and Software Engineering. These programs fulfill the need for the incremental training that helps individual engineers enhance their skills in order to sustain their careers. This incremental training, while critical for engineers to sustain their careers, is still not adequate to meet the needs of revitalizing an entire community.

VI. A Program for Retraining and Retaining

In order for the Austin community to sustain its economic viability, we propose a program to provide a significant retooling of the current engineers. The program, still in the planning stages, includes several elements.

A. A well-defined application, selection and matching process

In order for this program to be successful, it must have a well-defined application, selection and matching process. Engineers admitted to the program must have talent and intelligence as well as motivation to learn the concepts of a new domain. In short, they must be adaptable.

Participants accepted into the program attend a week-long orientation program. Initial assessments help match individuals with appropriate fields of study and point them in the direction of appropriate course work. Participants assess their professional strengths and create plans to build their skills and networks. Participants attend workshops on communication and presentation skills.

Video snippets of professors and their courses provide the engineers with a sample of what might be of interest to them.

B. Fall semester engineering coursework

Once admitted to the program, participants enroll in one fall semester course. They select the course that will help them establish expertise in a new field.

The coursework will be in growth technology fields, such as power engineering, battery engineering, and biotechnology.

C. Monthly workshops

During the orientation and fall semester, participants attend monthly workshops on communication skills and negotiation skills. They learn how to present a project idea and gain acceptance; how to present themselves at meetings and interviews; about gender and cultural differences and how to communicate effectively will all. They learn presentation skills, including videotaping, critiquing and practicing. They learn to understand their audience and speak in ways that the audience can hear. They learn leadership skills and entrepreneurial skills. They learn practical negotiation skills and how to expand the negotiation space.

D. A five-month and ten-month option

Some engineers find that a five-month program including assessments, workshops and one semester of academic instruction will be adequate to their needs. Others benefit from a second semester (the ten-month option) which includes a five-month internship at a local firm in a high-growth sector.

E. *Small teams*

Once admitted to the program, participants join small teams of three to five individuals. These teams meet weekly for accountability, encouragement and networking.

F. *Mentoring*

Once admitted to the program, participants begin working with a mentor, a senior member of the engineering community who can provide career guidance and advice.

G. *Broad community support*

In order for this program to be successful, it must have the support of the broader community, including the university, the engineering faculty, the Chamber of Commerce, local industry, venture capitalists, workforce commissions and career counselors.

H. *Support from the university*

Support from the university is critical, because it must be willing to accept non-traditional students into a program that crosses the boundary between academic degree courses and continuing education programs. If a university sees its role as a research institution only, it does not value community revitalization, nor does it see itself as a resource in an effort to revitalize a community.

I. *Support from the university faculty*

Support from university faculty is critical because the faculty must be willing to accept non-traditional students into their classes. Engineers in need of retraining are often 20 years out of college. They may have exceptional experience, but lack specific courses considered to be pre-requisites for certain classes. The engineering faculty has to work with the program administrators to ensure that the engineers are academically equipped to succeed in the courses while not restricting the admissions onerously.

J. *Support from local industry*

In order to provide post-training internships, the program requires support from the Chamber of Commerce and local industry. The Chamber benefits by retaining the community's engineering talent. Local industry benefits through the increased and better-trained talent pool. They will find excellent engineers who have taken the initiative to acquire new engineering skills.

K. *Venture capitalist support*

Venture capitalists support the program by coaching engineers with ideas to become successful entrepreneurs. Building new industries is notoriously risky, and novices need senior guidance.

L. *Public workforce commission support*

Support from the Workforce Commission provides funding for skills development for engineers.

M. *Career counselor support*

University career counselors provide assessments and advice to engineers entering the program.

N. *Financial support*

In order for this program to be successful, it must have the support of funding agencies, such as the National Science Foundation and the Workforce Commission. Unemployed engineers are unlikely to be in a position to fund their training. Moreover, this program is intended to benefit the community, whether it is seen as a local community, a region or a country, by retaining the talents of skilled engineers.

VII. Results from Preliminary Programs

The Center for Lifelong Engineering Education has provided training in leadership for engineering managers and has results of the usefulness of that training for sustaining careers, primarily in software engineering. Results from the Engineering Leadership Institute can be used to determine likely usefulness of various kinds of career and personal development training for engineers seeking to revitalize their careers through a retraining effort. Table 2 summarizes the usage of the skills acquired in this program.

A. *Communications skills*

Ninety-four percent of students who have taken the Engineering Leadership Institute's Communications Skills workshop report that they are using it extensively to support their careers, and 100% report that they are using the materials they learned in this program.

The workshop includes training in tailoring communications to your audience, presenting ideas with impact, understanding gender and cultural communication differences, listening to understand and delivering bad news.

B. *Skills for dealing with different personality types*

Eighty-two percent of students who have taken the Engineering Leadership Institute's workshop in Dealing with Different Personality Types and How to Work More Effectively With Them, using the Myers-Briggs Type Indicator, report that they are using it extensively to support their careers, and an additional twelve percent report that they are using the materials they learned in this program. Six percent of the program participants report that they are not making use of this training.

C. *Skills for managing up*

Seventy-one percent of students who have taken the Engineering Leadership Institute's workshop in Managing Up: What You Boss Needs from You, report that they are using the skills extensively to support their careers, and an additional twenty-nine percent report that they are using the materials they learned in this program.

D. Problem-solving skills

Seventy-one percent of students who have taken the Engineering Leadership Institute's workshop in Problem-Solving Skills report that they are using the skills extensively to support their careers, and an additional twenty-nine percent report that they are using the materials they learned in this program.

E. Skills for dealing with difficult people

Sixty-three percent of students who have taken the Engineering Leadership Institute's workshop in Dealing with Difficult People report that they are using the skills extensively to support their careers, and an additional thirty-eight percent report that they are using the materials they learned in this program. All of the students were making use of these skills in some way.

F. Risk management skills

Fifty-six percent of the Engineering Leadership Institute students reported that they were making extensive use of the risk management skills they learned in the program, and an additional forty-four percent reported that they were using the risk management skills in some way. .

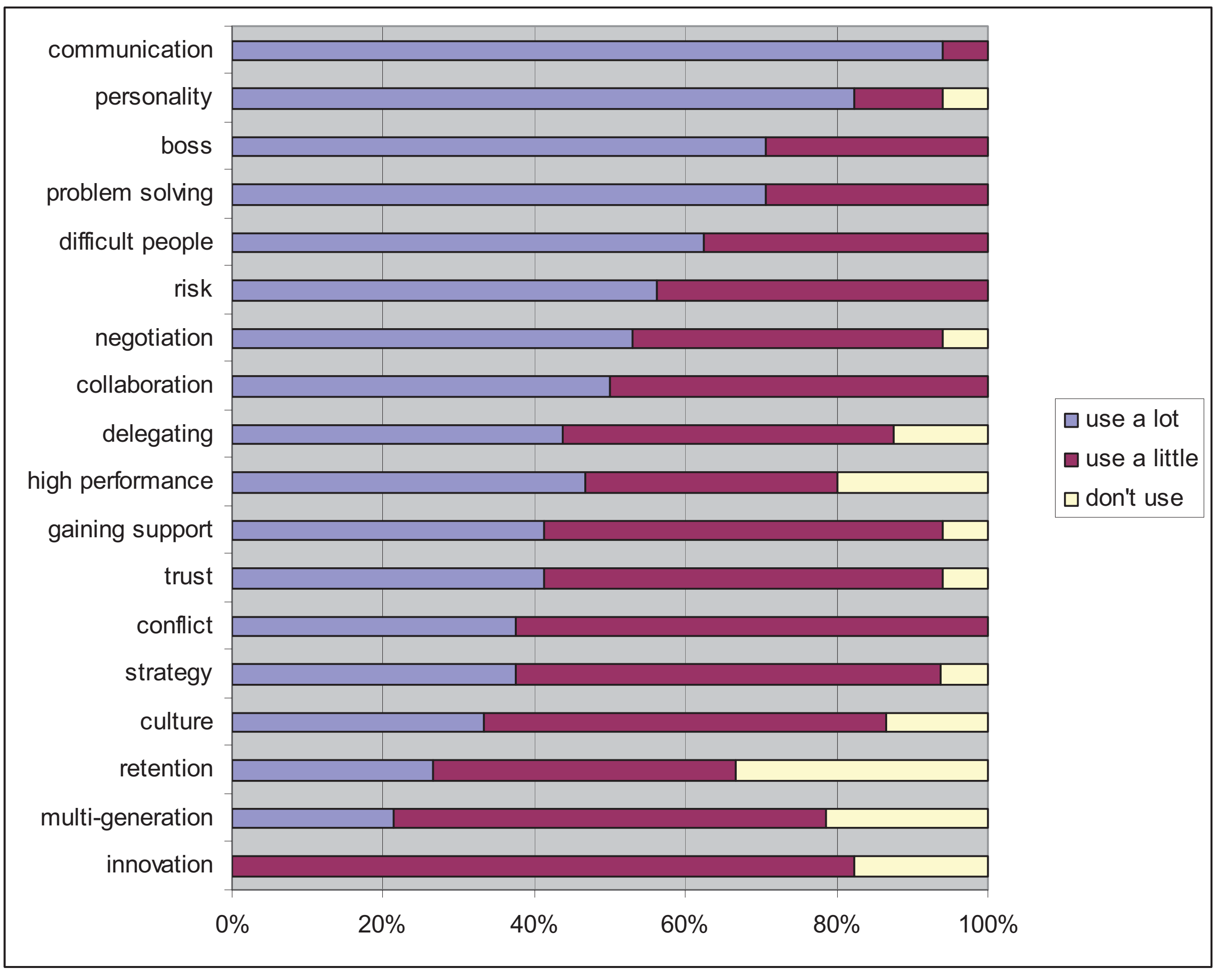
G. Practical negotiation skills

Fifty-three percent of the Engineering Leadership Institute students reported that they were making extensive use of the negotiation skills they learned in the program, and an additional forty-one percent reported that they were using the negotiation skills in some way. Six percent reported that they were not making use of the negotiation skills.

H. Collaboration skills

Forty-seven percent of the Engineering Leadership Institute students reported that they were making extensive use of the collaboration skills they learned in the program, and an additional forty-seven percent reported that they were using the collaboration skills in some way.

Table 2: Percentage Usage of Leadership Skills



I. Delegation skills

Forty-four percent of the Engineering Leadership Institute students reported that they were making extensive use of the delegation skills they learned in the program, and an additional forty-four percent reported that they were using the collaboration skills in some way. Thirteen percent indicated that they were not yet using these skills, primarily because they are not in leadership or management roles yet.

J. Skills for building high performance teams

Forty-four percent of the Engineering Leadership Institute students reported that they were making extensive use of the skills for building high-performance teams they learned in the program, and an additional thirty-one percent reported that they were using the skills in some way. Nineteen percent reported not yet using these skills, primarily because they were not yet leading or building teams.

K. Other skills

Sixty-three percent of the participants were using skills to attract and retain good employees. And more than three-quarters of the participants were using the remainder of the skills taught in the Engineering Leadership Institute, including building trust, conflict management, strategic planning, developing a culture of success, managing a multi-generational and multi-cultural workforce and innovation management.

VIII. Revitalizing a Community

Data from the Engineering Leadership Institute's participants validates the usefulness of the career and personal development skills workshops for enhancing and revitalizing individual careers, and will be useful in building a broader program. Many of the engineers in the program have provided testimonials as to their individual career growth as well as their contributions to their sponsoring company. Most significant: engineers who were technically proficient and had been moved into management based on their technical proficiency felt they were no longer immersed in their area of expertise. This program taught them to balance their technical growth with their leadership skills, thereby expanding their comfort and competency in leading technical projects and/or teams.

The program defined can be used in any community with a top level engineering university. It is customized to the group needs, providing just-in-time training that is immediately applicable. As a result, engineers are able to bridge the gap between their technical training and the demands of managing projects and people. We have defined it in such a way that the community sees the benefit from the program and sees that ongoing efforts to retrain and retain their engineering talent are crucial to economic viability.

Why is this program innovative? Most professional development or continuing education programs for engineers focus on improving on the base of established engineering skills, or on adding people skills to the existing engineering skills. This program is innovative because of its systemic approach; the individual's skills are enhanced within the context of the economic conditions, and they are enhanced in both the hard skills (new technologies) and the soft skills such as communication, negotiation, and proficiency in human interactions.

Abstract—**Bologna process establishes a big change from class-based lessons to active learning. This process shifts the focus from instructor-centered teaching to student-centered active learning, putting the student in the centre of his own learning. This paper presents a case study of active learning in Telecommunication Engineering at Rey Juan Carlos University. Specifically, it presents the experience of different active learning activities in Object Oriented Programming (OOP) subject, where students developed their initiative and critical thinking. This paper presents both global data (i.e. number of students, their background, description of the theoretical, practical and new active learning activities) and specific data (i.e. scores obtained in the different activities proposed, time spent in each learning activity, participation in the learning activities, students' interactions, etc.). Furthermore, the comments of the own students about their personal experience with these new active learning activities are included.**

Keywords: Engineering Education; Collaborative Work; Active Learning.

I. INTRODUCTION

Bologna process establishes a big change from class-based lessons to active learning. This process shifts the focus from instructor-centered teaching to student-centered active learning, putting the student in the centre of his own learning. Lifelong learning has been recognized as an essential element of the European Higher Education Area since the Ministers met in Prague in 2001 [1]. The '*Prague Communiqué*' signals that in a Europe built on a knowledge-based society and economy, lifelong learning strategies are necessary to face the challenges of competitiveness and the use of new technologies, and to improve social cohesion, equal opportunities and quality of life. Since then, there has been growing awareness of the need to embed lifelong learning within higher education.

This new educational paradigm requires other methodologies that enhance the active role of the student, his initiative and critical thinking. There are several pedagogical theories related to active learning such as '*Sociocultural Theory*' or '*Constructivism Theory*'. On the one hand, '*Sociocultural Theory*' [2] emphasizes that the human intelligence originates our society or culture, and that individual cognitive gain mainly occurs through the interaction with the social environment and the knowledge internalization. Knowledge is constructed and discovered by students and transformed into concepts, which students can relate [3]. Learning consists of active participation by the student versus passive acceptance of information presented by an expert lecturer. Students are actively constructing their own individual knowledge, and learn how to understand and appreciate different perspectives through a dialogue with their peers. On the other hand, '*Constructivism Theory*' [4] states that knowledge is not a fixed object but an object continuously evolving. Knowledge is constructed by the individual through his own experience of that object. Learners have to assume the responsibilities related to their own learning. They have to develop abilities to monitor and direct their own learning and performance. When people work collaboratively in an activity, they can see a problem from different perspectives and are able to negotiate, to generate meanings and solutions through shared understanding.

In both pedagogical theories, students collaborate with others in order to promote the active learning and the interaction between peers. The origins of collaboration activities are based on the real world, given that everybody is member of several groups. In our daily activity we are continuously interacting inside groups: in the family life, with our friends, in our work, etc. Our personal identity stems from the way of perceiving and of treating with other members of the groups. Within the group we learn to behave, to think, to educate ourselves and to learn from our interaction with the rest of the members of the group [5].

There are several research works performed at different fields that they evidence the goodness and the limits of active learning. In [6], it is found that there is broad but uneven support for the core elements of active, collaborative, cooperative and problem-based learning. This paper also shows that a unique technique is inadequate to achieve a better learning. Felder et al. [7] give some instructional methods to support these new paradigms, in order to teach more about "real-world" engineering design and operations.

Face-to-face collaborative learning has been applied in traditional classrooms since the 70s, although most of theoretical studies related with it date back of the 80s [8]. In these years different methods and studies arose trying to apply collaborative learning technologies to students of diverse ages and levels. These experiences pointed out that the learning process is not only the own identification of the knowledge finally acquired, but also includes the explanations that are provided in order to identify which information is missed, the inconsistencies that are detected, what needs to be clarified or is discussed from different points of view by different members of the group [2].

In this one sense, collaborative learning is a social activity that involves a students' community in which some knowledge is shared and other new one is acquired (knowledge construction) [4] [9]. It means that, apart from the solution itself, it is also important the process that has made it possible to reach that solution. Then, the goal of collaborative learning is that the students were actively involved in the exploratory learning process working together [10].

Collaboration has great benefits such as to promote the cooperation, the interaction and the familiarity among students and teachers. Moreover, from the computer scientists' point of view, collaborative environments facilitate the development of reasoning skills [11] such as making ideas explicit, arguing, interacting with other students to build a common solution, and so on [12]. There are some experiences that demonstrate that the student's motivation, participation and auto esteem increase when they obtain good results in the accomplished collaborative activities.

Also, there is another fact that has to be taken into, and has to with the huge number of students that have difficulties to express their opinions in public. In traditional classrooms when the teacher asks to one student, the focus of the attention is centered in him or her, while in collaborative environments the focus of attention is distributed among the members of a group. Therefore, collaborative learning creates a safe environment in which students can express and explore their own ideas without fear to failure or critics, helping to develop their skills of communication. The student companions can make constructive critics to the different ideas that are proposed [13], while the teacher can evaluate the learning process as a whole (the reasoning process), not only the final solution of the activity. In this sense, some studies on cooperative learning among students of different ethnics state that their communication skills have been clearly increased [8], due to the fact that students have been actively involved in the learning process, being able to understand the differences, and helping them to learn how to solve the social problems that could arise among them.

Collaborative workgroups should be constituted by the minimal number of people need to perform the work in a effective way. Although collaborative learning groups typically are constituted by two to four persons, the basic rule is: 'the smaller the better' [5]. However, there is not an ideal size for collaborative learning group. The group's productivity is determined by how well the members work together. Usually, homogeneous groups can achieve better specific aims, however, when students with different abilities, experiences and interests are combined (heterogeneous groups), they can obtain more advantages than homogeneous groups. In addition, if the students are allowed to organize themselves, they usually create homogeneous groups, and if the teacher is responsible for making up the groups, he or she selects homogeneous or heterogeneous groups according with his/her personal criteria [14].

To sum up, Bologna process motivates a teaching change where the student was the responsible to own learning process in order to promote the lifelong learning. Collaborative learning between peers has been used during years with this purpose. Furthermore, it contributes to development of personal and social skills such as critical thinking, teamwork, communication abilities and conflict resolution between others.

In this new frame, a combination of different individual and collaborative learning activities play an important role in providing new contexts and possibilities in order to develop these skills. This paper presents a case study of active learning in Telecommunication Engineering at Rey Juan Carlos University. Specifically, it presents the experience of active learning in Object Oriented Programming (OOP) subject.

This paper is structured in several sections. Section 2 describes the general characteristics of the case study including a description of the subject and the characteristics of the new active learning activities proposed to students in order to improve their own learning. In section 3, the global results of this case study and the scores of the new learning activities are shown. Finally, conclusions are presented.

II. THE CASE STUDY

Object Oriented Programming is an optional subject at third year of Telecommunication Engineering at Rey Juan Carlos University. This subject is structured in two main parts: principles of Object Oriented Design using UML and, basic concepts of OOP and applications in Java.

Although all the students belong to Telecommunication Engineering, their profile is different. On the one hand, some students have already studied other subject where they have programmed in Java language. They know some aspects of OOP (concepts of class, object, encapsulation, polymorphism, inheritance, etc.). On the other hand, other students have programmed in other structured programming languages but not in Java. These last students have not previous knowledge of Object Oriented Programming. Students of both profiles have not previous knowledge about object oriented design.

In past years, this subject was structured in theoretical and practical sessions. In theoretical classes, the teacher explained concepts, showed examples of the concepts and proposed exercises to students for solving in the classroom. In practical sessions, students developed Java applications in order to put in practice the theoretical concepts. With this model, students were already participated of their own learning process in an active way.

However, during the 2008-2009 academic year, the teachers of this subject thought that could be useful to include learning activities where students develop their initiative and critical thinking and promote the interaction between students with different background. With this goal, some practical exercises related to object oriented design; a collaborative activity with a public oral presentation; and new practical sessions were proposed to students. Each new activity is explained in the next sub-sections.

A. PACS ('Programming Assignment Correction System')

Teachers of OOP subject wanted students would acquire deep knowledge of "object oriented design" topic and participate in an active way on their own learning process. Furthermore, they wanted that students would develop some personal and social skills such as critical thinking and communication abilities.

In this way, the teachers decided to combine theoretical classes with some practical exercises related to object oriented design. The whole 'OO Design' teaching process can be observed in Figure 1.

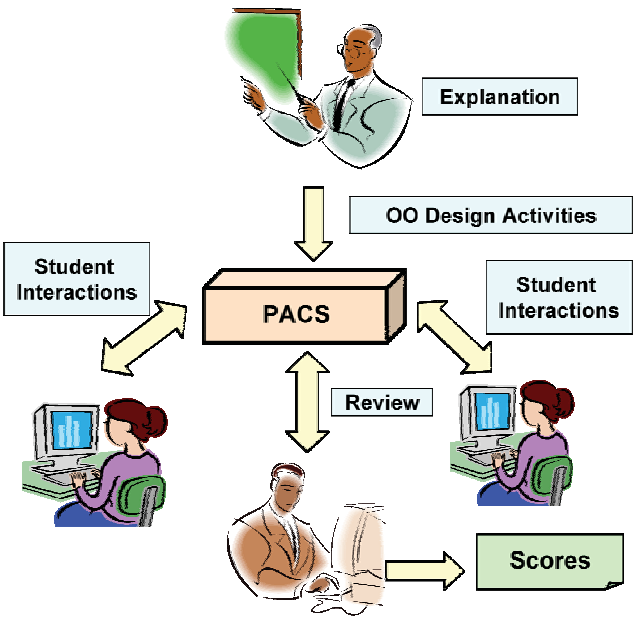

Figure 1. OO Design Teaching Process using PACS.

Firstly, 'Object Oriented Design' concept and the different types of UML diagrams were explained by the teacher in the classroom. Furthermore, students could observe design examples of different OOP applications and accomplish small exercises in the classroom related to every type of UML diagrams.

When theoretical bases had been explained, the teacher proposed a set of practical exercises related to OO design to the students. These exercises should be performed individually by each student. Once students finished their design exercises, they might send their solutions to PACS ('*Programming Assignment Correction System*'). This system is a CSCL ('*Computer Supported Collaborative Learning*') tool developed by Manuel Freire at Universidad Autónoma de Madrid [15]. Students uploaded their solution to this system and then, they adopted the teacher role. They should correct the designs of two classmates corresponding to the same set of exercises or a similar set.

Before using PACS, teachers provide an explanation of this system, how to use it, and a guide with the criteria in order to correct the solutions of their partners. This guide includes the following instructions:

- If the solution of his partner was perfect, the student should try to obtain alternative solution designs in order to give feedback to his partner. Furthermore, he should compare the solution of his partner with his own solution and then, analyze if he did mistakes or if he has misconceptions. If a student would realize he has made errors or he had misconceptions, he should think how to solve them.
- If the solution has mistakes, the student might detect them, explain them and provide solutions.

Furthermore, teachers explained that when they uploaded the correction to the partner solution, they would receive comments about their own correction. The system allows the interaction between students and peer-to-peer collaboration. In this way, if a student is not agreed the correction of their classmates, he could comment their doubts and discuss with them. A student can discuss with his reviewers and with his partners whom he have evaluated their designs.

The figure 2 presents a screenshot with the comments of two students regarding to a certain OO design using PACS. It presents a review accomplished by Víctor and an answer of his partner, María Angeles. They talk about the state diagram of a vending machine. They are discussing the correct solution for this problem. Víctor provides a correction to María Angeles. However, María Angeles is not agreed with some aspects of the Víctor's correction. She comments her doubts arguing the problematic aspects.

An example of a summary with the score given by a student with the teacher role to the solution of his partner is presented in figure 3. The students should assign two scores. The first one indicates if it is possible to improve the solution uploaded. The second score captures if the design of the problem proposed is right or not.

For each student, the final score of this activity is calculated taking into account the own solution of the student (40% of the final score) and the corrections performed to the exercises of his partners (60% of the final score). As it can be seen, the accomplishment of good corrections was considered more important than the own solutions. It was owing to the fact that some students did not take the correction seriously in previous experiences with this system. For this reason, teachers decided to attach more importance to the correction process. The maximum score is obtained when a student has an own good solution to the set of design problems and he corrects the exercises of his classmates in a critical way, as he was the real teacher of the OOP subject (giving feedback such as explanations of the mistakes and possible solutions, or alternative ways to solve the same problem).

Diagrama de Estados 2 responder

Creo que en este ejercicio has entendido mal el concepto de estado ya que lo que marcas como estados tienen nombre de acciones (IntroducirDinero, ComprobarLata, DarRefresco, etc) y algunos eventos tienen nombre de comprobaciones booleanas, según lo entiendo yo. Sin embargo, haciendo un esfuerzo por entender esto como acciones, yo modificaría algunas condiciones como, por ejemplo, las condiciones ifvacio e ifnotvacio que habría que ponerlas como [haylatas] y [¡haylatas] ya que las condiciones en estos diagramas no se ponen con if. Dependiendo de la interpretación del funcionamiento se podrían quitar los estados finales, y redirigirlos al principio, ya que una máquina de refrescos no se apaga cuando se expende una lata. Lo que yo hubiera hecho, descrito un poco por encima, es lo siguiente: - Tendría 3 estados (Espera, EsperaPeticionLata, Comprobacion) - De espera pasaríamos a EsperaPeticionLata cuando se produzca el evento IntroducirDinero(c) y aumentaríamos una variable dinero. Tambien podríamos ir a Comprobacion si pulsaran uno de los botones de lata. - Es EsperaPeticionLata podríamos ir al mismo estado si siguen introduciendo monedas o a otro si piden la lata. - En comprobación iríamos siempre a espera pero con diferentes eventos (expenderlata[dinero>=valorlata && haylata], precioIns[dinero<valorlata], latains[¡haylata]) Nota Diseño: 0.7 Nota Mejora: 0.5

El 2009.04.02-19:51:54, MARIA ANGELES escribió

Re: Diagrama de Estados 2 responder

En este caso no estoy de acuerdo contigo, los estados es cierto que los he llamado como acciones, digamos que tu EsperaPeticioLata yo la tengo dividido en dos estados CompruebaPrecioLata e IntroducirDinero. Si que me falta una transición al mismo estado "IntroducirDinero" y que vaya aumentamdo una variable dinero, eso se me ha escapado. Digamos que en realidad una vez que "crees" que has introducido el dinero siempre le das al boton del refresco por eso mi transición al estado "ComprobarLata" (en tal caso tambien deberia haberse hecho una transicion a DevolverDinero o algo parecido ya que no se va a quedar la maquina con el dinero si no hay lata....pero bueno jeje) y despues va a comprobar que se ha metido el dinero correcto con respecto a la lata que se ha elegido "Compruebo precioLata" . Si no es correcto el dinero la maquina vuelve al estado en que pide dinero y muestra un mensaje "Introduce Dinero".

Figure 2. Example of the interaction between students using PACS

Figure 3. Example of the summary of the review from a student to other

B. Collaborative work and oral public presentation

The main goal of this activity was to promote the collaborative work, the active and autonomous learning and the development of communication skills. This activity was proposed to students at the end of the year. The teachers suggested a list of topics related to theoretical concepts explained before to students in the classroom. Students should organize themselves in workgroups. Then, they should choose a topic from the following list in order to study the topic selected and perform the collaborative work:

a) Relationships between OO design diagrams and their implementation in Java

b) JavaMail

c) Java and mobile devices

d) Distributed Java programming with RMI

e) Java and XML files

f) Database access with Java

g) Servlets and JSP

h) Regular expressions in Java

i) Dates, calendars and formats in Java

j) Creational design pattern: Factory, Singleton

The number of students who constituted the collaborative workgroup depended on the complexity of the topic selected. After students chose the topic, they have to do work on the assigned tasks. Firstly, they should find information of the topic selected, study this information and understand the basic aspects for this topic. Then, they should do a PowerPoint presentation of the work. At least, this presentation should include: i) a brief introduction to the topic selected presenting the general aspects, the most relevant features, advantages, problems, etc; ii) easy examples related to this topic; iii) an exercise for proposing to the rest of the classroom, iv) the solution to the previous exercise, and v) a brief bibliography.

At the end of the year, one person of the group who would be chosen randomly by the teachers would present the work to their classmates.

The score for this activity took into account the contents of the PowerPoint presentation (inclusion of general aspects, descriptive examples, well-structured exercises and correct solution), the design of the presentation (clarity, structured information, etc.), and finally, the oral presentation accomplished (clarity when they were explaining the main ideas, time spent, etc.). All the members of the same workgroup had the same mark taking into account the previous criteria. This activity works the knowledge, the comprehension and the application level of Bloom's taxonomy [16].

Students performed high quality presentations, explained the general aspects for this topic in a clear and concise way. They were able to extract the significant information for each topic selected, to present relevant examples and to propose representative exercises to the rest of their classmates.

C. New practical programming sessions

In previous years, students performed practical programming sessions where they practiced the concepts explained in theoretical classes. This year, the practical sessions included new practical programming activities. These activities consisted of learning of two basic concepts: multiple inheritance and exceptions in an autonomous way.

In theoretical classes, students learnt that Java does not allow multiple inheritances, but can be achieved using interfaces. In order to illustrate how to do multiple inheritance in Java, teachers gave a research paper to students. In Spain, it is not usual that the teachers of the degree subjects give research papers to their students. The paper was titled "*Eliminando la herencia múltiple y el diamante de la muerte*" ("*Removing the multiple inheritance and the Death Diamond*"), by Diego Bravo Estrada [17]. It includes interesting reflections about some topics the students were learning. Besides, the paper contains many examples, so they could understand and even compile what the text explains. In fact, the exercise consists of solving the problems proposed in the article. These exercises illustrate a classical problem in multiple inheritance, that is related to topics such as simple inheritance and polymorphism. In the problem, there is a building with some properties and some methods associated. Furthermore, there are a hotel and a restaurant, which extend the building. And finally (what represents the key for the multiple inheritance), the paper proposes the idea of adding a hotel-restaurant to the model, which extends the hotel and also extends the restaurant. The students worked with inheritance and polymorphism. They also thought over the inheritance (simple and multiple), its problems and some possible ways to solve them. Of course, the solution is presented in the own paper, so they could consult if they would want, after having tried to do it. This practice respects their individual rhythm of learning. Furthermore, some questions related with the comprehension of the paper were asked to students. Mixing all, this activity is a full exercise, which works the knowledge, the comprehension and even the application level, talking in Bloom's taxonomy terms [16].

The second new practical session consist of teach the concept "Exceptions in Java" in a really practical way. Firstly, a very brief theoretical explanation was given to students. This explanation consisted basically of linking this concept with the "mistake" concept, and explaining (very briefly) the role that the exceptions play in the hierarchical structure of classes in Java. Then, a simple code related to exceptions was given in order to compile and run it. With this code, they understood why there are different types of exceptions. The code is gradually getting hardest, and new situations related to exceptions appear. At the end, they had seen the most typical scenarios they would find in many programs. This exercise, such as the previous one, is a guided exercise that assumes the students can see the solution when they would believe that it is time to do it. This type of exercises guides to students on their own learning, if they act with responsibility.

III. Results of the case study

Next, different results of the case study are presented including: i) the final scores obtained by the students of this subject compared to previous academic years, ii) results of the students related to the different learning activities proposed, and iii) data about the participation in the learning activities. The comments of the student experiences with the new active learning activities are included too.

Students of OOP subject at Universidad Rey Juan Carlos have two opportunities to pass the subject in the same year: June and September. During 2008-2009 academic year, there were 26 students in OOP subject. This year, the final score took into account all the activities performed by students and a final exam. Practical sessions, including the new ones, had a weight of 30%; the OO design exercises with PACS and the collaborative work with an oral public presentation were the 10% of the score and finally, the exam was the 60% of the total score.

Table I and II show the scores obtained by students of this subject along three different academic years, between 2006-2007 and 2008-2009 years in both two opportunities: June and September.

Table I presents the scores obtained in June opportunity. The total number of students who chose this subject is stable along these three academic years: 26 students for 2006-2007 and 2008-2009 years, and 25 students during the 2007-2008 year (see the last row in table 1). As it can be shown, the number of students who decide not to present to the final exam (NP row) decreases in the last year opposite to the previous years (only 9 students did not take the final exam against 15 students in other previous years). Furthermore, there are not any students who failed the final exam of June in the last year. These facts cause that the number of students who passed the final exam increased and, the better results rose too in the last year (see the increment of the ">=7 and <9" and ">=9" rows).

TABLE I. SCORES FOR DIFFERENT ACADEMIC YEARS - JUNE

	2006-2007	2007-2008	2008-2009
<5	4	3	0
>=5 and <7	3	5	11
>=7 and <9	2	2	5
>=9	0	0	1
NP	15	15	9
TOTAL	26	25	26

The improvement of the student scores during the last year can be observed in figure 4. The line with rhombus (blue colour) represents the number of students who failed the final exam. The line with squares (pink colour) represents the students who passed the final exam with the minimum knowledge required. The line with triangles (red colour) and the line with crosses (green colour) show the good and excellent student scores respectively at the bottom of the figure 4. Finally, the line with asterisks (purple colour) placed to the top of the figure, shows the number of students who decided not to present to the final exam. This last fact is really important because it means that students had been more motivated this year, and maybe the mix of the new learning activities with the previous ones would have contributed to it.

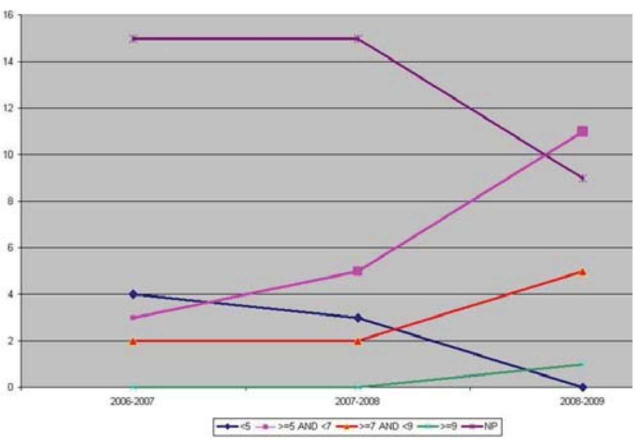

Figure 4. Scores for OOP subject during three years

Table II presents the scores obtained by students during these three academic years in the September opportunity. The number of students who had to present to the final exam in this opportunity were 21 students in the 2006-2007 year, 18 students in the 2007-2008 year and finally, 9 students in the last year. It is important to remark that the last row of this table does not includes the number of students who passed the subject in June opportunity.

TABLE II. SCORES FOR DIFFERENT ACADEMIC YEARS - SEPTEMBER

	2006-2007	2007-2008	2008-2009
<5	1	2	1
>=5 and <7	3	6	1
>=7 and <9	2	0	1
>=9	0	0	1
NP	13	10	5
TOTAL	21	18	9

The total number of students who did not pass OOP subject was 14 in 2006-2007 year, 12 in 2007-2008 year and, 6 in 2008-2009 year (obtained of "<5" and "NP" rows of Table II). We observed that this method achieves a significant decrement of these students. Only the 23% of total students did not pass subject in 2008-2009 year regarding to 54% in 2006-2007 year and 48% in 2007-2008 year. These global results show a clear improvement in the scores of the students and a fall in the number of students who drop out the OOP subject during the last course.

Regarding the results of the OO design exercises and the '*Programming Assignment Correction System*', there were 21 students who participated in this activity against 5 people who did not it. The participation of the students in this subject was high. Figure 5 shows the scores obtained in this new active learning activity by the students.

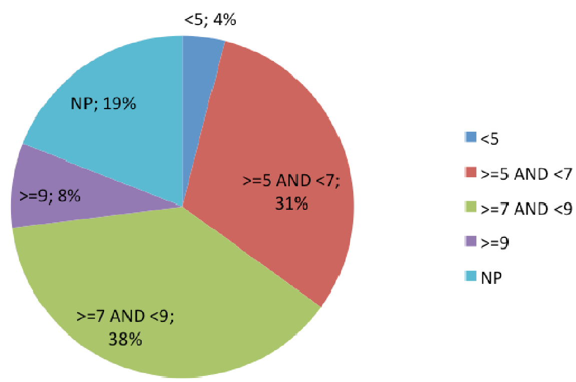

Figure 5. Scores of the students in the OO design exercise

In general, all the students did their exercises and corrected the classmates' exercises appropriately, taking into account the criteria given by the teachers of the subject. Only one person did not take seriously the peer review process of the solution of his partners, and he fails this activity because this is a requirement to obtain the maximum score. Furthermore, students performed better corrections to their partners than their own solutions.

After doing this activity, an opinion poll was done to the students in order to capture the feelings of the students about this type of active learning activity. The peer review process with PACS was easy for the students. They did not need to spend too much time reviewing the exercises of their partners.

This is owing to the fact they have already worked in OO design exercises previously. This type of activity is funnier than other classical learning activities because they can interact with their classmates and helping between them. They like seeing the correction process adopting the teacher role and teaching one another. They understand the comments of their partners in an easy way and they accepted better the critics and comments of their partners. The comments of their partners motivate them and they are a good feedback before obtaining the comments of the teacher.

Students who used Internet Explorer Web browser had some difficulties with PACS when they tried to upload their comments and corrections to the system because this system is optimized for Mozilla Firefox.

Regarding the collaborative work and the oral public presentation, the results were excellent as it can be seen in figure 6. Only three students had not presented this work to the rest of the classroom. Students made presentations whose quality was good or excellent. They explained to their partners the main characteristics of the topic selected and they established the relationships with the concepts explained during previous theoretical classes of the course. Furthermore, they were able to answer the questions performed by their own partners and the teachers. This activity motivates students because they knew new concepts that allow having a global view of more useful topics related with the concepts explained in the course.

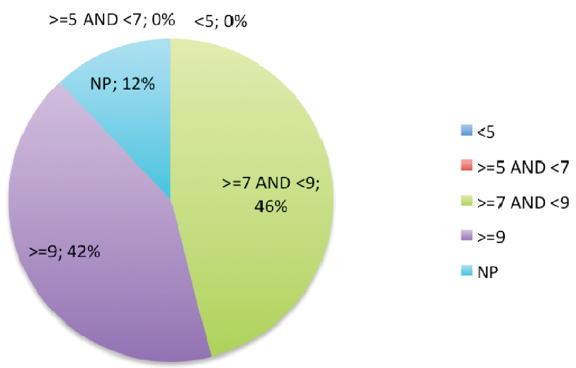

Figure 6. Scores of the students in the collaborative work and presentation

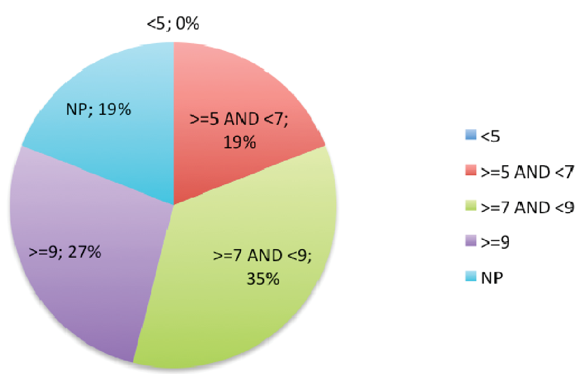

Figure 7. Scores of the students in practical sessions

Finally, the scores obtained by students in the practical sessions are presented in figure 7. As it can be seen, there is nobody who failed the practical sessions. However, there are five students who did not present their practice exercises. In general, scores are really good since 16 students (equals to 62% of the total) obtained a score higher than 7.

IV. CONCLUSIONS

This paper has presented a case study of the experience to include new active learning activities in the Object Oriented Programming (OOP) subject of Telecommunication Engineering at Rey Juan Carlos University. As it can be seen in the results presented of the previous section, the number of the students who drop out the subject decreased against previous year. This is a good indicator to continue applying this methodology. Also, students get higher scores than last years. These two facts are really important. We think that the mix of different active learning activities (theoretical classes, practical sessions, the use of PACS, and the collaborative work with the public presentation) improves that students are involved in their own learning process and they are more responsible on their study. For this reason, their motivation for the subject increased.

Furthermore, the new learning activities included the last academic year aroused interest for this subject. Many students of Telecommunication Engineering choose this subject and then they drop out because it is not enough related with their career. This year, we have achieved that students understand the usefulness of OOP in Telecommunication area and they are able to applied technologies connected with the concepts of this subject.

The peer review process using PACS allows to students receive feedback from other classmates immediately. They learn from the solutions of their partners. This system supports the interaction between students allowing becoming aware of their own mistakes or learning misconceptions, understanding multiple choices to solve the same problem, taking ideas to improve their own solutions or to do other similar exercises, and so on. This type of activity has allowed that students acquired deep knowledge of object oriented design. Furthermore, students put in practice the development of some personal and social skills such as critical thinking and communication abilities. Regarding the work load in accomplishing these activities, students did not spend too much time in the review process. Students are a really hard teacher with their corrections; they correct the exercises of their partners conscientiously, detecting small mistakes and explaining each error and the possible solutions.

The collaborative work performed in workgroups about a selected topic with a public oral presentation promotes the active and autonomous learning and the development of communication skills. The random selection of the person who is the responsible to present the work to their classmates guaranteed that each member of the groups worked in the collaborative work and he understood the topic selected. Students performed good and excellent presentations. They had to understand and analysis the possible uses of the topic. When students had to choose a topic of the list proposed, the most selected topic was "Java and mobile devices" because it is the most related topic with Telecommunication Engineering.

Therefore, although the new active learning activities have a small weight in the final score of this subject, we think that these activities have contributed to motivate to the students in their own learning process. Students like new teaching methods where they are the centre of their own learning and the activities proposed are more dynamic.

Mixing different types of activities, students understand better the concepts explained during the whole course because they are working the knowledge, the comprehension and even the application level, talking in Bloom's taxonomy terms. For this reason, their acquired knowledge remains during a long time. This mix promotes the lifelong learning.

ACKNOWLEDGMENT

Thanks to Manuel Freire Morán at Universidad Autónoma de Madrid for allowing us to use the *Programming Assignment Correction System* for this case study.

Reviews and Findings on Implementing Active Learning in a Large Class Environment

for Mechatronics and Computer Science students

Technical University of Munich (Germany)

***Abstract*— This paper tackled the issues of different learning preferences for Computer Science and Mechatronics students in a large class environment by using different active learning methodologies. Apart from implementing active learning methods in the class, another idea present here is coupling with another course. The efforts required and the effectiveness for these methods are being presented, with this the suitable methods can be selected depending on the participants and the resources available.**

***Keywords*—Computer Science education, Education, Engineering education, Mechatronics**

I. INTRODUCTION

The class size in the universities starts to grow when higher education ceases to be “only for the elites” but also “for the masses” [1]. The most common pedagogy form for large class setting is the lecture setting. A traditional lecture takes place when a lecturer recites or pass on the knowledge in verbal form while the students take note [2]. Among the challenges in a large class settings are it is more difficult to control the class behavior [3], to follow up on students’ understanding, and to encourage students’ participation in the class. In order to overcome these problems, different methods under the term “Active Learning” were introduced. Active learning means the students not only listen and take notes in the class but they also have the opportunity to participate actively in the class [4]. Among the methods implemented in active learning include informal group learning, formal group learning, problem based learning, group work, team-teaching, cold calling, in-class demonstration, muddiest card, flash card, concept test, evaluation form, pause method, laboratory work, and learn management system [2,5,6,7,8]. The different methods mentioned above can be divided into two categories, those that can be implemented in the class and those to be implemented outside the class (see Table I).

Implementation of active learning methodologies requires more effort and resources. As described by Bonwell and Sutherland [5], among the challenges include the decrease of total covered contents, the increase of preparation effort, and the lack of materials and resources. Active learning can be implemented in both large and small class. The size definition used in this paper is as described by Kuo [9]. A small class has less than 25 students, whereas a large class has more than 75 students.

This paper focuses on the introduction of different active learning methods implemented in the course for Mechatronics and Computer Science students in a large class environment with limited resources. Section 2 introduces the course content, the settings of the course and the challenges faced. Section 3 to 5 present the methods implemented in the class outside the class but within the frame of the course, and outside the class through coupling with another course. Section 6 to 8 discuss on the findings for the different methods implemented. The last section concludes this paper by comparing the different methods to its impacts and effort needed for implementation.

Legend: S- Small; M- Medium; L- Large; X-.Implemented

semester 2006 and winter semester 2006/07 respectively. These courses are compulsory for Mechatronics students and Computer Science students who are in their third and fourth semesters. The objective of this course is to train the students to think independently and be able to work in team when developing an embedded system.An embedded system is an embedded hardware/software system that regulates a physical device by sending control signals to actuators in reaction to input signals provided by its users and by sensors capturing the relevant state parameters of the system [27]. The ES1 subjects focus on the development of microprocessors. Among the subjects covered in ES1 are Logic and Gates, Computer Architecture, Scheduling, Programming Languages – PEARL, Assembly Language and VHDL, and Bus System. The ES2 subjects focuses on the development lifecycle of an embedded system [28]. The subjects in this course include Requirements Engineering, Modeling Methods, Automation Technology (with focus on hardware and architecture), Programming Language – IEC 61131-3, and Verification, Validation and Test.

Both these courses are courses with two semester hours a week. One semester hour is 45 minutes. The lecture and the exercise sessions take turn in almost alternate weeks. All sessions last for 90 minutes. There are no prepared lecture notes but the students are able to download the presentation slides from the professor a week before the respective lecture. The week before the exercise session, the exercise questions are uploaded to the internet. This enables the students to work on the questions prior to the exercise sessions.

B. Course Challenges

The first challenge is the discipline diversity of the participants in the courses. Averagely, 66% of the course participants are Computer Science students and another 34% are Mechatronics students. The participants from Electrical Engineering students are negligeble. They are less than 1 % if any. These students have different cognitive minds and response to the different methods differently. The students understand the term modelling differently. During a question answer in the class, the Mechatronic students relate modelling to the modelling of a physical system, where as the Computer Science students relate it to the design of a software system. According to Grimhenden and Hanson [13], Mechatronics students prefer practical work. As shown in Table II, the most implemented active learning method for Mechtronics students are group work, where the students develop a physical system. They are conducted in groups of two or three.

Secondly, the class size for both the courses are large. The average participants for ES1 is 100 students, whereas ES2 is 80 students. The implementation of active learning in a large class environment will be more challenging. Arias and Walker [29] argued that the small class students tend to fare better than those from large classes do. The research undertaken to implement active learning in large class environment [2,5,21,25] showed that much resources are required. This leads to the third challenge, the limited human resources.

The third challenge is the limited human resources. Interdisciplinary courses are courses where more than one disciplines are taken into considerations [30]. The course discussed in this paper is considered as interdisciplinary course [31]. From the research conducted (see Table II) the number of the contributing departments for interdisciplinary course is usually more than the number of disciplines. This also means that at least a professor and teaching staff from each department are available to conduct the course. As shown in item 21 in Table II, the course consisted of students from two different disciplines – the Mechatronics students and the Computer Science students. However, unlike most of the research done, where the number of contributing departments is more or same as the disciplines involved, here, the opposite happens. The number of disciplines is two, whereas the contributing department is only one. A professor and a teaching assistant are responsible for this course. The ratio between teaching resources to students is 1 to 80.

The three challenges faced in this course will be discuss overall. Different methods implemented in the course of 5 semesters to cater to the diversity of the class, to overcome the barriers of large class environment and to make full use of the limited resources available will be presented. The implemented methods will be addressed in three categories, namely the methods implemented

- in the class,
- partially outside the class but within the frame of the course, and
- outside the class as coupled with another course.

III. METHODS – IN THE CLASS

A. Methods implemented during the Lecture

In order to maintain the students' attention, the lecturer very often includes students' participations in the lecture. Among the methods used in the lecture are

- in class demonstration with participations from students,
- asking questions to the students without embarrassing them, and
- presenting the idea visually on the board even though the class also uses slides presentation.

An example of an in class demonstration with students' participation is the join process in a Petri Net. In order to explain the tokens, places and transitions, four students participate in this demonstration. One student will hold the pen cover, and the other the pen. Both these students are the places with the pen and the cover as the tokens. Next, the pen and the cover will be passed to a student who plays the "transition" role. The student will put the pen and the cover together, and then passed the covered pen as a single token to the next student. Different role plays were conducted to explain the different process that can take place in a Petri Net.

As to asking questions in the class, the round robin method was implemented. If the student is not able to answer the question, the person next to this student will be next in row to help him/her out. Not much time is spent waiting to avoid embarrassment. This method not only keeps the students involved but also awake, as the class starts at 8:15 in the morning.

Even though the information is available in the handouts for the students, it helps to draw the students' attention when this information is once more presented on the board. For example drawing a microprocessor part by part, and explain the functions of each component as they are drawn on the board.

B. *Methods implemented during the Exercise*

During the exercise session, which takes place almost alternate weeks, students are requested to work out the exercise problems on the board. However, the response had not always been positive. A few minutes will be given for the students to discuss the problem with their neighbor if most of the students did not work out the questions before hand. They would then be requested to solve the problem on the black board in front of the class.

In order to encourage the class participations, the teaching assistant tried to remember as many names as possible and to call these names in the class. However, the number of names remembered is at most 15. It was also not exactly "fair" to repeat the few same names weeks after weeks. The second method used to encourage students participation was to have a name list and to pick a name from this list. However, some students will pretend as if they were absent, choose to remain silent and not proceed to work out the problem even though they are actually in the class. In summer semester 2009, the teaching assistant tried a new approach. The tool was a packet of facial tissue paper. The teaching assistant posed a question and threw the packet to the first student who was supposed to answer the question. The student then in turn can throw the packet of tissue to another student for the next question. This method had been the most welcomed method as compared to the first two. This also brought some fun factors into the class.

C. *Bench Scale Equipment as Example*

Throughout the lecture of ES2, bench scale equipment was introduced. The purpose is to use a consistent example during the lecture and exercise, with the idea that this would help the students' understanding on the course content. The bench scale equipment is a stamping and sorting machine. The equipment can be divided to four modules, namely the storage module, the

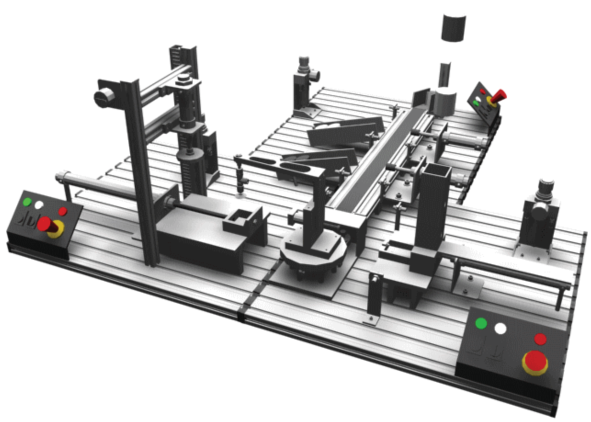

Figure 1. Bench scale equipment with four modules

crane module, the stamping module, and the sorting module. The students were taught how the sensors and the actuators function. The storage module is the simplest module where a tactile sensor will sense if there is a work-piece that needs to be pushed out. The crane will pick the work-piece and send it to the stamping module and than later to the sorting module. Examples for requirements engineering, system modeling, program development, and testing was based on this equipment when possible.

D. *Pop Quizzes*

Pop quizzes are impromptu quiz conducted at the beginning of the class. The purpose of pop quizzes is to encourage students' attendance and to have an in between overview on how much did the students understood in the previous lectures. Two or three pop quizzes will be conducted through out the semesters. Fifteen minutes were given to the students to finish up the quizzes. The motivation for participating in the pop quizzes is the possibility to include pop quizzes' results in the final result of the course. The students who participated in pop quizzes can at most increase their marks by 15%.

IV. Methods – Partially Outside the Class

A. *Group Work with Partial Life Cycle Development*

As the content of ES2 focuses on the development of an Embedded System, the idea is to allow the students to go through the different life cycle phases using group work. In summer semester 2007, the students were divided into groups of 10. Each group was responsible for a chapter covered in the course. As observed in Fig. 2, the students were divided into nine groups. In order to encourage communications from the different disciplines, it was a pre-requisite that the group should be 70% Computer science students and 30% Mechatronics students.

No specific tool was implemented here. The students can

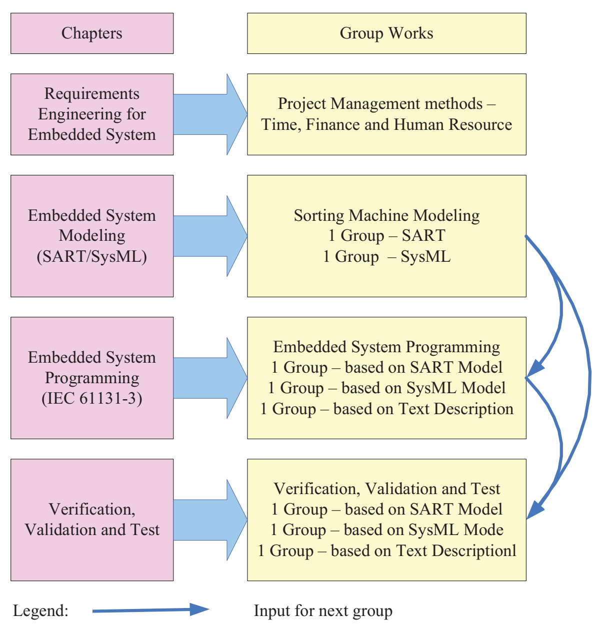

Figure 2. Bench scale equipment with four modules

select tools that they know or ordinary drawing tools to model the system in "Structured Analysis with Real Time Extension" (SART) [32] or "System Modeling Language" (SysML) [33]. The programming was conducted in the exercise session by writing the program either in structured text or in function block. The main objective here is to observe what the students can understand from the modeling diagram. The validation and test group will then compare if the functions mentioned in the modeling diagram were fulfilled in the program.

Each group was expected to deliver a written report and a 15 minutes presentation. Each group had a fix appointment with the teaching assistant two weeks before the presentation session. This ensured that the students are on the right track and well-prepared for the presentation. They can make extra appointments when necessary. The presentation was conducted during the exercise session. Therefore, during summer semester 2007, thirty minutes from the one and a half hour exercise was used for group works' presentation.

B. *Group Work with Whole Life Cycle Development*

In summer semester 2009, a different concept of group work was implemented. The students were again divided into groups of tens. This time instead of making it a pre-requisite, the students were encouraged to have a group with members from both disciplines. However, the Computer Science students grouped automatically with the Computer Science and the Mechatronics with the Mechatronics. This shows that students are still more comfortable to work with the people they are familiar. In order to encourage interdisciplinary communication and group work, the group distribution with students from different disciplines needs to be intentional.

TABLE I DIFFERENT ASSIGNMENTS IN GROUP WORK

Project Assignment	Description
Part A: Requirements Engineering	1) Decide on the job description of each member 2) Requirement document for the system
Part B: System Modeling (SART)	1) System modeling document
Part C: System Modeling (SysML)	1) Report on modules that can be reuse
Part D: System Development (Own Group)	1) System simulation 2) Report on document evaluation from part A to C.
Part E: System Development (Another Group)	1) System simulation 2) Report on document evaluation from part A to C.
Part F: Test and Validation	1) Test cases and test result for own system
Part G: Group Work Evaluation	1) Evaluation report

The same bench scale equipment was used as the foundation for the group work. Instead of working on one of the lifecycle phases, the same group had to start from requirements gathering and ends at verification, validation and test. Using the different actuators and sensors introduced in the class, the students were requested to design a system on their own. They needed to produce a requirement document, explaining the system description. Next, they would need to design the system using SART, and observe on any possible reusable modules and present it using block definition diagram and internal block diagrams from SysML. After that, they would develop a simulation for the system using TrySim [34]. Apart from developing their own system, the group received a copy of system description and system modeling from another group, and they should implement the system from another group as well. Table III describes the different assignments in this group work.

For assignment parts A to C, the students were free to use any drawing tools that they are familiar. However, the students were also encouraged to attend an additional related course, which will be described in the following chapter, to learn the tools that they can use for the whole lifecycle process. The simulation software needed for part D and E was presented during the exercise and was also taught in this coupled course. Unlike the former group work, no in-class presentation was arranged. The students only need to do one presentation at the end of the group work

V. METHOD – COUPLING WITH ANOTHER COURSE

A. *Loosely coupled Software Tools*

In summer semester 2007, the course Software Tools with course code FB16-6959 (SWT) was introduced. This was a two semester hours week course, meaning the students needed to attend a 90 minutes class/lab session each week. The objective of this course is to introduce different software tools that can assist the engineering process. These different software tools can be mapped into the different development life cycle of an embedded system. Therefore, the coupling is done by first teaching the theory in ES2 lecture and then practical in SWT. In summer semester 2007, the tools introduced in SWT were IBM RequisitePro Software [35] for Requirements Engineering, Visual Object Net++ [36] for Petri net, Enterprise Architect [37] for UML [33], and TrySim [34] for IEC 61131-3 programming. The students worked in pairs to solve the problem using the different tools.

Before the semester began, the schedule for SWT and ES2 were coordinated in such a way that the practical work in SWT should only be conducted after the subjects were taught in ES2. SWT also used the same bench scale equipment as case study for the class. However, the functions of the equipment were modified. The students were requested to sort the work-pieces differently as those in ES2. The students were graded base on the practical work delivered throughout the whole course. There is no written test for SWT.

B. *Closely coupled Software Tools*

Through the SWT course evaluation from summer semester 2007, we learnt a few lessons. The course arrangement scheduled during the beginning of the course was not optimal as there were times when ES2 lectures took longer than expected to finish or the subjects were rescheduled due to unforeseen circumstances. ES2 taught the students SysML but in SWT, UML was implemented. As a result, a number of students were confused as both mark-up languages share a number of similar points though they are different. The students who participated in both ES2 and SWT claimed that the same lab bench equipment with different software functions confused them.

For summer semester 2008, a few different methods were implemented. Firstly, the first three weeks of SWT were used for two lectures on lifecycle process and the selection of tools, as well as group organisation. This gave SWT a three weeks' buffer if ES2 schedule is delayed due to unforeseen circumstances. Secondly, instead of teaching UML, the students were taught SysML. This would avoid any confusion that might occur. SysML was chosen as SysML includes modelling of system architecture and behaviour.. Thirdly, throughout the whole ES2 and SWT classes, the students were reminded that the same hardware can have different software functions. The same lab bench equipment was used for ES2 and SWT but their software functions are different.

The tool IBM Requisite Pro Software excluded from the course Software Tools for summer semester 2008. This is due to two reasons. Firstly, from past experience, the students needed at least three weeks (three practical sessions) to be familiarized with the tool. Secondly, we received six sets of network kit where the students can configure the connections between computer and controller and test download the programs for the controllers. The network controller kit was coupled with the Bus System chapter that was brought forward from ES1.

VI. BASICS FOR ANALYSIS

A. *Data Source*

There are three batches of students involved in this study. As shown in Table IVA, they are batch 0607, 0708, and 0809. They each stands for the semesters where ES1 takes place. Batch 0607 includes ES1 in winter semester 2006/07 (ES1 WS0607) and ES2 in summer semester 2007 (ES2 SS2007). The same applies to batch 0708 and 0809.

TABLE IIA METHODS IMPLEMENTED IN THE DIFFERENT SEMESTERS

Batch	0607		0708		0809	
Implemented Methods	WS0607	SS2007	WS0708	SS2008	WS0809	SS2009
Pop Quiz	--	--	X	X	X	--
Group Work	--	X	--	--	--	X
Software Tools	--	X	--	X	--	X

TABLE IVB DATA SOURCE FOR ANALYSIS

Data Source	WS0607	SS2007	WS0708	SS2008	WS0809	SS2009
Course Exam Result	X	X	X	X	X	X
School Exam Result	X	X	X	X	--	--
Course Evaluation	--	X	--	X	X	X
Group work Evaluation	--	--	--	--	--	X

Three main data source were used to analyze the effectiveness of the different methods (see Table IVB). They are the course evaluation conducted at the end of the semesters, the group work evaluation for summer semester 2008, the group work, pop quizzes and exam results from the students. The data were collected across five semesters, from summer semester 2007 to summer semester 2009.

When comparing the effectiveness of different methods in a particular semester, no extra point grade will be used. The students who participated in the pop quizzes or group work had the opportunity to collect extra 15% points. A student who did not participate in pop quizzes nor group work can have 100% full score but a student who did can have 115% for full score. For example, a student earned 10% extra point from the pop quizzes or group work and in the final exam this student scored 70%. The no extra point (NEP) percentage is 70%, whereas the extra point percentage (WEP) is 80% (10% + 70%). "No extra point grades" are the grades according to the NEP percentage and "extra point grades" are the grades according to the WEP percentage.

In order to have fair comparison, the exam results for other courses from the same batch of students for that particular semester were taken into consideration. This will function as the control data for comparison with ES1 and ES2. Even though it is not compulsory for the students to follow the semester plan, from the course evaluation, we discovered that almost 57% of the Computer Science students and 97% of the Mechatronics students do follow the semesters plan. Therefore, it is reasonable to use the overall grade from the semester as control data. The ES1 and ES2 grades used here are the final grades that include the extra points accumulated through pop quizzes or group work. As the control data for batch 0809 is still in process, only control data for batch 0607 and 0708 are available.

The grading used in Germany is from scale 1 to 5, with 1 as the best grade and 5 as the poorest grade. The grades used for comparison are the average grades, unless mentioned otherwise. In the following, control grade means the average grade for control data and course grade means the average for course grade. 2-tail tests at $\alpha = 0.05$ are mainly used in the analysis, unless mentioned otherwise. The students' results from the different semesters fulfills the normal distribution.

B. *Comparison with Control Data*

TABLE III COMPARISON OF STUDENTS IN ES1 AND ES2 TO CONTROL DATA

Computer Science	Control Data			Course Data		
	N	Average	Std. Dev.	N	Average	Std. Dev.
WS0607	298	3,436	1,2232	71	3,515	1,3920
SS2007	139	2,900	1,0476	50	2,884	1,0223
WS0708	258	3,322	1,2917	52	3,404	1,0066
SS2008	147	3,354	1,1637	45	2,984	1,4327
WS0809	--	--	--	50	2,946	1,3577
SS2009	--	--	--	56	2,850	1,2262

Mecha-tronics	Control Data			Course Data		
	N	Average	Std. Dev.	N	Average	Std. Dev.
WS0607	78	3,082	1,132	25	3,932	1,3247
SS2007	91	2,924	1,1261	24	3,054	0,9302
WS0708	140	2,800	1,1000	33	3,036	1,3583
SS2008	149	2,951	1,0771	27	2,419	1,4531
WS0809	--	--	--	29	3,007	1,5597
SS2009	--	--	--	24	1,662	0,7523

Computer Science

The average grade for the course and control grade improved significantly for batch 0607. The average grade for ES1 WS0708 was 3.404 and it improved significantly (with p = 0.10) in ES2 SS 2007, with 2.984 (see Table V). There was no significant improvement for the control grade for batch 0708.

The course grade for ES2 SS2008 is significantly better than control grade. Similarly, to batch 0708, there is also no significant improvement for the course grade in batch 0809. Therefore, the following two conclusions can be made for Computer Science students:

- The students performed better in ES2 as compared to ES1 for batch 0607, 0708, and 0809
- The methods implemented in ES2 SS2008 have more positive impacts than the methods implemented in ES2 SS2007 and ES2 SS2009.

Mechatronics

There is no significant improvement between the semesters for the control data. The average grade for the control data was 3.082 for winter semester 2006/07, 2.924 for summer semester 2007, 2.800 for winter semester 2007/08, and 2.951 for summer semester 2008. Unlike batch 0607, the control data's average grade for summer semester 2008 was poorer than the winter semester 2007/08. As for ES1 and ES2 average grade, the average grade for batch 0708 shows no significant difference but the grade for batch 0607 and 0809 shows significant improvement. The average grades for batch 0607, 0708 and 0809 are as follow: 3.932 and 3.054; 3.036 and 2.419; and 3.007 and 1.662. The following two conclusions can be made for Mechatronics students:

- Just like the Computer Science students, the Mechatronics performed better in ES2 as compared to ES1 for batch 0607, 0708, and 0809
- Unlike the Computer Science students, the methods implemented in ES2 SS2008 were least significant for the Mechatronics students.

VII. Analysis – Methods in the Class

A. *Methods in the Lecture and Exercise*

The observation for the methods implemented in the lecture and exercise are done through the feedbacks in the course evaluation form and the students' participation in the class. We conclude that the question and answer, demonstration in the class and students having the opportunity to work out the problem in the class have positive impact.

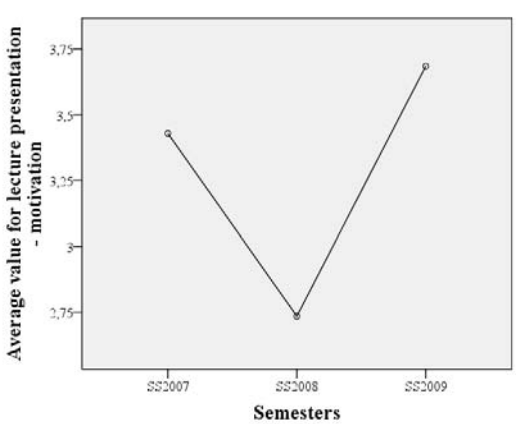

Figure 3. Average value for motivation in the lecture

The communication with the students in the class has more influences than the slides, in attracting students' attention and interest to the contents of the courses. The students who participated in ES1 and ES2 commented that there were too many slides. As comparison, other courses in the faculty provide lecture notes and as a result have simpler lecture slides. As there were no prepared lecture notes for ES1 and ES2, the slides had the function to provide the additional related information that the students need. Efforts to reorganize the slides took place in ES2 SS2008 but the students still find the slides and the course content overwhelming. In ES2 SS2009, another lecturer uses the same slide for lecture. However, unlike the previous lecturer, this lecturer had almost no communication with the students. Students were not questioned in the class, short pauses were made to ask if they have any question but the class remains silent most of the time. Using the evaluation feedback for ES2 SS2007, ES2 SS2008 and ES2 SS2009, there was a significant difference for the motivation in lecture for the different students. The motivation for SS2008 was the best, followed by SS2007 and SS2009 (see figure 3). Even though the understanding on the course lecture also follows the same pattern but the average did not differ significantly when using one-way ANOVA test. The attendance for ES2 SS2009 also dropped drastically when compared to other semesters. There were time when only 20 out of 80 students attended lecture.

B. *Implementation of Bench Scale Equipment*

The same bench scale equipment was implemented for both ES2 and SWT. This saved time in explaining how the different hardware functions and the slides prepared can also be used for both courses. There were few comments in the evaluation form saying that the bench lab equipment should be introduced earlier. In the group work evaluation for ES2 SS2009, 65.9% of the students graded the bench lab equipment as useful or very useful in helping them to understand the course content. Another 20.9% was neutral and only 13.2% graded it as not useful and not useful at all.

From the teaching assistant point of view, using the same bench lab equipment saved preparation time in terms of preparation of lecture slides, exercise slides, and helped students to understand what can be implemented in the group work. This gave the students the time to gain needed understanding on the selected hardware structures and the respective software implementations. However, as the same hardware with different software might cause confusion to the students, it is important to stress this frequently in the class. No students complained about this issue in the latest evaluation.

C. *Implementation of Pop Quizzes*

Generally, students who participated in pop quizzes fared better than those who did not. Except for winter semester 2007/08, the students who participated in pop quizzes scored significantly better. The expected advantage of the students' participation in the pop quizzes is to help students familiarize with the exam questions' pattern, besides having a more consistent revision on important course contents. Another possible advantage might be students who sat for pop quizzes are able to estimate time needed per question better.

TABLE IV COMPARISON OF PARTICIPANTS AND NON PARTICIPANTS FOR POP QUIZZES

Pop Quizzes			Participants			Non-Participant			Significance
			N	Average	Std. Dev.	N	Average	Std. Dev.	
Computer Science	ES1	WS0708	52	3,506	0,9662				
	ES2	SS 2008	25	2,692	1,1622	20	4,070	0,9251	0,000
	ES1	WS0809	29	3,069	1,3696	21	3,371	1,1829	0,419
Mecha-tronics	ES1	WS0708	30	3,100	1,1858	3	4,333	0,5774	0,088
	ES2	SS 2008	20	2,400	1,2703	7	3,857	0,8772	0,010
	ES1	WS0809	15	2,320	1,4047	14	4,114	0,9281	0,000

The average grade for students who took part in pop quizzes is significantly better in ES2 SS2008 but not in ES1 WS0708. The improvement of average grade for Computer Science students in batch 0708 who took part in pop quizzes is from 3.506 to 2.692, whereas the improvement for Mechatronics students is from 3.100 to 2.400 (see Table VI). This average grade improvement is not observed in batch 0809 where pop quiz is implemented in ES1 and group work in ES2. One reason might be that after two semesters of pop quizzes, the students can understand and answer the exam questions better.

There is a significant difference when comparing the attendance for group works that were implemented in ES2 SS2008 and ES2 SS2009, with the attendance for pop quizzes that were implemented in ES2 SS2008 and ES1 WS0809. The attendance when pop quizzes were conducted is better than the group work.

The implementation of pop quizzes seems to be the most effective methods in preparing the students to answer the exam questions. The extra effort needed to implement this are the time for the pop quizzes preparation, quiz marking, and the discussions with the students after each pop quiz. Averagely, 4 hours were needed to prepare a 20 minutes pop quiz, 30 minutes to correct the forty quizzes, 30 minutes to discuss the quiz questions and answers with the students, and another 30 minutes for extra organization works. Each pop quizzes is estimated be an additional 5 to 6 hours work for the teaching assistant.

VIII. ANALYSIS – METHODS PARTIALLY OUTSIDE THE CLASS AND COUPLING WITH OTHER COURSE

A. Comparison of Partial Life Cycle with Whole Life Cycle Development Group Work

Out of the 74 students in summer semester 2007, 57 took part in the partial life cycle development group work. There is a significant difference between the average grades. Students who participated in the group work scored 2.746 as average grade, whereas those did not scored 3.588. The average grade for those who participated in whole life cycle development group work in summer semester 2009 is also significantly better than those did not. The students who participated in the group work scored average grade 2.310 while those did not only scored 3.055. 51 from the 80 students participated in the group work in summer semester 2009.

Table VII separates the Computer Science students from the Mechatronics. It is interesting to note that the Computer Science students and the Mechatronics students have almost the opposite effects. The average grade for Computer Science students who participated in the partial group work was significantly better than those who did not, and the average grade for those who participated in the whole life cycle group project was significantly poorer than those who did not. The opposite is true for the Mechatronics students. One clear conclusion that can be drawn here is whole life cycle group work strongly influence the Mechatronics students, this supports the idea from Grimhenden and Hanson [13].

As compared to the partial group work in summer semester 2007, the Computer Science students' participance was lower in the whole life cycle group work in summer semester 2009. One reason given by the students who did not participate was the group work is too time-consuming. The partial life cycle group work requires the whole group work on one phase and the work can be completed in two to three meetings. The whole life cycle group work, on the other hand, will require more co-ordination effort and students might need to be involved in more than one phase of the life cycle. The Computer Science students commented that the extra 15% point is not worth the effort. They would prefer to use the time to revise on their own.

The effort needed to conduct partial life cycle group work was less than the whole life cycle group work. Only one to two appointments with the students were needed for the partial life cycle group work, where as the whole life cycle group work required at least four appointments, where each appointment had a duration of 30 minutes. The group work presentation for the partial life cycle group work was conducted in the class, where as extra appointment during the semester break was used for the group work presentation. Almost eight extra hours were required to conduct partial life cycle group work but at the expense of thirty minutes of the exercise. The whole life cycle group work required at least two to three hours extra time for each group. As there are eight groups, this amounted to an additional time of twenty four hours to implement the whole life cycle group work.

B. Comparison of loosely coupled and closely coupled Software Tools

Generally, loosely coupled SWT did not have any significant impact on the students who participated in it. During summer semester 2007, 32 from 74 students participated in SWT. However, closely coupled SWT made significant impact on ES2 grade for the students who participated in it. The average grade for students who participated in SWT in summer semester 2008 was 2.28 as compared to 3.05 for those who did not. The result for summer semester 2009 also supported the observation where closely coupled SWT has more impact and the approach had significant influence on the participants. The students who

TABLE V COMPARISON OF PARTICIPANTS AND NON PARTICIPANTS FOR SOFTWARE TOOLS

Software Tools			Participants			Non-Participant			Significance
			N	Average	Std. Dev.	N	Average	Std. Dev.	
Computer Science	LC SWT	SS 2007	10	3,200	0,7409	40	3,238	1,0081	0,913
	CC SWT	SS 2008	2	3,150	2,6163	43	3,312	1,2236	0,862
	CC SWT	SS 2009	7	3,857	1,0830	49	3,286	1,2057	0,241
Mecha-tronics	LC SWT	SS 2007	22	3,350	1,0541	2	4,500	0,7071	0,149
	CC SWT	SS 2008	24	2,583	1,2761	3	4,333	0,5774	0,029
	CC SWT	SS 2009	22	2,532	1,2029	2	5,000	0,0000	0,009

participated in SWT had 2.021 average grades, whereas those did not, only have 2.763.

TABLE VII COMPARISON OF PARTICIPANTS AND NON PARTICIPANTS FOR GROUP WORK

Group Work			Participants			Non-Participant			Significance
			N	Average	Std. Dev.	N	Average	Std. Dev.	
Computer Science	GW-Partial	SS 2007	41	3,029	0,8878	9	4,144	0,6966	0,001
	GW-Whole	SS 2009	34	3,659	1,0252	22	2,891	1,3140	0,018
Mecha-tronics	GW-Partial	SS 2007	16	3,544	0,9906	8	3,250	1,2581	0,537
	GW-Whole	SS 2009	22	2,532	1,2029	2	5,000	0,0000	0,009

Table VIII separates the Computer Science students from the Mechatronics. A few trends can be observed here. Firstly, the participation from Mechatronics students was higher as it was a compulsory course for them. Secondly, there was no significant difference if the Computer Science students participated in SWT or not. Thirdly, closely coupled SWT positively influenced the Mechatronic students' result. The ES2 result between those who took part in closely coupled SWT was significantly better than those who did not.

Generally, students who participated in SWT had better average grades than those who did not. The average grades for loosely coupled SWT were poorer than the control data. However, tightly coupled SWT's average for both Computer Science and Mechatronics was better than the control data average.

IX. CONCLUSION

In this paper different active learning methods for a large interdisciplinary class were introduced analyzed. There were three challenges presented in section IIB, namely – students from different disciplines have different cognitive mindset, it is difficult to engage students in a large class setting, and the limited teaching resources.

To the point different cognitive mind set the following points are summarized:

- The pop quizzes benefitted both Computer Science students and Mechatronics students.
- The Computer Science students prefers partial life cycle group work as it requires less time and effort as compare to the whole life cycle group work.
- The Mechatronics students on the other hand are willing to put in the effort required by whole life cycle group work and benefitted more as compared to the Computer Science students.

In order to engage the students in a large class setting, it is important to involve the students. Simple methods like round robin questioning, in class demonstration and "throwing tissue pack" should be implemented. Preparing good nice slides or explaining the slides in details is not sufficient to draw the students' attention.

In order to reduce the effort required to conduct the course, implementation of the same bench scale equipment for the different subjects is recommended. Apart from this, coupling with another course is another possibility to win new resources for the course.

Table IX summarizes the effort needed and the effectiveness of the different methods. "Pop quizzes" is a winner, followed by closely coupled software tools. Pop quizzes prepare the students to answer the exam questions for the final exam. However, one weakness with pop quizzes is the students do not get to implement the theory. In SWT, the students are able to implement the theory they learnt in ES2 in a software tool. The effort required to closely couple with another course is not high in term of man-hours but the two co-ordinators need to be in constantly exchange feedback concerning what was being taught and what difficulties faced by the students. Depending on the available resources and the participants in the class, one can select the most suitable method for the class using Table IX.

TABLE VI EFFORTS REQUIRED AND EFFECTIVENESS OF THE DIFFERENT METHODS

Method	Effort	Effect	
		CS	M
Round Robin questioning	Low	+	
In class demonstration with students' participation	Low	+	
Throwing tissue pack to students	Low	+	
Implementation of bench scale equipment	Low	+	
Pop quizzes	4 hrs + n(30 mins)	++	++
Partial life cycle group work	2 hrs + n(8 hrs)	++	-
Whole life cycle group work	2 hrs + n(24 hrs)	--	++
Loosely coupled software tools	2 hrs	-	+
Closely coupled software tools	3 hrs	o	++

++ significantly good — - poor
+ good — -- significantly poor
o no visible impact — n = number of group with 40 students

For teaching Embedded System in a large class environment, especially with participants from Computer Science and Mechatronics students, it is recommended to implement pop quizzes and closely coupled software tools. Pop quizzes significantly benefits both Computer Science and Mechatronics students in their exam. Closely coupled SWT provides the opportunity to implement the theory learnt in ES1, and has more impact than loosely coupled SWT.

Abstract— **The Bologna Declaration and the implementation of the European Higher Education Area are promoting the use of active learning methodologies such as cooperative learning and project based learning. This study was motivated by the comparison of the results obtained after applying Cooperative Learning (CL) and Project Based Learning (PBL) to a subject of Computer Engineering. The fundamental hypothesis tested was whether the academic success achieved by the students of the first years was higher when CL was applied than in those cases to which PBL was applied.**

A practical case, by means of which the effectiveness of CL and PBL are compared, is presented in this work. This study has been carried out at the Universidad Politécnica de Madrid, where these mechanisms have been applied to the Operating Systems I subject from the Technical Engineering in Computer Systems degree (OSIS) and to the same subject from the Technical Engineering in Computer Management degree (OSIM). Both subjects have the same syllabus, are taught in the same year and semester and share also formative objectives.

From this study we can conclude that students' academic performance (regarding the grades given) is greater with PBL than with CL. To be more specific, the difference is between 0.5 and 1 point for the individual tests. For the group tests, this difference is between 2.5 and 3 points. Therefore, this study refutes the fundamental hypothesis formulated at the beginning. Some of the possible interpretations of these results are referred to in this study.

Collaborative work; Education; Engineering Education

I. INTRODUCTION

"On 28 and 29 April 2009, the Ministers responsible for higher education in the 46 countries of the Bologna Process met in Leuven and Louvain-la-Neuve to establish the priorities for the European Higher Education Area until 2020. They highlighted in particular the importance of lifelong learning, widening access to higher education, and mobility" [1]. They emphasized as well on the significance of Student-centered learning and the teaching mission of higher education. "Student-centred learning requires empowering individual learners, new approaches to teaching and learning, effective support and guidance structures and a curriculum focused more clearly on the learner in all three cycles" [2]. New active learning methodologies such as Cooperative Learning (CL) and Project Based Learning (PBL) are found among the new approaches adopted in teaching and learning.

Cooperative learning is the instructional use of small groups so that students work together to maximize their own and each other's learning [3], [4]. In this work CL has been applied with the jigsaw technique [5]. The comparison, between the effectiveness of CL and the lecture/discussion method in higher education, has been examined in several studies [3], [6]-[8]. PBL has been established in the field of engineering as a significant experience which promotes cognitive activities and long-life learning [9]-[12].

The Educative Innovation Group DMAE-DIA [13] of the Universidad Politécnica de Madrid has been using active learning methodologies such as CL and PBL [14]-[18] for several years. This group is aimed at: 1) achieving a more active students´ participation in the learning/teaching process; 2) improving student's academic performance by promoting specific competences and 3) developing new learning and assessment methodologies.

A practical case, by means of which the effectiveness of CL and PBL are compared, is presented in this work. This study has been carried out at the Universidad Politécnica de Madrid, where these mechanisms have been applied to the subject Operating Systems I of the degree in Technical Engineering in Computer Systems (OSIS) and to the same subject of the degree in Technical Engineering in Computer Management (OSIM). The aim of the study is to compare the advantages and disadvantages of CL and PBL when applied to Engineering. Among the criteria to be compared we can find: 1) the academic performance of students; 2) the drop-out rate and the time in which it took place; 3) the opinion of students with regard to different aspects of the subjects: assessment methodologies, teaching methodologies adopted or the level of difficulty of the subjects studied.

As far as we are concerned, no studies of this nature which make a comparison between CL and PBL have been published. There are, however, some publications which differentiate between Project Based Learning and Problem Based Learning [19], [20], between Problem Based Learning and the traditional educational methodology [21], [22] as well as between CL and the traditional development of lectures [6], for instance. Hence the importance of this study, due to its originality.

The hypothesis of work is that the academic success achieved by students would be higher when CL is applied to the subject than in those cases in which PBL is applied. Two reasons support this idea: 1) The lack of maturity noticed in students during the first year to organize learning by themselves; 2) CL (as a "jigsaw") entails a more directed learning process than PBL. Therefore, a better academic performance is expected.

This paper is structured as follows: the number of participants who took part in the study, the teaching practice developed and the way in which data analysis was carried out are described in section 2. Section 3 presents the study results as well as a discussion about them. Section 4 is used to make a brief description of an experience in which both methodologies (CL and PBL) where combined and applied to two subjects of Computer Engineering. Finally, the main conclusions of this work are presented in section 5.

II. METHOD

A. Participants

This study has been carried out at the Universidad Politécnica de Madrid, where CL and PBL have been applied to Operating Systems I subject of the degree in Technical Engineering in Computer Systems (OSIS) and to the same subject of the degree in Technical Engineering in Computer Management (OSIM). Both subjects have the same syllabus, are taught in the same course and semester and share also formative objectives. The latter syllabus, OSIM, has been taught applying PBL to a group of 60 students, who were put together into an only group. The former, OSIS, has been taught applying CL to 107 students, who were divided into two groups. The three professors who have taught these subjects are highly experienced both in teaching the subjects and in using CL and PBL.

B. Procedure

Both subjects, OSIS and OSIM, are broken down into five topics: Introduction, Process and Threads, Memory Management, Input/Output and File Systems. Students had only one book of reference [23] to meet all these topics. Both subjects, OSIS and OSIM, were taught for 15 weeks, with two-hour sessions per week.

In the subject SOIM the tasks which constitute the project will be carried out by groups of 4 or 5 students. This project is aimed at making a comparison between the operating systems Windows XP and Linux along the course, regarding the aspects included in the syllabus of the subject. At the end of the term, students should be able to explain a series of essential differences and similarities between both operating systems, from the point of view of their interface, implementation and performance. The project will be divided into 4 tasks. Students will tackle a different topic in each of the works, which will be related to the contents of the syllabus. The professor will suggest a series of topics; however, any group can work on another topic suggested by them, which has to be previously agreed with the professor. The development of each topic consists of three phases. First, students carry out a search and study of information. Then, they have to design an experiment approaching the comparison between Linux and Windows XP, with regard to the topic studied. Finally, they present a report with all the work carried out, including the results obtained in the experiment, and also make an oral presentation. At the end of the term, a debate is established focusing on all the projects developed by students in order to answer a series of open questions: Are Linux and Windows XP actually so different? Is there any significant difference regarding their performance? Does any of the operating systems offer more advantages from the point of view of programming?

On the other hand, CL was applied to the fifteen OSIS sessions. At the beginning of the course, permanent groups of four students (base groups) were formed. Because of CL, each member of a group had to be an expert on some basic concepts of the topic during each session. For this reason, the homework students were given depended on the type of expert. There were four kinds of homework, one addressed to each expert. For each session, this homework was structured into three parts: the first described the learning objectives and skills to be acquired with the homework; the second indicated the information to be studied, and the third part consisted in solving basic problems, developing a simple program or answering some questions. Both the second and the third part were set estimated periods of time to be carried out. Homework had to be handed to the professor before the session in question started and the real amount of time it took them to do it must be indicated. Along each session, CL method was put into practice and all base groups tried to solve a problem which required the knowledge of the four experts (jigsaw). At the end of the session there was a global discussion about the difficulties encountered and the different ways to solve the problems.

C. Measurements and instruments

Three different types of measurements were used: the ones corresponding to academic performance, the ones relative to the drop-out rate and those regarding the opinion survey responded by students.

- Academic performance. It is considered as the set of grades achieved along the semester. Both grades, the ones achieved in specific tests of each methodology (group grades) and those grades achieved in multiple-choice exams (individual grades) are taken into account.

In the subject OSIM the final grade consists of two parts: an individual mark (50%) and a group mark (the mark obtained in the project carried out in group, 50%). Individual marks are made up of 4 tests (20%), some questionnaires with short questions (10%) and problem solving activity (20%). Each part of the project is assessed in two ways: 1) Co-assessment (50%) - each group has to assess the work carried out by the other groups as well as to classify them regarding their quality. Students are awarded a grade according to the mark they have been given and to the position reached in the ranking; 2) Professor's assessment (50%) - the professor makes a correction of each students' assessment and awards them the remaining 50% of the grade. In order to carry out these two assessments, rubrics with the criteria to be considered are provided for each of them. These rubrics are at students' disposal so that they are aware of the criteria demanded before carrying out every phase of the project.

In the subject OSIS a continuous assessment method was followed so as to evaluate achieved specific competences of the subject. During the course, four different kinds of activities were used, all of which were assessed: lab exercises, tests, CL and individual homework. The final grade consists of two parts: an individual mark (40%) and a group mark (60%). Individual marks are made up of 5 tests (20%), and 3 individual assessments (20%). Group marks are made up of 6 assessments (40%) and 5 lab exercises (20%). The individual assessments consisted in carrying out a short question or exercise which had been chosen from the homework of the session. Some of the tests and individual assessments were assessed by other classmates (peer-evaluation). In order to pass the course, students must achieve a minimum grade of 50% and at least a third must be achieved in each evaluated part.

- Drop-out. The drop-out rate and the time in which it took place are considered, as well as their relationship to the different phases of implementation of both methodologies.

At the beginning of the OSIM course, 39 out of 60 students started the project. These students were divided into 9 groups. These groups handed in the first of the four topics of which the project was constituted, although two groups (a total of 9 students) dropped out before submitting the second task and stopped attending classes. One of them had been awarded a low grade in the assignment they had handed in, while the other group achieved a considerably high grade (7.6 out of 10).

In the subject OSIS, the total number of students who dropped out the course was 27. During the first topic, which took four sessions, 18 students dropped out because they realized they were not able to dedicate 110 hours making a continuous effort for 15 weeks. The remaining drop-outs took place at the end of each topic; the rate was significantly lower at that moment, though, since only three students drop the course out after topics 2 and 3, two students after topic 4 and just one student after topic 5.

Therefore, the fact that most of the drop-outs, both with PBL and CL, took place during the first month of the course can be inferred from the information given above. The hypothesis considered is that students notice during the first month the workload required by the subject and consider whether they would be able or not to devote the time needed. However, more data are necessary in order to confirm the hypothesis.

- Opinion survey. At the end of the term, students respond to an opinion survey with questions about specific aspects studied along the course. In this section, the most important results obtained from the students' opinion are shown. Questions directly related to the contents of the course were excluded. In the first block, we asked four questions regarding the effectiveness of each methodology. Students' opinion is indicated below in a scale which ranges from 1 to 5:

1.- I consider the level of difficulty of the matters raised in the tests according to the themes studied in class to be:

	OSIM	OSIS
5.- Very difficult	12 %	22 %
4.- Quite difficult	64 %	53 %
3.- Appropriate	16 %	20 %
2.- Quite easy	8 %	3 %
1.- Very easy	0 %	2 %

2.- On the whole, I think that I have learnt a lot about operating systems and this knowledge will be permanent to a large extent:

	OSIM	OSIS
5.- Totally agree	16 %	6 %
4.- Quite agree	32 %	36.5%
3.- Agree	40 %	39 %
2.- Quite disagree	8 %	12.5%
1.- Totally disagree	4 %	6 %

3.- In general, I believe that PBL/CL methodology has helped me understand better and acquire deep knowledge of the concepts:

	OSIM	OSIS
5.- Totally agree	4 %	6 %
4.- Quite agree	40 %	39 %
3.- Agree	44 %	35 %
2.- Quite disagree	12 %	15 %
1.- Totally disagree	0 %	5 %

4.- Regarding the level of difficulty when it comes to understand the texts to be studied without any previous explanation, I find it:

	OSIM	OSIS
5.- Excessively high	4 %	16 %
4.- High	28 %	51 %
3.- Appropriate	60 %	28 %
2.- Low	0 %	5 %
1.- Really low	8 %	0 %

Two questions related to the assessment strategies followed were made in order to know students' opinion about their effectiveness.

1.- The results obtained are a reflection of the personal effort I have made:

	OSIM	OSIS
5.- Totally agree	4 %	4 %
4.- Quite agree	16 %	26 %
3.- Agree	24 %	33 %
2.- Quite disagree	48 %	30 %
1.- Totally disagree	8 %	7 %

2.- On the whole, I think that the assessment method used is better than the conventional, which was only based on the final test.

	OSIM	OSIS
5.- Totally agree	48 %	39 %
4.- Quite agree	24 %	33 %
3.- Agree	16 %	24 %
2.- Quite disagree	12 %	1 %
1.- Totally disagree	0 %	3 %

D. Data Analysis

For the Statistical Analysis we used version 5.1 of the statistical program STATGRAPHICS. The statistical techniques for the analysis were: for the distribution fitting to determine if data can be adequately modelled by a normal distribution we used Kolmogorov_Smirnov test and superimposed the PDF of the fitted normal distribution. We run F-Snedecor test to decide whether the equality of variances must rejected. We run a t-test with an m+n-2 freedom degree to decide if the equality of the means could be considered in those cases in which the equality of variances could not be rejected and the Welch approximation was ran whenever the equality of variances had been rejected. To decide whether the equality of percentages must be rejected or not, we run a Hypothesis Test for Difference Between Proportions.

III. RESULTS AND DISCUSSION

We carried out a comparison of the grades in both methodologies.

A. Analysis of the grades achieved in the test with PBL and CL methodologies

The first step was to conduct an exploratory examination of the data. This was carried out both analytically and graphically. We used the statistical software Statgraphics. Table I shows some statistics. GTEST_G variable corresponds to the subject OSIM, while STEST_G variable refers to the subject OSIS. Fig. 1 shows the histogram and density estimated [24] for the test grades achieved in OSIM, to which PBL methodology had been applied. Fig. 2 shows the histogram and density estimated for the test grades achieved in OSIS, to which CL methodology had been applied.

The results of the test ran in order to determine whether GTEST_G and STEST_G can be adequately modelled by a normal distribution are shown. The Kolmogorov-Smirnov test has been performed.

Tests for Normality for GTEST_G

Kolmogorov-Smirnov test
Estimated overall statistics DN=0.0770702
Approximate P-Value = 0.99281

Tests for Normality for STEST_G

Kolmogorov-Smirnov test
Estimated overall statistics DN=0.0869847
Approximate P-Value = 0.357309

Since in the test which has been carried out the computed P-value is not less than 0.05, the null hypothesis that STEST_G and GTEST_G come from a normal distribution with a 0.05 level was not rejected.

TABLE I. SUMMARY STATISTICS

	GTEST_G	STEST_G
Count	31	114
Average	4.89032	3.79737
Median	4.6	3.9
Mode	4.1	4.6
Variance	3.58424	2.73282
Standard deviation	1.89321	1.65313
Minimum	0.8	0.0
Maximum	8.7	8.5
Range	7.9	8.5
Lower quartile	3.7	2.9
Upper quartile	6.1	4.7
Skewness	-0.0181856	-0.208458

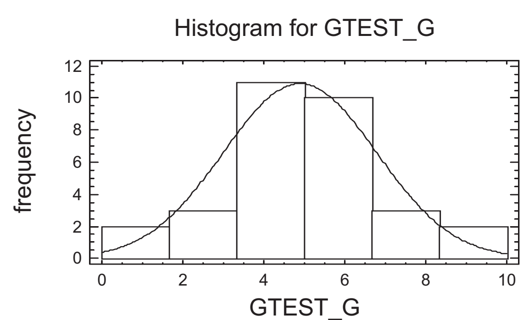

Figure 1.

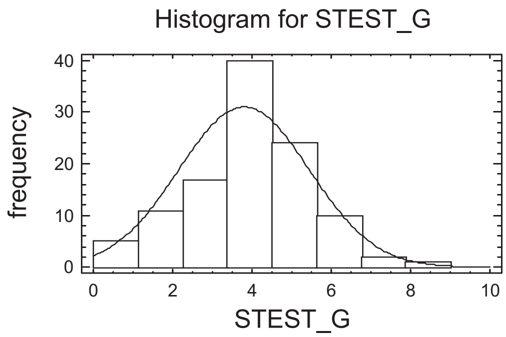

Figure 2.

After that, a comparison of GTEST_G and STEST_G, the two teaching methods for OSIM and OSIS, was carried out. Fig. 3 shows the box-plot of the data.

They turn out to be different. The length and the interquartile ranges of the group GTEST_G are not similar to those of the group STEST_G. The data of the groups GTEST_G and STEST_G were modelled as realizations of random samples X1, X2,…, Xm and Y1, Y2,...,Yn with m=31 and n=114 from two distributions: one with the expected value $\mu 1$ and the other with the expected value $\mu 2$; the hypothesis of the test was: H0: $\mu 1=\mu 2$ against H1: $\mu 1\neq\mu 2$.

First, we had to decide whether there is a statistically significant difference between the standard deviations of the two samples. An F-test [25] was ran so as to compare standard deviations. In this case: H0: $\sigma 1=\sigma 2$ against H1: $\sigma 1\neq \sigma 2$. Since the computed P-value is not less than 0.05, the equality of variances cannot be rejected. These results are shown in Table II.

Then, a t-test was carried out to compare the means of the two samples. A t-test was used: $H_0:\mu_1=\mu_2$ against $H_1:\mu_1\neq\mu_2$. Since the computed P-value is less than 0.05, the null hypothesis can be rejected in favour of the alternative. These results are shown in Table III.

As the confidence interval is as well shown for the difference of means (confidence 0.95), the following tests can be considered according to this. A t-test was run once again. In this case: $H_0:\mu_1-\mu_2 \leqslant 0.5$ against $H_1:\mu_1-\mu_2>0.5$. Since the computed P-value is lower than 0.05, the null hypothesis was rejected. Thus, we have to admit that there is a considerable difference with a 0.05 significance level between the means of the grades in GTEST_G and STEST_G, which is 0.5 points greater than. These results are shown in Table IV.

Finally, a t-test was performed again. In this case, the test had been carried out to determine whether the difference between the two means is equal or less than 1, versus the alternative hypothesis which states that the difference is greater than 1. $H_0:\mu_1-\mu_2\leqslant 1$ against $H_1:\mu_1-\mu_2>1$. Since the computed P-value is not less than 0.05, the null hypothesis cannot be rejected. Then we have to admit with a 0.05 level that there is a significant difference between the means of the grades of the test performed in the two groups, and the idea that the difference between the grades in GTEST_G and STEST_G is lower than 1 point cannot be rejected. These results are shown in Table V.

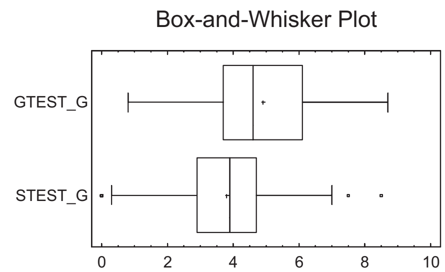

Figure 3.

TABLE II. COMPARISON OF STANDARD DEVIATIONS

	GTEST_G	STEST_G
Standard deviation	1.89321	1.65313
Variance	3.58424	2.73282
Df	30	113

Ratio of Variances = 1.31155

F-test to Compare Standard Deviations

Null hypothesis: sigma1 = sigma2
Alt. hypothesis: sigma1 NE sigma2
F = 1.31155 P-value = 0.312464

NOTE: these results assume that the distributions of the two samples can be adequately modelled by a normal distributions.

TABLE III. COMPARISON OF MEANS

95,0% confidence interval for the difference between the means assuming equal variances: 1.09295 +/- 0.683195 [0.409759,1.77615]

t test to compare means
Null hypothesis: mean1 = mean2
Alt. hypothesis: mean1 NE mean2
assuming equal variances: t = 3.16226
P-value = 0.00191215

TABLE IV. COMPARISON OF MEANS

t test to compare means
Null hypothesis: mean1 - mean2 = 0.5
Alt. hypothesis: greater than
assuming equal variances: t = 1.7156
P-value = 0.0442005

TABLE V. COMPARISON OF MEANS

t test to compare means
Null hypothesis: mean1 - mean2 = 1.0
Alt. hypothesis: greater than
assuming equal variances: t = 0.268945
P-value = 0.39418

These results consider the variances of the two samples to be equal. In this case, that assumption appears to be reasonable based on the results of an F-test which was carried out to compare the standard deviations (Table II).

To summarize, we have to admit that the grades achieved in the test with GTEST_G are greater than the grades achieved in the test with STEST_ G, between 0.5 and 1 point. Significance level: 0.05.

B. Analysis of the grades achieved in students group works with PBL and CL methodologies

A comparison on the grades in both methodologies was carried out. Therefore, the same steps than in the case of the comparison of the grades achieved in the test were followed. The first step was to carry out an exploratory examination of the data. Table VI shows some statistics.

Fig. 4 shows the histogram and density estimate of the grades achieved in OSIM, and Fig. 5 shows the histogram and density estimate of the grades achieved in OSIS.

The results of the Kolmogorov-Smirnov test performed in order to determine whether GGroup_G and SGroup_G can be adequately modelled by a normal distribution are shown.

Since in every test carried out the computed P-value is not lower than 0.05, the null hypothesis that GGroup_G and SGroup_G come from a normal distribution with 0.05 level was not rejected.

Next, a comparison between GGroup_G and SGroup_G, the two teaching methods for OSIM and OSIS, was carried out. Fig. 6 shows the box-plot of the data.

Tests for Normality for GGroup_G

Kolmogorov-Smirnov test
Estimated overall statistic DN = 0.211216
Approximate P-Value = 0.125848

Tests for Normality for SGroup_G

Kolmogorov-Smirnov test
Estimated overall statistic DN = 0.123826
Aproximate P-Value = 0.0606438

They turn out to be different. The length and the interquartile ranges of the group GGroup_G are not similar to those of the group SGroup_G. The data of the groups GGroup_G and SGroup_G were modelled as realizations of random samples $X_1, X_2, ..., X_m$ and $Y_1, Y_2, ..., Y_n$ with m=31 and n= 114 from two distributions; one with the expected value μ_1 and the other with the expected value μ_2; the hypothesis of the test was: H_0: $\mu_1=\mu_2$ against H_1:$\mu_1 \neq \mu_2$.

TABLE VI. SUMMARY STATISTICS

	GGroup_G	SGroup_G
Count	31	114
Average	7.62258	4.34737
Median	7.4	4.7
Mode		
Variance	0.445806	3.1142
Standard deviation	0.667687	1.76471
Minimum	5.5	0.0
Maximum	8.6	7.7
Range	3.1	7.7
Lower quartile	7.3	3.7
Upper quartile	8.1	5.4
Interquartile range	0.8	1.7
Skewness	-0.81226	-0.558472
Coeff. Of variation	8.75934%	40.5926%

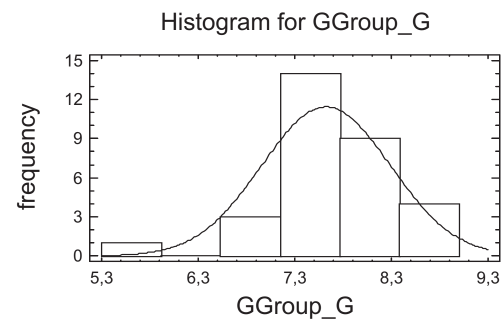

Figure 4.

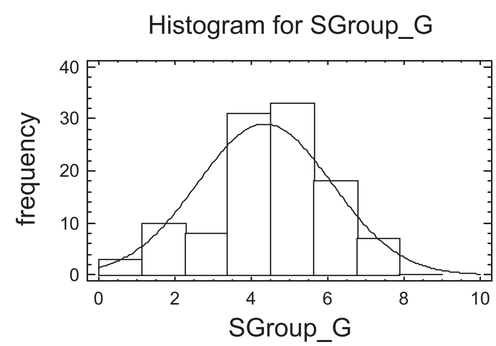

Figure 5.

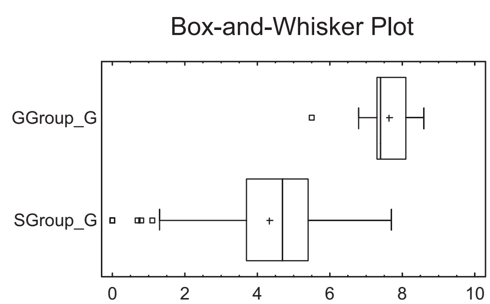

Figure 6.

First, we had to decide whether there is a statistically significant difference between the standard deviations of the two samples. An F-test was run so as to compare standard deviations. In this case: H0: $\sigma 1 = \sigma 2$ against H1: $\sigma 1 \neq \sigma 2$. Since the computed P-value is less than 0.05, the equal of variances can be rejected. These results are shown in Table VII.

Then, a t-test was carried out to compare the means of the two samples. A t-test was used: H0:$\mu 1=\mu 2$ against H1:$\mu 1 \neq \mu 2$. Since the computed P-value is less than 0.05, the null hypothesis in favour of the alternative can be rejected. These results are shown in Table VIII.

As the confidence interval is as well shown for the difference of means (confidence 0.95), the following tests can be considered according to this (Table VIII).

A t-test was run again. In this case: H0:$\mu 1-\mu 2 \leqslant 2.5$ against H1:$\mu 1-\mu 2>2.5$. Since the computed P-value is less than 0.05, the null hypothesis was rejected. Then we have to admit that there is a considerable difference with a 0.05 significance level between the means of the grades in GGroup_G and SGroup_G, which is greater than 2.5 points. These results are shown in Table IX.

Finally, another t-test was carried out. In this case, the test had been constructed in order to determine whether the difference between the two means is equal or less than 3, versus the alternative hypothesis which states that the difference is greater than 3. H0:$\mu 1-\mu 2 \leqslant 3$ against H1:$\mu 1-\mu 2>3$.

Since the computed P-value is not less than 0.05, the null hypothesis cannot be rejected. Then we have to admit with a 0.05 level that there is a significant difference between the means of the grades achieved by two groups in the test, and the idea that the difference between the grades achieved in GGroup_G and in SGroup_G is less than 3 points cannot be rejected. These results are shown in Table X.

These results consider the variances of the two samples to be not equal. In this case, that assumption appears to be reasonable based on the results of an F-test which was carried out to compare the standard deviations (Table VII). Different tests were performed for the Two-Sample Comparison, although one P-value was near 0.5 considering that the absence of normality has normally no influence on the F-test run by ANOVA and in the comparison of means [25].

To conclude, we have to admit that the grades achieved in GGroup_G are greater than the grades achieved in SGroup_G, between 2.5 and 3 points. Significance level: 0.05.

C. *Analysis of the opinion survey*

We had to decide whether there is a statistically significant difference between the percentages of the opinion survey answers given by the students of both methodologies. In this case we used an statistic T whose distribution is approximately N (0,1). We noted t the value of this statistic assuming equal proportions.

Relating to question 1 ("I consider the level of difficulty of the matters raised in the tests according to the themes studied in class to be: very difficult, quite difficult, appropriate, quite easy or very easy") we obtained the comparison of proportion shown in Table XI.

TABLE VII. COMPARISON OF STANDARD DEVIATIONS

	GGroup_G	SGroup_G
Standard deviation	0.667687	1.76471
Variance	0.445806	3.1142
Df	30	113

F-test to Compare Standard Deviations

Null hypothesis: sigma1 = sigma2
Alt. hypothesis: sigma1 NE sigma2
F = 0.143153 P-value = 6.71803E-8

TABLE VIII.

Two-Sample Comparison - GGroup_G & SGroup_G

Comparison of Means

95,0% confidence interval for the difference between the means not assuming equal variances: 3.27521 +/- 0.404024 [2.63468,3.91575]

t test to compare means

Null hypothesis: mean1 = mean2
Alt. hypothesis: mean1 NE mean2
not assuming equal variances: t = 16.0391
P-value = 0.0

TABLE IX.

Two-Sample Comparison - GGroup_G & SGroup_G

Comparison of Means
----

t test to compare means

Null hypothesis: mean1 - mean2 = 2.5
Alt. hypothesis: greater than
not assuming equal variances: t = 3.7963
P-value = 0.000112408

TABLE X.

Two-Sample Comparison - GGroup_G & SGroup_G

Comparison of Means
----

t test to compare means

Null hypothesis: mean1 - mean2 = 3.0
Alt. hypothesis: greater than

not assuming equal variances: t = 1.34775 P-value = 0.0900526

In Table XI, P1* y P2* are the proportion of students who answered appropriate, quite difficult or very difficult in OSIM and OSIS respectively and p* is the pooled proportion. Since the value obtained (assuming H0) is t = -0.7371, greater than -1.96 and less than 1.96, values from the Normal distribution for α=0.05, the null hypothesis cannot be rejected for this significance level. Similar results have been obtained in questions 2 (t= 1.11836) and 3 (t = 0.2835). Therefore we have to admit that the percentages of the answers given follow very similar criteria and no significant differences can be established regarding the assessment made by students of both subjects. It has to be highlighted that students have a good opinion about the methodologies applied to both subjects and believe to have acquired a deep knowledge in the two of them.

Relating to question 4 ("Regarding the level of difficulty when it comes to understand the texts to be studied without any previous explanation, I find it: Excessively high, high, appropriate, low or really low") we obtained the comparison of proportion shown in Table XII.

In Table XII, P1* y P2* are the proportion of students who answered appropriate, low or really low in OSIM and OSIS respectively. Since the value obtained from the statistic (assuming H0) is t=3.2157 greater than 1.65, value from the normal distribution for α=0.05, the null hypothesis must be rejected for this significance level. Therefore we have to admit that the percentage of students who answered appropriate, low or really low is greater in OSIM than the percentage of students who answered appropriate, low or really low in OSIS. In this respect, it is worth pointing out that some master classes have been programmed in order to help with the development of the subject OSIM; some basic theoretical issues were taught during these classes before the beginning of the student work. However, students had to deal with the study of OSIS before the subject had started.

TABLE XI.

Comparison of Proportions OSIM OSIS -- P_1* = 0.92 P_2* = 0.9557 p*= 0.9493 Null hypothesis: P_1 = P_2 Alt. hypothesis: P_1 NE P_2 Assuming H_0 the value of T: t= -0.7371

TABLE XII.

Comparison of Proportions OSIM OSIS -- P_1* =0.68 P_2* = 0.3302 p*=0.3969 Null hypothesis: P_1 = P_2 Alt. hypothesis: P_1 greater than P_2 Assuming H_0 the value of T: t= 3.2157

Concerning the two questions related to the assessment strategies, the comparison of proportions produced t = -1.7244 (question 1) and t = -1.6452 (question 2). Since these values of the statistic are greater than -1.96 and less than 1.96 , values from the Normal distribution for α=0.05, the null hypothesis (P1 = P2) cannot be rejected for this significance level. Consequently, we have to admit that students of both subjects seem to fully agree with the fact that the assessment method used is better than the conventional one, in which 80% of the grade was achieved in a final exam (the remaining 20% was achieved after carrying out some practical activities).

IV. AND, WHY NOT TO COMBINE CL AND PBL?

In spite of the fact that CL and PBL have proved to be useful regarding the meaningful learning acquired by our students, it is necessary to combine them at some point in order to reach an effective learning process. While an experiment was performed in order to make a comparison between CL and PBL in the Operating System subject, another experiment which combined both methodologies was conducted meanwhile, during the same course. Such experiment was tried in two subjects. The first experience was carried out in the subject Real Time Systems of the degree in Technical Engineering in Computer Systems at the Universidad Politécnica de Madrid; the second, in the subject Software Engineering II of the degree in Technical Engineering in Computer Systems at the Universidad Rey Juan Carlos. These subjects were taught adopting a PBL methodology in both cases. The experience acquired in the last years has proved to increase students' motivation for studying the subject when PBL is applied. On the other hand, with the implementation of PBL students have slightly relaxed when it comes to deal with the theoretical study of some aspects which are essential for the development of the project, though. In these cases, the role of the professor as the leader and supervisor of acquiring learning (as it is suggested by the PBL methodology) is not enough. In turn, it seems to be more effective if individual learning sessions are turned into active learning by means of the implementation of CL, for instance [26].

In the subject Real Time Systems the development of the project is carried out by teams of three students. We scheduled two CL sessions in which all the members of a team worked together in order to solve a problem related to their project. Each session lasted for 110 minutes. One session was designed to work on the last two chapters of the course which were not covered by the development of the project (Fault Tolerance and High Integrity Systems). At the end of the session, a small problem was proposed to every team. The second session was designed with a different purpose: helping students when it comes specifically to develop a critical phase of the project. In this phase, students have to do a creative design work. It is very important to know clearly the theoretical concepts on which this task is based in order to be able to use them, so students should avoid relaxing in the theoretical study. Furthermore, it is advisable to have the professor supervise the design while students are carrying it out, as well as hold a debate with them to discuss the proposed solution. The result of this task has a great influence on the complexity which they will find in the development of further phases of the project. That is why achieving a certain level of quality in their design is so important. CL was applied to both sessions as a jigsaw [5]. Besides, by improving the team-working skill, these self-contained sessions turned out to be really helpful in order to complete the topics included in the syllabus and to overcome the critical phases of the project. Students showed enough knowledge in both cases. Moreover, this educational methodology was favourably welcomed by students. A 60% of them strongly agreed with the following statement: "Cooperative Learning is a helpful methodology to learn the contents of the subject" in an opinion survey which was carried out at the end of the course. A 27% of students simply agreed with this assertion and the remaining 13% disagreed.

In the subject Software Engineering II the project is carried out by teams of four students along 30 sessions of 2 hours each. As it is said above, applying CL helps us to avoid students relax when it comes to study the concepts which are not covered by the project. However, CL can as well be a way to guide and supervise students in the autonomous learning progress required by PBL. In this subject, for example, students must learn JAVA (they can program, but they do not know the language). In order to guide students, the professor schedules 8 CL sessions which last 110 minutes each. Different aspects of the language are studied in every session. At the end of the session, the team has to develop a program. This way the professor is able to guide the study of the elements of the language and to supervise students' learning regarding the quality of their program. Another important topic are testing methods. Although there are several testing methods, students will only use two or three of them in order to test their project. A CL session of 110 minutes is scheduled in order to force students to study and use each method at least once. This session allows the professor to guide and supervise the work of students. The professor guides them when it comes to selecting some literature which they must analyse and study. After the session every team has to prepare a collection of test cases using the different testing methods. Furthermore, an individual test is also carried out. Thus, the professor is able to supervise the individual learning process. In this subject the sessions are structured as a jigsaw, just like in the RTS course. In this case the educational methodology was favourably welcomed by students too.

V. CONCLUSION

As it can be inferred from the results above, the work hypothesis cannot be proved. The lack of maturity of the students from the third term was one of the reasons that made us think of the idea that CL would give as a result a better academic performance. However, we have observed that students' performance is not affected by their lack of maturity when PBL methodology is supported by individual tuition addressed to each group of work. On the other hand, as it has been already proved in further studies [16], one of the advantages of PBL methodology is the increase in students' motivation, a fact that could be stated by OSIM professors. We are of the opinion that this aspect may have had a great influence on the academic results achieved. From our point of view, there are two possible ways of verifying this conclusion. First, another study should be carried out in order to calculate the different level of motivation among students from both methodologies and to establish a relationship to their academic performance. Second, we think that the study carried out in this work should be applied to other subjects and to different contexts so as to corroborate the results obtained.

***Abstract*— We describe use of partially distributed collaborative assignments in a Usability Engineering course with respect to (1) learning activity management and (2) technology support.**

Keywords- collaborative learning, case-based learning, collaborative software, learning technoloy, usability engineering

I. Introduction

The engineering students of today will most likely work in partially distributed teams during their careers, as network mediated collaboration becomes more routine. During the past three years, we have been experimenting with partially distributed team assignments in an upper-level undergraduate course in usability engineering at the Pennsylvania State University (Penn State). These assignments employ *case-based learning* [Carroll & Rosson, 2005; Jiang et al., in press]: students analyze and apply ideas from online case studies documenting real-life professional practices in usability engineering to their own design projects. The assignments also employ *distributed collaborative learning* [Ganoe et al., 2003; Xiao et al., 2008]; the students are asked to work together outside of class using collaborative software over a period of time ranging from several days to several weeks to develop a design analysis or prototype, and a report describing their work.

An example assignment we have used asks student teams to develop a user interface prototyping strategy for a web-based information system. Each team member was asked to review a different case study in which prototyping was employed in order to identify candidate prototyping ideas and approaches, and propose these to the team. The team was then to evaluate, select, and integrate these proposals and compose a joint report.

In this paper, we describe our experiences with case-based distributed collaborative homework assignments in the context of our problem-based usability engineering course. We also describe our experiences developing and employing an online library of case resources and collaborative technology to support these assignments and the other activities in the usability engineering course. We conclude with a summary of lessons learned to date, and some of our plans for upcoming versions of the course.

This research was supported by the National Science Foundation of the United States under awards 0231111 and 0354195 from the Division of Undergraduate Education (DUE), and under award 0735440 from the Advanced Learning Technologies (ALT) program, and by the Edward M. Frymoyer Chair Endowment. During the writing of this paper Carroll was Shaw Visiting Professor in the Department of Information Systems of the National University of Singapore.

II. Learning Activities

We are addressing three types of learning objectives. First, we want students to learn about and practice applying specific usability engineering concepts and techniques (like user interface prototyping). Second, we want students to exercise and develop their collaborative abilities (for example, learn to critically evaluate their team's ideas). Third, we want students to get experience working in teams using distributed collaborative software applications.

We have found that the activities we give students to do need a lot of scaffolding to get them to think more deeply about core course concepts (scenarios, design tradeoffs, etc.). Students, feeling they already know more than they actually do, are more focused on completing the assignment that understanding the underlying concepts of the activity. With respect to usability engineering, this is a well-known challenge: students think that because they are people, they will be able to understand and address the needs of users.

Students also overestimate their knowledge and skills with respect to their collaborative abilities and collaborative software. In general, our students have too simple a view of how to effectively collaborate. Thus, if collaborative process-goals are not explicitly stated, students may simply divide up the work and engage in minimal interactions. Experiencing these interactions are an important objective since they will need to understand users and engage in peer reviews during their careers.

Finally, students are highly experienced with social-networking systems, but rarely have they tried to coordinate activity through such systems. They know how to communicate and interact online, but not necessarily how to coordinate and carryout intellectual collaborative endeavors. Usability engineering rarely takes place in a closed room. Potential users, developers, designers, etc. can be globally distributed, and all play roles in the process.

Pushing students to recognize their knowledge gaps requires reflective activities, modeling, and explicit prompting. Motivating them to develop their abilities is a more difficult task, but holding them accountable for all three learning objectives is a crucial component to providing an authentic usability engineering experience.

A. Case-based Approach to Usability Engineering

Our usability engineering course was designed to be case-based. We created a collection of online case descriptions and made these available to the students. The cases were originally presented via an ASP (Active Server Pages) based Usability Case Studies (UCS) Library website (http://ucs.ist.psu.edu/). There are seven cases, though one is quite incomplete. We choose a variety of domains – mobile banking, telephony (PhoneWriter), online community (TappedIn), online business (Garden.com), nonprofit animal rescue (PAWS), as well as an online version of the virtual science fair prototype case which is also described in the students' textbook [Rosson & Carroll, 2002].

Each of the case studies is a separate hypertext organized, like the path the course follows and like the student semester project requires, by phases of the usability development process. These phases include requirements analysis, activity design, information design, interactions design, documentation, and user testing. Each phase describes how a particular design team developed its scenarios, worked with users, and ultimately validated its design through empirical testing with actual users. For further details on the design of the case studies see [Rosson et al., 2004; Carroll & Rosson, 2005].

Many of the homeworks and in-class activities in our usability-engineering course make use of the case library materials. For example, in the 2009 course, the second homework asked students to study the Tapped-In case and identify at least two conceptual metaphors the designers used to clarify and envision approaches to their requirements. The students were asked to explain how the metaphors contributed to this phase of the design activity. Another homework asked students to identify interaction design issues in the mobile banking case study, and to analyze the underlying tradeoffs for each issue. Students were asked to describe how each issue was resolved, or not resolved, in the actual design work.

Case materials help learners to engage with domain content and to vicariously experience domain practices and situated concepts through a narrative [Carroll & Rosson, 2006]. These cases also serve as models for students of how core concepts can be applied in practice. We found this approach to be attractive to students and effective with respect to learning outcomes [Carroll & Rosson, 2005]. One qualification is that our students have a somewhat narrow conception of what is up-to-date. Thus they sometimes perceive the cases as being less relevant to them since they describe system development projects and practices from the early 2000s. Though a valid criticism, this viewpoint also reflects students' lack of experience and difficulty in generalizing concepts.

B. Project-based Approach to Usability Engineering

Our usability engineering course originated in 1995 at Virginia Tech. Our design concept was to organize the course following the information and activity flow of a scenario-based system development process. We used scenarios as an integrating representational technique, since they emphasize the user's point of view and the importance of describing and supporting work activities as the user sees and experiences them [Carroll, 1995].

Our course starts with user requirements, and scenario-based methods to investigate and describe the users' mental model. The course then progresses to upstream design where user activities are designed by envisioning scenarios, but specific technology, display, information layout, and user interaction decisions are not considered. Following this stage of pure activity design, the scenarios are elaborated with user-interface details. Subsequently, design scenarios are implemented as prototypes, and evaluated with respect to a wide range of usability issues and criteria.

The course was organized around a semester-long system development project. As the course works its way through a curriculum organized by the flows of system development process, student teams define, implement, and test their projects. Roughly, a third of the way through the course they hand in a requirements plan describing how they worked with users to develop their design concept. Two-thirds of the way through the course, they hand in a design document describing how they developed their concept into a prototype. Finally, at the end of the course, students hand in an evaluation document describing how they tested their prototype with users. This course has been successful with computer and information science students. In 2002, we published a textbook based on the course [Rosson & Carroll, 2002]. For details on the course plan see http://ist413.ist.psu.edu/.

During the past two years, the course has changed in two significant ways. First, we have further integrated homework assignments and in-class activities with the semester project. The students take the semester project quite seriously and the grading is weighted to encourage them to do this. However, this makes the homeworks and in-class activities seem like distractions rather than smaller activities intended to help them develop concepts and skills required for the project work. Thus, we reorganized the content of many of the homeworks and in-class activities to more directly support the project work, hoping that this would improve students' engagement with these activities.

The second change we made to the course was to include out-of-class collaboration beyond the semester project. The semester project has always involved out-of-class student collaboration. However, in the 2009 version of the course we included three homeworks that were to be carried out collaboratively over a two-week period. These homeworks were designed to support the semester project-planning that the students were doing, but they were also separately graded deliverables from the project.

C. Taking Collaboration Seriously

When we first started using a collaborative project-based approach to the Usability Engineering course in 1995, we provided general coaching to student groups as to how they should try to collaborate. We suggested they should share all of their ideas, listen to others' views, criticize constructively, try to be sure that everyone did his/her part, and make their group work greater than the sum of the individual parts. In general, the student teams did behave cooperatively, and appeared to enjoy working together both in class and outside class. They frequently became passionate about their projects, and clearly spent much time and effort on this part of the course.

However, there also were recurring problems. Some students contributed little or nothing, and allowed their team members to do all the "joint" work. The remedy for this problem is to weight individual grades according to a student's team contribution, which can be assessed by querying each team member about the other members' contributions. Our students are uneasy with being asked to assess their peers, but this can be mitigated by providing the rationale for this assessment. A complementary approach is for the instructor to observe of group work sessions and try to note who is actively engaged in the joint work. Even just noting attendance at group work sessions can be a meaningful proxy for assessing contribution.

A more subtle problem was that most teams used a management strategy of "divide and conquer". The key joint work they did was to divide the project up into nearly independent subprojects, each of which could be carried out by a single student (i.e., non-collaboratively). At the conclusion of their work they more or less stapled the pieces together and handed the ensemble in as their "collaborative" project.

In the 2006 version of the usability engineering course we designed three distributed collaborative homeworks. Our objective was to provide the students with an opportunity to practice collaboration, and specifically to encourage them to try to use collaborative software. The collaborative homeworks involved analyzing case materials in the online case study library, and creating a collaboratively-authored document using an open source toolkit that supports integrated synchronous and asynchronous interactions BRIDGE (Basic Resources for Integrated Distributed Group Environments) [Ganoe et al., 2003].

There were three collaborative face-to-face activities, each of which had the same basic organization. Each group met in class to plan an approach that would be carried out during the following five days. On the fifth day, the group met again in class to finalize and hand in its results. Each of the activities involved analyzing a case study and trying to apply lessons learned to the team's semester project, and each involved some role-playing. For example, one activity requires members to review a case from the perspective of one of the following roles in a development project: product manager, usability manager, documentation manager, customer/user. Adopting their role's perspective, students were asked to focus on how key issues of documentation design were handled in the case, annotate the case documents, and download them to a collaborative environment.

The aim was for students to see the power of asynchronous collaborative work through such activities. We wanted them to be engaged by the roles and through the roles to experience the inherent conflicts and tradeoffs in decision making in the development process. These activities also provided them with opportunities to function as a thoughtful professional, reflecting on lessons learned in past projects and creatively extending and applying those lessons to new project contexts. In our assignments, the case studies provide a surrogate for prior usability engineering experience that the students generally do not yet have.

These activities did not work as planned. Most of the student teams simply did not carry out the distributed collaboration, but instead tried to cram their work into the two face-to-face meetings we had scheduled for them to coordinate their work. A major factor in this was that we did not explicitly weight collaboration in the grade for this activity. We expected that the opportunity to use collaborative software and engage in collaborative writing would be intrinsically attractive enough to the students that they would at least try these activities. Thus, a lesson we took away from this was that it is important to explicitly assess and grade any collaborative activity that is essential to a course component: providing students with concrete rubrics and expectations for performance beyond the product. This means emphasizing that how they execute their activity as a process is just as important as whether and when they get it done.

D. Distributed Collaborative Homeworks

In the Spring 2009 version of the Usability Engineering course we introduced three new distributed-collaborative homeworks. These were different from the 2006 activities in several respects. They involved far more complex analysis of the case studies, and therefore could not possibly be carried out in class. Each homework was intended to take between two and three weeks to accomplish. Also, we explicitly told the students that we would inspect their collaborative environments and assign grades based on their collaborative processes as well as their outcomes or products. We reclassified these assignments as special homeworks, instead of activities, which called attention to their status as out-of-class work. Reclassifying them as homeworks also made them worth more points toward the final course grade.

Students had to conduct a complex analysis of the case studies in the case studies library. They had to review different phases of design across different cases identifying ideas and techniques in the case studies that could be applied to their team's semester project. Even though the case studies were developed to address other stakeholders and other requirements, the cases could still be utilized as a model of how general course concepts would be applied in real world settings. For this reason we suggested they use the cases creatively, ensuring that their analysis also be informed by their own team's requirements analysis and field work with users and other stakeholders.

In order to ensure equity in participation we tried to structure that activity such that all members needed to make specific contributions. For example, each team member had to recommend user interface design ideas and design rationales to the team based on their individual analysis. They were told to first gather and consider all the different ideas that members had identified, and then prioritize, select and adapt ideas and techniques to their own project. The final result of this particular homework was to envision a user interface design with at least two user interaction scenarios.

This set of collaborative assignments worked better than the 2006 assignments: Every group actually carried out the assignment and produced a collaborative workspace populated with documents. However, the assignment did not work as planned. They were intended to take about three hours, distributed across three weeks. We used a jigsaw design [Slavin, 1980] in which each student carried out distinct but essential individual investigatory activities, the results of which had to be pooled and integrated to reach the specified result. The students were told that we would assess evidence of their collaborative process in the document versions and chat logs in their BRIDGE workspaces.

Their deliverables demonstrated that the teams gathered information, but there was more scattered evidence of synthesis and critical evaluation of the individually gathered information. One out of eight teams clearly integrated concepts from the case studies library with their semester project. Most teams handed in either a summary aggregation of the individual information that was gathered, or a planning statement for how the information would be applied in the design work on the group's semester project. Furthermore students spent little apparent effort identifying which ideas from their individual analyses were the best ideas to carry forward into the group project. Most groups tended to satisfice, to adopt the first reasonable idea identified.

E. Collaboration as a First Class Course Topic

We have found that one of the challenges in making collaboration a course outcome is that many students believe they know how to collaborate. Their understanding of collaboration, however, is "divide and conquer": they see the key to working together as a matter of breaking down the overall project into parts, and are clearly assigning responsibilities that are as independent as possible. They are confident that they can do group work in this fashion, and are therefore impatient about being coached and provided with cognitive scaffolds to enable better collaboration. This is actually a formidable teaching challenge: The students think they have a basic professional skill that they really do not.

In the 2009 version of the course we addressed this directly by introducing an articulated model of collaboration [Borge & White, 2009; Carroll et al., 2008]. We analyze effective collaboration as consisting of effective communication (team member's build on each other's ideas and work to develop a joint understanding), planning (the group's activity is directed by an agenda of goals), productivity (the team stays on track with respect to task goals and ensures work quality), and evaluation-negotiation (different perspectives among members are made visible and addressed, and the group's results are critically assessed). These four facets of collaboration can be embodied in actual roles that students adopt [Borge & White, 2009], in our usability- engineering course we have treated them more abstractly as four essential qualities of the collaborative interaction.

In the 2009 version of the course, we made a systematic effort to teach the four facets of collaboration. In week 2 of the course, student teams videotaped their own interaction as they worked on an in-class activity on requirements change (they were presented with one further requirement for the garden.com design, and asked to analyze the impact of this requirement on the upstream design. In week 3, they were given a brief lecture on the four facets of collaboration and video-based training on the facets (they viewed student team interactions from a prior version of the usability engineering course to see the collaborative facets modeled and then to classify snippets of team behavior.

In the third week of the course, student teams were given their own team interaction videos to review with respect to how they enacted the four facets of collaboration. We felt that a direct self-confrontation would help the students to recognize that their own collaborative skills could indeed be improved. This collaboration thread of instruction during weeks 2-4 of the course was actually fairly lightweight. The lecture we provided was only a few minutes long, and the other activities were interleaved with discussions and other activities focused on various other usability engineering topics.

In week 7 of the course the student teams started the first of the three distributed collaborative homework assignments, as described in II-D above. The instructions for each of these homeworks asked the students to make clear in the writing they did in their collaborative workspaces how they were using the four facets of collaboration in carrying out the homework activity. They were asked to make their collaborative process clear in the chats and other work products they created.

III. TECHNOLOGY SUPPORT

Through the past three years, we implemented our distributed collaborative homeworks using an open source toolkit that supports integrated synchronous and asynchronous interactions (Basic Resources for Integrated Distributed Group Environments, BRIDGE, [Ganoe et al., 2003]). The software supports distributed collaborative team authoring of reports as well as commenting on and construction of new usability cases. Over the history of our usability engineering course, we have explored the integration of these collaborative tools for team work with the content of the UCS Library website. We have found that collaborative software is sometimes too tightly integrated to be effectively used by student teams. Email in particular is problematic in that students rely on it, but already have email clients and accounts they use outside the collaborative suite. We are currently developing an open, web-based collaborative workspace to help students integrate their existing tools and practices with support for collaborative learning.

A. Read-only Usability Case Study (UCS) Library

The usability case study library (http://ucs.ist.psu.edu/) was originally implemented as a ready-only repository using Microsoft's Active Server Pages (ASP) technology. We wanted to exploit the flexibility of hypermedia to allow students to study the cases at various levels of depth, drilling down on demand. This is depicted in Figure 1.

In the figure, a student is investigating the garden.com case study. The student has navigated to "envisionment work" in the information design phase of the case study, using the indented list widget on the extreme left of the window. This displays a

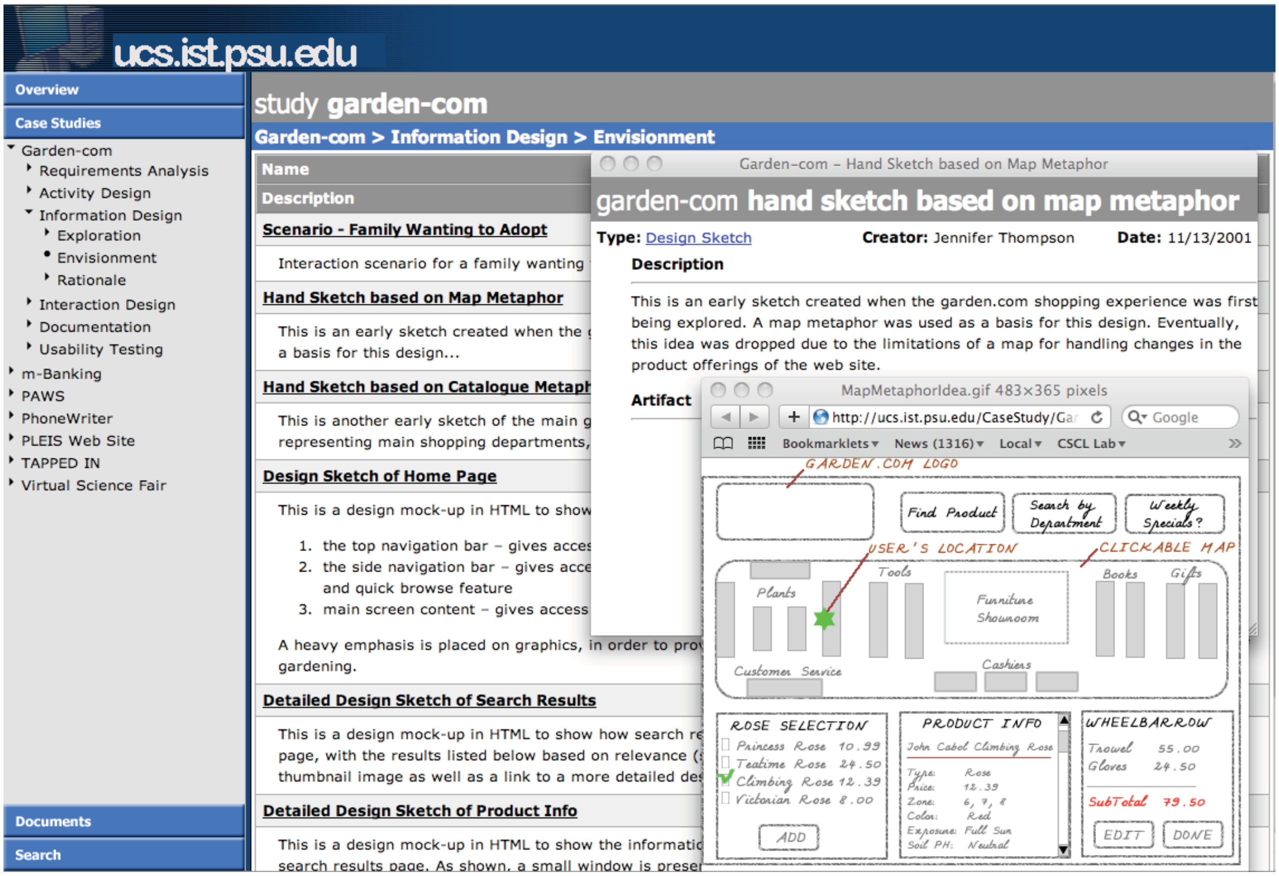

Figure 1. The original, read-only, Usabilty Case Studies (UCS) Library.

series of design artifacts, documents, sketches, notes, and so forth that were produced in the garden.com project during the envisionment part of its information design phase (viewable in Figure 1 in the large right-hand pane of the UCS window). The student is studying a particular design artifact, a hand sketch made by one of the designers illustrating the map metaphor that the designers used during this phase of the design. The description of the hand sketch appears in a pop-up window that displayed on top of the main UCS window. The student has opened the hand sketch, which displays in a pop-up on top of both other open windows.

We have had success with project-based and collaborative case-based assignments using this UCS library [Carroll & Rosson, 2005]. However, through using it we also identified several areas for further development. The original does not support several learning activities that we believed would be useful, and that are highly consistent with the active learning approach we have adopted. Students cannot annotate case-study objects, thus they cannot make notes in the browser as they read case study materials, they cannot highlight or mark them in any way for future reference (including sharing their reactions with fellow group members), and they cannot easily return to materials they have examined before.

Most importantly, students could not create their own cases. Once we started using case-based approaches it seemed obvious to consider having students create a case study analysis of their own semester project. Starting with the 2005 offering of the usability engineering course, we have had the student teams create case study reports of their own projects. Students have reported that this activity helps them to reflect on their own work. However, the original UCS library neither supported multiple user accounts nor convenient means for project teams to create and edit cases. During 2005 and 2006, we jury-rigged functionality to allow students to create cases. As students could not create cases, teachers and practitioners from entities other than Penn State could not either. We know from informally asking colleagues and from a survey we conducted in 2005 that many instructors do use cases in teaching usability engineering (and human-computer interaction). We wanted to make it easier for others to contribute content to the UCS library.

B. *Collaborative Case Builder*

For the 2006 offering of the usability engineering course, we created a collaborative case builder using the BRIDGE toolkit (see III-D for detailed on BRIDGE). This was a partial solution to some of the design challenges of the ASP browser.

The collaborative case building allowed students to download case study content from the UCS into their own BRIDGE workspace where they could collaboratively annotate it, and even directly edit the source content. This functionality allowed student groups to carry out the distributed collaborative activities described in II-C above.

However, a major limitation of this approach was that the case study objects edited in BRIDGE could not be uploaded. Thus, students could work on an editable version of a case study, and could collaborative create their own case study materials as well. But they could not directly save or render this work to the UCS Library website. That step still had to be carried out through a manual, jury-rigged process. Also, potential case authors from outside our university still could add content to the case library on their own.

C. *Editable Usability Case Study (UCS) Library*

During 2007-2008 we developed an editable UCS Library [Jiang et al., in press], addressing the limitations of the original UCS. The new system focuses on allowing users (students and/or educators) to create cases and supporting more authentic learning activities (more usability engineering related practice, more social interaction, more reflection, etc). There are four aspects we especially take into consideration in our design: social interaction, authentic activities in usability engineering, resource accumulation and updates, and communities of practice. For a detailed discussion, see [Jiang et al., in press]. These four perspectives are tightly related and contribute to each other. The functional categories in Table 1 summarize the main functions and design concerns in our UCS redesign, which are affordances for our educational and learning goals.

TABLE I. NEW UCS LIBRARY FUNCATIONS AND REQUIREMENTS

Category	Brief Description	Requirements (Touchstones)
Case schema	Capturing case study activities, procedures and key contents (documents, scenarios, artifacts, etc)	Authenticity
Distributed case authoring	Providing means to allow users to contribute remotely	Resource accumulation and updating
Comments and tagging (Shared)	Providing channels for users to communicate and share information	Community of Practice, Social interaction
Administrative functions	Providing administrative and security functions (authentication and authorization, version control, etc)	Supportive functions

1) Case schema and conceptual framework: In order to capture and support the authenticity of usability-engineering practice, the software follows the phases of the usability process described in II-A. Rosson and Carroll (2002) formulated this case schema for usability engineering case studies, in which the key stages and activities of usability engineering are integrated together into a case structure. This case schema captures the flow of usability-engineering activities and types of documentation corresponding to them. The case schema is represented in the newly designed UCS library similar to the one in the read-only UCS library described in III-A. Students can navigate throughout a case with this schema on the left of the window shown in Figure 2. The team assignments usually cover all stages and activities described in the case schema. For example, when the student team starts to work on their projects, it begins with requirement analysis phase and the students work on detailed activities such as gathering information from user site, interviewing intended users, etc. The structured case schema provides scaffolding for the students to follow the usability engineering processes.

2) Online case authoring: Online case authoring allows students, and other users who have proper access level, to remotely contribute case material to the library through standard web browsers. Our read-only UCS did not provide a convenient authoring method to the wider usability engineering community. This inherently limited the source of usability cases. The addition of proper access controls increases the opportunity for remote contribution of cases to the library. Now, case authors from different institutions and educational sites can contribute to the library.

Users with proper authorization can create new case materials, edit existing content, and delete content objects. During usability engineering activities (interviewing, on-site note taking, videotaping, etc), multimedia data may be collected and uploaded to the system and then referred to with URL links. In order to fully capture and support authentic materials, the UCS system supports digital objects in different media formats, such as video, audio, rich text formats, etc.

The system provides a web user interface for students and instructors to author cases. Thus all the actions needed to create a case are available through a standard web browser. For example, to modify an existing document in a case, someone who has the access can just click edit button on the page which turns the document into editing mode; after editing, one can just click the save button to save it. The UCS Library server will automatically keep a retrievable version as well.

Allowing online case authoring not only brings more case resources, but also provides a means to increase the sense of community [McMillan 1996; Rovai 2002]. Allowing users to create contents is a step toward full participation and engagement within the community, because in our situation, creating a case covers all activities we described in the case schema. In the UCS, we also capture information such as the contributor of content, which gives case authors visibility and credit.

In our usability engineering course, student teams' semester long projects are usually usability engineering projects from real-world. Thus, they essentially create new cases. During the project, students work on each phase and produce reports on their projects. After two semesters, student groups have created 15 cases in the library.

3) Commenting and Tagging: The system allows users to contribute and communicate by commenting on and tagging of

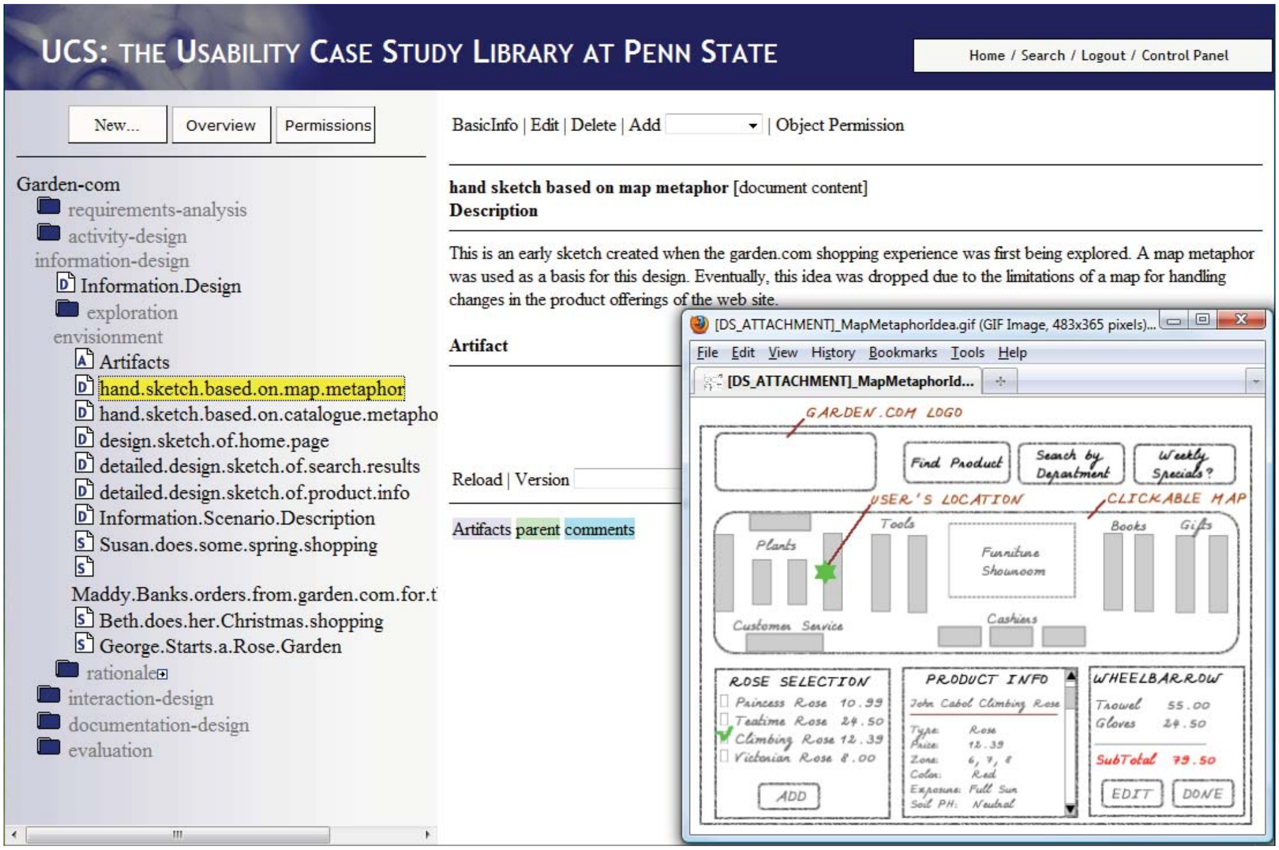

Figure 2. Updated UCS Library with user editing, and commenting features.

case contents. Users who have access to a case can make comments on it, providing their thoughts, ideas, suggestions, criticisms, and so on. Other users can review these comments and add their own. Since comments can be shared across users, the comments can promote discussion and convey information during collaboration.

Tags can help users by providing coded reminders to content or as a way to organize information of interest. In our design, the system will support both public and authorized tags. An example of an authorized tag might be where an instructor would want to set up tags that will only be used by students in her class to find the relevant content for a lesson. Tags will be stored as metadata of the objects. Some services related to tagging is searching on tags, filtering content by tags and displaying all the valid tags in a user's workspace or on the main page for a case. In this way, comments and tags improve the case studies by extending the memory of a user and enabling the user to write down their thoughts, ideas and other reactions on the cases.

4) Administrative functions: Besides functionalities we mentioned above, the system also needed other administrative functions, to make the whole system work smoothly. Those functions are, for example, version control which records histories of all digital objects and from which users can retrieve those histories; authentication and authorization subsystem that secure case contents, etc.

With these basic functions implemented, we deployed the system on an Internet-accessible server. The newly deployed system has been in service for two semesters, spring 2008 and spring 2009, to support usability engineering education. The size of our courses is about 45 to 50. Each week, the instructor selects materials corresponding to the topic of that week from the case collection and asks students read them and reflect on them. Along with other activities and readings, students are asked to review existing cases hosted in the UCS Library and reflect on those cases. In their distributed homework assignments, members of student teams are asked to reflect on case materials and pool ideas contributing to their ongoing projects. For example, in the week we introduce usability evaluation, the students go through the evaluation section in different cases (e.g., Garden.com, Tapped In, Phone Writer, PAWS, m-Banking, Virtual Science Fair), and they are asked to comment on the approaches used in those cases and come up with ideas and approaches of their own when they are in those situations.

The student team semester projects are applications coming from real-world contexts: commercial companies, non-profit organizations, etc, and they are already put into use or on

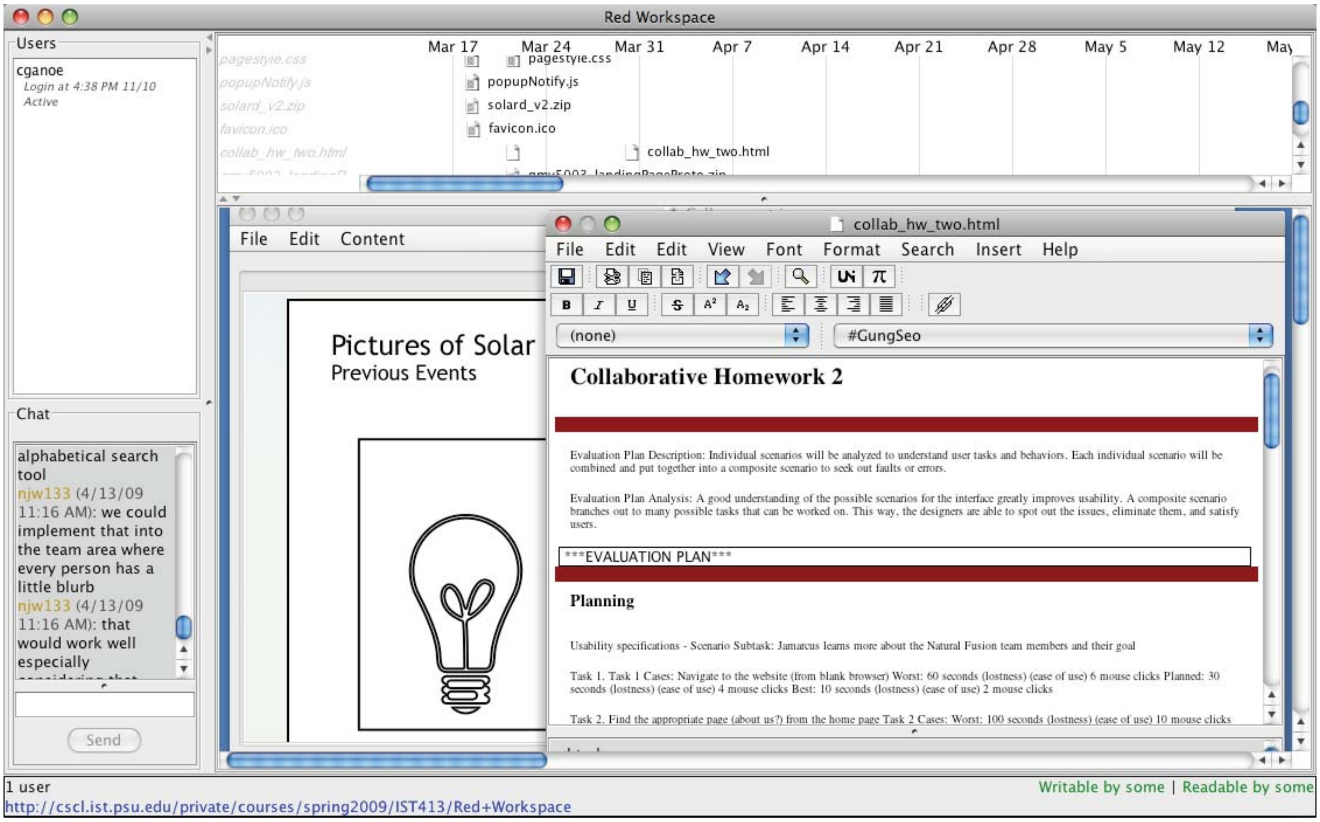

Figure 3. Students develop an evaluation plan in the BRIDGE workspace for one of the collaborative homeworks.

testing. We asked students to work with these organizations and discover possible usability improvements, design/redesign them and evaluate their new designs. The students post their semester-long projects into the UCS Library, so those projects become valuable case resources. In spring 2008, the seven student teams contributed seven cases to the UCS library. In 2009 spring, eight cases were contributed to the library.

D. BRIDGE

In the 2009 version of the usability engineering course, the three distributed collaborative homeworks, described in II-D, were carried out using BRIDGE (Basic Resources for Integrated Distributed Group Environments) [Ganoe et al., 2003], an open source system that supports the kinds of collaborative activities that we are trying to encourage and support among the usability engineering students (Figure 3). Our design for these learning activities requires members of the student teams to be able to individually contribute to the group work. For example, a team might develop a document analyzing how PAWS website designers carried out their activity design, information design and interaction design phases of the non-profit's project. Team member contributions might be made at any time during the 2-3 weeks of the assignment, and their contributions need to be immediately accessible and editable by their fellow team members.

In addition, we wanted the team members to have access to lightweight interaction tools, such as persistent text chat, so that they could exchange ideas, raise issues, and comment on work that was planned or completed. These interactions need to be shared and persist both synchronously, if they happened to be in the workspace at the same time, and asynchronously, if they happened not to be working at the same time.

Finally, we want students to be able to develop the team's final product collaboratively, both synchronously and asynchronously, as possible. In all three of the distributed collaborative homeworks, teams were to create a final document, synthesizing the work that each member had carried out and directing this analysis towards the team's semester project. As mentioned above, we also want the teams to tell us how they had used the four collaborative facets in organizing their work. We left it to the teams to decide exactly how to do this; for example, it could have been done in the chat and/or embedded in the final homework document.

IV. FURTHER WORK

We are currently planning for the Spring 2010 version of our usability engineering course. Our planning is directed at refining our approaches to both learning activities and learning technology. With respect to learning activities, we want to more explicitly articulate the presentation of the collaborative homeworks to help students experience a more sophisticated collaborative interaction. We also want to integrate the collaborative homework activities even more closely with the semester project. With respect to learning technology, we want to create a lightweight, browser-based shared workspace for distributed collaboration.

A. Plans for learning activity design

One development vector in the usability engineering course over the past two years has been greater integration of homework assignments and in-class activities with the group semester project, as described in II-A. We want to further pursue this. First, the students have a huge amount of work to do in this course, and integrating that work under the rubric of the semester project makes it more coherent for them. Second, the semester project is intrinsically motivating to the students; by ensuring that homeworks and in-class activities are more tightly bound with the semester project we may be able to leverage this to increase students' overall motivation.

In the 2009 version of the course, the distributed homeworks were separate assignments that pushed students to apply concepts important to the project, but not directly connected to project deliverables. We want to rectify this in the next iteration. As part of their final semester project, students have to create a case study of their design process; our plan is to design the distributed collaborative homeworks so that they directly contribute to the students' case studies. The distributed homeworks would be used as opportunities for students to reflect and evaluate on their own projects. Students would be expected to incorporate the language of the course to explain their design processes and apply important concepts like trade-off analyses to discuss and defend their design ideas. Thus these homeworks would become artifacts of their design process that would be included as part of their case study and overall semester project.

In order to provide students with more opportunities for collaborative interactions and learning through hands-on activities, our usability engineering course has also evolved from being a lecture-based course with many activities and a collaborative project to being a workshop. We have essentially ceased lecturing as of the 2006 version of the course; the students are involved in interactive activities in every class meeting. Our latest plan would orient this workshop more univocally on the semester project as an integrating workshop activity.

This instructional approach brings with it some inherent difficulties as evaluation of student learning is in many ways dependant on students' in-class discussions. In order for us to be able to evaluate how well students are grasping and applying core usability concepts we need to be able to peer into their thought processes. Rich, collaborative discussions are a useful way to accomplish this type of formative evaluation by drawing out students' ability levels while at the same time providing them with useful feedback. The problem we have encountered thus far is that students are not always comfortable with the risks involved with these sort of discussions: admitting they do not understand, applying concepts incorrectly, making themselves targets for criticism. The challenge for us will be to create a classroom environment where students feel it is okay if they do not have the "correct" answer as long as they can work with others to find it.

B. Plans for learning technology design

Ten years after its initial development [Isenhour et al., 2001; Ganoe et al., 2003], BRIDGE is still a powerful collaborative environment. However, it is too complex for the usability engineering course application. It intimidates the students.

Beyond the specific requirements for distributed collaboration in the usability engineering course, we believe that Internet-based collaboration requires lighter-weight support that more easily integrates with various other Web-based services and information systems. Thus, we have begun to define and develop a new collaborative workspace for use in usability engineering course, and hopefully beyond it.

We think that a core functionality for such a system is the ability to collaboratively author documents. However, we do not think that it is necessary (or perhaps even desirable in some applications) to support character-by-character pushed synchronization, as we did in BRIDGE [Isenhour et al., 2001]. Thus, we are shifting toward asynchronous collaborative writing. Our approach is to allow collaborators to open and work on segments of a shared document. While a document segment is open, it is locked to other users. However, when saved, it becomes available to collaborators, who can open and continue to work on it. As we did in BRIDGE, we will support the coordination of such collaborative writing by maintaining an easily-accessible change history for document segments.

It is vital for students to master a range of collaborative skills in order to successfully accomplish complex collaborative projects. For this reason, we aim to scaffold important team processes such as planning, critical evaluation and reflection. We plan on accomplishing this through instructor modeling, hands on collaborative activities, reflective activities where students evaluate their team's processes to identify the team's collaborative weaknesses, and repeated practice in applying strategies to improve these weaknesses.

A system that supports education and learning should also be able to capture team process at a finer level in order to properly support the full range of collaborative competencies our students display. It needs to support planning, reflection, and evaluation of collaborative tasks and processes in order to allow instructors to help teams: diagnose problems, structure important collaborative processes, and support reflective activities centered on improving these processes. So in the collaborative workspace under design and implementation, besides collaborative writing service, we provide simple and flexible web services to support collaborative team-processes, such as meetings. Teams can create meeting agendas in a workspace and members can contribute by pooling their comments and thoughts as input; the output will be a meeting memo for their future reference. Teams can also create a shared to-do list by which they can track progress of their projects. For critical evaluation on their project design, students can create an idea pool to put their innovational ideas and do pros-and-cons analysis for each idea.

V. CLOSING THOUGHTS

In this paper we discussed our experience with a particular assignment developed for our usability engineering course. We explained the main goals of the assignment and how it connected to the overall goals of the course. We also described the technological tools that could be used to support this activity. We then evaluated the activity after its implementation in order to identify ways that we could improve the activity and make it more useful for our students. Implementation and subsequent evaluation of the activity gave us better insights to our students and to the ways in which the activity was succeeding/failing to meet the original goals we set forth. This process of planning, implementing, evaluating, and refining our educational activity in many ways mirrors the iterative design process used in the development of technological systems. Indeed, it is only through the disciplined use of this design-feedback-redesign process that we can create useful and powerfully rich tools that can advance education and technology and the growing intersection of these two important disciplines.

ACKNOWLEDGMENTS

Professor Mary Beth Rosson was co-investigator of the original UCS project, and led the original development of the project-based usability engineering course, the textbook for that course [Carroll & Rosson, 2002], and the Usability Case Study library. Professor Lu Xiao designed and developed the Collaborative Case Builder described in III-A. We thank our many usability engineering students at Virginia Tech and, at Penn State who have allowed us to study their learning activities during the past 14 years.

Abstract—**The paper describes the design and implementation of a set of visual modeling editors. They aim to provide users with easy to use and customizable but yet semantically powerful tools for collaborative modeling in diverse domains of interest. The tools allow the creation, use and evolution of visual models and their underlying languages. The design, software architecture, technical implementation and graphic user interface of visual modeling language tools are discussed. The results of current field trials with the tools are also briefly outlined.**

Keywords-collaborative semantic modeling; ontology; visual models

I. Introduction

Collaborative design is a core element of engineering activity. While in some cases artifacts are designed by an individual engineer [1], design is most often a collective endeavor in which a group of individuals with different backgrounds and interests has to envision, explore, discuss, and evaluate proposals and claims towards the artifact at stake [2][3]. In addition to basic design skills, such as the ability to transfer theoretical knowledge to a particular design problem, to tolerate ambiguity, maintain the big picture, handle uncertainty, and making informed design decisions, collaborative design also requires participants to coordinate and orchestrate the joint effort and to communicate and integrate multiple perspectives effectively [4][3].

To prepare students for the practice of design and engineering in the 21st century, collaborative design exercises and projects became an important element of many study programs. While these efforts appear to have quite positive effects on both learning outcomes and motivation (cp. [4] for an overview of recent findings), research also indicates that collaborative design might suffer, among others, from failures to create a common understanding of and to reflect on the design problem at hand. Typical problems towards that end include an insufficient or inappropriate analysis of the design problem [5][6], design fixation and preoccupation with a particular solution [8][7], as well as tendencies to reduce the complexity of the problem in order to arrive at a solution as soon as possible [7]. In addition it has been argued that from an educational point of view the aim of collaborative design projects is not just to learn how to solve practical problems but also to understand and be able to articulate why a particular solution is supposed to work [10].

To address these challenges various authors have advocated the use of collaborative modeling techniques as a means to foster shared meaning making and reflection in collaborative design, e.g. [1][11][10]. While in recent years various tools and modeling languages have been developed to support collaborative work and learning in general, as well as collaborative design in particular, these tools either make little or no use of recent advances in semantic web technology or they are overly complex to use and hardly in line with the pragmatic requirements of students and professionals alike (cp. [12]).

To answer these challenges the paper describes the design and implementation of a set of visual modeling editors. They aim to provide users with easy to use and customizable but yet semantically powerful tools for collaborative modeling in diverse domains of interest. The described tools are part of the web-based collaborative working and learning Knowledge Practices Environment (KPE) currently under development in the Knowledge-Practice Laboratory project (KP-Lab). The tool set consists of two core components: the Visual Model Editor (VME) and the Visual Modeling Language Editor (VMLE). The Visual Model Editor allows users to create and evolve visual models in the form of two-dimensional graph diagrams such as flow-charts, argument-graphs, organigrams, decision trees, program logic models, conceptual maps, etc. both individually as well as collaboratively. The Visual Modeling Language Editor in addition allows users to create, share and edit the visual modeling languages as such, thereby providing users with the possibility to create their own domain specific ontologies.

This paper focuses on modeling as an inherent epistemic activity relevant to various scenarios in design and engineering education. Based on an outline of the role of modeling for collaborative design and a short review of state-of-the-art tools, we describe high-level requirements for computer-supported collaborative modeling. Against this background a visual modeling languages design, software architecture, tools implementation and graphic user interface are discussed. Finally, we provide a short overview of an initial field trial with the prototype as well as future plans.

The reported work is developed within the Knowledge-Practices Laboratory (KP-Lab) project funded by the EU 6th R&D Framework program.

II. Visual Models and Collaborative Design

Visual Models as means to depict and work with complex knowledge structures have been employed in various domains, including design and engineering, for many years. In its broadest sense visual models are any form of diagram in which concepts or statements are represented as nodes and relations between these concepts are represented as arcs or links. The syntactic and semantic constraints of a visual model are defined by the underlying language. Examples of visual modeling languages proposed for use in design and engineering include concept maps [13], causal maps [1], petri nets, but also argumentation based notations such as IBIS [14] or QOC [15].

Despite the adoption of collaborative modeling techniques and tools in various professional and educational settings, current tools often do not exploit recent advances in semantic web technology nor do they sufficiently address the pragmatic requirements that arise when modeling is not seen as an end in itself but as a means to support collaborative design.

A. Modelling as an Integrated Activity

While in some cases collaborative modeling exercises are aimed to foster the development of particular skills, such as systems thinking [16], collaborative modeling is often embedded in a more encompassing assignment such as a design project. For example, students are asked to develop conceptual models of an actual problem domain [11], to collaboratively articulate and negotiate different stakeholders' perspectives [1], or to explicate and justify the design decisions they made [10]. In all these cases modeling is not an end in itself but a means to support the collaborative design process.

Visual modeling thereby fulfills a variety of often highly intertwined purposes. Even though models are often seen as tool of representation aimed to depict known or assumed properties of a given target system, they can also be understood as "investigative instruments" in that they require an ongoing conversation of participants with the topic at stake, in order to gain better understanding of what is not known yet [17]. As communicative devices visual models can be used to create shared understanding but also to discuss divergent perspectives [1]. Additionally, visual models allow integrating ideas and reference resources throughout the design process, hence providing an evolving record of the design process [11]. Finally, by forcing participants to explicate and document their ideas, visual models provide insightful means for monitoring and assessment [11].

The added value of visual modeling usually arises from a combination of these purposes. While existing tools such as CMap [1], Compendium [2], FreeStyler [3], or the Visual Understanding Environment[4], support the representational and communicative functions quite well, they provide stand alone applications providing hardly any support for other collaborative design activities. Hence, they force users to switch and exchange resources across applications undermining the potential value of visual models as an integrative record. Furthermore, existing tools neither provide sufficient support to track the evolution of the visual models nor to discuss and comment on the elements within the model, making it difficult to orchestrate or monitor the modeling process.

B. Utilization of Visual Modeling Languages

In educational contexts visual modeling languages, such as those mentioned above, are primarily seen as a scaffold to guide the modeling process. While it has been acknowledged that visual modeling languages provide quite powerful tools in that they entail ontological commitments and make some aspects of a domain more salient than others [18][19], the users, including teachers, are usually not in control of the semantics (i.e. the modeling languages) themselves but can select from a set of predefined languages at best. The specification of modeling languages is usually seen as an expert task and priority is given to well-defined "standard" languages, which can be used in a variety of contexts. Consequently tools for the specification of modeling languages usually require substantial background knowledge and enforce explicit and complete specifications, often beyond users' interest [12] and are not attuned to the particular task or problem at hand. Alternatively, tools such as CMap provide only minimal semantics leaving it up to the user to informally agree on the semantics implied by color-coding and selection of various shapes within the models.

Based on the assumption that collaborative modeling requires users to have a common understanding of the concepts and categories used but also acknowledging that ontological commitments are at least partly situated in nature and hence not universally valid [20], both of the current solutions appear quite insufficient. Instead it appears desirable that users can adapt visual modeling languages to their particular needs. Furthermore, limitations of existing modeling languages often only become apparent when being engaged in a concrete modeling exercise. Therefore, it would be preferable to be able to extend or modify the modeling languages on the fly.

III. Pedagogical Scenarios and Design Objectives

To address the challenges outlined above we are currently designing and implementing a set of visual modeling tools which provide users with easy to use and customizable but yet semantically powerful means for collaborative modeling in diverse domains of interest, including design and engineering education.

Pedagogical scenarios to be supported by these tools can take quite different forms. Nevertheless, strong emphasis is put on scenarios that necessitate intensive collaboration on a given topic. Prototypical scenarios include the following:

- Project-based courses where students are asked to work on actual design problems and have to articulate and keep track of the problem space as well as the design decisions they make.
- Inquiry-oriented settings where students are asked to describe and analyze a particular system or phenomenon (e.g. needs assessments, evaluation studies or empirical studies of user behavior).

[1] http://cmap.ihmc.us/
[2] http://compendium.open.ac.uk
[3] http://www.collide.info
[4] http://vue.tufts.edu/

- Topic- or theory-related settings where students are asked to (re-)construct scientific arguments and/or to structure a particular domain of interest (e.g. collaborative literature reviews or state-of-the-art analyses).

Against this background the tools we are currently developing are designed to meet the following goals:

- The creation and use of visual models and their underlying languages should be as integrated as possible. Instead of treating modeling as a separate activity, collaborative modeling should be as tightly integrated into the groups' work processes as possible, allowing for easy access and reference to other resources used. Towards that end, tools for collaborative modeling should be directly integrated into the respective learning and working environment.
- Rather than restricting users to a predefined set of modeling languages, they should be able to modify existing or create new languages whenever needed (e.g. when modeling). To allow for an integrated work on visual models and modeling languages users have to be able to easily move between both levels of abstraction without mixing them up.
- Users should be assisted in developing alternative models and to support the triangulation of different perspectives; these models can be based on the same or different modeling languages.
- Supporting long-term and boundary crossing processes of knowledge creation affords the reuse and evolution of the visual models and languages. Towards this end, users have to be aware of existing models and languages, to understand their specific purposes but also to adapt them to their local circumstances and own ideas.
- Allowing users to create and maintain their own modeling languages also requires powerful metaphors and easy to use tools to overcome the formalization barrier imposed by current tools.
- As concepts and their interrelations often become apparent and crystallize only over a series of consecutive refinements and applications, learners should be supported in the systematic refinement and enrichment of models and their underlying languages. In order to trace the rational of their evolution means for comparing successive versions of models and languages have to be in place. Furthermore, whenever feasible, feedback should be provided to learners regarding possible consequences that a suggested change of the language will have for their model.

IV. KNOWLEDGE PRACTICES ENVIRONMENT AND VISUAL MODELING TOOLS

The Knowledge Practices Environment (KPE) [21] is a web-based collaborative working and learning environment offering various facilities for creating and interacting with knowledge artifacts and knowledge process models. The prevailing user interface paradigm in KPE is based on "shared spaces" – a graph-based view on collections of knowledge objects, which provide real-time and history based awareness to facilitate multi-user collaboration (Fig. 1).

KPE offers various tools for evolving the shared knowledge objects and organizing them visually – wiki, note and sketch editors, annotation and commenting tool, one-to-one and group chats, semantic tagging and semantic search.

A. *KPE Architecture and Technical Implementation*

The Knowledge Practices Environment is a web based distributed software system, which consists of user client, real-time synchronization service, front-end services and data storage (Fig.2).

The client is implemented in Adobe Flex/Flash. When the

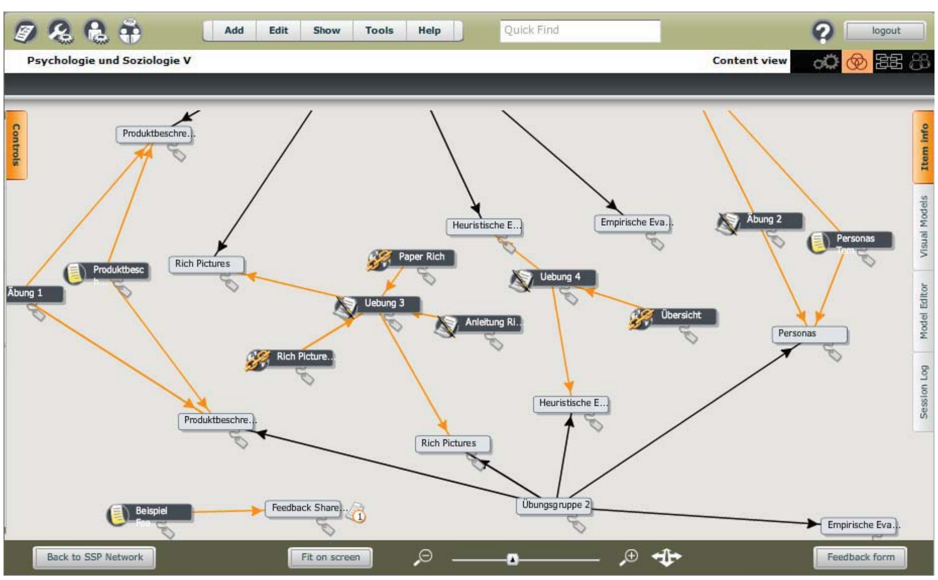

Figure 1. KPE Shared Space.

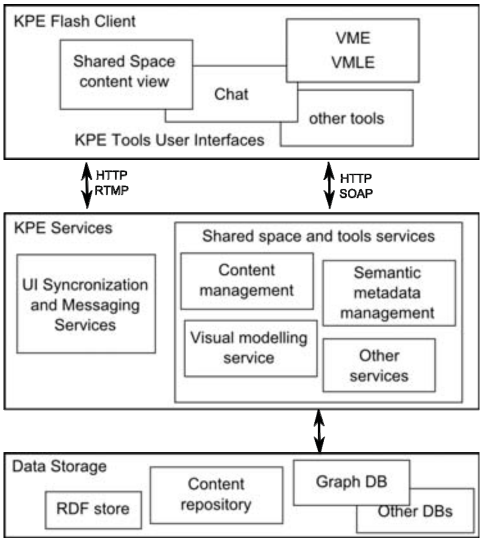

Figure 2. KPE architecture.

user initiates a KPE session, the client is loaded in the web browser and provides a graphical view of the shared space content. The client relies on the front-end services for data manipulation, retrieval and persistence tasks. Most of them are implemented as JAX-WS web services and deployed in Java EE application servers. This architectural decision allows for a truly distributed KPE deployment with different services residing on different servers.

KPE knowledge objects are stored into a heterogeneous database, consisting of RDF store [22] for metadata, Jackrabbit repository [23] for the content (uploaded files, notes, sketches, chat histories), wiki engine and some tool-specific data stores.

A dedicated server, running Adobe Flash Media Server software, is tasked with synchronizing the client's views. All users of a particular shared space can see the changes in the shared space content and layout, inflicted by other users, almost simultaneously.

B. KPE Visual Modeling Tools

The Visual Model Editor (VME) and Visual Modeling Language Editor (VMLE) are KPE tools, whose purpose is to allow users to create visual models and the underlying visual modeling languages as another type of shared artifacts. The direct integration into the KPE allows for an easy transition between modeling and other collaborative activities.

The KPE visual modeling tools support both synchronous and asynchronous collaboration. Users can work on the same model at the same time and changes are propagated in real time to all members of the group or users can work on the same model at different times and when they get back to the system they can retrieve the changes. Moreover visual models can evolve not only based on direct user-inflicted changes but also because the underlying visual modeling languages can also evolve.

Both collaborative developments of visual models as well as the underlying modeling languages are supported. The users

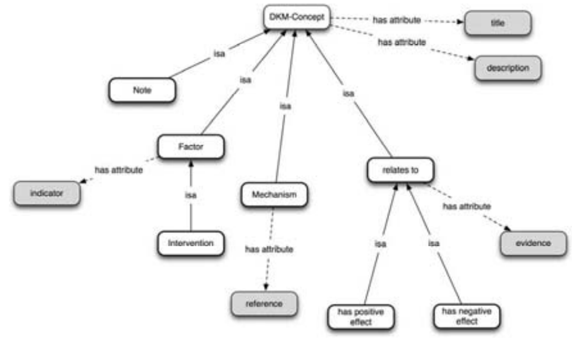

Figure 3. Example of a visual modeling language tree representation.

are free to specify the semantics of the modeling elements used which facilitates the creation of a shared understanding. The tools allow for a controlled evolution of a modeling language preserving consistency with selected existing instances of it.

In KPE the visual modeling languages are modeled as trees, with vertices symbolizing language concepts and attributes and edges representing *is-a* and *has-attribute* relations (Fig. 3).

The KPE users employ the Visual Modeling Language editor to modify the language tree by adding/removing concepts, changing their attributes and defining constrains on the way concepts can be linked together in the visual models.

The visual models are represented as directed multigraphs. Each model is based on a particular modeling language and is constructed from the concepts, defined in this language.

Fig. 4 depicts the user interface of the KPE Visual Model Editor. On the figure, the visual model elements can be identified as white rectangles with arrows between them. The VME allows for references to be created from the model elements to the knowledge objects in the shared space (shown as darker rectangles in the background). The figure also shows a context-chat window, which allows the users, working on the same visual model, to collaborate more effectively.

In order to support the research activities focused on analyzing the evolution of visual models and languages, both VME and VMLE tools keep detailed logs of all changes to the language or model graphs.

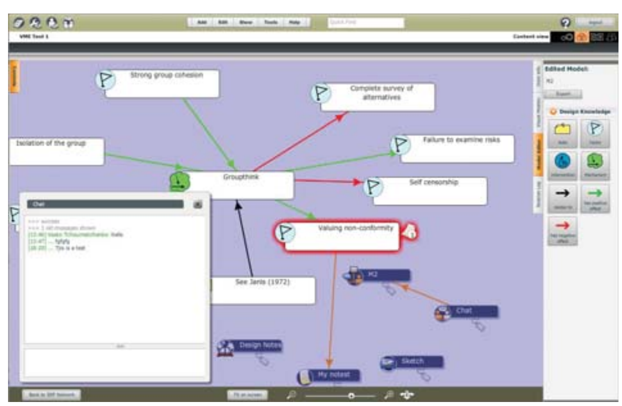

Figure 4. KPE and Visual Model Editor user interface.

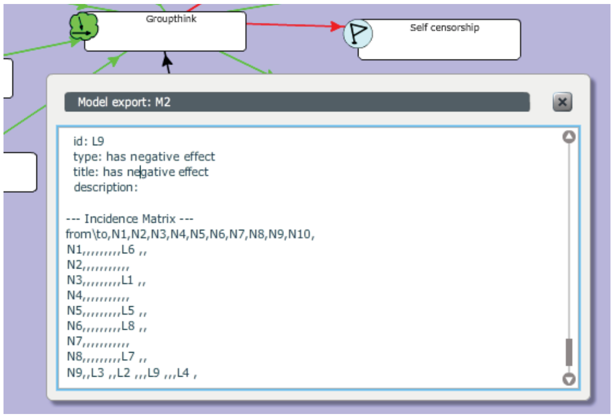

Figure 5. Visual model graph and history log export.

The logs, as well as the models, can be exported in textual format (Fig. 5) for detailed analysis outside the KPE.

The user interface and the presentation logic of the KPE visual modeling tools is implemented as part of the KPE Flash client. A dedicated web service handles the information exchange between the VME/VMLE client components and the models database. The language and model graphs are stored in an embedded graph database, based on Neo4j [24] persistence engine.

V. First Field Trial and Findings

To better understand the appropriation and utilization of the VME in an educational context, the first release of the VME has been tested in two university courses held by the University of Helsinki as well as the University of Applied Sciences Upper Austria in winter-term 2008/09. In the following we provide a brief description of the pedagogical scenario and findings obtained from the field trial at the University of Applied Sciences Upper Austria in the bachelor program "Communication and Knowledge Media".

The field trial was carried out in the context of cornerstone course "eModeration" that is aimed to promote an understanding of design as a form of open-ended inquiry and to engage students in a concrete design activity. Throughout a period of one semester the students are asked to envision, develop, implement and evaluate a solution for a complex design problem in the fields of eCommunication and eModeration. To foster in depth exploration of the design space and to trigger reflection on the proposed solutions, the teams were asked to continuously explicate their evolving understanding of a common design space by means of the VME. Towards this end students were provided with an introduction to principles and methods of needs and problem analysis as well as access to the KPE and the Visual Model Editor. A simple modeling language was introduced to scaffold the needs and problem analysis. Throughout a period of five months 35 students in 10 project teams took part in the field trial. Throughout the semester, the groups met face to face with the instructor alternately every second week.

The main aim of the field trial has been to better understand how students actually make use of the Visual Model Editor and the semantics of the language provided as well as to inform the further development of the VM(L)E. The following observations and findings are based on an exploratory analysis of the models created by the project teams (screenshots had been taken on a weekly basis), the responses to a questionnaire administered to all students at the end of the course, as well as interviews with representatives of four teams and the instructor.

Besides some usability problems, the accompanying research study also shed light on the actual modeling practices. In general the project teams responded quite differently to the modeling assignment, which is reflected for example in the number of additions and modifications made to the models over time as well as their structure. While three groups hardly made any use of the Visual Model Editor or abandoned it after some first tryouts, the other seven groups worked on their models fairly continuously. Among those who used the Visual Model Editor more regularly two groups worked on a single model, while the remaining four groups created 3-7 distinct models.

Even though the "Problem Analysis Language" had been introduced explicitly to the students and scope notes for the different concepts are easily accessible via the Visual Model Editor, the "specified factor", which provides a kind of default concept, was used quite excessively by all teams. Especially those groups who started to work on their models right from the beginning, hardly made any use of the specific concepts provided to depict their design space. This behavior only changed later on after the instructor provided additional suggestions on how the different concepts could be used efficiently. In contrast, two teams that started to work on their models relatively late, made more sophisticated use of the different concepts available right from the beginning. This finding is partly in conflict with the expectation that explicitly defined concepts would scaffold students' elaboration of the design space. It might be that in the early phases of the design process, the effort to explicitly classify ideas according to a predefined scheme does not outweigh the expected benefits or even hinders a brainstorming like collection of ideas. This assessment might change later on when the scope of the project becomes clearer and there is more need to structure and integrate the existing ideas. This interpretation is at least partly supported by the students' reports on how they created and used the models at the different stages of the project.

Some students also mentioned that the predefined modeling languages are too restrictive and that they had difficulties to map their ideas to the concepts provided. Closer examination of the models revealed that several teams had problems to make proper use of the concepts provided e.g. they mixed up resources and actions, and/or to understand the idea of typed nodes e.g. they introduced a concept specified in the Problem Analysis Language as a separate node. On the other hand we also found attempts to proactively introduce additional concepts not provided by the Problem Analysis Language (the Visual Modeling Language Editor has not been available yet). For example on of the teams added a kind of prefix, in this case "problem", to the title of several nodes providing additional categorization. Together with findings from similar courses this underlines the need for a possibility not only to edit the models but also the underlying modeling languages.

The comparison across teams revealed that those who used the Visual Model Editor more intensively often created more than one model in the project's lifetime. While in some cases the creation of multiple models was reportedly due to the fact that the current release of the Visual Model Editor does not allow changing the type of a concept or relationship in a model once it has been created, which make the update of models somewhat tedious, other groups created different models by purpose. One of the interviewee's reported that they had created multiple models in order to be able trace back their understanding at different stages. In another case the participants reported that they produced different models to depict different aspects of their project.

Even though these findings are only preliminary and more in depth analysis of students' modeling practices is needed, it appears that the adoption and utilization of semantically rich visual models might strongly depend on the direct added value for the user. Nevertheless, the assessment of required efforts and expected benefits might change depending on the stage of the project as well as the actual task at hand. Consequently, tools to support collaborative modeling have to be quite flexible in order to accommodate for the changing requirements that arise during the lifecycle of a project. For instance, it requires that users can easily restructure the models they created as well as change the concepts and relations or even introduce new concepts at runtime, which could extend as far as modifying the modeling languages itself. Furthermore, the findings point to the complexity of collaborative modeling as a real world practice that might not only fulfill an epistemic but also a social, pragmatic or even reflective purpose.

VI. Conclusions & Future Work

In this paper we briefly discussed the role of collaborative modeling in the context of design and engineering education and outlined our primary design goals. Against this background we introduced the Visual Model Editor and the Visual Modeling Language Editor as a set of tools aimed to provide users with a flexible and easy to use but still semantically powerful tool for the creation of visual models and their underlying modeling languages. The vision behind this tool is to provide users with the possibility to create their own conceptual tools and thereby to advance pre-existing perspectives while being engaged in a meaningful activity, such as a design project. Based on findings from a first field trial with the Visual Model Editor, it appears that the adoption and utilization of semantically rich conceptual models to a large extend depends on the direct added value for the user, while at the same time modeling fulfils not only epistemic but also social and pragmatic purposes for the user.

An updated version of the Visual Model Editor as well as a first release of the language editing component are currently under development and will provide users with full capability to create and update their own modeling languages in the near future. In parallel, in depth analysis of students' modeling practices and the impact of the modeling activities on the project outcomes are ongoing. These will inform both the further development of the tools as well as respective pedagogical scenarios.

Embedding Sustainability in Capstone Engineering Design Projects

Abdallah M Hasna
Faculty of Engineering and Surveying
The University of Southern Queensland,
Toowoomba, Queensland, Australia

Abstract— **The pace of change in education curriculums is growing exponentially due to numerous legislative arrangements and changes. Carbon tax, carbon pollution reduction schemes, emissions trading legislation are paving the way for environmental accountability in engineering industry. Engineering education moves into the twenty first century charged with an environmental agenda due to response to wider changes in society. Educators are regularly modifying curriculum content to embrace sustainability in learning outcomes. However this crosses over between a number of multi-disciplinary, multi-dimensional study areas that include philosophy and ethics. Consequently a major challenge for educators is to encourage engineering students whose primary focus is purely technical to include sustainability viewpoint in their designs. Unlike technical or financial evaluations where measures are either empirical or numerical estimates, sustainability position includes criteria in economic, natural, social, technological and time indicators. For the most part sustainability evaluations are content and competency driven and rely sometimes on rather intangible and proximal criteria. These criteria form the basis of assessment for measuring the sustainability of a design. The purpose of this article is to present various criterion, and indicators available to evaluate sustainability in engineering designs feasibility assessments. The paper presents the application of sustainability design criteria in the context of capstone design projects by way of applying social, economic, ecological, technological and time SEETT framework. These criteria form the basis of sustainability education embedment in engineering capstone design projects. Finally this paper argues the thesis that Sustainability feasibility studies and assessment in capstone engineering design projects are of grave importance for the success of the new frontier.**

Keywords- Engineering eduction model,capstone,new century, indicator, criteria, sustainbility, design, assessment feasibilty.

I. INTRODUCTION

The engineering industry uses vast quantities of natural resources (energy, water, materials and land), and produces products and services. Sustainability is a societal challenge; that also requires the contribution of engineers and technologists. The application of sustainability in engineering is about the implementation of sustainable product and process for the benefit of wider community. Consequently, traditional engineering curriculums were entrenched in the industrial needs of the 19th century; today the new 21st century engineering education model needs to incorporate 21st century principles and ideals including sustainability in the engineering curriculums. However the increasing knowledge needed to practice as a professional engineers and the accelerating rate of change within the discipline suggest that traditional learning models may not address the requirements of learners [1]. Then again the concept of sustainability falls outside the regular numerical subject engineers are classically skilled for. The notion of sustainability education in engineering curriculums is growing at different levels in literature as indicated in TABLE I. Although there are a number of independent efforts to fold environmental issues in existing undergraduate curricula like the Barcelona Declaration Engineering Education in Sustainable Development EESD 2004 which described today's engineers need to acquire new dimensions in ethical, social and cultural issues and systemic vision. No dominant method has emerged as a means of including these concepts. One of the difficulties in adjusting our materials science and engineering (MSE) curricula is the problem of how and what to include in an already full curriculum [2]. Therefore the challenge for the 21st century engineering education model 21EEM is to educate engineers in non-technical issues, which deal with the social subject. This is not to suggest that mere training- equipping engineers with the available analytical tools would be enough to achieve sustainability.

TABLE I. ENGINEERING EDUCATION AND SUSTAINABILITY

Technology to address the challenge.	[3]
Process of change aimed at introducing concepts of sustainable development into activities.	[4]
students' difficulties in differentiating between values and descriptions of phenomena	[5]
sustainable development concepts using cognitive maps	[6]
university engineering courses accreditation requirements	[7]

Sustainability's position in 21EEM would require not just new tools but what's more a new role, being "bilingualism" across disciplines. Therefore, interdisciplinary learning outcomes need to take preference in (21EEM) curriculums to educate the new generation of engineers and technologists. Another vital issue that requires attention in curriculum development is the prima facie of incompatibility between the promotion of an environmental ethic 'sustainability virtues, greener' ideals in education and the political liberal's commitment to 'neutrality' "… the state is not to do anything intended to favor or promote any particular comprehensive doctrine rather than another, or to give greater assistance to those who pursue it…" According to Rawls's political liberalism, which was debated by Derek [8] and Allen [9] arguing that engineering expertise would need to contribute at an early stage in the framing of problems, not just in problem solving; i.e., engineers should have a normative role as well as their more familiar analytical role. The idea of engineering adopting (or returning to) a normative role can be understood by examining the kinds of decisions in which professional engineers as decision makers may be involved with, this presented is as a useful classification of decisions shown in Fig.1.

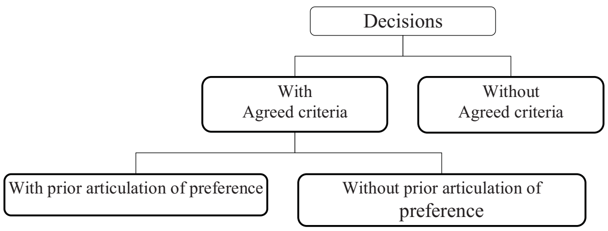

Figure 1: Classification of decisions [10]

The quantitative assessment of engineering design during research, planning and structuring, and implementation and management phases of technological development is important for identifying and prioritizing overall contributions towards sustainability [11]. 14 criteria suggested as vital for the choice of strategies decision makers apply to a given design listed in TABLE II.

TABLE II. DESIGN ALTERNATIVES

Equity	Do those creating the hazard pay for mitigation? Or where inappropriate, is cost equitably distributed among all?
Timing	Will benefits be quickly realized?
Leverage	Will action lead to further risk reduction by others?
Cost	Is there a less expensive way of achieving the same results?
Efficiency	Can the policy be administered efficiently?
Continuity	Will the effects be continuous or short-term?
Compatibility	Is this strategy compatible with others that may be adopted?
Jurisdictional	What authority will have to enact this policy?
Economic	What is the economic impact of this strategy?
Environment	What is the environmental impact of this strategy?
New hazards	Will the strategy itself introduce new risks?
Potential	How much of the risk will the strategy reduce?
Reaction	Are there likely to be adverse political repercussions?
Freedom	Does the strategy deny basic rights?

Adapted from [12, 13]

II. SUSTAINABILITY PHILOSOHOPY

Embedding sustainability education in engineering requires addressing engineers' contribution towards net positive outcome by focusing on minimizing negative impacts on the environment and society. Hasna [14] reported on a taxonomy of sustainability attitude existing within practicing engineers as shown in Fig. 2. In order to respond to these challenges no discussion on sustainability would be complete without mention of the one sustainability philosophy two distinct views, i.e. the pessimism of neo-Malthusians is a sharp contrast with the optimism of cornucopians. Accordingto Malthusians sooner or later population will outgrow natural resources[1]. This is described in the following model;

$$P(t) = P_0 \, e^{rt} \quad (1)$$

The cornucopian school of thought endorses some degree of intractable natural limits to growth and believes through the advancements of technology the world can provide limitless natural resources. However as engineers we view the cornucopian philosophy with a degree of reservations in context of the second law of thermodynamics governs the conversion of energy from one form to another,

$$\partial U = \partial W + \partial Q = \partial W + T\partial S \quad (2)$$

Where dU, the change in the internal energy of a system is equal to the sum of the reversible work done on it dW and the heat irreversibly exchanged with the environment dQ = TdS (which is associated with a change in the entropy of the system). Simplifying the second Law: Law of increasing entropy or unidirectional flow of thermal energy, hence no system is 100% efficient. According Atkisson [15] who reported that we must accelerate our industrial and technological development, or the forces we have already unleashed will wreak even greater havoc on the world for generations to come. We cannot go on, and we cannot stop. We must transform. The natural conclusion here, would be one of comprise between the two viewpoints, therefore contemporary engineering philosophy regarding sustainability is ought to subsume all known definitional variations and takes responsibly of the world's finite natural resources in a manner which will not compromise the ability of future generations. Building on this basis as engineers discussing sustainability in design projects, we have proposed the use of criteria for assessment, in this way we remain true to the physical laws that govern our universe as it is impractical to totally reject it all. Since all of our current practices support Malthusian theory. Hence our role is to achieve a net positive outcome, by putting forward a premise of balance and moderation through the assessment against known criteria.

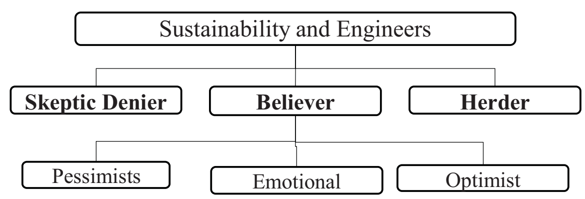

Figure 2: taxonomy of philosophy

Similarly the discussion of how to define sustainability is not new, literature is rich with interpreted meanings and definitions post Bruntland Report [16], whilst these definitions varied linguistically they all share similar nonfigurative, idealistic chic, covering four to six known dimensions[2]. Hence definitional and interpretational meanings directly relate to sustainability assessment. These include converging on protecting the environment and balancing consumption of natural resources.

[1] Where P_0 = Initial Population, r = growth rate, sometimes also called Malthusian Parameter and t = time.

[2] Note that sustainability principles should remain constant over time, whereas the choice of criteria and indicators may change rapidly as knowledge advances.

III. ASSESSMENT TOOLS AND THE ENGINEERING INDUSTRY

Sustainability assessment tools are typically used to estimate achievements of the transformation. Literature is scoured with non-specific, aggregated and ideal indicator sets, proposed by various organizations with interests in sustainability, for example the report on organizations environmental reporting published by [17]. we have reviewed sustainability assessment tools and metrics available for use in the process industries for example; the United Kingdom Institution of Chemical Engineers; Environmental Sustainability Index [18], Ecological footprint [19-22]; World Business Council for Sustainable Development [23] ;United Kingdom Government Strategy indicators [24]; indicators produced in the academic arena [25]. These indicator sets have been identified as having a general focus on reporting towards sustainability. However the literature proposes a bewildering array of tools and processes in sustainability feasibility assessment for engineers. Some are 'graphical integration' tools, aggregating scores of indicators others are 'numerical integration' tools, aggregating indicators. An detailed literature review that covered theoretical and practical approaches to assess sustainability reviewed some assessment tools which may not be widely known amongst engineers but are nevertheless clearly rooted in engineering science cited 55 tools for sustainability assessment framework with an additional 25 software tools [26], Sigh [27] reported on 38 sustainability composite index that included formulation strategy, scaling, normalization, weighting and aggregation methodology. The mentioned tools do not cover industry specific rating schemes and initiatives, that are non comprehensive and non global. Finally it would not be possible to brand any tool as a total environmental solution. According to Spangenberg and Bonniot [28] sustainability per definition is a composite and thus an ambitious policy target.

IV. PRINCIPLES ,CRITERIA AND INDICATORS

In the literature on sustainability much attention is given describing how sustainability criteria should be but little information on the detail, it was found literature lists the criteria to varying degrees by conventional normative criteria. It is stated in Agenda 21 the need for acknowledging the importance of sustainability indicators by both national governments and the international organizations which should be followed by the identification of relevant indicators [29]. The explicit incorporation of sustainability in the decision support process requires assessment of the social, economic and environmental consequences of potential options. This requires the use of sustainability criteria by which to assess these consequences in terms of whether the option is likely to move the system towards or away from sustainability objectives [30]. Sustainability criteria are defined here as the set of factors that may be used to assess which of a range of options, in this case for the development of engineering sustainability criteria which offers the greatest contribution to achieving sustainability objectives. It is helpful, first, to draw distinction between principles, criteria and indicators of sustainability. Principles are normative definitions or goals for sustainability aspire to a universal validity, which can be agreed upon by all. Criteria are the set of factors that may be used to make a judgment about the relative sustainability of a set of options. Indicators measure the past and current values of specific criteria, and may be used to set standards against which future performance can be assessed [30]. Parsons [31] highlighted the usefulness of conceptual models that can explain complex political processes and issues. Sustainability indicator systems encompass a variety of frameworks, dimensions, criteria, indicators, targets and visualization strategies. The variety of processes and measurements can be analyzed from a systems approach and classified by policy purpose and scale. A key component of the system is the interpretation of the term sustainability and how the concept is applied to the particular issue. Chapter 40 of [32] called for the development of indicators for sustainable development at multiple levels. sustainability indicators development are needed in order to provide decision makers with information on sustainable development that is simpler and more readily understood than raw or even analyzed data [33]. In particular, there is a need for highly aggregated and composite indicators, here defined as indices, in which condensed information is assembled. Comparable (SI) indicators and indices with broad international acceptance remains lacking [34].

V. CHARACTERISTICS OF SUSTAINABILITY INDICATORS

Typically sustainability is measured using indicators; Indicators are an essential component of sustainability measurement, but what are indicators ,the word "indicator" has its roots in Latin "indicare" which means "to direct or to point out" [35], however what is a sustainability indicator? The scientific roots of sustainability Indicators lie in the shore of limnology. Sustainability indicators (SI's) science emerged post the United Nations Conference on Environment and Development Agenda 21, Rio Earth summit[36]. The definition of SI's is an important step, as the selection of sustainable solutions is based on these indicators [37]. Many specific definitions in literature exist, they tend to vary little. However there is a distinction between data and Indicator, hence in a general sense, an indicator is a sign. SI's address the crucial issue of sustainability: how can it be measured [38]. In pursuit of influential factors of (SI) for use in feasibility and assessment, it imperative to settle on characteristics of these indicators, to determine what is to be sustained?

TABLE III. CLASSIFICATION OF SUSTAINABILITY INDICATORS

Definition	Author
measurable variable, that provides information sometimes hypothetically linked to another (latent) variable which cannot be observed directly	[39]
variable describes a characteristic of a phenomenon	[40, 41]
parameter, or a value derived from parameters, which points to, provides information about, describes the state of a phenomenon/environment/area, with a significance extending beyond that directly associated with a parameter value, Parameter is a property that is measured or observed	[42]
statistics or measures that relate to a condition, change of quality, or change in state of something valued	[43]
measure that summarizes information relevant to a particular phenomenon, reasonable proxy for a measure	[44, 45]

Hence with respect to indicators for sustainability in engineering, it is therefore crucial to represent a merit-based indicator that provides a snap shot of the design. It is particularly important that the (SI) can be compatible with design criteria hence lending it to be resolved early in the design process. Indicators typically provide key information about a physical, social or economic system [46] provided a comprehensive analysis of various definitions, and demonstrates that an indicator has been defined as "variable", "parameter", "measure", "statistical measure", "a proxy for a measure", and "a subindex", among others. At the concrete level indicators are considered variables. A variable is "an operational representation of attribute (quality, characteristic, property) of a system". Each variable may take different values depending on the specific measurements or observations. Thus, indicators are variables, and data are the actual measurements or observation. TABLE III. presents a summary of the most cited characteristics in literature. Sustainability indicators integrate environmental, social, and economic factors such that the complex cause and- effect relationships between these multiple factors can be more readily investigated [47]. In addition an indicator is a representation of linkages whereby multiple effects can be monitored by a fundamental indicator [48]. Indicators have received increasing attention in the decade, reflecting growing concern by the public and policy makers over environmental trends [49]. However there are two contrast perspectives on indicators:

(I) Indicator-based monitoring tools are frequently applied as effective tools for sustainability assessments [50].
(II) Much of the measurement of indicators has, at the end of the day, largely resulted just in the measurement of indicators [51].

TABLE IV. QUALITY OF SUSTAINABILITY INDICATOR

Scientific quality	Data management
Uncorrelated Independent clear-cut measures what it is supposed to detect measures significant aspect Problem specific Distinguishes between causes and effects Can be reproduced and repeated over time	Easy to quantify Cost effective Data available Comparable across borders and over time Quantifiable Representative Transparent physically relevant Relevant to users User friendly Widely accepted

Spangenberg and Bonniot [28] described proactive indicators cannot focus on symptoms or damages, which only permits an ex-post analysis, but have to concentrate on the underlying trends in order to permit exante measures to be taken on emerging problems therefore, they will usually be response indicators in the (PSR) pressure state response (terminology). Despite the interest in the development and use of indicators the actual operationalisation of indicators to in influence or change, for instance, policy is still in its infancy since there is not enough effort for indicator validation [52]. TABLE IV. lists key attributes for the selection of sustainability indicators, the characteristic are separated into two parts, scientific quality and data management issues, [53]. Therefore, what is the application of these principles, concepts, criteria, factors from engineering design perspective? In this section, we have highlight the central findings in dependent and independent variables, also known as factors, or indicators most prominent sustainability assessment literature to form the empirical foundation in sustainability feasibility assessment in engineering capstone design projects.

A. The Time perspective

Time is the most valued determinant of sustainability; it permits the fuller and more graceful development and deployment of still better techniques to achieve sustainability. Basically the more time is available; the more information will emerge to sustain more robust choices. The time perspectives of most natural resource systems must be at least 250 years, but rather 500-1,000 years is required for any serious sustainability perspective. This can be set against the time perspectives of global climate change/carbon dioxide pollution measures which are planned to fall within the range of 4-500 years. Summarized in TABLE V. a list of four time classifications that can be used to asses an engineering design.

TABLE V. TIME DIMENSION IN SUSTAINABILITY PLANNING

Time Perspective	Years	Description
Instant	2-4	Blink of the eye of the natural system
Short-term	10-30	Fraction of the natural system rotation period
Intermediate	70-120	Is comparable to that of the length of one rotation period
Long-term time	100- 400	Involves more than one to three rotation periods of the natural system

adapted from [54]

B. Sustainability Indicators (SI) Advantages and Pitfalls

Historical research on indicators has been descriptive in nature. This has been useful in the developmental phase of indicator application. Descriptive research in terms of criteria and indicators has been the frameworks [55]. Indicators are different from primary data or statistics in the sense that they provide meaning beyond the attributes directly associated with them and thus providing a bridge between detailed data and interpreted information [56], they have significance beyond the value of the parameter [57]. Thus, indicators provide meaning and concentrated information which otherwise would require an extended detailed amount of information [58]. However, there are limitations of using indicators; one major pitfall is that of subjectivity. Subjectivity enters in two fields: on the selection of the representative indicators and on the evaluation of the indicators results. What Meadows referred to as dependence on a false model and certain scientific and social background and therefore certain degree of subjectivity is inevitable? Other problems include: lack of appropriate data which may result on missing vital information, this further could lead to measuring what is measurable rather what is important [59]; and over aggregation of too many things resulting in an unclear meaning and therefore bad communication and analysis capability. If indicators are not chosen carefully and as systematically as possible they will carry the wrong message resulting in misleading conclusions. Consequently most indicators have not generally been accepted for actual decision-making because of measurement, weighting and indicator selection problems [60].

VI. Principles of Risk Management

Engineering design is subject to multiple, competing tensions. Traditionally, engineering design involves some inherent design risks in the early stages of design that are not always carefully managed, one of main reason is the lack of tools and knowledge to simulate stochastic events (Amir,2004). Four of the main tensions during system or product development have been identified by [61] and are shown Fig.3. According to Australian standard AS/NZS 4360:2004, risk analysis may be undertaken to varying degrees of detail depending upon the risk, the purpose of the analysis, and the information, data and resources available. Analysis may be qualitative, semi-quantitative or quantitative or a combination of these, depending on the circumstances.

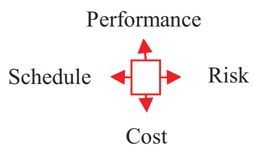

Figure 3: Architecting and design tensions [61]

A comprehensive review of risk management was completed by Pennock and Haimes [62] it was reported that there is a growing body of literature on project risk management composed of a myriad of different approaches and methodologies. In general, there is no one "right" way to conduct project risk management. A comprehensive approach to project risk management can be found in [63], which suggests that project risk management should be a project in of itself. To streamline the subsequent discussion on engineering projects risk and sustainability, this section defines and explains terms and concepts used in this chapter. According to Pennock and Haimes [62] two basic types of risk; technical and programmatic; Technical risk denotes risk in a project will fail to meet its performance criteria. This encompasses the realm of hardware and software failures, requirements shortfalls, and the like. Programmatic risk has two major subcomponents delay in schedule (the project exceeds its projected completion schedule) and cost overrun (the project exceeds its budget or operating costs), this where we propose the interlinks between engineering project technical performance, cost and project's complete sustainability as shown in Fig.5.

. In all cases risk is defined as the probability and severity of adverse effects [64].

$$Risk = \sum_i N_i \times p_i \quad [3] \qquad (3)$$

[3] Where Ni is the consequence (e.g., persons killed, injured) and pi=the probability of occurrence, the two-dimensional components of risk capture its complex nature, but they also make risk a more difficult entity with which to work.

Several systemic methods and approaches are available for identifying and tracking risks. While techniques such as Failure Modes and Effects Analysis FMEA [65] fault trees work well for assessment of pure system failure analysis because there are a finite number of pans. Each part can be examined individually to determine its failure modes and how those failures will affect other parts and the overall effectiveness of the device. However, it has limited effects for assessing sociotechnological systems failure which largely include all engineering projects; hence we recognise need for broad-based, interactive, multifaceted approach to track the projects sustainability risk whilst we identify difficult to capture all of them with a single model. Hierarchical Holographic Modelling HHM is based on the premise that no real-life system can be adequately represented by a single model, to do so would be to present only one dimension of the system[66, 67]. Hence we propose investigating the critical and important facets that make up a constitute sustainability system criteria, this is proposed through a comprehensive qualitative assessment to establish topics or set of subtopics for engineers to refer to similar to sustainability assessment criteria.

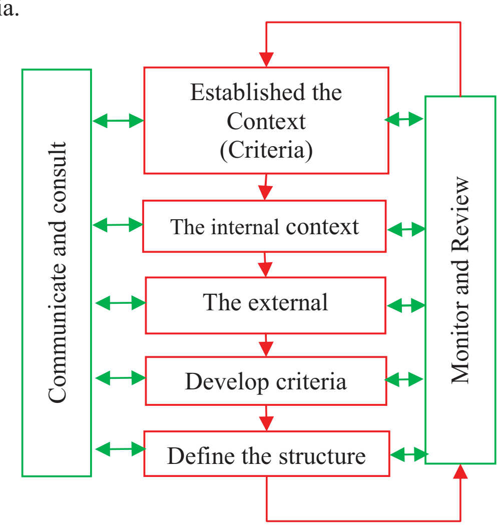

Figure 4: portions of risk management process[68]

VII. SEETT Methodology

SEETT is a simplified sustainability framework in which it combines social, economic, ecological, technological and time; it addresses complex relationships between these dimensions. The SEETT framework is a conceptual model that integrates sustainability boundaries between goals and indicators. The boundaries of sustainability indicators found are illustrated in Fig.6. It can not only help with the selection of indicators, but show what is not being selected and what might be important in the future [57, 69].Without a framework, indicators can easily proliferate and be little more than a conglomeration of disparate data. There are already numerous evaluation frameworks, however, they are industry specific and do not offer versatility for users to utilize a universal sequence. It is crucial in fact to separate indicators of un-sustainability to gain a common understanding, about what is to be measured. because engineering student need to realize that sustainability is related to risk assessment of a project since one of the core concepts of sustainability is good environmental stewardship [70] for the engineer, technologists and designer, creating sustainable systems involves making engineering and design decisions based on multiple dimensions: technology, ecology, economics, and socio-cultural, including ethics [71].

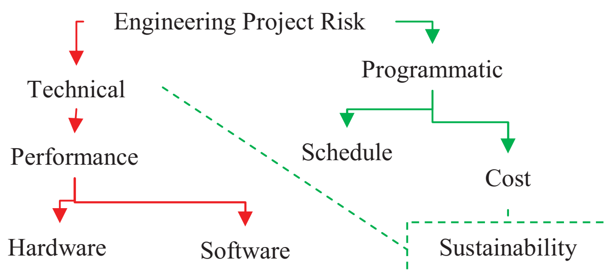

Figure 5: Engineering projects risk identification.

There are already numerous evaluation frameworks in existence, however, they are either industry specific or do not offer versatility for users to utilize a universal sequence. It is crucial in fact to separate indicators of un-sustainability to gain a common understanding, about what is to be measured. because engineering student need to realize that sustainability is related to risk assessment of a project since one of the core concepts of sustainability is good environmental stewardship [70] for the engineer, technologists and designer, creating sustainable systems involves making engineering and design decisions based on multiple dimensions: technology, ecology, economics, and socio-cultural, including ethics [71].

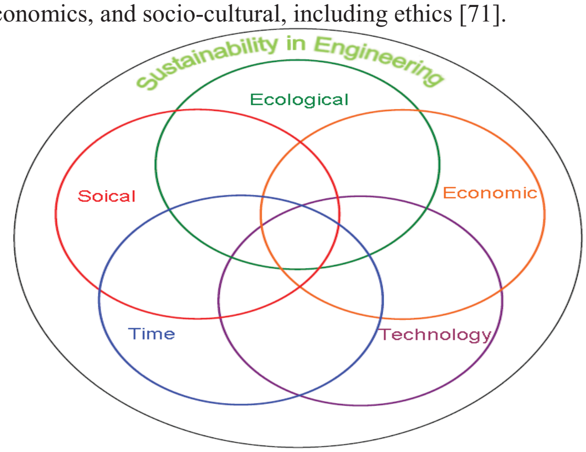

Figure 6: SEETT (social, economic, ecological, technological and time)

The general methodological framework proposed in this paper is an attempt to contribute towards standardization of the indicators of sustainable development for industry. The standardized indicators have many advantages for bench marking. The reviewed indicators suggested a common reoccurring theme, demonstrating a similar array of indicators, with different terminology, goals, scopes and end use, the indicators were streamlined into six distinct categories, social economic, ecological, technology, and time but not implicitly displayed expressed. A summary list of criteria from a large body of literature was selected from the most recurring, is listed in TABLE VI. In addition institutional vastly discussed and recommended as a separate theme, and other times it was integrated within social. Therefore in the assessment we are looking for;

(i) Measures of relative dependence of the economy on non-renewable sources of energy and materials,
(ii) Measures of the productivity of energy and materials consumed by the economic system and
(iii) Measures of dissipative loss, especially of toxic and hazardous substances.

VIII. Discussion

Risky technological projects might affect the well-being of people. Technological risks directly give rise to ethical issues [72]. The criterion provides answer to the students many questions for example when is it justified to impose dangers on others? And how should we judge whether a risk is morally acceptable or not? Engineers define risk as a function of probabilities and unwanted consequences. Examples of unwanted consequences are the number of deaths or injuries, or the degree of pollution. Policy-makers use cost-benefit analysis to weigh the possible advantages of a technology against its possible disadvantages. Many social scientists who work in the field of risk analysis argue that cost-benefit analysis and the definition of risk as a function of probabilities and unwanted consequences are not sufficient to determine whether a risk is acceptable or not. Many social scientists claim that since all risk judgments, also those of experts, include values, all risk judgments are subjective and socially construed. objectivity equates with what is 'out there' and with what is quantitative[73], whereas all of the following notions are grouped under the label 'subjective': 'social construction', 'values', 'assumption-ladenness', 'judgment', 'intuitions', 'subjective assessment', 'qualitative', 'emotional', 'contextual'. Some of these notions are by definition subjective or at least not objective, i.e., subjective assessment and social construction. However, the other notions are not necessarily subjective.

Values, judgments, intuitions, qualitative, emotional and contextual are also not necessarily subjective notions. Judgment, intuition and emotion are 'subjective' in the sense that they are bound to persons who have them, but this holds for all our cognitive abilities. The question is whether these abilities can help us assess what is really there? This is a philosophically controversial issue; it is far from philosophically obvious whether emotions, judgments and values are subjective projections or rather, if they are forms of objective discernment. According to most contemporary moral philosophers, moral values are not arbitrary or subjective. Whilst sustainability indicators act as a critical monitoring tool vital to the sustainable management of societal and natural resource and one of the most used tools for communicating information to decision makers indicates that there has been no agreement or consensus on a common set of scientific and management criteria for evaluating indicators from several points of view i.e. reliability of supporting data, scientific rigor of definitions of indicators, validity of underlying assumptions and concepts, relevance of positive or negative trends for sustainability. If decision makers and engineers are to continue basing their decisions on the information thus provided, we must therefore ensure that such indicators be not only scientifically valid but also policy relevant. In order to obtain a scientific validity of the aggregated indicators a scientifically sound methodology is required on the elaboration of indicators, data gathering, data processing, measurability. Integrating, environmental, social, economic, technological and time Indicators of sustainability must be agreed on, transparent, and sufficiently broad criteria, subject to rigorous scientific assessment to be widely accepted. This "wide-angle" is even more critical as it is necessary to discuss the complex interlinkages between the biophysical, social, economic, technological, institutional aspects are appropriately taken into account. Since existing aggregated indicators are often criticized for their shortcomings in this respect. "…everything is an indicator of something but nothing is an indicator of everything…"[74]. This view suggests that a 'sustainability index' is impossible to design. They also suggest that indicators should be selected 'to maximize unique, relevant information and to minimize redundant information'. This presumes that we understand what is relevant and what is not. One thing that scientists have learned over the years is that our knowledge is very limited, otherwise how could we have had an acid rain issue or an ozone depletion issue? But Cairns et al [74] also refer to the consequences of two forms of uncertainty: (1) false negative (FN) signals and (2) false positive (FP) signals. FN signals provide no warning of potential harm when it is bound to occur and FP signals warn of potential harm when none exists. They conclude that multiple lines of evidence (redundancy) are more likely to protect against unpleasant surprises. So rather than minimizing redundancy, the 'sustainability index' should use many indicators (hoping that some of the information obtained will be redundant). Although it is recognized that no single process can describe a universal engineering approach to (SI) however this is a roadmap reflections on the indicator design process that yielded the following key points: Lyytimaki [75] described building a sustainability indicator collection without a concrete, well planned conceptual framework may provide a cheap and quick solution that is sufficient for some situations. The drawback is that the organizing structure and relations between issues and indicators remain obscure and elusive. This kind of ad hoc framework may also easily neglect important issues and highlight wrong issues.

IX. CONCLUSION

This generation is charged with an unprecedented responsibility underpins all human activity; sustainability in engineering education is often referred to as the new frontier due to the numerous legislative changes which are in the pipeline, overlaid with challenges for engineering educators. Therefore the need to prepare engineers to identify and analyse energy usage, areas where reductions can be made through sustainability assessment is paramount. In addition using sustainability criteria in design curriculums can engage engineers to contribute to sustainable development through designing, developing and implementing solutions that are socially acceptable. Given that there is no universal framework or uniform methodology to apply the vision in capstone engineering design projects. In this paper, we propose SEETT a path for integrating environmental and sustainability concepts within the framework of existing curricula conducive towards sustainability in engineering capstone design projects. The presented list of SEETT criteria is a first attempt, intended for achieving a common-metric to address limitations sustainability assessment in class rooms. From this point of view we argue that it would be uncomfortable for students in engineering classes to assess sustainability or work in cohesion if we do not have a similar contextual engagement.

RECOMMENDATION

The global engineering educator's community recognizes the critical need to develop and practice sustainable techniques in design curriculums; one way of achieving this framework is by developing cases study banks to translate experiences of using indicator. The table below collates sustainability criteria SEETT, (social, economic, ecological, technological and time). One way of increasing criteria confidence and value usefulness to potential users is through case studies validation checks which can also assist improving the indicators to meet a satisfactory degree of 'accuracy', and 'credibility'.

TABLE VI. SEETT CRITERIA

Social Assessment Criterion
Aesthetics appearance and nuisance
Social Cohesion Dislocation and Culture
relocation of people
Knowledge or skill enhancement
Education & Training
Recreational value
Provisions for underprivileged
Shelter Impacts upon indigenous, or minority ethnic groups
Heritage perseveration
Improving of living standards
Employment opportunity
Occupational hazards (e.g. falls, fires, explosions, operation of machinery)
Perceived Risk Loss of livelihoods
Increased risk of natural hazards (e.g. floods, slips)
Exposure to physically hazardous wastes (e.g. 'sharps')
Nutritional value provided
Increases Food supply
Mortality reduction-quality of life
Impact upon cultural, historical or religious sites or values
Accessibility increases competition, Ethnic Diversity
Incorporation of women Impacts upon women
Impacts upon the poor
Economic democracy
Avoids Illnesses
Stress at work
Spirituality , Promotes justice , Security
Transparency Participation
Sanitation, Communal violence
Credit and investment
Democracy Transparency
Quality of Life , Equity, Ethics
Institutional , Illness & Disease
Accident & Injury, Health & Wellness

Ecological Assessment Criterion
Virgin source of materials
Recycled materials
Origin of materials
Greenhouse gas
Manufacturing waste

Packaging Existence of rate/ endangered species Disturbance of existing fauna Noise pollution Water Run off Monitoring environmental impact Smog creation Ozone Depletion Climate regulation Biodiversity reduction Design objective Non recyclable waste Energy efficient Use of fossil fuels for energy needs (i.e. CO 2 emissions) Energy consumption Acid rain precursors Global Warming Carbon monoxide (CO), nitrogen oxides (NO_X), sulphur dioxide (SO_2) Heavy metals (e.g. lead, mercury, chromium, zinc) Water quality Destruction of carbon sinks (e.g. forests) Release of other greenhouse gases Release of CFCs ploychlorinated dibenzo(p)dioxins (PCDD) polychlorinated dibenzofurans (PCDF) polynuclear aromatic hydrocarbons (PAH)polychlorinated bipenyls (PCB) hazardous chemicals dioxins1, furans2, PAH3, PCB4, nitroaromatics, hazardous chemicals pesticides, herbicides, asbestos

Economic Assessment Criterion
costs Operation costs (raw material, labour, upgrades) Closure cost (i.e. site restoration, legal liability costs Construction costs (i.e. land, equipment, infrastructure) Maintenance costs (new parts, down time, labour) Competition effects Stability Resource depletion Ecosystem productivity loss **Employment** GDP Deficit; and capital flow; debt Stability in prices; debt Social factor productivity **Raw material** Waste hazards Solid Wastes or Hazardous Products Liquid Wastes or Hazardous Products Gaseous Wastes or Hazardous Products Capital, Labour, Fixed Viability CBA ,LCA , NPV Energy resources , Fossil fuels Useful product lifetime Product disposition cost Clean technologies; adequate waste management reduction of all forms of pollution Resource depletion, Recycling revenue Consumption of goods and services Institutional Ethics

Technology Assessment Criterion
Source of the technology Indigenous to the area or Imported Relatively new/unproven System performance Decommissioning of technology Type of technology Existing Processing/manufacturing Based on the use of natural resources Flexibility and adaptability Business interruption Customer warranty cost Ecosystem productivity loss Loss of goodwill due to customer concerns Residual consequences Disruptive to the environment Resource depletion Ecosystem productivity loss

Design iterations Resource Scarce Renewable /non Hazardous materials used Product & packaging mass Power use during operation Biodiversity reduction Needs and basic rights Leisure time and enjoyment of family life Social assistance and culture Sate of right and public safety Identity and self-esteem Health and social security Corruption, participation of civil society cooperation , and agreement; solidarity and altruism Creativity governance expansion of civil liberties

Time Assessment Criterion
Does the project, product or process have a lifecycle? What is the deign life of the project, product or process. Does the proposed project, product or process contribute towards reducing non-sustainable practices to zero over the project time frame? What is the expected usability for the project, product or process? If outcomes cannot be accurately foreseen, is your planning based on risk reduction and the precautionary principle?

Project-Based Collaborative Learning of Electrical Engineering Master Students

Zoja Raud and Valery Vodovozov
Department of Electrical Drives and Power Electronics
Tallinn University of Technology
Tallinn, Estonia
zoja@cc.ttu.ee

Abstract—**The paper outlines a project-based collaborative learning methodology developed for graduate courses on Electrical Drives and Power Electronics in Tallinn University of Technology. An underlying principle of the described environment is the coursework arrangement directed to designing optimal application-specific drives with power electronic converters based on the active learning approach. The role of advanced computer-aided design tools is also identified and shown. To illustrate the effectiveness of this method, the industry-relevant course projects performed in the curriculum are presented in detail. An important result found is that all students acquired knowledge and skills to design more complex and sophisticated electromechanical systems.**

Keywords-active learning; collaborative learning; project-based learning; electrical drive; power electronics

I. INTRODUCTION

As shown in [1], [2], [3], the traditional methods of teaching encourage a *surface approach* to learning, where students try to follow the routine solution procedures and match patterns rather than follow a *deep approach* where students develop a conceptual understanding of how the study system operates. Focus in the surface approach is on the ability to repeat what has been read without necessarily understanding it. Students' learning habits concentrating almost exclusively on exams, lead eventually to an overload, which in turn tends to result in a low level of knowledge. This effect is certainly causing students' stress and missing motivation. Therefore, traditional teaching appears to be ineffective in generating student enthusiasm and passion for learning. In this case, students may not be able to achieve the required goals to the full, or may be slow to reach their full creative talent and engineering potential.

Meanwhile, engineering companies require an aptitude for collaborative work, team and task management, concept synthesis, and decision-making from the graduates, thus promoting creation of a new environment for learning, which would provide all of these job-related skills. The main objectives are to provide high-quality teaching in terms of content in order to motivate students to learn additional skills not directly related to a speciality, however, considered very valuable in the professional working environment.

Contemporary changes in the business area, responses of companies to these changes and the available technologies pose a number of challenges to the present and future engineers, as well as to the educational institutions, including

- collaborative work in the cross-functional, multidisciplinary, multinational, geographically dispersed teams
- creative work with a global customer base through developing communication skills with regular application, transfer and improvement of engineering knowledge

The Bologna meeting of 1999 set the convergence of all the national university programs of the European partners on a path towards a common frame. The main recommendations of that meeting concern the equivalent degrees implementable in more specific subjects and areas of shorter duration. A practical approach to teaching becomes more important in technological degrees, where students graduate and search for jobs in fast evolving companies.

As learning is a cognitive process, knowledge has to be constructed in the mind of the learner, in his/her efforts and activities. Learners can develop complex reasoning skills effectively when actively engaged in the material they are studying. They build meaning when reading, writing and discussing. Learning is aided by conversation that seeks to describe and clarify the ideas of the learners. Clarifying of understanding requires that students be provided opportunities to articulate their ideas, to test those ideas through experimentation and discussion, and to consider the connections between them.

From this viewpoint, an *active learning* strategy involving project-based learning and collaborative learning seems prospective [4], [5], [6].

Project-based learning, called also *learning by doing*, is a student-centered strategy that fosters initiative and focuses a student on authentic real-world open projects that can increase motivation for the majority of students and enhance their education [7], [8], [9], [10], [11], [12]. One aim of this approach is to organize the courses so that the students would be motivated to study.

Collaborative learning, called also *team-based learning*, is an educational method where students work in small self-directed teams to define, carry out and reflect upon a research task, which can often be a real-life problem [13], [14], [15],

[16], [17], [18]. The tutor acts here as a facilitator and resource person who they can meet for advice or guidance. This approach emphasizes cooperation and creating team learning and developing culture and makes it possible to include and use various scientific perspectives and methods of learning, research and development in operation and action.

To develop a new curriculum in Tallinn University of Technology, an experience of the partner institutions was used. Particular attention was paid to the 25-year experience of project-organized undergraduate education based on a unique pedagogic model of teaching gained at Aalborg University. In this method, a large part of semester teaching and student work revolves around the complex real-life problems or issues that the students consider and try to resolve while working together in groups [3]. Similarly, the curriculum structure proposed in [7] consists of eight courses: four theoretical courses and four project-based courses (including a compulsory master's thesis). In the project-based courses, the students working together in groups develop multidisciplinary systems, which become progressively more complex. An important result is that all students have developed effective systems, while considering that the results are worth the effort invested.

The following sections of the paper analyze the benefits and restrictions of the active project-based collaborative learning techniques based on their implementation experience in the master study program of Tallinn University of Technology. The description of each method is followed by the recommendations concerning possible ways of their use in electrical engineering education.

II. Design Objectives

One example of active learning is the system built by the authors to study the disciplines included in the electrical engineering curriculum. The Advanced Course of Electrical Drives (AAV0040) and the Advanced Course of Power Electronics (AAV0050) are the master study optional courses provided in the Faculty Handbook. Course duration is 16 weeks, consisting of 3 contact hours per week and at least three hours of weekly independent work.

An electric drive is an electromechanical system that provides controlled inductive conversion of electrical energy into mechanical motion. It consists of mechanical transmission, an electric motor, an electronic power converter, and an informational controller. The power of supply lines is transformed into motor supply energy by the power electronic converter. Then, the motor converts it into electromagnetic energy, which in turn is transmuted into a shaft's mechanical energy. The controller forms the input references using information of the set-points, outputs, and disturbances. The engineering goal is to build an effective system using the components proposed by many world companies. Effective assembling of electric drives can solve the problems owing to rather complicated algorithms. Here, the mechanical, electrical, electronic, and power engineering problems are encountered in close integration.

The procedures of a motor drive and power electronic converter design involve a number of complex problems. Some of them are

- timing calculation and the mechanism travel diagram construction
- computation of mechanical forces and the torque/power patterns synthesis
- gear and motor dimensioning and selection
- the optimum motor-gear set choice and checking
- power electronic converter dimensioning and selection or design of the new one
- building the motor drive and power converter wiring diagrams
- development of controllers for the multi-loop control and adjustment
- the process simulation along with the analysis of the steady-state diagrams and transients
- economic considerations and efficiency evaluation of the project
- report generation, presentation and defense of the obtained results

Today, two ways of the drive development are used in the designers' community [19].

The first of them starts from the selection of a manufacturer; further, the manufacturer design technology and recommendations are used. For computation and equipment selection, the leading world companies have developed their specific technologies. Examples are the guidelines and software of Siemens, Omron, Sew Eurodrive, Maxon Motors, Mitsubishi Electric, etc. Such an approach is common for the majority of firms that carry out project design and have rich experience in acceptance of the decisions based on extensive computer data sources, making up numerous catalogue archives and "absorbing" their contents and structures.

The main drawback of the approach is the restriction of the design technology by the vendor company selected as a preferable manufacturer. Data limitations deprive a designer of an optimum way in the project. It is especially sensitive in the first project stage when the most responsible decisions are taken. Different manufacturers have worked out hundreds of databases and soft tools that provide most of the stages described above. All of these data sheets use different languages and operation systems. They have multiple structures, data types, data fields, keys, names, and inter-sheet connections. Not all required data are published; occasionally the knowhow of manufacturers may be concealed from the user. It is frequent practice that the provided information carries an advertising style, unnecessary for design purposes. Some data are published in the Internet; other information is accessible through printed materials and journals.

The second approach was proposed first in [20], [21] and then developed by further research into a computer-aided design system. As different from the companies, which manufacture and propagate their production, the proposed approach is addressed to the overall equipment selection, tuning, and optimization process independent of company

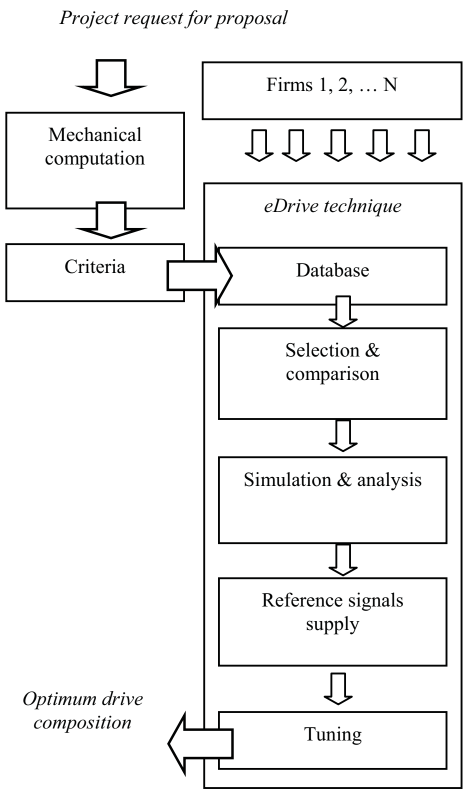

Figure 1. Project mastering structure

interests (Fig. 1). Using a search technique, the system transfers multiple data from a variety of databases into the uniform *eDrive* database (Fig. 2) with the specific data management system, which provides the search and updating of the data using the open-access corporative databases. The design process starts from the load computation using the project developers' own experience and methods. Further, a designer selects a group of gear types from different companies using the results of the load calculation. Through these gears, the forces and mechanism speed found before are converted to the equivalent values on the motor shaft. Then, the particular motor type that matches each gear type is to be selected based

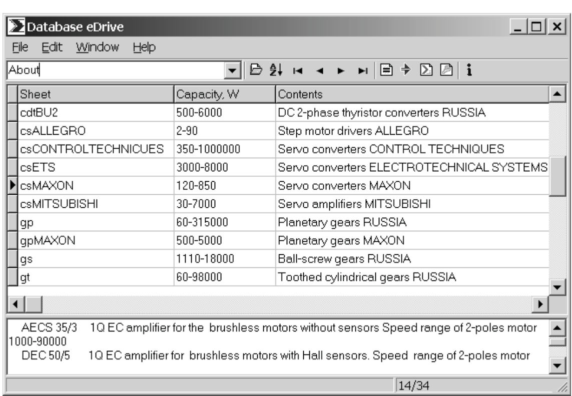

Figure 2. Database window

on the converted forces and speed. Thus, a set of possible drive variants is generated. Once the equipment framework is found, the new problem appears – which of the suitable motor-gear combinations is optimum? To find a solution, a designer can form appropriate criteria and sort them. It may be a criterion of maximum accuracy or speed, minimum weight, power, or inertia, highest rigidity, etc. Thus, the whole scale of the electromechanical and electronic properties is collected, from which the choice is done based on judgments about preferences of that or another criterion. Then, simulation of the open-loop system is done using the standard or the original simulation software. On the next stage, the power electronic converter equipped with a control system, which includes some regulators and sensors is designed or selected. Their transfer functions, gains, factors, and time constants are calculated to meet the standard settings. Then, the closed-loop system testing is carried out on the model and its optimization is executed, if necessary. This approach is more suitable for the educational targets thanks to its universality.

The learning outcomes for the multiple subjects in the master training program were listed by the researchers and industry agents. Senior engineers from various industries were contacted for their ideas regarding suitable industry relevant projects for the master students. Following a series of industry meetings and feedbacks, suitable topics were specified. The modules were designed, built and tested by the researchers. Then the specification sheets were handed to the students at course start. The projects are designed in a modular fashion, so that any independent module can be completed during the course that the student has enrolled in. The independent modules are assessed by the instructors teaching the course.

The master students are expected to design, build and test various modules as specified in the projects within a period of some months. In some projects, the students work individually, in other they are joined in groups of four while working on the project. They have to use the theoretical knowledge of Electrical Drives and Power Electronics as well and Computing Engineering, Mechanics, Automatics, etc. gained during their bachelor and master study. On completion of the project, students' learning experience and learning outcomes will be used to prepare their master's theses. The students' practical skills are assessed while working on the project, and their theoretical knowledge is graded on a written exam after the project completion.

III. PROJECT-BASED LEARNING

The main aims of an educational project are

- to set interactions and collaborations between teachers, students and industry partners
- to develop and sustain students' interest in engineering courses
- to satisfy industry demands, strengthen industry links and improve employability rate in industry
- to utilize effectively the teaching time for various courses in the curriculum

In accordance with the active learning principles stated above, it is not sufficient just to learn about professional and other issues and pass exams. The techniques need to be used in real situations by the master students and graduates. For the project-based approach, it is extremely important to emphasize the connections between different aspects, to encourage a broad-based system view and to illustrate the practical, technological and human constraints of solving the real-world problems.

The theoretical component deals with the formal theory of electric drives and power electronics. Today these theories have reached a degree of complexity that can only be managed by a lecturer. Moreover, a theoretical study does not always have to be passed before taking the practical assignments. To one part of students, it is more beneficial to acquire theoretical knowledge first, but to the other it is more reasonable to pass practice beforehand because this can provide a good basis for building the theory, thus helping students to understand some of the theoretical concepts. Consequently, multiple educational trajectories may be built that depend on student abilities and course contents and differences in the ratio of lecturing, practical and assessment classes are possible.

In our study, within the framework of the course, each student was required to design and develop, build, and test separately the personal drive unit equipped with a power electronic converter. The types of gears, motors, and power converters for the particular design problems had to meet the demands set by an instructor. To support learning, a series of problem exploration were proposed. One set of design problem examples is given in Table 1.

TABLE 1. PARAMETERS OF THE DRIVES DESIGNED

Loading mechanism	Drive composition*	Mass m, kg	Speed v, m/s	Acceleration a, m/s²	Path Δl, m	Cycle T, s
Support	gs-ms-c-φ	1500	0.1	0.2	3	35
	gs-ma-c-ω	1250	0.15	0.3	2	15
	gs-md-ct-φ	1000	0.2	0.4	1	7
Hoist	gp-ms-c-ω	300	–	–	1	6
	gw-ma-c-ω	400	–	2.0	2	8
	gt-md-ct-φ	500	–	–	3	9
Truck	gw-ms-c-ω	3000	0.6	–	–	–
	gt-ma-c-ω	2500	0.5	1.0	–	–
	gp-md-c-φ	2000	0.4	–	–	–
Conveyor	gp-md-ct-ω	250	0.7	–	–	–
	gt-ma-c-ω	230	0.5	0.3	–	–
	gw-ms-c-φ	210	0.3	–	–	–
Roll-table	gp-ms-c-ω	500	0.9	–	–	–
	gp-ma-c-ω	1100	0.5	0.3	–	–
	gw-md-c-φ	5000	0.4	–	–	–
Rotary table	gw-ms-c-φ	300	–	–	–	10
	gp-ma-c-ω	250	–	–	–	8
	gp-md-c2-φ	200	–	–	–	9
Crane	gp-ms-c-ω	100	0.2	–	0.5	10
	gw-ma-c-ω	150	0.3	1.0	0.8	8
	gt-md-ct-φ	200	0.4	–	1.0	6

Here, the required drive compositions include multiple variants of gears: gt – spur, gp – planetary, gs – ball screw, gw – worm; motor drive types: ma – asynchronous, ms – synchronous servo drive, md – direct current; converters: c – transistor, ct – thyristor; control systems: φ – with speed and path feedbacks, ω – with current and speed feedbacks.

The final design report usually includes the following results:

- request for proposal with the individual input data
- timing calculation and the mechanism travel diagram
- mechanism's forces calculation and torque/power patterns
- optimum motor-gear set selection and checking
- power electronic converter dimensioning and selection or design
- data and simulation results with transients of an open-ended system
- block diagram of the control system
- controller development and tuning
- data and simulation results with transients of a close-loop system;
- conclusion of the project summary
- appendix 1 with an operation diagram of the thyristor phase modulation or the transistor 2-phase block or 3-phase pulse-width modulation
- appendix 2 with a wiring diagram with power circuit and drive specification

To implement project-based learning, the traditional style of lectures was changed so that the behavior analysis would replace partially the formal explanation of the theory within limits. Accordingly, if necessary, practice and lab work may precede lectures; moreover, new kinds of study may appear. In the lectures, problem scenarios are presented to the students before any relevant theory or practice is given. The open problems are framed by the teacher in accordance with the topics in the syllabus and a lecturer acts as a contractor. He/She asks the students (acting as subcontractors) to design and implement a fully functional motor drive or electronic converter that covers most of the topics reviewed in the theory lessons. The first classes are spent creating a systematic design of the final product − the specifications and main functions are described, and a functional block diagram is conceived. This policy means that students find the explanation of systems and ideas to be useful because they can see the target application. In addition, the start-to-finish design, from the block diagram until the final implemented system, helps the students in the task of determining, solving and grasping the problems. Another benefit is that the students must pay particular attention in the classes in order to complete the proposed prototype. During the next lessons, the lecturer reviews the designs and products and advises the students about the possible errors or mistakes. Therefore, the teacher is responsible for ensuring that each student's design is correct and that the final prototype is a working unit. Finally, he/she also acts as a vendor as the final prototype is usually implemented on the prototype boards.

The specially prepared textbook [22] and its web release contain sections supported project-based learning. Some of the sections are intended to complement the lectures for beginners and for advanced learners, summarizing basic terms and conditions as well as the topical mathematical bases of the course. Other sections explain the broad self-learning part of the course. Calculation examples, experimental and assessment problems of the course are also provided. The multiple links connect the textbook with analogous and supplemental assignments in the field. The properly structured index and the reference list serve as the powerful navigation tool.

In addition, the assessment strategy was redefined and reformulated for project-based learning and additional evaluation methods were proposed to stimulate the learner. Particularly, the new assessment procedure invokes to evaluate

- problem statement and understanding
- learning objectives
- methodology used
- problem solution under the theoretical and practical headings
- calculations, simulation execution, and software selected
- practical results, presentations, and the printouts

An original toolbox *eDrive* opens multiple possibilities for learners and instructors [20]. It was developed to support the course in accordance with the project-based requirements as well as to assess the goals. The main features of an educational soft tool that discern it from the models meant for the professional designers are as follows:

- descriptiveness and compatibility of results
- clearness of physical essence
- suitability of report generation and format conversion
- independence of particular company interests
- matching the standards and design rules
- availability of learning-oriented manuals, textbooks, and guides

The described software offers solutions to the next typical educational and project management problems:

- informational support in electrical, mechanical, and electronic equipment selection
- mathematical and computer simulation and full computation with the use of databases
- testing and result verifying in accordance with different criteria
- drive tuning and load optimization

The toolbox includes the next components:

- powerful database
- set of adjustable controller schemes
- models of motors, converters, and gears
- graphic package for representation of the steady-state and dynamic simulated processes with an automatic and manual scaling, report generator, system analyzer, and preview facilities
- signal generator to produce the test reference and load signals as well as the nonlinear curves, noses, and filters

Thanks to the strong mathematical core, it supports all the laboratory works of the departmental curriculum. Moreover, the environment provides a possibility to simulate the same assignments using equipment of a number of companies that cannot be acquired in the institution. Comparison and discussion of the results obtained serve as a very beneficial instrument in the development of student skills and experience by using both simulations and the real equipment.

The following principles underlie project-based learning:

- students are encouraged to work regularly throughout the course and to take an active role in their learning process
- active and reciprocal interaction appears between students and lecturers as well as among the students themselves
- the course content focuses on essentials and emphasizes comprehension of overarching principles
- students are stimulated to obtain relevant concepts and knowledge from preceding courses
- students have to use the new concepts, and conceptual understanding is valued
- teaching of the new content is connected to the students' prior knowledge

Thanks to project-based learning, the staff, students as well as the community have benefited. Industry relevant projects provide students with knowledge of how theory can be related to current industrial practice. Students show a lot of interest and enthusiasm while working on projects. The work gives a holistic approach to student learning as it integrates the commercial projects with the core courses and learning objectives. Students' technical skills are tested when working on designing, building and testing the project. While designing the project, the students integrate and connect knowledge from various courses to work on an optimized solution for the mentioned problems in the project. They have to know the background theory and consider all practical issues while designing. Project design also tests the mathematical skills of the students. After designing a module, the students use software simulations to test the design before they actually build it, thus checking the ability to use computer software appropriately.

Once the module is simulated, the students build some of its components using a laboratory platform, thus obtaining their manual skills. The laboratory equipped by the leading companies in the field accompanies the study. It includes a number of test benches the most part of those supports the e-learning on-site and off-site activities [23], [24], [25].

IV. Collaborative Learning

As with any engineering discipline, Electrical Drives and Power Electronics are based on the integration of multiple fields of knowledge. Insofar as a certain number of systems with the components of different nature are merged, a conflict between technological complexity, cost, and simplicity of maintenance naturally occurs. The corresponding educational aim is to teach specialists working at the intersection of electronics, mechanics, and control. Course assignments and master's thesis are suitable tools for this kind of training.

Collaborative learning has become a necessary part of the project-based approach. To stimulate teamwork, a specific team-based methodology has been developed [15]. The goal of the collaborative design is to build effective real-world electromechanical equipment.

One of the typical course projects is devoted to the design of the robot drive system. Schematic plan of the transportation robot is given in Fig. 3. The work includes two stages: the stage of individual creativity and that of collective work, particularly via the Internet. These phases are detailed in Table 2.

TABLE 2. Stages and Disciplinary Bases of Design

Stages and items	Disciplinary base
Individual design stage	
1. Force, torque, and power computation	Mathematics, physics and computer science
2. Equipment selection	Database theory
3. Optimization of the electrical drive content	Function analysis and optimal control theory
4. Synthesis of regulators	Discrete mathematics and control theory
Collaborative design stage	
1. Composition and interrelation of axes	Linear algebra and programming
2. Trajectory description	Mathematics and numerical control
3. Motion programming	Programming, CAD
4. Estimation of the project	Function analysis, reliability, and economics

In the first part, each student designs a drive of one of the mechanisms: the carriage, the arm, the lever, or the capture. For the forces, torques and power calculations, the data of the inner mechanisms are required, thus co-operation is needed to obtain a successful result. In the second part, the intercommunications of the robot sub-systems are organized.

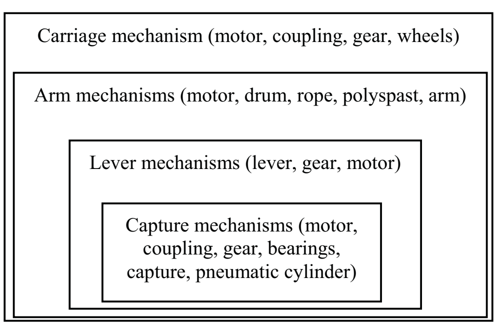

Figure 3. Schematic plan of the transportation robot

Programming of motion, efficiency, and economic evaluation depend on the joint efforts and personal solutions. The same concerns the overall estimation and project assessment.

The final and the most important part of the project is integrating the various modules and testing the overall functioning of the project. This part needs programming and debugging skills. Students learn about project management when they work on resources, timelines and procurement of components. The generic skills are tested based on students' attitude when working in teams and submitting the technical report on the project. Hence, working on a project covers all the aspects of learning.

A student group comprises usually 15 to 20 participants, randomly shared into 4-5 interaction-oriented teams with a proper mix of both academically weaker as well as stronger students. This grouping is done at the beginning of the course when the learners are informed about the practical set of the discipline that would require the study of real world systems and that the teams are a key component of the project. For each problem, the team is encouraged to elect a leader who would organize work distribution. Team leaders are appointed by the course lecturers to coordinate group activities and ensure close interaction among all team members. All teams are charged to meet regularly and to achieve the set objectives on the event driven basis. The students are assigned 12 weeks to work on the research problem. They distribute the work amongst themselves, with team members performing tasks such as searching for information from various resources, compiling the data, doing calculations, performing experiments and finally recording the work done and preparing a presentation. Ideally, these various tasks are rotated among the team members. The teams discuss issues, decide their own theoretical, practical and software goals and explore these learning and mistakes. This encouragement is given by continuous monitoring and by instructing them to record each relevant finding, any mistakes committed and the corrective action taken. Once the team members reach the solution, they are also asked to frame similar kinds of problems and identify application areas. Throughout, they are guided by an instructor who would correct students as they encounter difficulties and help them to draw conclusions to reach the desired goal.

The project is worth 30 to 50% of the final grade and the remaining 50-70% is covered in the course examination. The criteria used to score the students are listed in Table 3.

TABLE 3. Scoring Criteria

Item	Score
Problem formulation	3 – 6
Team participation	5 – 10
Minutes of meetings	5 – 6
Report	5 – 10
Proposed system design	5 – 10
Presentation	7 – 8
Total	30 – 50

As a result of the project-based collaborative learning, the average student final grade increased 1,4 times as compared to the traditional approach and reached 4,3 on the 5-based assessment scale. The students interested in active approach obtained the highest scores whereas the weak students also improved their results to some extend.

Thanks to the team-based approach, the students not only maximize their practical learning experience to achieve the project goals, but also develop other important abilities in the following:

- *self-directed learning* − as a project may involve multidisciplinary knowledge which is not covered by the standard lecture material, students are driven to study and seek solutions which serve to enhance their understanding of the theoretical material
- *project management* − students organize a task based on the talents of each group member, and each defines their own task and manages their progress against a specified timeline
- *product design* − students have more scope to develop the project so as to display their inventiveness

V. CONCLUSION

The proposed project-based collaborative learning approach encourages the reinforcement techniques that focus on a conceptual understanding and new opportunities for students to choose the content and study methods. It shows students that teaching is stimulating and caring and gives them time to process the concepts in contrast to overworking within the course or curriculum. Students who take an active approach to learning reach a higher, more integrative level of understanding and demonstrate longer retention of the material. Engineering graduates of this type have a strong inclination to apply the type of learning that forces passing the courses. Since a student's orientation to learning can be modified by the course environment, instructors have the possibility to influence which approach a learner will adopt.

Ensure Program Quality: Assessment A Necessity

Mudasser F. Wyne
School of Engineering and Technology
National University
San Diego, USA

***Abstract*— In an effort to achieve high quality programs and courses both formal and informal measures are used the teaching and learning process through direct and indirect methods. Assessment has become even more important since education institutes show great interest in the educational experience outcomes and how they map to institutional goals as well as to the needs of the society. Institutes either develop a formal internal assessment process or through external accreditation try to continuously improve and revamp their programs. It is now perceived that students are more active in building their knowledge rather than simply listening to the lectures. Assessment of student work therefore helps us to determine the effectiveness of programs from student's point of view. This also gives an opportunity to the students to show us what they have learned and how they can contribute when they graduate. It is therefore all that important, for institutes interested in accreditation, to assess learning outcomes as a component of program review process. The accreditation guidelines in general seek to encourage institutes to think about accreditation as a continuous process and go one step further to data collection, analysis and change in order to ensure good quality program. This paper addresses the necessity of assessment through seeking accreditation and also provides a more structured mechanism for accessing, evaluating and improving the quality of the program. This paper details various assessment tools (AMS, Web-Based, Directory Structure, etc.) used by different institutes, to help in organization and gathering of the related material. The paper also presents a model for sharing responsibilities to monitor and evaluate gathered material and assessment data.**

Keywords-component; Accredidation, Assessment, Course Learning Outcome, Program Learning Outcome, Rubrics.

INTRODUCTION

Aiming for good quality programs is on the wish list for almost all the institutes. A collection of good quality courses is thus essential to ensure high quality program. In an effort to achieve quality among the courses both teaching and learning process should include assessment using direct and indirect measures. We see a widespread interest in the educational experience outcomes and their link to the goals for students, institutions and society, making assessment even more important instrument. Students at this time and age participate actively in the building of their knowledge rather than passively receive what we lecture; this gives us a better understanding of the student learning process. In that respect, assessment gives us an opportunity to evaluate effectiveness of our programs from the learner's perspective. In addition it gives an opportunity to students so they can show what they know by the time they graduate. One of the ways to ensure this is by assessing learning outcomes of the program.

In general, universities support the assessment of student learning as an integral part of their core commitment to graduate students with high value degrees. Institutes in general review their academic programs, to ensure continuous improvement, through a formal automated or manual internal assessment process. As per definition by the U.S. Department of Education, accreditation can be considered as a process by which a third party accrediting agency assures that a program meets quality standards that are established by the respective profession [4]. Generally, preparing for an accreditation visit, at regional or national level, is a huge task for everyone involved. The accreditation guidelines in general recommend not viewing accreditation as a onetime event rather it is a continuous and progressive process especially when accreditation agencies place lot of emphasis on not only outcomes and assessment, but also on continuous improvement, in order to endure good quality program.

The Accreditation Board for Engineering and Technology (ABET) USA criteria for program accreditation require that programs make decisions using assessment data collected from students and other program constituencies thus ensuring a quality program improvement process. This requires development of quantitative measure to make sure that students have satisfied course learning outcomes and consequently the program learning outcomes. Figure #1 show this cycle of continues growth and improvement involving activities like revising program learning outcomes (PLOs), course learning outcomes (CLOs), and assessment leading to yet further improvement in program.

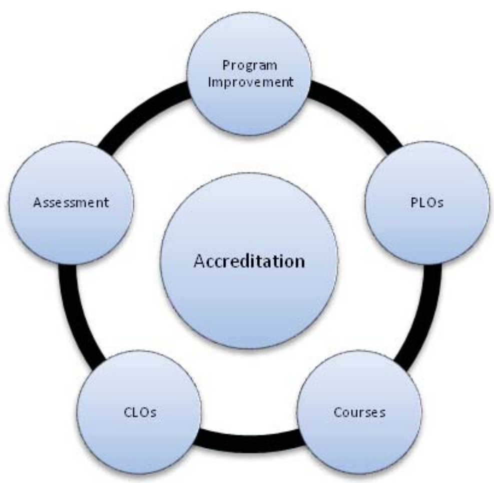

Figure #1 Accreditation and associated activities

We argue that seeking accreditation is a desire that leads to providing a very structured mechanism that helps to assess, evaluate and eventually improve the quality of the program. Following sections detail various assessment approaches used by various institutes seeking accreditation, emphasizing that computer assisted assessment would help in organization and gathering of the related material. A brief review is provided of different tools (AMS, Web-Based, Directory Structure, etc.) that can be used for assistance in collecting data for program assessment. The paper also presents a model for sharing responsibilities to monitor and evaluate gathered material and other assessment data.

PROGRAM LEAD

The latest trend of getting institutional accreditation, for all the academic programs has sparked a greater interest in assessment. However, since majority of the faculty members are not too keen to get involved in the assessment process, mostly because they are not familiar with the assessment process and/or the methods used, so we need to explore avenues by which faculty can be engaged actively in the assessment of a program, at college or university level. The new accreditation standards for computing, technology and engineering disciplines put a lot more emphasis on course and program outcomes, assessment activities and continuous improvement in their statements of intent [10, 13]. This provides justification for an approach to get the entire faculty involved in the assessment process, while mapping outcomes and other collected data against expectations. Later each faculty member can plan curriculum revisions based on the analysis of this data. These curriculum revisions and developments, from accreditation perspective, can be seen as a part of continuous assessment process [12].

In order to establish clear criteria against which a program needs to be evaluated, one needs program learning outcomes (PLO) that are clearly stated. In addition course learning outcomes (CLOs), statements of student learning as well as development expectations are also required. All these will help to determine the basis for future program planning [7]. Clearly stated PLOs also serve as a guideline for the faculty teaching the course to be aware of the knowledge and skill set needs to be developed by the students. In a broader sense these objectives not only provide basis for curriculum development and revisions but also for selecting the faculty to teach the course. The PLOs therefore should be relatively stable over time however, at the same time be expected to change because of the results from assessment activities. In general, the stated assessment objectives are quite similar to these PLOs. For the sake of not overburdening the faculty with extra task it is recommended to not assess all of the program learning outcomes in one given year. It therefore leads to establish a set assessment schedule to make sure that all of the given program learning outcomes are assessed by the end of 4-5 year cycle and before the institute decides to seek accreditation.

In an effort to have faculty involvement and understanding of accreditation and assessment we propose the concept of assigning a faculty to be the program lead with the understanding that this person will be responsible for not only staffing the courses in the program but also for leading and organizing annual assessment of the program. A single person responsible for such an activity would lead to a more focused approach to assessment and more involvement of the faculty in the process of assessment itself. The lead faculty will also ensure PLO and CLO mapping and thus further revisions of CLOs and courses as well as, other assessment related activities. Departments establish their mission statement and the program leads will define their own program goals and determine how they are to be addressed, form an Academic Program Assessment Advisory Board or committee that provides timely feedback to facilitate the assessment process and help revise and improve program. The emphasis of assessment is on program evaluation to improve student learning, and to further a culture of student learning; assessment measures are employed to help achieve that goal. Therefore, for assessment to be effective and helpful, results obtained from various assessment activities need to be utilized to further develop new programs and improve existing programs. Finally, assessment results can also be helpful in decisions regarding resource allocations and reallocation for the program.

III. ASSESSMENT

The assessment's role is to determine what a student can gain at various levels of a learning experience in typical educational setting or environment. There are two types of assessments, formative and summative assessment [3]. Formative assessment, determines the incremental out comes and occurs during the entire learning process. Summative assessment on the other hand determines more holistic and integrative outcomes at the end of the learning process. Assessment data collected during various stages are subsequently used for multiple purposes, as stated in [3]: (a) Management and monitoring of instructional part (b) Evaluation and accountability of the program (c) Placement and selection of students in the program. The information gathered from assessment activities is then utilized to develop a model of the student's ability to evolve a conceptual knowledge structure keeping in mind the target structure. Assessment provides means to focus our collective attention for examining assumptions that we have made and our efforts in creating a kind of a culture that is dedicated to improve the quality of higher education and associated learning. The assessment exercise requires that all of the expectations and standards, established for the program, be announced and available to public. It also needs that evidence be gathered systematically from time to time to determine how well these standards and expectations are being met. At the same time the analysis and interpretation of the gathered evidence data can be used to document the achieved performance, explain any shortcomings and to further improve the performance [14].

IV. ASSMENT: THE PROCESS

As Gloria in [2] states that, it is important that one understand the question before being able to come up with the correct answer. Similarly we should try to think about the questions related to assessment process in connection with accreditation and program effectiveness. This exercise is very important since we may generate lot of random activities for collecting material that we do not need after all. So it is important to understand the question being answered and its implications on the assessment process design. A program or a department should first try to create mission statement to describe the programs in the whole department. A program can then establish its goal and learning outcomes. These outcomes basically describe what students should be able to do by the time they graduate from this program. In order to verify that the graduate do actually have these attributes a thorough analysis of the student work (Written assignment or class project or capstone project) can be used as a direct assessment method to access program learning outcomes and goals. In order to quantify program indicators it is always beneficial to develop and use rubrics to measure student performance which ultimately leads to the measure of the program effectiveness. For example, a program outcome can be divided into various components. Later, each of these components can be evaluated using one of the developed rubrics. Finally merger of all of these individual components will lead to assess a range of program learning outcomes [4].

The assessment process begins when programs identify Program and Course learning goals and outcomes. In most cases goals are finalized based on both faculty expertise and requirement of the professional or accrediting agencies. Once learning goals are established, the departments and programs devise ways of measuring or assessing how well students are meeting those learning goals. These assessment methods most often directly measure student learning and are frequently embedded in courses offered in the program, including capstone courses. Appropriate assessments may also include indirect measures like employer surveys, alumni surveys, exit surveys or interviews and rates of enrollment to advanced degree programs. Departments analyze these data, identify strengths and challenges of the programs, and make appropriate changes to improve their success at achieving program learning goals. Program also need to evaluate their success in other critical areas, such as, meeting the needs of the general education program, offering service courses, and other functions that serve the university's broader mission [9].

Figure #2 shows the activities required to ensure a high quality assessment process that requires direct and indirect measures of the course and program learning outcomes as well as input from the advisory board. All these measures are vital both for credible assessment process and program quality.

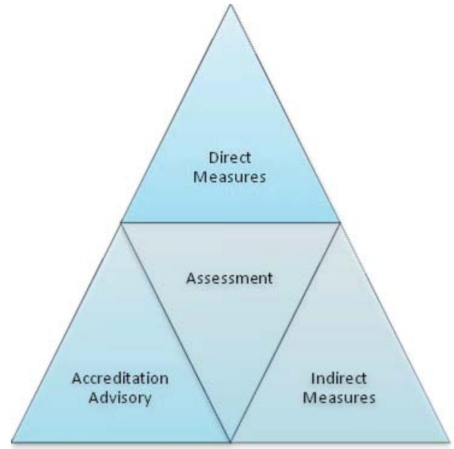

Figure #2: Quality Assessment

University graduate or undergraduate council, at most of the universities, is responsible to oversee assessment of each individual program. This council is also responsible for conducting the Annual and Five-Year Program Reviews to ensure quality and consistency among various programs offered by the university. Among its other assignments the Graduate or Undergraduate Council also examines the main components of assessment plan for each program, particularly student learning and program outcomes. For the purpose of review and assistance in the assessment process of the annual and five year assessment, each graduate or undergraduate degree program is required to provide information on [5]: (a) educational objectives of the program; (b) measures to evaluate success in achieving these objectives; (c) the goals that are being successfully met in addition to those that need attention as determined by the analysis of the gathered data; and (d) how assessment data is used to improve quality of the program.

V. Direct and Indirect Measures

These measures are considered as the primary source of data in assessment of a program. To ensure consistency as well as equal quality and rigor in all of the courses in the program [7] suggests writing a Program Quality Improvement Report (PQIR) by each faculty member teaching in the program. The report contains (1) Assessment data displayed, (2) a complete analysis of the assessment data, (3) evaluation of the conclusions regarding course strengths and weaknesses, (4) course modifications as a result of analysis of the assessment data. These modifications may be in goals, objectives, or strategies (5) modifications proposed for course improvement, (6) projected time lines for implementation of all the suggested modifications, (7) any additional resources requirement estimation for implementing recommended changes, (8) assessment methods evaluations, and (9) the annual assessment plan update. In our proposed setup, all of the PQIRs are then analyzed by the program lead for an academic program and approved not only by the program lead but also by the Chair of the department, the Dean of the Academic School or college, and the provost. Collective PQIRs can be used as the basis for initiating any actions aimed at improving the corresponding individual academic program.

The capstone experience becomes a very effective direct measure if it is clearly linked with the identified learning outcomes. This can be achieved when standards are carefully structured and documented, with well defined rubric for written and oral communication. A very qualitative internal and external review of senior project can be used to legitimize the entire capstone experience and evaluation. Among other means for direct measure are; Student performance on certification or professional exams, for internship an external evaluation, based on stated program objectives, of performance. For indirect measures; alumni, employer, and student surveys, exit interviews or survey of graduates, graduate taking higher degree programs, length of time to graduate, job placement can be used as indirect measure for the program quality. Assessment process also include the faculty and staff members input to the process when the next year's academic plan is prepared by the department chairs in consultation with the faculty and staff outlining realistic budget requests, including both operating and personal costs. Figures #3 outlines different components of the assessment process.

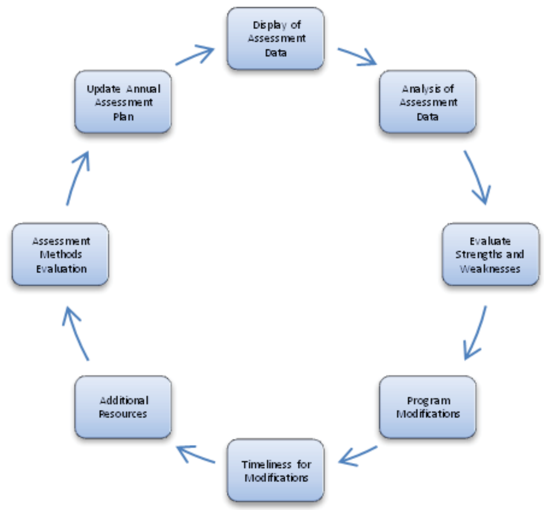

Figure #3: Assessment Process

VI. ASSESSMENT TOOLS

To prepare for an accreditation visit generally involves lot of preparation work and hence is viewed as a huge task. However, the accreditation guidelines suggest that accreditation should be looked at as a continuous process; an iteration of data collection, analysis, and modifications. The accreditation should not be viewed as a onetime event. Authors in [10] report a prototype system to automatically map ABET-CAC's outcomes to the department and course learning outcomes for Information Technology Programs. In this system students are required to submit their work through the web, these assignments are then mapped to program and course outcomes. Program as a whole or an individual course is then revised using the assessment data. Assessment methods and tools cover the measurement options that can be used for each program learning outcome; which courses are to be considered based on the PLO to be assessed in a particular year; assessment data collection and analysis needs to follow a certain time line; analysis methods used on the collected assessment data; formulate conclusions from the analyses results drawn using a certain rubric or criteria. Rubrics are used in assessment as a good technique to improve communication and feedback between faculty and students. Faculty use rubrics to relate the contents that they want to evaluate with some feedback, taking into account the possible results of the students in an exam, work or exercise. Learners use rubrics to know which topics they have to improve and why [20]? The assessment model in [7] relates program strengths and weaknesses to conclusions concerning student weaknesses and strengths. Each analysis method and the assessment data collection is evaluated every year using assessment results. Then suitable modifications and updates are included in the program for the next year's assessment cycle.

There are many assessment tools proposed by researchers and practitioners with the aim of facilitating faculty by using good techniques for assessment. A research line of interest in technology enhanced learning is focused on integrating good assessment techniques in Computer Assisted Assessment (CAA) [17]. It enables the provision of formative feedback to students in a more efficient way than with the traditional assessment. A user-friendly assessment editor helps faculty in the design of eQuestionnaires and rubrics. Brinke et al. [16] propose an educational model for CAA where rubrics are used in the response stage of assessment when reviews of assessment material are evaluating program learning outcomes. [11] proposes a novel more interoperable solution supporting interoperability through the IMS Test Interoperability specification (QTI) specification [18], by using rubrics more extensively, and enhancing user support through a new editor implementation. In this paper, they add an editable rubric functionality into previously implemented QTI compliant eQuestionnaires CAA editor [15]. By means of this functionality, faculty can create a rubric using QTI *questionsItems* ((re)using existing items or creating new ones), and relate them with the assessment activities they want to evaluate and the grades and feedback they have to assign depending on the students' results (which are facilitated by the use of QTI).

The North Carolina Agricultural and Technical (A&T) State University has been experimenting with standardized exam questions in their chemical engineering program. In this effort a large database of questions has been created. These questions are prearranged by CLOs, difficulty level and type of questions. The questions are made available to students via WebAssign® (a web-based homework system) [1]. The statistical analysis of student performance validates these individual questions in the database. This assessment tool further supports the idea that the assessment should create minimum extra work for the faculty. The tool will quickly and easily provide assessment data to the individual faculty in the program. It is understood that faculty will adjust both their teaching style and the course material by using this readily available assessment data. This will also help them to meet two objectives; be well informed to advice students who may not be willing to take such a course and to satisfy student's demonstrated needs. An alternate assessment instrument used for design learning is reported in [3]. The paper presents three tools (portfolios assessment, cognitive maps and a writing technique called "freewritng") for assessing a freshman level Introduction to Design course based on the development of design skills and knowledge.

VII. Assessment Model

It is important that program faculty is involved in every step of the assessment. This is the basis for the design and development of the assessment model presented in this section. The faculty has a key role in the decisions regarding the control and development of the data collection. The committee level involvement to monitor and control course and program development is also essential. Faculty should be free to make any kind of decisions regarding program and course improvement, this also ensures academic freedom. The Accountability Management System (AMS) by TaskStream [21] provides the tools to assist educators for uploading the data required to show institutional effectiveness. AMS is a system that can be modified to help facilitate and manage institution-wide strategic planning and assessment initiatives to strengthen teaching and learning. Institution and program level learning goals can be documented and managed through the use of AMS by universities and colleges. Activities at the program level are planned to define essential student skills and for measuring performance out comes using institutional learning goals. The results of the student achievements, institutional goals and initiatives and community participation collectively provide new powerful ways for the demonstration of effectiveness and improvement over time.

For all of the institution's initiative regarding outcomes assessment and continuous improvement AMS provides a resource and communication center. It also helps in promoting communication and collaboration among campus wide community. Great communication and collaboration capabilities of AMS also allow university management and administration to share with third party stakeholders' access to the entire accreditation process. Educational excellence culture is effectively promoted when both administrators and faculty use real time activity status reporting facility of AMS during the entire assessment process. Faculty and other administrators do not any more need to document the entire accreditation process on papers. The system will allow them to effortlessly add their comments, detailed instructions and already agreed templates. Accreditation agencies can utilize online reporting capabilities of the system if given access to this system by the institution. Real time access to data allows faculty to analyze, recommend or implement changes in a timely manner.

Accreditation as well as reporting process is facilitated and accelerated because of the instant feedback provided due to the review of the contents and reports provided by the online content and documentation review capability of the system. Program faculty can define their own program learning goals for a specific program using objective and learning outcome definition facility provided in the system. This assessment model helps in building an agreement among the faculty and administration regarding defining PLOs, assessment planning, analyzing results and then later implementing the changes based on this analysis. It also allows use of appropriate terminology as well as terminology to customize templates and thus making using of the system even easier. Curriculum mapping, courses (Course Learning Outcomes) versus PLOs, provides a clear indication to all the strengths and weaknesses in the program. Any gaps in the curriculum are also exposed through this mapping.

Figure #4: Assessment Model

Programs under consideration for accreditation need to participate in all of the program assessment activities. However, in most of the cases the faculty with the responsibility to get the program accredited asks this simple questions where do I get started? The response to this question is very simple and straightforward just follow these steps;

Develop plan: Start with identifying the program learning objectives or out comes, criteria and measure for the program.
Program Input: Insert all program related data to the system.

Implement your plan: During each academic year assess your programs based on selected program learning outcomes for that year.

Report your results: All the data from the program assessment should be reported to the system using assessment tool.

Close the Loop: This is the most important step in the accreditation process. Once the assessment results are available examine the data. The analysis of the result will help you determine if changes in curriculum (or instruction) are required. Once these changes have been implemented start your assessment again.

The use of any assessment tool to facilitate assessment activities will still need to follow a certain assessment model. Figure # 4 present a assessment model that ensures faculty involvement at every step either as teaching faculty, assessment committee, or at the top as undergraduate or graduate council.

VIII. CONCLUSION AND FUTURE WORK

The work proposed in this paper represent a preliminary approach towards the use of assessment in combination with various tools as a useful method to organize assessment information and to provide automatic formative feedback, so that assessment activities can be meaningfully embedded in learning flows. Results from this study suggest that although participants in the assessment process generally accepted the responsibilities in the assessment process, they did not necessarily fully appreciate the potential benefits of assessment and reflection activities. Thus, it is apparent that greater effort, further support in the form of tutorial input, extended explanation are needed to embed the assessment process as part of the learning culture. We are also aware of a need to revise assessment approaches in relevant courses. The overall aim of such revision is to reassure participants that formative and reflective assessment is a safe and effective means for improving courses and programs. This paper presents some of the prominent features for most effective and efficient assessment process. The paper also describes the important step to serve as a guide for the faculty member who wishes to engage in the accreditation and hence assessment of their programs.

Abstract-- **Using computers for assessment can provide several benefits for educators and test-takers. However, in the literature, there is no consensus on the equivalence of paper-and-pencil and computer-based test environments. Accordingly, more evidences are needed especially for the engineering education. In this study, students' performance on different test modes was evaluated on 209 first year engineering students of a chemistry course. The results of this study showed that, there is no significant performance difference between paper-and-pencil and computer based tests. By comparing results with the previous studies, this study concludes that, personal characteristics of test takers, the features of computer-based testing systems and the test content are all possible confounding factors when comparing test modes and need to be considered by the implementers. The results of this study show that, once these factors are controlled, students' performance on computer-based tests and paper-and-pencil tests in chemistry courses for the engineering students will not vary. This finding is encouraging the educators to get benefits of computer-based tests without any affect on students' performance.**

Index Terms— Computer based exams, Test-Mode Effect, Paper-and-pencil Based Exams, engineering education

I. INTRODUCTION

Exams are an important instrument of student assessment. As stated by Brown, Race and Bull [1] the style of assessment can have an important influence on student learning. It has been suggested that if an aspect of a course is not assessed, students will probably not learn it [2]. Hence, assessing students' performance is always an important issue for educational systems. Depending on the number of students, it is not easy to implement such techniques more often. In that sense, Computer Based Testing (CBT) systems can provide alternatives for implementing tests more often on different educational settings.

Even though there is a trend toward alternative assessment methods, CBT is definitely in ascendancy, especially in distance education, certification, and licensure [3]. According to Sawaki [4], in order to support construct validity of computerized tests such that the construct being measured is not being affected by the mode of presentation, the equivalence of corresponding conventional and computerized test forms must be established from various direction. According to Ricketts and Wilks [5], issues related to student performance should be carefully considered when computer-based assessment is introduced. According to them, mode of presentation of assessment can significantly influence student performance. Questions about differential impact of paper-and-pencil (P&P) versus CBT on test performance are referred to as test mode effects.

The literature has contradictory results on the CBT vs. P&P tests. For example, there are some studies showing that there is no significant performance difference between P&P tests and CBT [6]-[14]. Among those studies, Ashton et al [14] have analyzed the medium effect (the screen dumps of the computerized version vs. computerized version of paper test) and rewording effect (original paper test vs. computerized version of paper test). They could not find any evidence of either medium effect or rewording effect.

However, results of some other studies showed that, students perform superior on the P&P test than the CBT [15], [16]. Contrary to these findings, in some cases students benefit most from CBT compare to P&P based tests [17]-[20].

By analyzing the findings in the literature, we can categorize main confounding factors when comparing test mode as: personal characteristics of test takers, features of computer-based testing systems and test content. The related literature shows that some personal characteristics of test takers may have impact on students' performance on different test modes. There are some studies showing that gender, socioeconomic status and computer experience affect performance on computer based testing [15], [18], [21]. For example, results obtained from 1,114 examinees that completed computer and P&P versions of the Graduate Record Examination indicated that the overall performance of male examinees on the computer version was better than would be expected from their paper scores, whereas female examinees performed better on the paper version than their scores on computer version [22]. Although gender does not interact with mode of test administration for relatively low-stakes tests such as psychological assessments, gender differences in perceived self-efficacy regarding complex computer tasks are evident in other studies [22], [23]. It may be possible, however, to decrease gender differences by preparing female students for complex computer tasks. Consequently, female students with more experience in relevant computer tasks may feel more prepared for high-stakes, complex computer tasks. Specifically, female students with CBT experience most likely feel prepared for CBT [24]. Computer anxiety is considered one of the significant factors that would have negative effect on students' performance in computer-based testing [25]. Bugbee [3] pointed out that computer anxiety, combined with other things like test anxiety, computer experience, may influence the test taker. On the other hand, for some studies, computer experience and anxiety about using computers are not confounding factors for the test-mode effect [26]. When considering the mode of presentation, Noyes, Garland and Robbins [27] found that cognitive workload associated with P&P and CBT tasks can be another test-mode effect. They found that, the computer-based test should require more effort compare to the P&P tests.

Some features of a CBT system such as the reliability of the CBT system, abilities of the system, user interface design of the system, font sizes and font types can be another confounding factor. Supportive exam types such as essay type or multiple choice types as well as the evaluation procedure of the exam can all be considered in this category. For example, Bodmann, & Robinson, [11] did a research on user interface design of CBT systems such as various levels of flexibility to change and review answers. The results of this study show that, students completed the least-flexible mode faster than the other two modes [11]. In that context, Ashton et al [28] have used a tool called PASS-IT, which is capable of giving partial credits for mathematical calculations. In this study, they have shown that, testing platform which uses technology in a proper way, have minimized the effect of test mode on test takers' performance for the partial credit mathematical exams. Ricketts & Wilks [5] also showed that presentations which require scrolling are less acceptable than those in which questions are presented one at a time.

Test content should also be considered as another factor affecting test performance in different test-modes. For example, Russell [15] found that about 20% of the students who performed the math test on computer indicated that they had difficulty showing their work and/or needed scrap paper to work out their solutions. Another issue is the reading speed of the test takers which also can be related as test content. Generally, the literature review suggests that reading from computer screen is slower than that of on paper, which may positively or negatively affect test performance. For example, high rates of online reading speeds are positively correlated with good performance on the CBT TOEFL subset of reading comprehension [29]. In that sense, if the test content requires long reading passages, then reading speed of the test takers need to be considered as well.

From the review of the literature, we understand that, both modes of tests (CBT and P&P) are some how different from each other and there is no consensus on the equivalence of P&P and CBT. Additionally, there are not many studies in the literature that focus on the engineering education students. On the other hand, many characteristics of engineering students and engineering education systems need to be considered for this specific domain. In order to better understand the factors effecting test mode for the engineering students, we need more evidences. Accordingly, this study aims to evaluate and compare engineering students' performance on P&P and CBT.

II. Research Methodology

This study was conducted within 209 students. Main research question of this study is,

Do engineering students perform better or worse on computer based test compare to paper and pencil test?

Students took three midterms and a final exam during the semester. In order to answer the research question, in the second midterm, the students were randomly divided into two groups according to their last names. The first group of the students (96 students) took the CBT version; whereas the second group of students (113 students) took the exam in P&P form.

The students did not have any practice on the computer-based exam interface before the midterm exam. After the exam, interviews were conducted with 7 students (2 female) who have taken CBT. Each interview took 45 minutes and they were held during the following week of the examination. Students were asked several questions about their feelings and opinions of the CBT that they had taken. In addition to this, an interview was conducted with the course instructor, to get her comments about both versions of the exams. Each interview session was recorded by a tape recorder and later transcribed by the researcher. To measure examinee characteristics such as gender, department, computer ownership, computer experience and CGPA, a questionnaire was used. On the test day, students first completed the questionnaire and then took their exam either on computer or on paper.

A. Course Description

In that university students are thought and examined in English. General Chemistry course (CHEM102) is a service course in our university, which is offered for all first year engineering students. The content includes introduction to atomic theory, chemical stoichiometry, thermochemistry, electronic structure, molecular structures, gases, properties of solutions, chemical kinetics, electrochemistry, and introduction to thermodynamics. The course has two parts: theoretical and laboratory. The theoretical part covers 51 hours of instructions during the semester. The laboratory part covers 7 experiments in total. The instructor teaches the class in lecture format and assessment is made by 3 midterms, one final exam and laboratory assignments. Multiple choice or short answered questions are selected from each topic in order to cover whole chapter.

B. Midterm Exam

The second midterm exam covers thermochemistry, electronic structure, molecular structures and gases. There were 20 multiple choice types of questions in the exam. Students were asked to select the most appropriate answer among the given five different choices for each question. Most questions did not require mathematical calculations, however for a few questions students needed to make some mathematical calculations. Students were also given the periodical and the Molecular Geometries Based on VSEPR Theory tables (supportive materials) to be used to answer questions.

Both exams (P&P and CBT) were organized in the same way. However, in the computer version, there was only one question on each page, whereas in the P&P version of the test there were approximately five questions on each page. The supportive materials were provided as a web-link (Figure 1) in the computer version whereas they were provided as separate pages in the P&P version. Both exams were limited in time and the students were asked to finish it in 90 minutes. We have offered the second midterm in both versions by switching the groups in order to provide both groups a fared equality in the course. However, we did not consider the results of the second midterm in our study.

As shown in the Figure 1, the computer-based exam page is divided into three sub-windows. Students can always open a new window to reach the supportive materials by using the left window. In the right window, students read each question, type the answer for each question and by using the navigation buttons they can move around questions. By using the bottom window, students can finish the exam and submit their exam results to the server.

The question numbers are not shown on the screen. Font types used in both versions of the exams are the same. Both groups of students were provided some extra empty sheets of papers to make necessary calculations. Figure 2 shows the P&P version of a sample exam page.

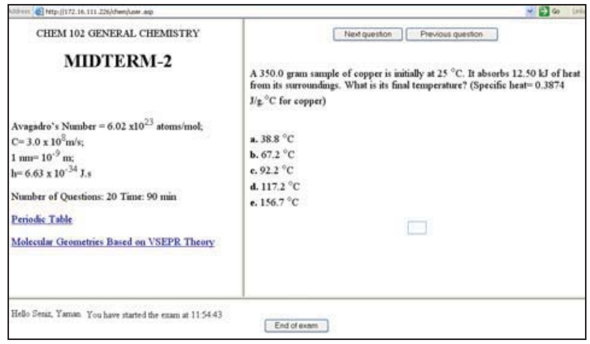

Figure 1. A Sample CBT Exam Page

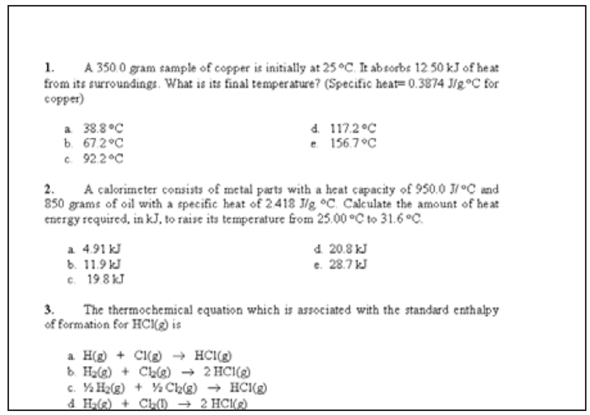

1. A 350.0 gram sample of copper is initially at 25 °C. It absorbs 12.50 kJ of heat from its surroundings. What is its final temperature? (Specific heat= 0.3874 J/g.°C for copper)

a. 38.8 °C
b. 67.2 °C
c. 92.2 °C
d. 117.2 °C
e. 156.7 °C

2. A calorimeter consists of metal parts with a heat capacity of 950.0 J/°C and 850 grams of oil with a specific heat of 2.418 J/g °C. Calculate the amount of heat energy required, in kJ, to raise its temperature from 25.00 °C to 31.6 °C.

a. 4.91 kJ
b. 11.9 kJ
c. 19.8 kJ
d. 20.8 kJ
e. 28.7 kJ

3. The thermochemical equation which is associated with the standard enthalpy of formation for HCl(g) is

a. $H(g) + Cl(g) \rightarrow HCl(g)$
b. $H_2(g) + Cl_2(g) \rightarrow 2\,HCl(g)$
c. $\frac{1}{2} H_2(g) + \frac{1}{2} Cl_2(g) \rightarrow HCl(g)$
d. $H_2(g) + Cl_2(l) \rightarrow 2\,HCl(g)$

Figure 2. A Sample P&P Exam Page

C. Participants

The participants of this study were first year engineering students (from software engineering (SE), Manufacturing Engineering (MFGE), Mechatronics Engineering (MECE), Civil Engineering (CE), Industrial Engineering (IE), Electrical & Electronics Engineering (EE) and Computer Engineering (CENG)). Before taking this course, the previous semester, all of the students have completed a computer literacy course which is offered as two hours theoretical and two hours laboratory sessions in each week. The content of that course covers an overview of information technology, hardware and software components, CPU, peripherals, I/O devices, primary and secondary storage units, data communications, networks, and Internet. Word processing, spreadsheets, presentation software, and Internet applications are also introduced during the laboratory hours.

As shown in Table 1, 35 female and 174 male students participated in this study. Since in engineering departments the number of female students is usually lower according to the male students, this situation is also reflected in our sample as well which is very usual for the engineering departments.

Table 1. Students' Profile - Gender

Group	Female	Male	Total
CBT	16	80	96
P&P Test	19	94	113
Total	35	174	209

Table 2 summarizes students' distribution among the departments. Most of the students were from industrial engineering (IE) department. Among the students who have taken the CBT, only 10 of them were from computer engineering department. The rest were the students from other engineering departments.

Table 2. Students' Profile - Departments

Group	SE	MFGE	MECE	CE	IE	EE	CENG	Total
CBT	2	14	2	18	37	13	10	96
P&P	2	11	10	14	47	13	16	113
Total	4	25	12	32	84	26	26	209

III. RESULTS

In this section the results of the study presented in two parts: quantitative and qualitative.

A. Quantitative Data

The study was conducted at a private university. Compare to public universities, students' socio-economic status (SES) is higher in private universities of Turkey. As shown in Table 3, most of the students (203 students, 97%) have reported that, they have their own personal computers.

Table 3. Students' Profile – Computer Ownership

	Yes	No	Total
CBT	94	2	96
P&P Test	109	4	113
Total	203	6	209

In order to better understand students' computer experience, some questions were asked in the questionnaire. Students' responses on these questions summarized in Table 4. Majority of students like computers (79%), use computers very often (83%), use the Internet and web applications (85%) and access their e-mails very often (94%).

Table 5 summarizes the averages of Cumulative Grade Point Average (CGPA) for both groups. This shows that, the average CGPA of computer-based test group is slightly higher than P&P group. However in general, the female students' average CGPA is higher than that of males.

Table 4. Students' Profile – Computer Experience

Question	Students' Response
I use computers every day	173 (83%)
I frequently use the Internet and web applications	178 (85%)
I like computers	165 (79%)
I often access my e-mail	196 (94%)

Table 5. Students' Profile – CGPA

Group	Mean	Std. Deviation
CBT	1,34	0,86
P&P Test	1,13	0,75

An independent t test was conducted to evaluate if there is a statistically significant difference according to their CGPA between two groups. The result was not significant, $t(206)=1{,}86$, $p=0{,}064$. Students who have taken the exam on computer ($M=1{,}34$, $SD=0{,}86$) on the average have close CGPA with the students who have taken the exam on P&P ($M=1{,}13$, $SD=0{,}75$).

In the second midterm, 96 students took the exam in the CBT form, while 113 of them took the exam in P&P version. Table 6 summarizes the exam results.

Table 6. Exam Results

Test Mode	N	Mean	Std. Deviation
CBT	96	42,96	20,10
P&P Test	113	40,08	19,28

The average exam score of students who took the exam in CBT form is slightly higher than the P&P group. An independent-sample t test was conducted to evaluate if there is a significant difference between the exam results of these two groups. The result was not significant, $t(207) = 1{,}055$, $p= 0{,}77$. On the average, the students who took the exam on CBT form ($M= 42{,}96$, $SD=20{,}10$) had similar grades as the P&P group ($M=40{,}08$, $SD=19{,}28$).

A 2x2 ANOVA was also conducted to evaluate the effects of test mode (CBT or P&P) and gender on students' midterm scores. Means and standard deviations for the exam scores as a function of the two factors are presented in Table 7.

Table 7. Gender Effect

Gender	Test Mode	Mean	Std. Deviation
Female	CBT	53,38	18,54
	P&P Test	50,26	20,51
Male	CBT	40,88	19,85
	P&P Test	38,02	18,46

The results of the ANOVA indicated a non significant effect for test mode, $F(1, 209) = 0,69$, $p=0,40$. Results also indicates a significant effect for gender, $F(1,209) = 12,01$, $p<0,01$. However, the results indicated a non significant interaction between test mode and gender, $F(1,209) = 0,001$, $p=0,97$. Female students were more successful in the exam than the male students. However, the test mode (taking the exam on computer or P&P), did not effect this result.

B. Qualitative Data

The results of interviews are also supporting the quantitative results. During the interviews all students have reported that they use computers at least one hour in a day. Even two students have declared that they use computers more than 7 hours in a day. When we asked what they think about taking the exam on computer, three students said that, at the beginning they felt uncomfortable, however after ten minutes they got used to the system and they felt better. For example, one student said, "For the first 5 minutes I worried a little if I would accidentally press a wrong button. Because it was my first time to take the exam on computer. However, 5 minutes later I started to feel better". Another student also reported:

The P&P exams are what we have used to. However, taking the exam on computer is something very new to us. For this reason at the beginning I was in panic. After 10 minutes, I continued the exam as if I am taking it in P&P format.

Parallel to this, another student also declared that taking the exam on computer or paper does not affect his performance:

Taking the exam on computer or on P&P does not matter. They are the same. In both versions, you have to use paper to make some calculations. Once you know the concepts that the exam covers, they are the same. However, for those who are not familiar with computers it is normal that they feel a little bit uncomfortable. I liked the idea of taking the exam on computer.

When we asked them, what would happen if they had taken the exam on paper, all of them said that their grades would not change. For example according to one student, his exam grade would also not change. He said:

My grade would not change. The content is the same. It was easy for me. It is an exam, taking it on computer or on paper are the same.

When they were asked which format is better, taking the exam on computer or on paper, 6 of them declared that it does not matter, but two of them preferred computer version. For example one student said,

I think taking the exam on computer is easier and better. In fact they are the same; we only look at the monitor instead of the paper. For the next time I would prefer to take the exam on computer. Because reading the questions one by one on the screen increases my concentration on each question.

Another student prefers to take the exam on computer. He said, "I would like to take all of my exams on computer". One student said, "I would not say no for both of them. However to be sure, I would prefer the P&P version. You may face with some technical problems on the computer environment, such as loosing the Internet connection etc."

Since students did not have any experience with the CBT system, at the beginning they were not very comfortable with it; however, after some time they felt better. They also said, this did not affect their scores. And finally, all students believe that their performance would not change if they have taken the exam on P&P form.

IV. DISCUSSIONS AND CONCLUSIONS

In this study, data were collected and analyzed to better understand the test mode effect on students' test performance. The subjects' socioeconomic status were high, most of them were computer owners and computer literate. The results of this study show that, students' performance on the CBT and P&P versions of the exam does not differ significantly. The qualitative data also supports this result. All students declared that, their exam grade would not change if they had taken the exam on paper.

In this study, there were some differences between the computerized and P&P versions of the exams (i.e. number of questions in each page and question numbers). However this difference did not affect the test results significantly. This result supports findings of Ashton [14] which they could not find any evidence of either medium or rewording effect on test mode.

Gender effect was also tested and we could not find any relation between gender and test mode.

The results of this study supports the results of several studies which have found no significant difference on students' scores in CBT and P&P testing environments, [6]-[14], and [28].

The result of this study is contradictory to some of the results found in the literature. For example, Lee and

Weerakoon, [16] and Russell [15] have found that, students perform better on P&P based tests than the CBT. However, they have also reported that, their subjects have little computer experience. For example, Lee and Weerakoon [16] reported that 27% of the students had moderate to high experience with email and 37% of students having moderate to high experience with the web. However, in our case, students have declared that they frequently use the Internet and web-based applications (85%) as well as they frequently access their emails (94%). Similarly, in Participants of Russell's study [15] subjects did not have a great deal of experience working with computers. We believe computer experience of test takers is a confound factors when comparing test modes.

The result of this study is also contradictory to the results of studies which have found that students' performance on CBT is higher than that of P&P [17]-[20]. However, Clariana and Wallace [19] have conducted their research on "Computer Fundamentals Course" which covers the fundamental concepts and use of a computer system. Similarly, Bocij and Greasley [18] conducted their research on elementary courses in Information Systems, Computer Science and Information technologies. We believe that, in courses teaching about computer systems, asking questions in computer could benefit students to better visualize and understand the question and this may positively affect their performance on the test.

On the other hand, Bugbee and Bernt [17] could not rule out substantial differences among the groups that have taken the exam on different exam modes. This may cause the performance difference between the test modes. Pomplun et al [20] conducted their study on a speeded reading comprehension placement test. They have also reported that, the main reason for the higher scores on CBT could be the clicking a mouse which allows an examinee to move quicker through the items than when forced to record answers with a pencil on a bubble sheet.

This study shows that, while considering the test-mode effect, characteristics of test takers, features of computer-based testing systems and the test content are possible confounding factors when comparing test modes. Once these parameters are controlled, on CBT, similar test performance can be reached with the P&P tests. This result is very promising to better get benefits of the CBT environments in classical and distance learning environments. Accordingly, once the CBT environments are decided to be set, the possible confounding factors such as personal characteristics of test takers, the features of computer-based testing systems and the test content need to be controlled.

Abstract—**Quality assurance principles applied at the remote laboratory network there are similarly with the same principles applied at the production process, which has as a result products used by society. Remote experiment is a product used by learners, a part of our society, with the main reason to increase the quality of knowledge. Learners are the consumers (the clients) and teachers are the producers.**

At limit, one student must to open all of the remote laboratories referred at the same experiment to be able to declare that his knowledge and image about this experiment there is complete. But, similarly with the classic production process, there are a various grades or levels of quality. These differences are the result of the *intentional* design of the experiment, determined by the level of the laboratories endowment, of the level of Internet connection, the type and complexity of the subjects approached in the remote way, the acceptance of national language or of the English ones. All of the above factors being *intentional*, the quality aspects are named QUALITY of DESIGN.

There are other factors which influenced the quality of the remote laboratory. They are: hardware and software utilized for the remote experiment, knowledge level of the producers (teachers) and of the consumers (students), type of quality assurance system in use inside of the schools, assessment and evaluation rules applied for the student knowledge, etc.. This group of factors will determine QUALITY of CONFORMANCE, indicating how well the laboratory works (as product) conforms to the specifications required by each training system who intend to use the remote experiment network.

There is a considerable necessity of the clarifications about quality in the field of the remote laboratory network, many times above notions being often used without a clear distinction. Being a global system, the remote experiment network includes an unavoidable conflict between *quality of design*, which represents a local decision and *quality of conformance*, which is a global requirement. As a result, in the paper the authors want to propose the application of some statistics methods, to do the above distinction and to start new approach regarding quality assessment in the remote experiment network.

Keywords-component; quality of design; quality of conformance; remote experiment; sampling; null hypothesis; OC curve; F ratio;

I. INTRODUCTION

If we agree the idea to consider all of laboratory works from the remote experiment network as a products and the students as a consumers, then quality is becoming the basic consumer decision. As every consumer from the market, student feels that the products of certain universities are substantially better in quality than the others. In this situation it is possible to apply in the laboratory work selection, the statistical methodology used in the quality control from manufacturing process? During the search of the laboratory works, the student has two alternatives: to accept the opened laboratory work or to reject it for some reasons. Because the student do not have time to do his acceptance after opening all of the similar laboratory works, it means that he made acceptance and rejection using only a sample from the entire ***"lot"*** of laboratory works. Up to now, the above operations seems to be similarly with acceptance sampling from statistical quality control. Three peculiarly aspects must to be mentioned:

1. Acceptance sampling, like above, do not estimate the "lot" quality; it simply accepts or reject laboratory works using some subjective criteria;
2. Acceptance sampling do not provide any direct form of the quality control;
3. The most effective use of the acceptance sampling is an audit tool which, ensure the customer that the output of a design ***conforms*** to its requirements.

There are some differences in the acceptance sampling applied to the laboratory works contained in the remote network:

1. Middleware, which ensure sampling of "n" laboratory work at one trial, selected at random from the "lot", will not be able to characterize the entire "lot" quality, as in the manufacturing process;

2. The final acceptance number "c" of laboratory work used by the student after selection, does not represent the limit of the defective items in the sample, as in the manufacturing process. It has the significance that: "if "c" laboratory work fulfill student's requirements, than will exist other with similar quality in the "lot" so that the next decision of the student-client will be to take a second sample";
3. The second sample will not offer to the student the right to do a global decision regarding the quality of the laboratory works contained in the "lot". It is due the fact of the huge diversity of evaluation of the laboratory work content, produced by the large diversity of the cultural heritages involved in the network;
4. In the case of the manufacturing process, the random numbers "n" is generated by a computer. In the case of the remote experiment network, the sampling is random because the middleware accessed diverse sites of the laboratory works in dependence with the situation of the momentary Internet connection.

II. SAMPLING ANALYSE

In the case of a single sampling plan, if the number of the similarly laboratory works are "N", then the sample size is "n" and the acceptance number is "c". If the nonconforming laboratory works observed is "d" and d ≤ c, then the student has minimum two laboratory works of the good quality? It is the question, because the criteria accordingly with comparisons and selection are made, will be also random, in direct connection with the student prerequisite knowledge.

The measure of the acceptance sampling plan is the operating characteristic (OC) curve. This curve plots the probability of the "lot" acceptance versus the lot fraction with nonconformities. The probability of observing "d" nonconforming laboratory works is:

$$P\{d\} = f(d) = \frac{n!}{d! \cdot (n-d)!} \cdot p^d \cdot (1-p)^{n-d} \qquad (1)$$

The probability of acceptance is the same probability when d ≤ c or:

$$P_a = p\{d \le c\} = \sum_{d=0}^{c} \frac{n!}{d! \cdot (n-d)!} \cdot p^d \cdot (1-p)^{n-d} \qquad (2)$$

where: p is the fraction of the nonconforming laboratory works in the "lot".

For example, from 500 laboratory works referring at Ohm law, suppositional existed in the remote network, the random sampling gives n=50 and the acceptance number c=3. Considering the variation of the lot fraction nonconformities "p" with the values given in the table 1:

TABLE I.

p								
0,01	0,02	0,03	0,04	0,05	0,06	0,07	0,08	0,09

the OC curve of the single sampling action there is in accordance with the Fig. 1:

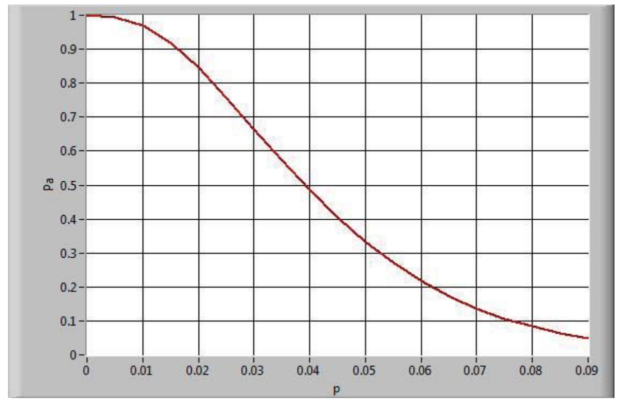

Figure 1. OC curve at single sampling action

As we have mentioned above, a warranty of the good selection impose a double sampling action. Obviously, a double sampling plan is defined by the four parameters:

- n_1, n_2 – sample size on the first sample respectively of the second sample;

- c_1, c_2 – acceptance number of the first respectively of the second sample with the condition $c_1 < c_2$;

The conditions which results from this action are:

- if $d_1 \le c_1$ the lot is accepted on the first sample;

- if $d_1 \ge c_2$ the lot is rejected on the first sample;

- if $c_1 < d_1 \le c_2$ a second random sample of size n_2 is drawn from the remote experiment network and the number of nonconformities d_2 are observed.

The combined number of observed nonconformities from both samples, $d_1 + d_2$, is used to determine the lot nonconformities:

- if $d_1 + d_2 \le c_2$ the lot is accepted;

- if $d_1 + d_2 > c_2$ the lot is rejected.

The OC curve for a double sampling activity has two curves. One P_{a1} for the n_1, c_1 and the second P_{a2} for the n_2, c_2 . P_{a1} , denotes the probability of acceptance of the first sample and P_{a2} the probability of acceptance of the second sample. P_a = P_{a1} + P_{a2} denotes the probability of acceptance on the combined samples. The calculation manner is mentioned in the following. First is calculated the P_{a_1} probability:

$$P_{a_1} = \sum_{d=0}^{c_1} \frac{n_1!}{d_1! \cdot (n_1 - d_1)!} \cdot p^{d_1} \cdot (1-p)^{n_1 - d_1} \quad (3)$$

with the condition: $d \le d_1 = c_1$

The second sample is drawn only if there is the condition: $c_1 < d_1 \le c_2$. The lot is accepted in the following situations:

a. $d_1 = c_1 + 1$ and $d_2 = 0$ or 1

That is, we find $c_1 + 1$ nonconformities on the first sample and zero or one on the second sample. The probability for this situation there is:

$$P\{d_1 = c_1 + 1, d_2 \le 1\} = P\{d_1 + c_1 + 1\} \cdot P\{d_2 \le 1\} =$$
$$= \frac{n_1!}{(c_1+1)! \cdot [n_1 - (c_1+1)]!} \cdot p^{c_1+1} \cdot (1-p)^{n_1 - (c_1+1)} \cdot \quad (4)$$
$$\cdot \sum_{d_2=0}^{1} \frac{n_2!}{d_2! \cdot (n_2 - d_2)!} \cdot p^{d_2} \cdot (1-p)^{n_2 - d_2}$$

b. $d_2 = c_2$ and $d_2 = 0$

That is, we find c_2 nonconformities on the first sample and zero nonconformities on the second sample. The probability of this is:

$$P\{d_1 = c_2, d_2 = 0\} = P\{d_1 = c_2\} \cdot P\{d_2 = 0\} =$$
$$\frac{n_1!}{c_2! \cdot (n_1 - c_2)!} \cdot p^{c_2} \cdot (1-p)^{n_1 - c_2} \cdot \quad (5)$$
$$\cdot \frac{n_2!}{0! \cdot (n_2 - 0)!} \cdot p^0 \cdot (1-p)^{n_2 - 0}$$

Thus, the probability of acceptance on the second sample is:

$$P_{a_2} = P\{d_1 = c_1 + 1, d_2 \le 1\} + P\{d_1 = c_2, d_2 = 0\} \quad (6)$$

For the entire lot, the probability of acceptance is therefore:

$$P_a = P_{a_1} + P_{a_2} \quad (7)$$

The OC curve fir the double sampling activity is shown in the Fig. 2.

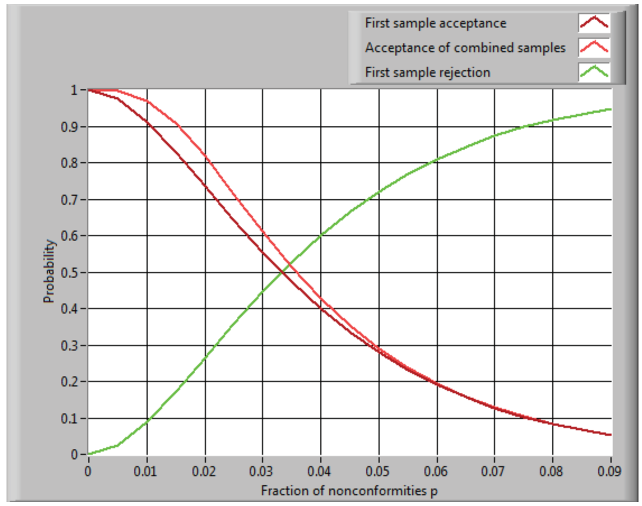

Figure 2. OC curves for the double sampling

Comments:

It is the first step of the quality analyze with statistic methods. It is referred at the quality of conformance because is a tool which indicates the manner in which the students accept or reject the laboratory works from the remote experiment network.

But, this action depends in a great measure by the some factors proper of the Internet environment:

- The number of the connections requested in the same time and the capacity of the remote site to accept one or more;
- The capacity of the middleware to do connections in conformance with the student solicitations;
- The speed of the Internet connection, used by the students;
- The student ability in the English language which determine the connection duration;

As a result, the quality analyze might be distorted. We have mentioned above that only sampling analyze will not give too much information about the laboratory works quality. It only gives us some indications about the quality of conformance. And the levels of the conformance there is distributed and diverse between users. We must introduce in the quality system of the remote network, in completion of the above tool, other analyze regarding quality of design [8].

III. KEPPEL METHOD

In our point of view, the good analyze of the quality of design applied at laboratory works is the method of null hypothesis applied by Keppel* in the behavioral sciences. We need a tool which allows us to state if the laboratory works opened by the students will produce effects on the student knowledge. The null hypothesis method evaluation gives us this certainty.

In short, for remembering the statistic assumptions regarding the null hypothesis, we have:

$H_0 : \mu_1 = \mu_2 = \mu_3 .... \mu_i -$ The null hypothesis;

$H_1 : \mu \neq \mu_1 -$ The alternative hypothesis;

The null hypothesis mentioned that we have the same values of the mean to the different populations analyzed. If H_0 is true, our treatments (learning from the remote network) do not give effects on the population.

The alternative hypothesis states that the values of the means are not equal. If H_1 is true, we expect to find some treatments effect with influence on the students knowledge.

The evaluation of the above situations is made through F distribution. Simply and direct, F ratio is defined as:

$$F = \frac{BETWEEN \quad GROUPS \quad VARIANCE}{WITHIN \quad GROUP \quad VARIANCE} \tag{8}$$

Between groups differences are the result of the combined effect of the experimental treatment and of the experimental errors. Within group differences represent the influence of experimental error alone.

F is a numerical index which is "sensitive" to the presence of treatments effects in the population. Only the value F > 1 indicate the existence of the treatment effect (see above definitions of the numerator and denominator of the F ratio).

We will present now the way and the motivations which will conduct us towards F ratio calculation and interpretation.

If we have an independent variable as factor A, with three levels of variation: a_1, a_2, a_3, applied at "s" subjects dawn form one population, the frequency distribution of the three sets of scores are presented in Fig. 3:

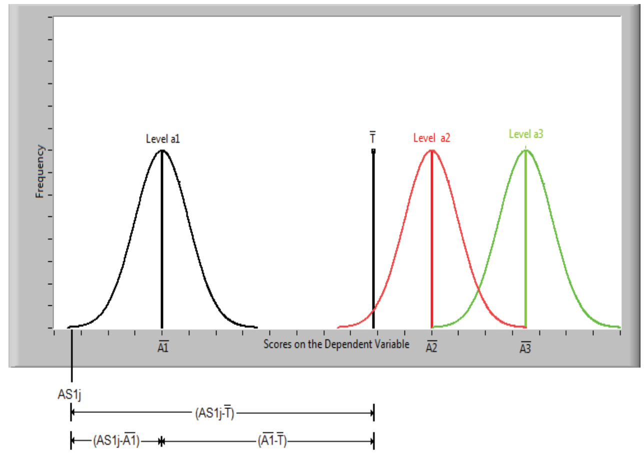

Figure 3. The components of deviation scores* [1]

According with the Fig. 3, AS_{1j} represents the scores at level factor "1" having "j" values, and the correlations showed are:

$$AS_{1j} - \overline{T} = \left(\overline{A_1} - \overline{T}\right) + \left(AS_{1j} - \overline{A_1}\right) \tag{9}$$

where: $AS_{1j} - \overline{T}$ - is total deviation;

$\left(\overline{A_1} - \overline{T}\right)$ - is between groups deviation;

$\left(AS_{1j} - \overline{A_1}\right)$ - is within group deviation

In the [1] this relation is written accordingly with the Hays [2] and Winer [3]:

$$SS_A = \sum_i^a s \cdot \left(\overline{A_i} - \overline{T}\right)^2 - \text{Between groups sum of squares;} \tag{10}$$

$$SS_{S/A} = \sum_{j=1}^{s} \left(AS_{ij} - \overline{A_i}\right)^2 - \text{Within group sum of squares;} \tag{11}$$

with the obvious correlation:

$$SS_T = SS_A + SS_{S/A} \tag{12}$$

Starting from these notions, we will calculate the F ratio. For this we need to have the "degree of freedom" df , which represents the number of scores with independent information which enter into the calculation of the sum of squares. Accordingly with the Keppel definition:

$$df = \begin{pmatrix} number \quad of \\ independent \\ observations \end{pmatrix} - \begin{pmatrix} number \quad of \\ population \\ estimates \end{pmatrix}; \tag{13}$$

* *we will use the same notations as Keppel*

For SS_A, $df_A = a-1$ and for $SS_{S/A}$, $df_{S/A} = a\cdot(s-1)$

As a result:

$$df_T = df_A + df_{S/A} = a-1+a\cdot(s-1) = as-1\,; \qquad (14)$$

The next step of calculations is the mean of squares:

$$MS_A = \frac{SS_A}{df_A} \quad and \quad MS_{S/A} = \frac{SS_{S/A}}{df_{S/A}} \qquad (15)$$

Where: MS_A estimates the combined presence of treatment effects plus error variance and $MS_{S/A}$ independently by MS_A estimates error variance.

Finally, the F ratio becomes:

$$F = \frac{MS_A}{MS_{S/A}} = \frac{\frac{SS_A}{df_a}}{\frac{SS_{S/A}}{df_{S/A}}} = \frac{SS_A}{SS_{S/A}}\cdot\frac{df_{S/A}}{df_A} \qquad (16)$$

Numerical example

Suppose that we were interested in the effect in the comprehension of three different instructions referring at one laboratory work. One group are verified if they succeed to memorize the basic law settled at the laboratory work, a second similar group is asked to concentrate upon measurement units, and their influence upon experiment, and the third group will work free, without recommendations. All of groups will receive finally a test regarding the comprehension of the laboratory work as a whole. In the hypothetical example there are s=5 subjects who were randomly assigned to each of a=3 treatments conditions. It means that, the subjects connections with the remote network was randomly, so that they will encounter one of the above instructions. Using the Keppel notations, the AS_{ij} matrix applied at the above experiment has the aspect (tab.2):

TABLE II.

AS_{ij}	a_1	a_2	a_3
1	13	7	8
2	17	9	10
3	11	8	6
4	10	6	7
5	14	7	8
6	15	10	9
7	9	6	8
8	11	7	5
9	13	5	9
10	17	5	10
$\sum A_i$	130	70	80
$\overline{A_i}$	13	7	8
$\sum_j^s (AS_{ij})^2$	1760	531	664

With these data we may compute, following the above scheme, successively:

$$SS_A = \sum_i^a s\cdot\left(\overline{A_i}-\overline{T}\right)^2 = \frac{\sum(A_i)^2}{s} - \frac{\left(\overline{T}\right)^2}{a\cdot s} = 206{,}7$$

$$SS_{S/A} = \sum(AS_{ij})^2 - \frac{\sum(A_i)^2}{s} = 135$$

$$df_A = a-1 = 2$$

$$df_{S/A} = a\cdot(s-1) = 27$$

$$MS_A = \frac{SS_A}{df_A} = \frac{206{,}7}{2} = 103{,}35$$

$$MS_{S/A} = \frac{SS_{S/A}}{df_{S/A}} = \frac{135{,}35}{27} = 5$$

$$F = \frac{MS_A}{MS_{S/A}} = \frac{135{,}35}{5} = 20{,}67$$

Because $F > 1$ we put into discussion the correctness of the null hypothesis.

Comments

Remote experiment network there is similar with a large population from which teachers drew at random three sets of 10 scores for each level of factor A, with the final goal to assess the quality of the content (design) [6], [7].

Assuming that this operation there is made by a large number of teachers, from different places, each operation consisting of three groups of 10 scores with the final goal to compute the value of the F ratio (standard method imposed by the remote network administrator), it is possible to be constructed a graph relating F and frequency of occurrence. We are in two situations:

- Curve of sampling distribution of F, when the null hypothesis is true;
- Curve of sampling distribution of F', when the null hypothesis is false;

All of teachers involved in this assessment expect to find some treatment effects, as a result of the described experiment.

The problem is to decide if, calculated value of ratio F, came from the F distribution of from F' distribution.

In the Fig. 4 is shown the empirical (F) and theoretical (F') sampling distribution of F (2, 27) the F ratio computed in the above numerical example. The empirical F (2, 27) distribution was obtained supposing that $\overline{A_1} = \overline{A_2} = ... = \overline{A_i}$ =7 (H_0 = true). The theoretical distribution was obtaining supposing that $A_1 = 7, A_2 = 8, A_3 =$ 13. In the both distribution, $SS_A = 206{,}7$.

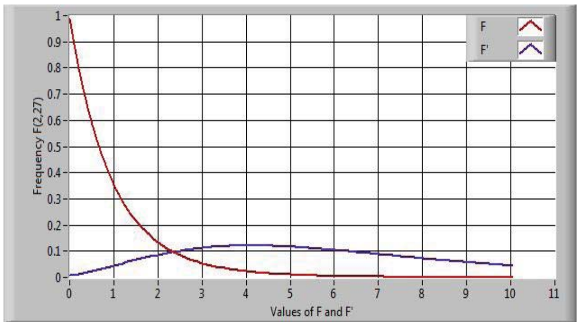

Figure 4 Sampling distribution of F and F'

The decision to reject of not the null hypothesis will be made by comparing the observed (computed) value of F with the value $F' = F$ located at the critical point of transition. The values of the critical F have been tabulated and, as we observed in the table 3, it is specified by three factors: $df_A(df_{numerator})$, $df_{S/A}(df_{denominator})$ and α , which is refers at the portion of the area to the right of an ordinate drawn at F_α .

The shortest explanation of α significance there is shown in the Fig. 5. As we observe, α define the region of incompatibility of the F distribution. It is in fact a probability called "*significance level"* and the investigator may pick any probability he wants. In the table 3 it is present a fragment of tabulated values for F at different α probabilities.

The decision to reject of not the null hypothesis is made by comparing the observed (calculated) values of F ratio with the value of F' ratio drawn from the above table consider: $df_{nom}; df_{denom}; \alpha$.

TABLE III. (FRAGMENT)

df_{denom}	df_{nom}							
	α	1	2	3	4	5	6	7
3	0,25	2.02	2.28	2.36	2.39	2.41	2.42	2.43
	0,10	5.54	5.46	5.39	5.34	5.31	5.28	5.27
	0,50	10.1	9.55	9.28	9.12	9.01	8.94	8.89
	0,025	17.4	16.0	15.4	15.1	14.9	14.7	14.6
	0,010	34.1	30.8	29.5	28.7	28.2	27.9	27.7
	0,001	167	148	141	137	135	133	132

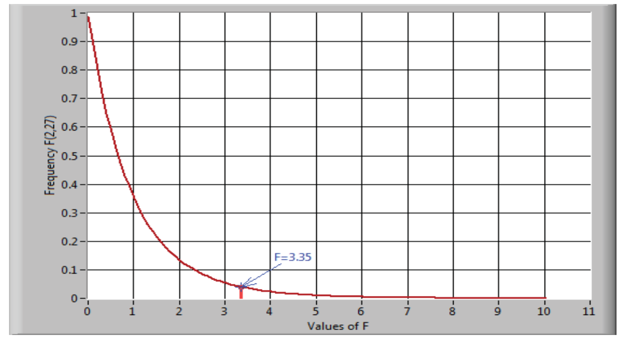

Figure 5 Sampling distribution of $F(2{,}27)$

With above clarifications we have the possibility to write the rule of decision:

- when $F_{calculated} \geq F_\alpha(d_{nom}, d_{denom})$ -reject null hypothesis H_0 . Otherwise do not reject H_0

In other words:

- If the value F - computed from experiment – falls within the region of incompatibility, the null hypothesis is rejected and alternative hypothesis is accepted;
- If the F value falls within region of compatibility, the null hypothesis is not rejected.

In our numerical example, df_{nom} = 2 and df_{denom} = 27. If we set α =0.05 the critical value of F (the value which share the F' distribution in incompatible and compatible regions) is 3.35 (from tables similarly with the table 3).

Because:

$$F_{observed} = 20{,}67 > F_{critical} = 3.35$$

we reject the null hypothesis H_0 , and we should conclude that treatment effects were present in this experiment. It means that, learning materials have some influence on the student knowledge. This conclusion means that the design of the laboratory work fulfill the quality requirements in some measure.

IV. CONCLUSIONS

It is possible to analyze the quality of the laboratory works existed in the remote experiment network with two methods:

- Quality of conformance with double sampling method;
- Quality of design with Keppel method;

The first method is useful in the case of the assessment of the laboratory work selection by the "clients" (i.e. students). Taking into account the number of the selections and the number of the rejections, it is possible to discuss about the quality of conformance. It isn't an absolute criterion regarding quality because of the fact that there are some outside limits which influenced the selection (Internet connection, Internet speed, language, middleware possibilities, etc.) with not direct dependence with the student opinion about the laboratory work utility.

In the second method, it is necessary to do some questionnaires, with real evaluation of the content, applied to a sampling from the entire population of the remote laboratory works having the same topics. The students will answer at these questionnaires, and using the proposed way, will be possibly to state if these laboratory works have some treatments effects on the student knowledge.

Because the problem of the quality in this environment is quite new, the present paper reflects the first preoccupations of the designers, both of the network and of the content, regarding quality assessment [5]. Sure, the development of this environment will increase these preoccupations and other quality evaluation method will be proposed. The most important thing is the fact that this problem of the quality is raise from the beginning of the development of this remote network [9], [10].

ACKNOWLEDGMENT

The authors express their gratitude to the National Research Council of Romania, owing to its financial sustaining during research running.

Introducing alternative assessment into engineering language education at the Technical University of Madrid

Joana Pierce McMahon,

Pilar Durán Escribano

Paloma Úbeda Mansilla

Department of Applied Linguistics
The Technical University of Madrid
Madrid, Spain.

Abstract— **Engineering Institutions across Europe are currently involved in a major process of reform and restructuring as part of the Bologna Process, which stresses the role of competencies and outcomes in curriculum design. In the field of languages, the Council of Europe has developed the Common European Framework of References for Languages (CEFR), which aims to provide a reference framework for describing different qualifications, identifying different language learning objectives and setting out the basis of different achievement standards. Using this framework of language competence levels, our research group, over a three year period, has developed and piloted the Academic and Professional English Language Portfolio (ACPEL) especially designed for Engineering students and professionals. This portfolio was accredited by Language division of the Council of Europe in 2008. This paper will report on an ongoing project dealing with self and peer assessment based on the ACPEL portfolio. The project's aim is threefold: first, to train university language professionals in the use of self and peer assessment through the implementation of the ACPEL portfolio; secondly, to gradually introduce these assessment processes into the engineering language curriculum and finally to monitor and evaluate these two processes at the seven engineering schools.**

Keywords-assessment, higher education, second language, self assessment

I. INTRODUCTION

Actively involving students in their own learning and focusing on how to teach students to become more independent learners is a major educational goal in most European countries. The preamble of the Declaration of Barcelona on sustainability on Engineering education [1] asks us as engineering educators to address the whole educational process in a more holistic way implementing an integrated approach to teaching knowledge, attitudes, skills and values which incorporate disciplines of the social sciences and humanities. It also emphasises the need to promote multidisciplinary teamwork, creativity and critical thinking as well as to promote reflection and self-learning. Rompelman [2] argues that as engineering curricula are shifting from traditional teacher-oriented, individual programs toward learning oriented programs aimed at cooperation between students , not only is the role of the student changing but the role of the professor as well. Referring to this 'academic culture' of teaching, especially in tertiary education, Rogers [3] commented the following:

> When we put together in one scheme such elements as prescribed curriculum, similar assignments for all students, lecturing as almost the only mode of instruction, standard tests by which all students are externally evaluated and instructor chosen grades as the measure of learning, then we can almost guarantee that meaningful learning will be at an absolute minimum (p 21).

Since meaningful learning is a goal, emphasis should be on a student centred approach where learning is viewed both as a product and as a process. The acquisition of knowledge is then under the student's control. This implies that students should be actively involved in the planning and management of their own learning and take more responsibility for it as they progressively develop as independent learners. Teaching, learning and assessment practices are considered inseparable; and students should be active participants in the development of assessment procedures. Both the process and product of assessment tasks should be evaluated. Consequently, the assessment results should be reported as a qualitative profile rather than as a single score [4]. Hence the actual situation at our university with an intensive exam period and an overload of exams do not stimulate involvement in classroom sessions nor retention of course material [5].

II. SELF ASSESSMENT: WHAT IT IS AND WHY USE IT

Assessment in general is regarded as a process of collecting, synthesizing and interpreting information in order to

This work has been funded by the Technical of Madrid through the Innovation group APLAI and the research group DISCYT.

make decisions on student performances. Assessment can be conducted to diagnose student problems to judge their academic performance, to provide feedback to students and to plan future learning. Self assessment in the educational context involves the learners in a process of evaluation and monitoring their own level of knowledge, performance and understanding. Enabling students to self-monitor their learning helps the students to develop knowledge through conscious control over that knowledge or to develop metacognitive awareness of knowledge and thought [6]. In a student-centred learning environment, this kind of assessment aims at preparing students to be autonomous, critical and responsible graduates and lifelong learners as promoted in the Bologna declaration.

Traditional assessment practices according to Boud and Falchikov [7] can undermine students' capacities to judge their own work. Students have to learn not to over rely on the opinion of others since in a working situation, these future engineers must be able to judge or evaluate the adequacy, completeness or appropriateness of their own outcomes. Hence, allowing self assessment opportunities that provide the learner with increasing responsibility helps them to be prepared for lifelong learning and assessment of this learning. Self-assessment plays an important role in helping the student extract meaning from the new experience and also helps him or her to reach an optimal level of performance. Practice in self-assessment helps students reflect on their own performance using relevant criteria and analyze strengths and weaknesses, becoming more critical toward their own role in outcomes.

III. Factors Affecting Self Assessment

Much of the literature on student self assessment has over emphasised the agreement of self awarded ratings and ratings awarded by the professor overlooking the value of self assessment as a learning tool. Orsmond, Merry and Reiling, [8] stress the importance of student development during all stages of the assessment process and Tan [9] argues that in classroom practice, professor-student mark agreement should be de-emphasised, and research should concentrate on the process and its outcomes that are experienced by the academics and their students.

In an extensive survey of research studies [10] on the impact of self and peer assessment in secondary schools, the following factors were found to have an impact.

- teacher attitude
- weaning away from dependence on other opinions, teachers included
- student involvement in criteria setting.

The professor, in this new paradigm, needs to be committed to learners having control over the process, and to be able to discuss learning and develop effective feedback. Also, it was found that this alternative assessment types have a larger impact on student outcomes when there is a move from a dependant towards an interdependent relationship between teacher and students. Finally, in situations where the students become "co-designers" of the criteria for evaluation, it seems to help them develop a better understanding of their own strengths and weaknesses. Oscarson [11] mentions six advantages of using self-assessment

- promotion of learning
- raised level of awareness,
- improved goal orientation,
- expansion of range of assessment,
- shared assessment burden
- and beneficial post-course effects.

Blue [12] identifies benefits such as encouraging greater effort, boosting self -confidence and facilitating awareness of distinctions between competence and performance as well as self awareness of learning strengths and weaknesses. Being motivated by the advantages of implementing self assessment, our research group has set up an ongoing project which intends to implement this assessment process.

IV. The Context

With an expected increase in workforce mobility, the need for engineers and architects to acquire communicative language skills is paramount [13]. These skills include not only formal linguistic goals such as improved pronunciation, better command of vocabulary etc. but also social and cultural language skills, as well as the ability to use different compensatory communicative strategies (like paraphrasing) when linguistic means are inadequate. Students are arriving at the university with varied levels of English language achievement. The European language reference framework (CEFR) [14] divides language achievement into 6 levels; A1 level is the most basic level and C2 the most advanced being equivalent to a bilingual capacity. A total of 232 from the schools of Architecture, Technical Architecture, Technical Aeronautical Engineering, Agricultural Engineering, Civil Engineering, Technical Mining Engineering, and Mining took the placement exam. Fig. 1 shows total distribution for level according to the CEFR.

	A1	A2	B1	B2	C1	C2
%	1	25	47	22	5	1
N	2	59	110	50	11	2

Figure 1. Percentage results of Oxford placement test

If we assume that the total levels are representative of the student body a near 77% are below the B2 level. The Chancellor of the university and his team have decided that all engineering and architecture graduates of the Technical University of Madrid must have at least a B2 level upon leaving the university. This requirement has been put into place in view of the European Space of Higher Education for student mobility and future job requirements. Hence it is paramount that the teaching staff and the students make an effort to improve their communication skills in English. Much work needs to be done with 73% of the student body falling below the B2 level..

The research group consisting of Technical English teaching staff and researchers from the above mentioned schools are making an attempt to move towards this goal. The wide range of teaching content areas included in the research group motivated us to develop a language portfolio which includes competence descriptors, i.e. learning outcomes covering all skills, which serve as criteria for the different genres taught. These learning outcomes will be used in curriculum design and for defining specific course objectives. The Academic and Professional English Language Portfolio (ACPEL) portfolio serves two major assessment purposes. The detailed list of language competencies can be used for student self assessment, to guide them through their learning process, to identify and set goals and to assess their learning progressively, inside and outside the educational framework, thus promoting self directed learning

A second rationale for developing the portfolio was to provide an interface between language learning, teaching and assessment. Learning outcomes can be a pedagogical resource for professors to determine the key purposes of the course and a practical tool for students to take control of their learning processes under the professor's guidance. Students do not become self-directed learners instantaneously; rather they need opportunities as well as clear directions and careful planning in many instances. The development process underwent several stages. Existing curricular programmes throughout the different schools of engineering and architecture were analyzed to determine the genres (both academic and professional) and criteria were set up for skill areas as well as genres. Five sets of 50 to 85 specific learning outcomes were developed and researched with the students for clarity and calibration, corresponding to the five categories: spoken production and interaction; written production and interaction; reception-spoken; reception-written; and working with oral and written texts [15] [16] [17]. After three years of development, piloting

TABLE I. SELF ASSESSMENT GRID (ADAPTED [14]

SKILL	B1* LEVEL OF REFERENCE	B2* LEVEL OF REFERENCE	C1* LEVEL OF REFERENCE
SPOKEN PRODUCTION AND INTERACTION	1 can connect phrases in a simple way in order to describe experiences and events. 1 can orally summarize a short experiment or a simple article in my field.	I can present clear, detailed descriptions on a wide range of subjects related to my field of interest. I can explain a viewpoint on a topical issue giving the advantages and disadvantages of various options.	I can present clear, detailed descriptions of complex subjects integrating sub-themes, developing particular points and rounding off with an appropriate conclusion.
WRITTEN PRODUCTION AND INTERACTION	1 can write simple connected text on topics which are familiar or of personal interest. 1 can write personal letters describing experiences and impressions. I can write brief reports of experiments and summarize articles.	I can write clear, detailed text on a wide range of subjects related to my interests. I can write an essay or report, in support of or against a particular point of view, and write letters highlighting the personal significance of events and experiences.	I can write clear, well structured text, expressing points of view at some length. I can write about complex subjects in a letter, an essay or a report. I can select style appropriate to the reader in mind.
RECEPTION / SPOKEN	1 can understand the main points of clear standard speech on familiar matters regularly encountered in work, school, leisure, etc. 1 can understand the main point of lectures or current affairs when the delivery is relatively slow and clear.	I can understand extended speech and lectures and follow even complex lines of argument provided the topic is reasonably familiar. I can understand most TV news and current affairs programmes, the majority of films in standard dialect.	I can understand extended speech even when it is not clearly structured and when relationships are only implied and not signalled explicitly. I can understand TV programmes and films without too much effort.
RECEPTION / WRITTEN	1 can understand texts that consist mainly of high frequency everyday or job-related language. 1 can understand articles in my field.	I can read articles and reports concerned with contemporary problems in which the writers adopt particular attitudes or viewpoints. I can understand contemporary prose.	I can understand long and complex factual texts, appreciating distinctions of style. I can understand specialised articles and longer technical instructions, even when they do not relate to my field.

and testing, writing and rewriting, the Academic and Professional English Language Portfolio (ACPEL)[18] was validated by the Council of Europe. The goal of this current study is to train students as well as academics in the area of alternative assessment procedures especially self assessment using the criteria set out in the portfolio.

V. THE PROJECT

The overall question to be addressed is "How does the implementation of peer and self assessment impact on students and academics in engineering education at the Technical University of Madrid?" In order to compare the impact of the implementation of self and peer assessment, the current assessment and evaluation procedures needed to be analyzed. To acquire this information, two procedures were carried out.

First, at the end of academic year 2008-2009 students were asked to fill out a questionnaire on their impressions of the different aspects of the course and professors wrote a report on methodology and evaluation procedures used up to this point. Table 2 shows types of evaluation used in the different schools. There seems to be a strong correlation between the number of students in the course and the number of different types of evaluation procedures. Small classes need fewer evaluation procedures, though more holistic (e.g. an oral presentation), while larger classes depend on more types of evaluation, (shorter and more frequent).

As to the student reactions to the course and the evaluation procedures, the results were important so as to get a profile of the students and the course content in the different schools. Various blocks of evaluation were included in the questionnaire: genres taught in the course (8 types), learning activities, assessment method, hours dedicated to the course, satisfaction and global learning competences.

TABLE II. MOST VALUED GENRES FOR EACH COURSE

Genres and competences	Tech. Mining	Tech. Aeron	Tech, Agric	Mining	Agricul	Civil	Architec
oral presentations	3	3					
reading skills	2	2	1	2		1	
summary writing			2	1		2	3
report writing	1		3	3	2		
Curriculum vitae					3		1
letter writing					1		2
e-mail composition		1				3	

We shall concentrate here on the students' evaluations of the genres, global learning and satisfaction. The eight genres included in the questionnaire were the following: oral presentations, research skills in internet, reading skills, summary writing, report writing, curriculum vitae, letter writing, and e-mail composition.

Table II demonstrates the results of the student evaluations for the genres and competences included in the questionnaire. The students were asked to evaluate their learning in following genres and competences on a 5 level Likert scale from "very low" to "very high". The three most valued for each course/school are included with 1 depicting the most valued. These results have set the basis for the course assignments that are being included in the self and peer assessment.

TABLE III. ASSESSMENT AND EVALUATION PROCEDURES

	Tech. Mining	Tech. Aeron	Tech. Agric	Mining	Agricul	Civil	Architec
oral presentation	x	x					
attendance & participation	x	x	x	x	x		
project work		x	x		x	x	x
exercises							x
final exam	x		x	x			x
continuous evaluation	x		x	x		x	
periodic quizzes	x			x		x	

Other information important to the study was also gathered in the questionnaire. The students were asked to evaluate how satisfied they were about their language learning from "very low" to "very high". Another question posed to the students was "How do you evaluate the amount of learning in the course?". Finally, we asked to students to appraise the amount of information supplied to them about the grading and evaluation system utilized by the professor in the course. None of the students choose "very low" on any of questions hence this alternative has been removed from the graph for more clarity. Fig. 2 shows that the level of satisfaction of the students learning to be quite high with nearly 80 percent marking "high" or "very high". We can see that their opinion of the amount of learning is high but substantially less than satisfaction about their language learning. A surprising 97 % of the students considered the amount of information to on the methods of evaluation "high" or "very high".

	low	average	high	very high
Satisfaction	2%	32%	55%	11%
Learning	1%	20%	57%	22%
Evaluation	0%	3%	49%	48%

Figure 2. Results of student questionnaire

VI. THE ONGOING PROJECT

Well designed self-assessment procedures that present students with explicit criteria, that provide for student involvement in assessment decision-making, that elicit student opinions about their performance, that base student goal setting on achievable targets, are the keys for enhancing student learning. Fig. 3 highlights the processes involved in self and peer assessment and how it affects student performance. One can see that the learner is at the centre of the assessment and the learning process being affected by many factors. Goals, effort, performance, self-judgment, and self-reaction all can combine to impact self-confidence in a positive way. However, a negative cycle can develop if there are significant gaps between the different factors and learners tend to perceive themselves as unsuccessful performers. Professors must be involved in the process of training students to assess effectively. The goals of our ongoing research and the practical model and ideas that follow are aimed at assisting professors with this important work.

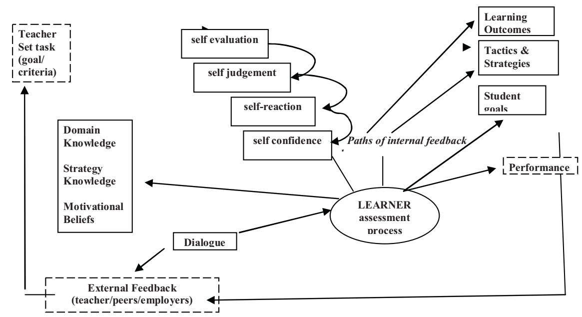

Figure 3. Process of learning through assessment

The procedures being followed by the members of the project are numerous. Once the professors were informed and trained in a 4 hour workshop, each professor has involved their students in defining the criteria that will be used to assess their work with the help of the learning outcomes descriptors from the portfolio. Table IV is a small selection of can do language descriptors currently being used for self and peer assessment in the Technical school of Aeronautical Engineering. In addition to increasing student commitment to instructional goals, negotiating criteria and learning outcomes enables professors to help students set goals that are specific, immediate, and moderately difficult, characteristics that contribute to greater learning.

TABLE IV. SELECTION OF CAN DO STATEMENTS

A2	Can give a short, rehearsed presentation on a familiar academic or professional topic, being aware of the use of body language to transmit information.
B1	can structure a simple talk in a comprehensible way, indicating the beginning and end of each section, using cohesive devices and present it clearly, speaking from notes or visual aids (e.g. outlines, diagrams, charts, etc.)
B2	Can give a clear, prepared presentation, discussing the advantages and disadvantages of various options or solutions to a problem, using cautious language and modality.
C1	Can attract the attention of the audience using appropriate presentation strategies e.g. intonational clues, voice volume, etc.

Once the criteria have been established, students can then apply the criteria to the examples of the genres dealt with in the course. These models or examples help students understand specifically what the criteria mean. Templates can also be used to provide lower level students with guidelines for improving their learning cycle. Once the criteria are clear the students develop an assignment and apply the criteria to their own work. The next step in the process is to apply the criteria to peer work. This can be done in a cooperative learning environment, such as group work. At this point, the professors will provide feedback on the self and peer evaluations. Discussion regarding differences can follow and perhaps adjustments are needed. An important part of the process can be the support provided to the students in setting up their goals and developing strategies to achieve them.

VII. CONCLUSIONS

Self assessment is a process where students are involved in and are responsible for assessing their own piece of work. It encourages students to become independent learners and can increase their motivation. Peer assessment is where students are involved in the assessment of the work of other students. Research evidence, outside of the field of language learning, report that students experience increased self -esteem, increased engagement with learning, especially goal setting, clarifying objectives, taking responsibility for learning, and/or increased confidence. Assessment is acknowledged as a major influence on student learning. Thus, all assessment activities need to be examined from the point of the view of what they contribute to prompting student learning which should be the intended outcome from the course. Assessment needs to be demystified to allow students to become confident enough to use it as well as make connections between assessment activities and learning. Since students will inevitable have to make their own assessments in the real world, ample opportunities should be offered to practice this skill.

ACKNOWLEDGMENT

The authors thank all the teaching staff participating in this study for their dedication both to the project and to innovative assessment procedures.

Abstract— **A special session is proposed to present the current status of OpenCourseWare Consortium from different viewpoints: from the OCWC Board of Directors's view, UNIVERSIA as leader of a regional OCW consortium, and best practices of other universities.**

Keywords: open educational resources, ocw

I. Introduction

Global educational systems are unable to meet current needs. Systems of primary, secondary and higher education around the world are struggling to find the resources and trained educators required to meet the demands for education and certification, particularly in the face of rapid population growth and economic development. The current global economic crisis exacerbates these problems through the creation of a displaced labor force in need of retraining at a time when resources supporting educational systems are further diminished.

Technology is an increasingly disruptive force on educational systems, both positively and negatively. The Open Educational Resources (OER) movement is a trend toward the creation of openly-licensed resources including open references such as Wikipedia, open access journals, open educational technologies, open text books, open data sets, open learning object repositories, shared resources such as iLabs and many others. Open educational resources are proliferating in type and number. There is a rapidly increasing number of open educational resources attracting ever-higher levels of use. As of yet, few synergies have emerged between these related but separate undertakings, and as a whole the movement often provides a confusingly kaleidoscopic array of resources and opportunities. The progress and promise of OER, however, both remain substantial. Open educational resource creation and use is becoming a widespread global best practice. The spread of OpenCourseWare publication, open access publication, as well as the use and integration of OER into new materials, are all increasing. Forums such as the UNESCO-OER mailing list are bringing together a global OER community.

The OpenCourseWare (OCW) project, as part of the OER movement, started at the Massachusetts Institute of Technology (MIT), in the year 2001, with the aim of offering pedagogical materials in an open and free of charge basis to society. The mission of the OpenCourseWare Consortium is to advance formal and informal learning through the worldwide sharing and use of free, open, high-quality education materials organized as courses. An OpenCourseWare (OCW) is a free and open digital publication of high quality university-level educational materials – often including syllabi, lecture notes, assignments, and exams – organized as courses. This philosophy is being spread to the world main universities creating the OCW Consortium (OCWC), in which more than 250 universities and associated organizations worldwide committed to advancing OpenCourseWare sharing and its impact on global educational opportunity. The OpenCourseWare Consortium (OCWC) has been formed [4] with the proposal of expanding the reach and impact of opencourseware by encouraging the adoption and adaptation of open educational materials around the world.

II. Focus Areas

Papers of this special session will highlight some of the work related with OCW movement with representation in the following areas:

- The OpenCourseWare Consortium (OCWC) is undergoing a period of rapid growth and organizational development. The number of participating institutions, live OCW sites, and total available courses are all increasing rapidly. The Consortium is straining to develop the organizational structures needed to accommodate this growth. The OpenCourseWare Consortium is just developing as an organization. We will count on the representation of the OCWC Board of Directors of the OCWC to explain how the Consortium faces the dual challenges of developing initiatives to support Consortium goals and developing the systems and infrastructures needed to operate the organization.

- Subconsortia are emerging in increasing numbers around the world. Regional groupings of OpenCourseWare projects are emerging around the globe, bringing large groups of universities into the OpenCourseWare Consortium. UNIVERSIA, one of the greater networks of university cooperation, which merges 1,070 universities and higher education institutions in 11 countries of Latin America, leads the OCW UNIVERSIA and tries, under the cultural and geographic affinity of the Latin American space, to facilitate the presence of the institutions of higher education of this region in the world-wide OCWC and to promote the open publication of its courses and others educational contents in the languages of our community. The OCW Universia view for our current situation will be presented in this session.
- The consortium helps you create content—more effectively and more efficiently—by providing an environment for the sharing of best practices among our members. Some of these practices developed by other technical insitutions will be presented.

Development of the OCW Consortium

Abstract—**This paper documents the development of the OpenCourseWare Consortium, from the origins of the OCW concept at MIT and that Institute's early commitment to supporting other adopters of the model, to the rapid growth of the community in the period 2004-2007, to the Consortium's incorporation as an independent entity and current activities and status.**

Keywords-OpenCourseWare; open educational resources

I. A NEW MODEL FOR OPEN SHARING

In the year 2000, an MIT faculty committee on lifelong learning made a proposal that was as simple as it was revolutionary. The committee was charged with recommending a strategy for MIT in confronting the growing impact of the Internet on higher education, and in particular, in confronting the emerging field of digitally supported distance learning. After surveying the online education landscape, they saw that distance learning was both difficult to provide profitably and at some level fundamentally at odds with the Institute's mission to disseminate knowledge. Online education—as it was conceived at the beginning of the century—would take the academic riches of the Institute and lock them behind a firewall for only those who could pay.

Instead, the committee proposed, why not use the Internet to give away the academic content at use in MIT's classes? Rather than trying to create entire new programs specifically designed for online delivery, why not take the core academic documents already created at the Institute—the syllabi, lecture notes, assignments and exams handed out in MIT classrooms—and make them widely and freely available on the World Wide Web? Instead of pursuing profit, as was the prevailing model, the committee suggested the goal should be generating global benefits through a philanthropic approach. They further proposed that MIT should share materials not from a select few courses, or from the subjects for which the Institute was best known, but from the entire MIT curriculum, undergraduate and graduate.

In sharing these materials, the committee hoped to provide educators around the world resources they could build upon in creating materials for their own classrooms. They also hoped to provide students everywhere with access to additional resources to supplement the materials they received in their classes. Independent learners, too, might benefit from accessing theses materials to learn for pleasure or to solve professional problems. Rather than online instruction, the committee hoped to provide open resources that would benefit the widest possible population and change the overwhelmingly commercial direction of online higher education.

As sweeping as this vision was, the faculty had a more ambitious idea. They recognized that if MIT undertook such a program, it might provide benefit to hundreds of thousands, maybe millions, but the concept—which they dubbed OpenCourseWare (OCW)—would not fundamentally change education unless it was widely adopted by universities around the world. As they sought funding to start the program, which was quickly provided by the William and Flora Hewlett and Andrew W. Mellon foundations, they proposed that in addition to publishing all of MIT's educational materials, the team assembled would also provide advice and assistance to other schools seeking to publish their materials openly.

It was this commitment that would, in five short years, result in an independent organization with a globally distributed staff that serves the needs of more than 200 universities and affiliates—the OpenCourseWare Consortium.

II. A SHARED MISSION

While the MIT team had been tasked with helping other universities with adopting the OpenCourseWare model, they fully expected it would take several years to prove the effectiveness of the model before OpenCourseWare began to see widespread adoption. The mission of sharing educational materials openly and freely, however, was itself far more resonant that anyone at MIT had expected.

Almost as soon the MIT OpenCourseWare site was launched in 2003—with no advance contact—another OpenCourseWare site appeared on the Web. The Fulbright Economics Teaching Program OpenCourseWare site (http://ocw.fetp.edu.vn/home.cfm) launched in the fall of 2003 as well, with the following reference to MIT's program on the home page:

> *Inspired by the Massachusetts Institute of Technology's OpenCourseWare Initiative (OCW), the Fulbright School has begun to publish its teaching and research materials online. FETP OpenCourseWare is not a long distance learning project, rather it is a resource for people working or studying in policy-related fields to increase their knowledge and explore new approaches to learning and curriculum development.*

Beginning in early 2004, before evaluation of the early stages of MIT's program had been published, MIT began to receive inquiries and invitations to speak from universities in the United States and around the world. During 2004 and into 2005, the MIT OpenCourseWare team spoke with leading universities in Japan and in France, as well as US schools including Johns Hopkins, Notre Dame, Tufts and Utah State University.

The common thread connecting all of this communication was a commitment to the mission of openly sharing educational materials. Tufts University already maintained extensive international partnerships, and OCW was seen as a natural extension of these commitments. Johns Hopkins Bloomberg School of Public Health saw OCW as a powerful new tool they could employ in the service of global health. For Utah State University, OCW enhanced the school's ability to serve the residents of Utah. Notre Dame saw OCW as a way to give global visibility to their specialty in ethics. Even before MIT had solid proof of OCW's effectiveness, these schools were planning OCW programs of their own.

Schools outside the United States demonstrated an equally enthusiastic response to the mission. In 2004, MIT linguistics professor Shigeru Miyagawa, a member of the original faculty committee on lifelong learning, was invited to speak about OpenCourseWare with the presidents of leading Japanese universities. In the span of a few months, this series of meetings would result in the launch of the Japan OCW Consortium (http://www.jocw.jp/), a collaboration of nine top Japanese universities. In early 2005, the MIT OpenCourseWare staff was also contacted by representatives of a group of top French engineering schools, ParisTech, who were interested in launching their own OpenCourseWare initiative. This contact would ultimately bear fruit in the launch of the ParisTech "Graduate School" site (http://graduateschool.paristech.fr/?langue=EN).

III. From Community to Consortium

During 2004 and early 2005, MIT struggled to keep up with this early and unexpected interest in the OpenCourseWare model. MIT's site had received over 4 million visits in its first year, and evidence was quickly being collected demonstrating the effectiveness of the model. This attracted the attention of an even wider group of interested universities around the world, each with its own set of questions about how they might implement an OpenCourseWare site.

In March 2004, the MIT staff produced and launched a "How To" site, providing thousands of pages of documentation detailing MIT's implementation approach for OCW—a resource that would receive more than 23,000 visits before it was finally archived in March 2009. But the MIT staff quickly discovered that these new projects joining the nascent movement often had better advice to offer one another than MIT did.

The MIT program had been implemented at a scale and with a budget far beyond those of the other programs, and MIT's solutions were often a misfit. The MIT staff shifted gears from providing direct advice to facilitating communication between emerging OCW programs. A clear cluster of issues emerged as key challenges to this group of early adopters, including faculty recruitment, technology choices, intellectual property management, and sustainability. As the new programs began implementation, each began to provide leadership in these areas.

Utah State University sent a team of technologists to examine the MIT's technical infrastructure and created a scaled-down open source content management system appropriate to the needs of the emerging OCWs, a system since adopted by scores of other programs. Notre Dame and the schools of the Japan OCW Consortium introduced innovations in the management of intellectual property and licensing. Johns Hopkins developed a unique approach to image management. Tufts University distributed their OCW staff across existing units at the school, embedding the costs of site production across numerous budgets and enhancing program sustainability. The challenge for MIT became how to capture this burst of innovation and share it back with the rest of the community.

The early adopters of the OCW model were joined in 2004 by energetic organizations that began translating OCW materials produced by MIT and others. Universia.net, an IberoAmerican educational portal supported by Banco Santander, began translations of MIT courses into Spanish and Portuguese. The American-based IET Foundation, led by Dr. Fun-Den Wang, established China Open Resources for Education (CORE), an organization tasked with translating course materials from many of the early OCWs into simplified Chinese. These efforts, funded by the translating organizations themselves, were important in bringing OCW to a wider global audience.

By early 2005, it was clear that the MIT staff could not facilitate the volume of discussion generated by the sharing of publishing innovations and coordination with translation partners. A structure was required in order to support more direct exchange of ideas and information. On February 17, 2005, a meeting was held on the MIT campus that brought together representatives of China Open Resources for Education, Japan OCW Consortium, Johns Hopkins Bloomberg School of Public Health, Tufts University, Universia, University of Notre Dame, Utah State University and MIT. At this meeting, the participants agreed the time had come to form an organization to support the production and use of OpenCourseWare materials.

IV. Early Development of the Consortium

At the meeting on MIT's campus in early 2005, participants agreed to hold the first meeting of the OCW Consortium in conjunction with Utah State University's OpenEd conference planned for that fall in Logan Utah. But even this decision created challenges, as the Consortium was not a legal entity and had no staff or budget. As the program with the largest staff and budget, MIT stepped forward to manage the planning of the meeting, and the Hewlett Foundation provided a small line item in MIT's grant to support the Consortium.

At that first formal gathering of the young organization, the members articulated a mission for the organization, "to advance education and empower people worldwide through

OpenCourseWare.” The group further defined a set of goals in support of that mission and decided to create a portal Web site that linked all of the member OpenCourseWare sites and shared best practices to encourage more schools to join. Finally, the members agreed to meet again April 2006 on the campus of Kyoto University.

In collaboration with Kyoto University staff, MIT staff once again supported the planning and execution of the April 2006 meeting, which saw the launch of the OCW Consortium portal (http://ocwconsortium.org). Through 2006, participation in the Consortium continued to grow, with new projects emerging in regions including the United Kingdom, China and Taiwan, Vietnam, South Africa and Venezuela. In all some 70 universities and affiliated organizations were represented by the time the Consortium gathered again in Utah during OpenEd 2006.

MIT had reached the extent of its capacity to manage the Consortium, and the decision was made to hire a full-time executive director to support the activities of the group. The Consortium was still an informal organization, however, and so MIT hired a full-time employee on their OCW staff to serve the Consortium. This staff member catalyzed tremendous growth in global participation during the period 2006 through 2008, managing three additional meetings, overseeing the incorporation of the Consortium as an independent entity, and securing a three-year $1.5 million dollar grant from the Hewlett Foundation to support the organization.

V. Emergence of an Independent Consortium

During the Spring of 2008, in preparation for the formal incorporation if the Consortium, the members elected the organization’s first board of directors. The board met for the first time at the Consortium’s April 2008 meeting in Dalian, China, and included representatives from China, Japan, Korea, Mexico, the Netherlands, Spain, South Africa, the United Kingdom, and the United States. When the formal incorporation papers were signed July 9th, 2008, the Consortium was officially an independent organization under the direction of these community representatives.

In order to ensure the direction of the organization reflected the interests of the full community, the board undertook an organizational planning process in late 2008 and early 2009, resulting in the Consortium’s first formal strategic plan. This plan articulated the vision of this growing body of international universities and their affiliates:

> *We envision a world in which the desire to learn is fully met by the opportunity to do so anywhere in the world, where everyone, everywhere is able to access affordable, educationally and culturally appropriate opportunities to gain whatever knowledge or training they desire. The Consortium acts to realize this vision by addressing one issue—that of access to high-quality educational materials—and by partnering with organizations addressing related problems that must also be solved to make this vision a reality.*

The document also reexamined the previously articulated mission statement, declaring the purpose of the Consortium was “to advance formal and informal learning through the worldwide sharing and use of free, open, high-quality education materials organized as courses.” The document likewise refined the goals of the organization as follows:

1. *Increase the number of members in the OCWC, and the number and diversity of OpenCourseWare courses they make available;*
2. *Enhance the value of OCW courses to all types of users around the world; and to*
3. *Build and nurture a vibrant, culturally diverse global OpenCourseWare community that is connected to the broader OER movement.*

The strategic plan further identified a series of strategic initiatives in support of those goals that provided direction to the small staff..

VI. Serving Producers and Users of OCW

The Consortium today supports emerging OpenCourseWare projects, builds global awareness and use of OpenCourseWare materials, and connects the vibrant OCW community to the education, government and private sectors. More than 200 universities around the world participate in Consortium activities, and collectively they have published materials from an estimated 13,000 courses in more than 20 languages. Volunteers around the world have translated an additional 3,500 courses from their original language.

This vast collection of academic materials provides opportunities to individuals around the world for personal and professional development. It also supplies an infrastructure to governments, NGOs and educational institutions for use in addressing a diverse set of challenges including workforce development, educational system improvements, and public health enhancement. All OCW materials are available through the Consortium’s Web site (http://ocwconsortium.org), and the Consortium staff builds general awareness of OCW through media and outreach.

The OpenCourseWare Consortium has also clarified and diversified its categories of membership to make the organization as inclusive and sustainable as possible. Member categories now include:

- **Institutional members** – the accredited higher education institutions that make up the bulk of the membership and are the primary producers of course materials.
- **Associate consortia** – consortia of universities affiliated by region or common interest, such as the Japan OCW Consortium, which are important coordinating bodies in the community.
- **Associate institutional members** – accredited higher education institutions for which the primary connection is through an associate consortium, and which pay reduced dues and have reduced voting rights for board elections.

- **Affiliates** – organizations that are not accredited higher education institutions but nonetheless further the mission of the Consortium in one or more ways; includes standards groups like Creative Commons and NGOs like Fahamu publishing educational materials.
- **Corporate members** – corporations supporting the OpenCourseWare Consortium and providing services to other members.

In a very brief span of time, the OpenCourseWare Consortium has grown from of a common commitment to serving world educational needs through an innovative model into a global organization supporting a diverse community of OCW users and producers. The Consortium faces the significant challenge of transitioning from grant funding to sustainable sources of revenue including significant member support. To begin the transition, the Consortium introduced membership dues this year of between US$50 and $500 depending on membership category and member region. In a demonstration of commitment to the Consortium, a core group of leading universities and organizations, including most of those described throughout this paper, have each pledged US$5,000 per year in each of the next five years to the Consortium. This statement from across the community indicates the strength of the OCW movement and suggests Consortium will be supporting the production and use of OpenCourseWare materials for many years to come.

***Abstract*—In this paper, we explore the idea of using Peer-to-Peer (P2P) networks as advanced educational tools. A P2P network can disseminate complex learning objects that act as anchors for creating collaborative learning communities. The goal is to create collaborative spaces of learners with similar interests to exchange knowledge, opinions, and experience so that they can learn, understand, and help/teach each other. The use of the P2P technology for disseminating learning objects requires extending current P2P systems with a support for precise indexing and searching. In this way, potential learners can easily find and choose relevant objects. The present paper describes the design of an indexing and searching scheme for disseminating complex mutable SCORM learning objects over BitTorrent.**

***Index Terms*—learning objects; peer-to-peer systems; indexing; DHT**

I. Introduction

In this paper, we explore an idea for future educational tools based on Peer-to-Peer (P2P) networks. Although such networks offer a wide-spread means for disseminating media content, currently they are mostly limited to music and movies. However, a P2P network may also provide easy access to educational resources instead of, or in addition to, standard publishing of course material on Web servers, which often requires considerable management and maintenance effort. In a similar way to video or music files, we can easily disseminate complex *learning objects* in a standard format such as SCORM [1] among interested learners. As P2P networks operate in an autonomous and spontaneous way with minimal management overhead, users can use P2P applications with little or no training.

We have begun to investigate how educational activities can benefit from P2P networks and how we need to enhance current P2P applications for disseminating learning objects. This goal requires addressing the problem of precise indexing and searching so that potential learners can easily find and choose relevant objects. Another idea to explore is to use learning objects as anchors for creating *collaborative learning communities*. Current P2P applications only disseminate content, but users are not aware of who downloads a given file. Knowing that somebody else is interested in a movie or a music file may lead to interesting user interactions such as following the choice of somebody else or establishing collaborative opinions and advices. If we can attach some information about users interested in specific content to files disseminated over P2P networks, we would enable creation of collaborative spaces of users with similar interests. Once such a social network starts, its members can exchange knowledge, opinions, and experience as well as they can extend their activities to learning processes by providing support, explanations, discussions, and even mutual teaching. One interesting feature of such a set up is that collaborative learning communities may enhance the existing content and add more resources to a given course material. Thus, we need to take into account that learning objects become mutable unlike files disseminated in current P2P networks.

The present paper describes the design of an indexing and searching scheme for disseminating complex mutable SCORM learning objects over BitTorrent [2]. Our approach takes advantage of attributes extracted from SCORM objects and of indexing concepts and terms added by the user from a domain ontology. We use OpenDHT [3], an open distributed storage service implemented over Planet Lab [4] to store all needed indexes and associations. We have implemented the proposed schemes in GLEN (Global Lecture Exchange Network), a prototype P2P client based on Azureus (Vuze) [5].

II. Design goals

Our goal is to disseminate learning objects in a P2P network in a way that enables creation of collaborative communities of learners. We recall below the design goals of our system:

- Support wide and easy distribution of learning objects. Extend existing P2P applications for sharing, searching, and downloading learning objects in a fully distributed way without a central server.
- Change the traditional hierarchical teaching model into a flat one in which anybody can teach anybody. Anybody can download any learning object, extend its content, or add a new learning object.
- Create collaborative communities of learners having common interest and objectives based on the access to the same learning objects.
- Use learning objects as anchors for easy interactive communication between learners (e.g. through Voice over IP (VoIP) applications such as Skype or Gizmo). Down-

loading a learning object gives information about other learners that share the same interests.

Based on this set of requirements we have developed several new schemes for structuring, indexing, and searching learning objects. We describe them below.

III. Structure of complex learning objects

We consider learning objects in the SCORM 1.2 format that allows linking various resources and adding descriptions in the LOM format [6]. Popular engines like Blackboard or Moodle can display such learning objects and several editors exist such as eXe [7].

A. BitTorrent and DHT

We have decided to use BitTorrent as the underlying P2P network and enhance a P2P client based on Azureus (Vuze) [5] to support advanced functions of indexing, searching, and retrieving learning objects. BitTorrent disseminates objects through a *torrent* file that contains the information on an object needed for downloading (name, piece length, number of pieces, tracker, etc.). A *tracker* is a HTTP server that keeps information on *peers*—nodes downloading the same object. There are two categories of peers: *seeders* that have already downloaded the whole object and can provide its pieces to *leechers*, the peers that have not yet obtained all the pieces.

To download an object, a peer first downloads a torrent file, computes the SHA1 hash function on its information part, and contacts the tracker to obtain seeders (their IP addresses and ports) that can send the pieces of the object. Then, it queries them to obtain a bitmap of pieces stored at each seeder and requests their download. A leecher also provides already downloaded pieces to other peers.

In the *trackerless* operation of BitTorrent, the information usually maintained by a tracker (peers, their addresses and ports) is stored in the DHT (Distributed Hash Table) organized on peers in a fully distributed way. Even if Azureus only uses the DHT for storing the information usually maintained by a tracker, we explain below the operational principles of the DHT, because we rely on such a distributed storage service for indexing and searching.

Azureus uses a modified Kademlia implementation for its DHT [8] to store $(key, value)$ pairs on different nodes. The DHT interface offers the following operations:

- $Ping$ to verify routes to other peers,
- $Lookup(key)$ to find nodes that are near to the key in the keyspace (nodes are identified by the SHA1 hash of the node IP/port combination),
- $Store(key, value)$ to store the $value$ on the nodes close to the key in the keyspace,
- $Get(key)$ to retrieve the $value$ from the nodes close to the key in the keyspace.

To explain the operation of the DHT, we take an example of storing files in the DHT (other P2P networks such as eDonkey or eMule for example use a DHT to store and retrieve files). A file is identified by a key derived from its filename—a key is a 20 byte SHA1 hash function on a filename: $key = h(filename)$. The DHT maps keys to nodes in the P2P network: the keyspace is the set of 20 byte strings and each node has its place in the keyspace. To store a file, a node first performs the $Lookup(key)$ operation to find nodes that are near to the key and then stores the file as the value of the $Store(key, value)$ operation at 20 nodes close to the key in the keyspace. Retrieving the file proceeds in the inverse way: a node looks up nodes close to a key and gets the file from one of the nodes.

When Azureus operates in the *trackerless* mode, it uses its DHT to only store the *torrent* information on *peers*, then downloading of pieces proceeds in parallel from a large number of peers. The key of the *torrent* information is a 20 byte SHA1 hash function on the descriptor (the information part of a torrent): $key = h(descriptor)$ and the stored value corresponds to the information on the seeders usually maintained by the tracker and necessary for downloading.

B. Learning objects and their structure

We want to design the structure of our learning objects so that they may evolve while they disseminate in a collaborative community: we want to be able to enhance the existing content and add more resources, which results in multiple versions of a learning object. However, existing P2P objects like an MP3 or a video file are immutable, i.e. they cannot be modified once published on a P2P network. Thus, we need to enhance the structure of P2P objects so they can be modified within a collaborative community.

We obtain this goal by associating multiple identifiers with a learning object. The first identifier is called `LOID` (Learning Object Identifier) and multiple versions are identified by a version specific `VSLOID`. Both identifiers follow the same scheme as identifiers in BitTorrent—they are unique 20 byte values generated by computing SHA1 function on the object descriptor. Finally, each version is associated with a *torrent* that allows to download a given learning object.

We need to maintain the associations between the identifiers and an object by storing them in a persistent database. In the spirit of P2P networks, we wanted to use a DHT to store all needed associations as well as the indexing information described below. One choice of a DHT would be to use the Azureus DHT for this purpose, however running an operational service would require upgrading many nodes with our modified version of Azureus, which was difficult to achieve. Instead, we have used an open distributed storage service called OpenDHT, a similar system that presents the same basic DHT interface of the operations $Store(key, value)$ and $Get(key)$. It provides a continuous DHT service over a large number of Planet Lab nodes distributed all over the world.

Our learning objects are thus represented as the following associations of identifiers and stored in OpenDHT as $(key, value)$ pairs (the left part of the association serves as the key and the right part as the value):

```
LOID -> VSLOID
VSLOID -> LOID
```

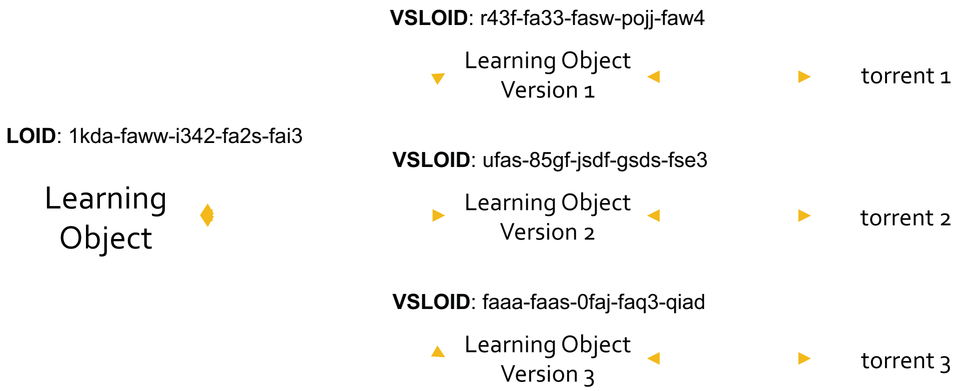

Figure 1. Learning object identifiers.

```
VSLOID -> torrent
```

When we know an identifier of a given learning object, we can retrieve its version identifiers and the torrent information required for downloading. Figure 1 illustrates the notions of `LOID`, `VSLOID`, and their relationships.

IV. Metadata and Domain Ontology

We propose to enable precise searching through the use of *metadata* extracted from a learning object such as traditional attributes Author, Title, Description, and others defined for instance in the Dublin Core [9]. Metadata also includes *concepts* from a domain ontology defined for a given class of learning objects. A domain ontology is a network of domain model concepts (topics, knowledge elements) that defines the elements and the semantic relationships between them [10].

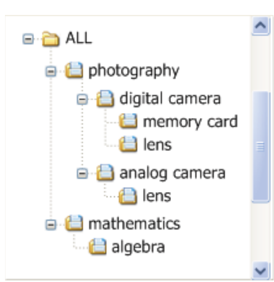

Figure 2. Example of a domain ontology.

Figure 2 presents an example of a predefined ontology with simple inheritance relationships created in the RDF format [11] and built-in in our modified Azureus client. The ontology forms a tree of concepts and terms from the most general one to more specific concepts and terms. For instance, we have the concept of `digital camera` that belongs to the concept of `photography` or `algebra` belonging to `mathematics`. The advantage of using such an ontology is that we can add more general concepts to indexing terms and use them as querying criteria to find related objects. We can obtain an opposite effect for terms that have several meanings—we can distinguish between them by specifying a more general parent concept (such as `lens` for `digital camera`) to restrict a query to more specific and precise results.

Indexing consists of creating an inverted index that associates metadata information with a given `VSLOID` representing a learning object. We use attributes from the SCORM description (Dublin Core) or the LOM part of the object, for instance attributes like `Title: Digital Photography Tips`, `Author: John Smith`. The example attributes are stored in the inverted index as the following relationships:

```
Title_Digital -> VSLOID
Title_Photography -> VSLOID
Title_Tips -> VSLOID
Author_John -> VSLOID
Author_Smith -> VSLOID
```

Similarly to maintaining the structure of a learning object, we store the inverted index in OpenDHT as $(key, value)$ pairs. In the example above, the first association is for instance stored as $key =$ `Title_Digital` and $value =$ `VSLOID`.

When indexing an object, the user can also add indexing terms from the domain ontology. We encode ontology terms by concatenating `ONT` prefix to a term or a concept. Thus, the association has the following form in the DHT:

```
ONT_<TERM> -> VSLOID
```

For instance, when indexing a course on digital photography, the author chooses the concept of `lens` to describe the learning object, we also add more general concepts from the domain ontology—the parent relation between `digital camera` and `photography`. Thus, the following indexes are

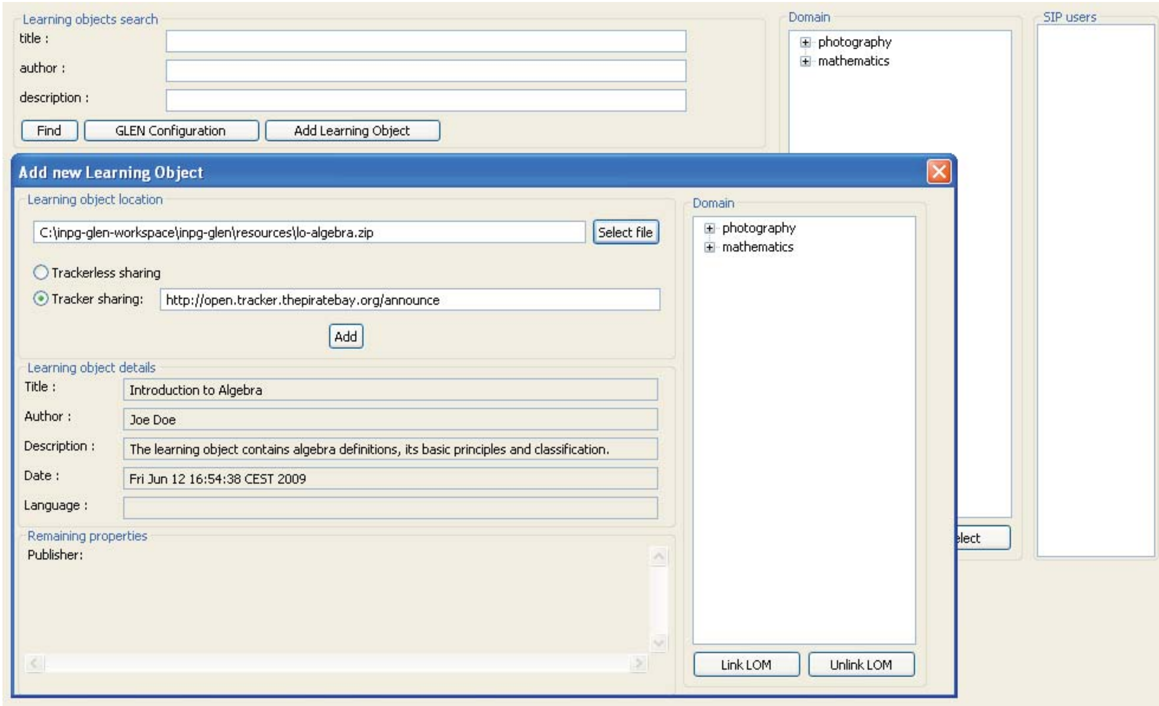

Figure 3. Indexing interface of GLEN.

stored in the DHT:

```
ONT_lens -> VSLOID
ONT_digital-camera -> VSLOID
ONT_photography -> VSLOID
```

Using the ontology for indexing enables for instance finding the course relevant to digital photography even if the user specifies `lens` as the searching term.

Finally, we add support for creating communities by associating the information of VoIP addresses with a given learning object. In this way, those who download a given object can contact other learners in an easy way via VoIP communication. We store the object identifier with the `COM` prefix and the SIP address of the user as the following association in the DHT:

```
COM_'VSLOID' -> SIP-ID
```

When the user finds and downloads an object, we need to present its metadata information to the user. For this goal, we store direct indexes in the DHT—they have the following form in our example:

```
VSLOID -> Title_Digital
VSLOID -> Title_Photography
VSLOID -> Title_Tips
VSLOID -> Author_John
VSLOID -> Author_Smith
VSLOID -> ONT_lens
VSLOID -> ONT_digital-camera
VSLOID -> ONT_photography
```

V. Implementation

We have developed GLEN (Global Lecture Exchange Network), a prototype of a P2P client based on Azureus (Vuze) [5]. We have extended the Azureus interface to offer the function of adding a learning object and searching the network. The indexing and searching schemes presented above use the DHT functionality of OpenDHT. In the current version, we use a tracker for downloading and we work on the development of the trackless version.

To present the possibilities of the prototype, we illustrate its main features. Figure 3 shows the window for adding a new learning object. The user publishes the object in the SCORM format and the most important semantic attributes are extracted from the object. Then, the user can add terms and concepts from the domain ontology (on the right of the figure) with the two main built-in concepts for testing purposes: `photography` and `mathematics`. GLEN stores the indexing information in OpenDHT as described previously and offers a searching interface to the user.

The user can specify search attributes such as title, author, or description keywords, and choose a concept from the domain ontology. The parent terms of the concept are automatically added and the system queries OpenDHT to find relevant `VSLOID`s.

Figure 4 presents the searching interface in which the user specifies `Author: joe`. GLEN retrieves `VSLOID`s linked to the attribute and lists the learning objects relevant to the query (in our example there is only one relevant object—`Introduction to Algebra`). When the user clicks on the title, more details are shown and user can decide to

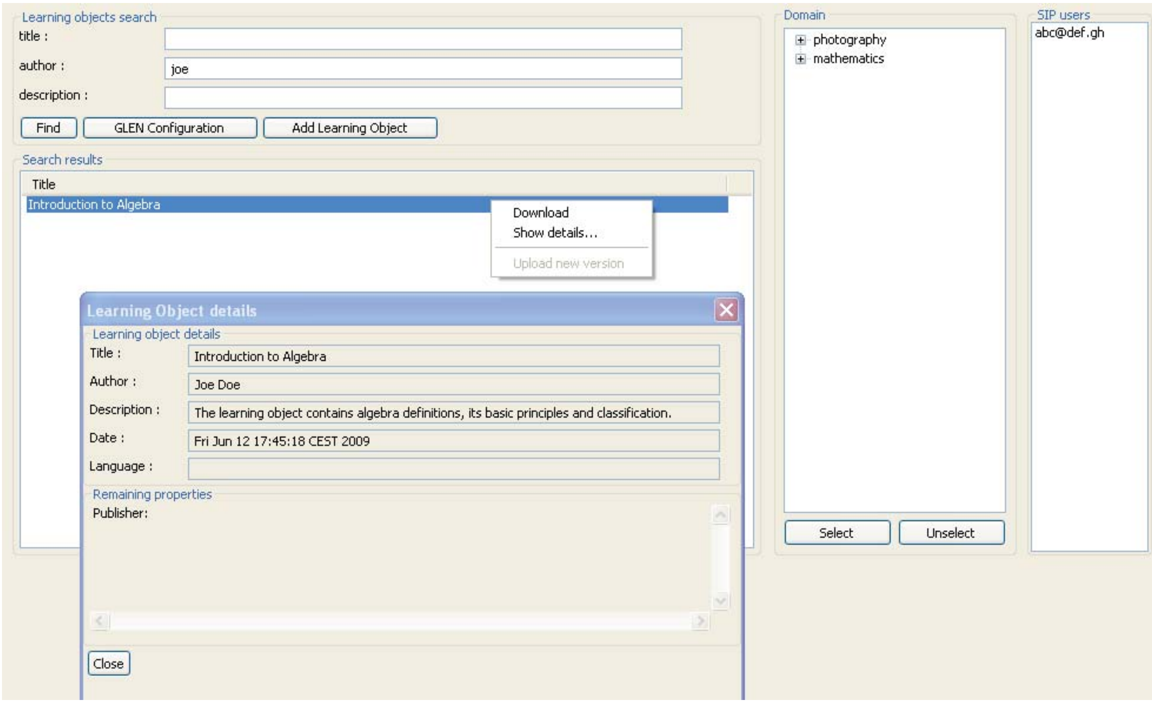

Figure 4. Searching interface of GLEN.

download the object. Its SIP address is stored in OpenDHT and she becomes the member of the community related to the object.

VI. Related work

Some work has already pointed out the importance of applying P2P technologies to education. Edutella has proposed a peer-to-peer architecture for exchanging RDF-based metadata [12]. It builds upon Semantic Web techniques and the JXTA middleware. Its purpose is to make the reuse of globally distributed learning resources easier. Berman and Annexstein has considered P2P technologies as crucial in future educational systems [13]. In particular, they propose to integrate them in a new *personal knowledge management* paradigm, which is useful for students and educators in many activities encountered in everyday teaching, researching, and learning.

Much work considered indexing schemes for P2P networks and we mention here only a few proposals. Felber et al. describe techniques for indexing data in P2P networks based on hierarchically organized multiple indexes and distributed across the nodes of the network [14]. They present several interesting properties, but require a profound modification in the DHT operation of existing systems. Our design attempted to reuse the existing DHT structure for indexing and searching learning objects. Semantic Overlay Networks (SON) represent another approach to searching in P2P networks: nodes connect to other nodes with similar content so that queries can be propagated to appropriate semantically related nodes [15].

Although DHT networks that we used in our indexing scheme offer efficient access to searched items, they can not effectively support partial-match or approximate (proximity) queries. Cohen et al. proposed a design based on unstructured architectures such as Gnutella and FastTrack with the support for partial match queries and relative resilience to peer failures while obtaining orders of magnitude improvement in the efficiency of locating rare items [16].

VII. Conclusion

In this paper, we have presented an approach to enhance current advanced educational tools. Our idea is to take advantage of widely-spread and adopted P2P networks for disseminating learning objects. We consider them as an ideal means for creating collaborative communities of learners with similar interests.

We have described a scheme for indexing and searching complex mutable SCORM learning objects over the P2P network of BitTorrent. We use OpenDHT, an open distributed storage service implemented over Planet Lab to store all needed associations: links between a learning object, its versions, and a torrent, as well as inverted indexes and the information on SIP addresses of community members. Our indexing scheme extends traditional attribute-based approaches with precise indexing terms from a domain ontology. We have enhanced Azureus, an open source BitTorrent client with our indexing support and added a searching interface. Our first experiences with the prototype show that the indexing functionalities contribute to improved searching. We continue to test the support for creating collaborative communities and providing easy VoIP communication between its members.

Public Displays and Mobile Devices in an Augmented Objects Framework for Ubiquitous Learning

Rui Neves Madeira
DSI/ESTSetúbal
Instituto Politécnico Setúbal
Setúbal, Portugal
rmadeira@est.ips.pt

Abstract— **We are facing promising developments in the area of mobile services where context-aware systems can take the location and position of a user, her preferences and 'smart' objects into account, adding (implicit) interaction between a mobile device (of the user) and the real world. The assimilation of ubiquitous computing by education marks an important step forward, as being pervasive and persistent it allows students to access education calmly, flexibly, and seamlessly. This paper focus on a framework proposal with a well contained and defined application goal in Ubiquitous Computing and a prototype directed for Ubiquitous Learning environments. This system can augment physical objects in an educational environment with additional multimedia information, which is displayed in public shared displays according to the user (student or teacher) that faces the system. The information is contextual, based not only in the object, but also in its specific location, in the environment and in the detected user profile. A generic architecture was designed to help on the implementation of this augmented objects framework in any physical space.**

Keywords- Ubiquitous framework, Mobile devices, Public displays, Augmented objects, Bluetooth, Ubiquitous learning context

I. INTRODUCTION

Ubiquitous Computing (UbiComp) has the main goal of building computing systems that support and facilitate the daily lives of users, but being the least intrusive possible.In 1991, Mark Weiser wrote the article "The Computer for the 21st Century" [1], which outlined his vision for UbiComp, based on the creation of environments saturated with computing and communication facilities, with a smooth and unobtrusive integration. Nowadays, mobile devices, particularly the handheld ones like mobile phones, PDA's and smart phones, are essential tools for our daily living. We are facing promising developments in the area of mobile services where context-aware systems can take the location of a user, her preferences and real objects into account, and add interaction between the user, with a mobile device, and the 'real world'.

The assimilation of UbiComp by education marks an important step forward, as being pervasive and persistent it allows students to access education calmly, flexibly, and seamlessly. The integration of adaptive learning with UbiComp and Ubiquitous Learning (u-learning) offers great innovation in the learning process, allowing its personalisation and customisation to student needs. The term mobile learning is frequently used to refer to the use of handheld mobile devices that enable the learner to be 'on the move', providing anytime anywhere access for learning [2]. With the move of computation into the physical environments in which we live and interact, mobile and ubiquitous computing also provide the opportunity to enhance and support learning in more ways than the 'anywhere, anytime' conception, moving into the u-learning concept. One major opportunity is the facility to digitally augment the 'real world' by linking digital information with physical objects or the environment. Information can be displayed in different ways, e.g., it can be serendipitously 'pinged' through a user passive interaction by using embedded sensor technology and according to various conditions in the learning environment, or it can even be requested with an active interaction by a learner [3].

Following these concepts, this paper introduces a framework proposal and a system based on recognized technologies and directed for u-learning environments. The developed prototype, u-learnEST, is designed for user interaction with situated public displays using mobile devices. This system augments the physical objects, in a learning environment, with additional digital information. It displays information according to the user (student or teacher) that interacts with the system. The information that augments an object is contextual, based not only in the object, but also in its specific location, in the physical space and in the profile of the detected user. A generic supporting architecture is also presented as it was designed to make possible the implementation of this computing framework in any physical space. The implementation of the system u-learnEST was made at the installations of ESTSetúbal (Polytechnic Institute of Setúbal), for an engineering course, although the same concepts could be applied to other places. The main idea was to convert the laboratories of a specific course into big objects 'visited' by multiple users, automatically augmenting them with additional information every time a user is detected in its area. An instance of the system is composed by a situated public display, by a sensor server to manage detections, presentations and communications, and by the mobile devices of the users.

This paper is organized as follows. Section II presents a set of systems with points in common with our project. The requirements and guiding principles for the supporting framework are described in Section III. Section IV is dedicated to the presentation of the supporting framework, highlighting the generic architecture. Section V is dedicated to the implementation of the prototype u-learnEST, with relevance to the architecture instantiation issues and used technologies. Finally, in Section VI, conclusions are made and future work is presented.

II. RELATED WORK

This section presents projects that have application issues, principles and/or applied technologies in common with the present work.

In [4], we presented for the first time a computational framework that would integrate interactions between mobile devices and large displays. The framework was in an initial phase, but led to the present work. Moreover, the divingForPearls prototype [5] is centered on activities distributed by objects/public displays in a museum kind of scenario. Based on ambient information systems [18], the museum's system should be the least intrusive as possible, not distracting the user from the activity considered normal.

We are working on another project, UbiSmartWheel [6], that is also based on the same supporting framework. It is a pervasive biomedical assistive environment for the elderly, with a wheelchair as the smart augmented object, having embedded sensors, an RFID reader and a touch-panel interface. Additionally, interactions with large displays are being integrated in the environment of the application.

ActivitySpot [7] is an interesting framework with relevant points to the present work. It is used to support located activities by occasional visitors of the application spaces. Users are directed to actively interact with the implemented system by personal handheld mobile devices, public displays, and other additional technologies, such as, RFID, Bluetooth or cameras. Therefore, each visitor must be registered as a user with a personal profile. Depending on the action, the system response can be personalized as, for example, presenting information in a display targeted to the user profile.

Rememberer [8], which is based on the Cooltown project [9], works as a tool to capture personal experiences while visiting a museum. The system allows the construction of a record of the visit and may be accessed during or after it. The record is composed by web pages about the visited exhibitions, including annotations and photographs taken during the visit. In the exhibitions, cameras have been installed to take sequences of photographs every time a user requests it making gestures. Initial tests were carried out with RFID technology, with passive tags, as cards or embedded in watches, to indicate that a visit would be to register. Alternatively, PDAs with Wi-Fi communication were also used.

A different project to consider is GroupCast [10] that uses infrared badges to detect audience and present content in a public display to start or enhance conversations between individuals or groups. The correct content is automatically selected according to previous profiles and preferences, defined for each user in the area where the system is implemented. On the other hand, BluScreen [11] uses Bluetooth-enabled mobile devices to influence a public display by detecting the audience around it. Users influence the content of a public display only by their detection, thus having a passive interaction with the system. BluScreen seeks to maximize exposure to the current audience as opposed to matching content to known interests, like GroupCast. The user's passive interaction with the screen (such as stopping in the zone to view the contents) is co-opted to incidentally provide feedback and thereby change the content a user receives in the future.

The DiABlu project is also based on Bluetooth technology and Bluetooth-enabled personal mobile devices [12]. It has the goal of developing a computational framework for the detection of people in an environment. In function of the detection type, there can be created several answers in the form of arts applications. The framework is divided in 3 modules: the server that manages the detections, the Bluetooth-enabled mobile device client, and the final application that receives messages from the server. There is an alternative scenario that allows active interactions between the server and Java-enabled mobile devices.

It is also interesting to focus on projects supporting learning application goals. One of them is the SHAPE project that has the aims: to enhance the conceptual understanding of how to undertake design of computing in public spaces; and to create exemplars for how new computing can be used to augment educational and social interaction in public environments, specifically galleries and museums [13]. A part of the project is used to simulate an archaeology dig, where the aim is to enhance children's collaborative learning in museums, through supporting sensorial experience and capturing embodied knowledge, and using a combination of WebCam shape detection and RFID sensing technology.

One emerging concept of digitally augmented classroom environments is that of 'embedded phenomena', where the augmentation is designed to enable learners to experience various scientific phenomena in the classroom, like in RoomQuake [14]. It implements a classroom embedded with a combination of sensor technologies and physical artifacts used to simulate scientific earthquakes. Pocket PCs served to provide dynamic readings of the simulated earthquakes, which students had to then re-represent as physical models using the physical artifacts.

In the Ambient Wood project [3], a playful learning experience was developed where children could explore and reflect upon a physical environment that had been augmented with a medley of digital abstractions. These were represented in a number of ambient ways, designed to provoke children to stop, wonder and learn when moving through and interacting with aspects of the physical environment. A variety of devices and multimodal displays were used to trigger and present the added digital information, sometimes caused by the children's automatic exploratory movements, and at other times determined by their intentional actions.

UNIWAP [15] is a mobile learning project designed to assist in teacher training. The project used relatively simple technologies, short message service (SMS) and digital pictures, to enable students to create digital portfolios in a central database built from materials created in the field. Messaging was used to enable the trainees, who were widely distributed when training in different schools, to collaborate with each other and share their experiences. Feedback from the participants showed that the immediacy provided by the mobile devices was an important factor. Messages and pictures could be shared immediately with other students. The supervisors benefited from being able to access the material generated by the students in the shared database while travelling between work placements.

Finally, The Augmented Knight's Castle project bases its infrastructure in RFID technology, pointing the pervasive augmentation to a Playmobil playset named "Knight's Empire Castle" [16]. The scenario of the game is educationally enriched and augmented by music, sound effects and verbal comments made by pieces that react to the moves executed by the players. Therefore, they don't use displays with additional information. Some pieces of the set were chosen as the actors of the augmented scenario and were marked with RFID tags. Additionally, it integrates mobile devices equipped with RFID readers for the users' active interaction with the game.

III. REQUIREMENTS AND GUIDING PRINCIPLES

In this section, we identify and describe main requirements and guiding principles for a proper specification of the desired supporting framework for systems like the proposed.

Although, initially, we didn't have the concern to implement ambient information systems, we think that the framework should be directed to follow, as much as possible, the requirements and features of these systems. The other principles are natural options to what was pretended, being adopted as core guidelines in the orientation process of defining the pretended systems.

The framework definition is based on the detection of persons involved in their everyday life activities, which have passive interactions that might be considered incidental with the augmented objects. In a first scenario of application, the basic aim is to ensure that only the detection of the user's co-presence near the object will activate the presentation of additional contextual information in a public display. There is a one to one relationship between an object, or part of it, and a public display. An object can be considered a physical, inanimate and easily viewed entity, or can even be considered as an institution or another user with activity in the environment of the application. In any of these cases, we are augmenting objects by providing embedded contextual information, not available by just looking at them.

The framework should take into account a second level of interaction. Though triggered by a passive interaction, even "incidental", coming from the co-presence of the user in the environment, there can be an active interaction with the object/display pair, using for this purpose ordinary personal handheld mobile devices. These devices also allow the provision of additional information in a private mode.

Fig. 1 shows a generic scenario of application where a user interacts with smart objects that are augmented, mainly, through a public situated display. The guiding principles are followed in a kind of scenario where the present work application is inserted.

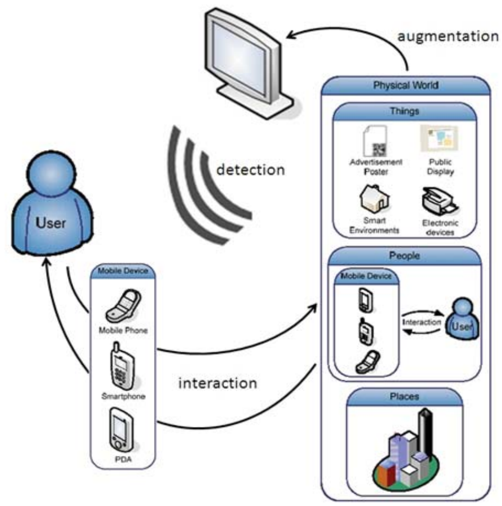

Figure 1. Generic scenario: user detection, object visual augmentation and active interaction between user and object (adapted from [17]).

A. *Principles*

After the definition of the main requirements, the guiding principles are clearly described as follows:

- Ambient Information System Concept

Considered a sub-domain of Ubicomp, the concept of Ambient Information System (AIS) has the main goal of presenting information through smooth and integrated changes in the environment, allowing that users are not distracted from their regular tasks, but being able to receive and be aware of not critical additional information. Being this a recent research area, there is still no commonly accepted definition for these systems, but Pousman et al. [18] attempted to unify the various existing terms, proposing the name used here and setting the following main features: 1) Show important, but not critical, information; 2) Getting attention from the periphery to the centre, and vice versa; 3) Aesthetically pleasing and environmentally appropriate integration; 4) Presentation of subtle changes to reflect updates in information (not to be focus of distraction); and 5) Preference for the use of existing resources in the environment for information presentation.

- Incidental Interactions with Co-Presence Notion

The notion of "incidental interactions" was proposed by Alan Dix to describe actions that are co-opted by a system to serve a purpose other than the one initially thought [19]. An incidental interaction can be seen as a situation where actions executed for another purpose (or unconscious signals) are interpreted in order to improve future interactions in everyday life. This notion is important for the present work, since the framework should start with the user interaction with an object to automatically augment it, without an obvious additional effort by the user.

It should be noted that incidentally does not imply that an action, or the subsequent goal, is not intentional. The user may have previously specified to the system its intention not needing to think consciously while performing the corresponding actions. Incidental interactions also differ in terms of feedback received by users. In a traditional application, the feedback received by the user about its actions will be direct, explicit. However, in an interaction called incidental, this feedback may be, in many cases, minimal, discrete and even delayed. Related with these interactions is the detection of persons that allow the computation of co-presence to be embodied within the real–world. The embodiment means that through normal real-world interactions, a user automatically participates in co-presence systems, without the need of participating in activities outside of his normal daily routine [20]. In a computational system, a technological solution, like RFID or mobile devices, should exist to detect the user co-presence.

- Use of Public Situated Displays

There are two trends, somewhat conflicting, with regard to providing information and services in collaborative environments [21]. The first directs itself to the use of public situated shared displays that can cover a wide audience while the second explores the mobility of small displays on mobile devices to offer more personalized content. Public displays, categorized as "boards" and preferably large, exist in various forms and scales, including, for example, street displays (used mainly for advertisement), projection displays used at conferences and in schools, kiosks, and even small screens next to objects. On the other hand, the second trend is related to mobile devices such as mobile phones, laptops and PDAs, which function not only as input for interactions with systems, but also as displays. These devices offer more personalization options, but the limited computational power and small displays, limit a more dynamic presentation.

Beyond other referred points, since public situated displays offer greater power and a better resolution for the presentation and combination of information, the framework's architecture presents a component that takes into account their integration in a system. In a first approach, the goal is to have the information that augments an object displayed next to it, with the display being a direct extension of the object. Thus, the action to augment the object becomes, initially, contained and dependent on the user approximation, being less intrusive and not forcing the user to take an active interaction. According to their availability and access modality, the framework's displays are categorized as: public, shared, proactive and even interactive [22].

- Ubiquity of Mobile Devices

Nowadays, handheld mobile devices are essential tools for our daily living, being present when interactions between users and objects occur in computational environments. So, they are becoming ubiquitous computational devices, since they find themselves in almost all locations, and are almost universally connectable. In parallel with the evolution of the available functionalities it also increased the diversity and capacity of wireless communication technologies of the devices.

Therefore, the proposed framework should take into account the ubiquity of the mobile devices. Depending on the context and type of physical space for application, the devices may be valuable tools when used for the detection of users. Thus, the space or the objects can feel the co-presence of a user in a natural and non-intrusive way. The user does not need to carry an extra identifier to be recognized in an application scenario. To accomplish this, using personal devices, it is assumed that there is a one to one relation between a user and her personal mobile device. An object/display pair can detect the co-presence of a device with the use of, preferably, one short-range wireless communication technology. Moreover, in a complementary option, the devices are used as tools to add to the framework active interactions and more personalized information. Knowing that situated displays are the choice in many Ubicomp systems, others prefer to use the small screens of mobile devices for mobility and personalization flexibility purposes [23].

The framework should enable the object augmentation through the combination of large public situated displays with small private mobile displays.

- Embedded Contextual Information

An environment may contain only one display or even a large number of display devices distributed in the environment and close to respective objects, casually available to environment users. The aim is to provide contextual information at decision points, which are where the objects are placed or exist. This process can be seen, merely, as a simple action of getting more and better information about an object, but also as an aid to make better decisions regarding the activities to be performed in an augmented space.

Therefore, it is considered that augmenting objects through situated displays is to provide additional information integrated, embedded, in the corresponding context. This option does not prevent the mobile devices displays to be used, as they can also be embedded in the context. Following this principle, it is essential to point that the information presentation is made where and when is needed, being as unobtrusive as possible, and with passive interaction [24]. Finally, the information that augments an object is contextual, based on not only in the object, but also in its specific location, in the physical space, or application scenario, and in the profile of the detected user.

IV. THE SUPPORTING FRAMEWORK'S ARCHITECTURE

This section is dedicated to the presentation of a generic and modular supporting architecture [25]. The architecture must be comprehensive, covering various types of scenarios. A generic modular architecture permits to maximize its application in different scenarios, decreasing the duration time of the systems' implementation phase. This approach allows us to understand how the various components can and should connect, adapting the architecture to the needs of each application project.

A. General Architecture

The implementation of a pervasive system to augment physical objects with additional contextual digital information involves multiple components and presents some particular issues. The proposed architecture for the system is based on three main basic components, which can be viewed as generic and independent modules, corresponding to three layers of implementation (Fig. 2). The components are the following:

- Tracking - Any application of this type must have a mechanism for identification and location of the user/device (tag). Additionally, this component can be extended to include an interface for short-range communication with the user.
- Application Core - This is the component responsible for implementing the application logic of the scenario. It must be able to analyze and process the information given by the module described above, crossing it with the contextual information related to the object. This component represents the independence of the application, which depends on the scenario and relative goals.
- Display Interface - In this work, displays were considered (the used technology varies with the application) as being versatile enough to achieve a reliable, rich and less intrusive representation of the extra information.

The three listed components are in the augmented object layer, considering the fundamental principle of pro-activity of the object/display pair in relation to the user. The latter can be seen as a simple tag (e.g., RFID or Bluetooth-enabled mobile phone) which has a passive interaction, resulting from her natural presence in the scenario of application. Additionally, for active interactions scenarios, the architecture provides a component for the mobile augmentation of the object. In this case, besides the public situated visual augmentation, the tracking component provides an extended augmentation communication module and the user is more than just a tag. Using a mobile device, which can be personal, enables communication with the object through short-range technologies or via GPRS/UMTS. It also allows viewing private information on the screen of the device, working as a supplement to the public display.

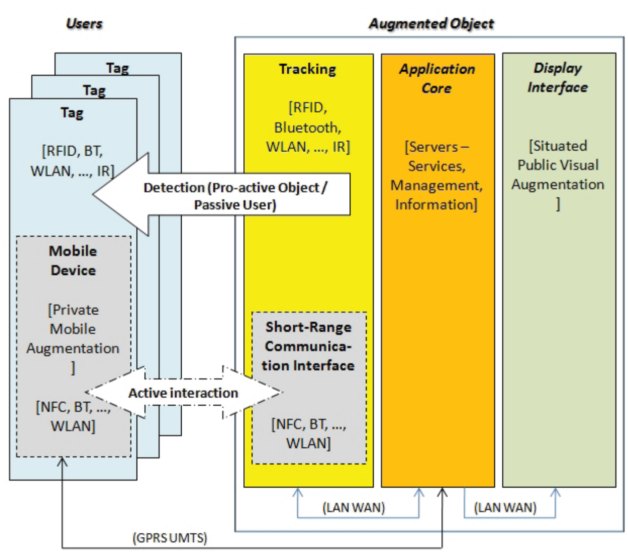

Figure 2. Main components of the general architecture.

The proposal can be seen as typical client/server architecture, given a set of servers dedicated to providing information to various clients. Therefore, the set formed by the user and the object can be seen as a client. Both the Tracking and the Interface components are considered close to the object, thus, being on the client side. The presence of the user in the area of the object is detected by the Tracking component that requests a service to the Application Core, the server. This one sends the results to the Display Interface. It can also communicate directly with the Tracking component, and even with the user's mobile device. Depending on the application scenario, the Application Core can be shared by several clients (objects) or be dedicated to only one object, with the latter having an extension by several users with mobile devices.

Since there are several modules/components communicating with each other, which may be remotes, it is necessary to have an interface for communications (which includes, e.g., NFC, Bluetooth, GPRS and/or WAN/LAN) capable of supporting, in a transparent and efficient way, the data communication between those modules.

B. *Architecture's Main Modules*

Fig. 3 presents a detailed architecture of the components corresponding to the augmented object layer, thus, only showing how the infrastructure faces the primary principle of user's passive interaction (or object's pro-activity). It follows a detailed description of all the architecture's main modules.

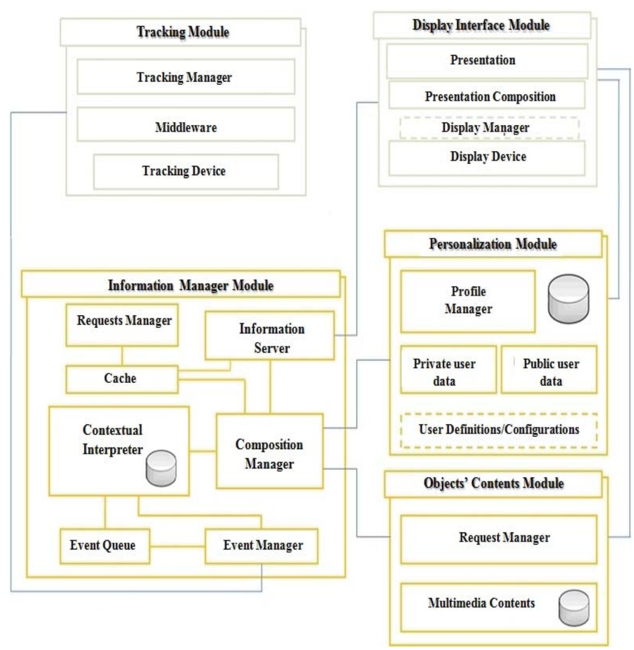

Figure 3. Architecture´s modules (augmented object components).

- **Tracking**:

This module is the basic complement to the object visual augmentation, and it is essential for any system implementation. It is responsible for the detection and identification of users, adding to the object the ability to perceive human co-presence (through technological means). Through this module, it is possible to know how much time a user spent in the pre-defined object area. There are several technologies that can be used with this module (e.g., RFID and Bluetooth). So, it is advisable to create an abstraction layer – Tracking Manager – to work as output interface, providing, transparently and uniformly, all data to the application core. Also noteworthy is the Middleware layer, which is dependent on chosen technology for a specific project development. This layer makes the abstraction of the Tracking Devices (hardware) used in the implementation, being essential for the top layer, which thus only has to integrate the interface(s) provided by the Middleware.

- **Display Interface**:

It is the real output module of an implemented system, being responsible for the final Presentation of the contextual information about an object. It can be programmed to integrate and provide other services, in case it is pretended to complement the main service of information presentation. The information should be presented to the user as soon as possible, verifying the lowest latency time between the user detection moment and information visualization. The application scenario, and in particular the users rate in the space, is crucial to the display technology choice. Since there is a great diversity for this choice, there may be a need to create an abstraction/management layer - Device Manager - for certain use cases, i.e., o create uniform protocols for the management of the Display Device(s), facilitating the programming of the Presentation Compositor sub-module. This module requests and receives messages from the server of the application module. These messages provide information about those involved in the interaction, i.e., object, user and her profile, and also the information type, which is the element that indicates what type of graphical user interface must be built/used. It also makes requests to the Personalization and Object's Contents modules to obtain the final content for presentation.

- **Personalization and Object's Contents (in Application Core component)**:

The first module acts as a data service that manages the application profiles and user data, and may include an optional sub-module for individual settings. The Object's Contents is another data service that is 'responsible' for the data repository about the scenario's objects. The repository is typically large and bulky, including a wide variety of multimedia content, such as text, sound, image and video.

- **Information Manager (in Application Core component)**:

The system architecture is event oriented because each time the user changes her status, i.e., being, or ceasing to be, detected next to an object/display pair, this is an event for which there is a handler, ensuring the application status update. The main entry of this module is the Event Manager, which controls the inputs generated by the Tracking module.

The module core is composed of a Contextual Interpreter (CI) and a Composition Manager (CM). After getting information from the Tracking module, the CI is responsible for correlating the detected user, which has a specific profile, with the detected object to obtain the corresponding additional information. As a next step, it sends a message (document) to the CM, giving knowledge about the executed interpretation. The CM sub-module combines this information with data gathered from data servers, producing another document to send to the Information Server. The document must also be produced according to the detection or request origin. If the CM has received a message from the CI, then the produced document must contain a minimum of information, because it is directed to the Display Interface module. In case the received request is from a mobile device (in an active interaction context), then the produced document must be the final, containing all the information asked or expected. Depending on the scenario of application, the CM can also take into account, for example, the local settings, user preferences, and object location. This composition module is the responsible for composing, structuring and selecting the information to be displayed.

The CM sub-module is dependent on the application, but the CI sub-module is completely independent, having a supporting model (architecture) prepared to suit any scenario. The model works for a scenario composed of multiple objects, such as a museum room, but also in cases where a conceptual large object is considered, such as an institution. It allows the association of multiple displays to one object, being useful in institutions scenarios.

The Information Server provides the final documents, created by CM, for both the Display Interface and the requests made by mobile devices, which are integrated in the infrastructure for active interactions. As for the Requests Manager, this is responsible for the information transmitted to the Tracking module, which can also perform a short-range communication with mobile devices.

C. Mobile Augmentation Modules

The generic architecture also presents an additional blue layer on the user side (Fig. 2). It will be implemented every time mobile devices are used in applications. Fig. 4 (left image) presents the Mobile Augmentation module that provides to the user an object additional augmentation, which can go outside the environment of application.

It allows the direct communication with the Tracking module, via short-range technology, and long distance communication with the Information Manager system. It has a Communication Manager that provides an abstraction in relation to the technology used for connectivity. This will make the programming of the Mobile Manager/Presentation (application) pair less complex and independent of used technology. The Mobile Manager includes an optional sub-module for management services, providing the facilities made available to the user in the process of enhancing the object, being strongly dependent on technology.

To accomplish the mobile augmentation purpose, on the Tracking module of the object layer, a new sub-module was integrated in Tracking Manager. Called SRCI (Short-Range Communication Interface), it permits the manager to be aware of devices that want to communicate with him. As an alternative to the near active interaction there is the possibility of the device to make direct requests to the application core (e.g., via GPRS), which provides augmentation documents in the Information Server. The purpose of this paper is not to present a detailed specification of the manager modules, but there are two important issues that should be described at this point, taking into account their importance to the present work. The first one is related to the possibility of SMS communication between the mobile client and the server and the second one is related to the CL competitive module.

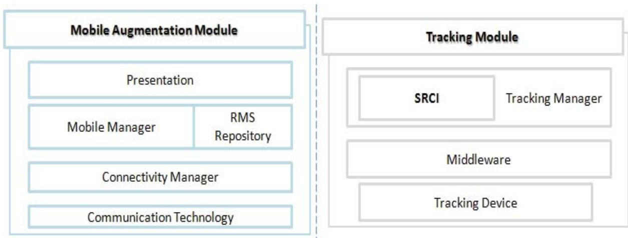

Figure 4. (left) Module of the mobile device and (right) SRCI addition to the Tracking module.

V. THE U-LEARNEST PROJECT IMPLEMENTATION

The implementation of the system u-learnEST was made at the installations of ESTSetúbal, for an engineering course, although the same concepts could be applied to other places. The main idea was to convert the laboratories of a specific course into big objects 'visited' by multiple users (students and teachers), automatically augmenting them with additional information every time a user is detected in its area. This information can be generic, for any kind of user, or personalized and directed to users with a know profile. For this system, the goal was to follow all the proposed principles, with particular focus on the ubiquity of mobile devices, thus, to implement an application with human active interactions.

The system is composed by a public shared display, a computer (the server) to manage the detections, and by the mobile devices of the users. The display was placed at the entrance of a main course laboratory, with the server close to it. Bluetooth (BT) was adopted as the communication and detection technology and Java, in the J2SE (Java 2 Standard Edition) and J2ME (Java 2 Micro Edition) platforms, was the basic language for software development. We can find almost a Bluetooth sensor attached to any person, through the mobile devices. This aligns well with the embodiment principle wanted for the system. A student going to a laboratory lesson would have an incidental interaction with the system, having the opportunity to interact actively with the u-learnEST system. For this, a client application was created for the mobile devices registered in the system. When an unregistered device appears, it is asked to register and to install the application to maximize the capabilities of the system. It is not necessary to have the client application installed to be registered.

Fig. 8 illustrates the implemented architecture for the present system. Regarding the instantiation issues, it is important to focus only on those considered determinant. In relation to the Tracking Device, a USB Bluetooth dongle connected to the server transform it in a Bluetooth device, being able to detect and to communicate with Bluetooth-enabled mobile devices. The Middleware module integrates three layers, with focus on the JSR-82 API [26]. The JSR-82 hides the complexity of the BT protocols stack, providing a simple set of API's for Java development. Since initially the JSR-82 API was only implemented for mobile devices, it was needed to use the BlueCove [27] implementation of it for J2SE. The Tracking Manager uses the BlueCove API and was programmed exactly as the correspondent in the other prototype. But, in this case, it interfaces directly with an Event Manager in the Application Core. Due to the fact that detecting "BT tags" does not work exactly as detecting RFID tags, this module has to manage the XML messages received from the previous module, filtering and organizing them for the Contextual Interpreter (CI). Its programming must be set and changed according to the conditions to be established for the system application.

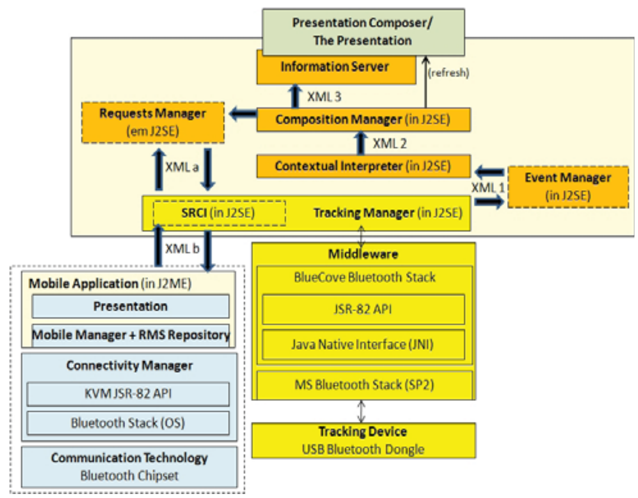

Figure 5. Architecture instantiation for the u-learnEST project.

The Application Core component includes three important implemented sub-modules: Contextual Interpreter, Composition Manager and Information Server. The first two are written in Java and the latter is a web server, which receives HTTP requests, and all the communication messages between them are XML documents (see Fig. 5). The Contextual Interpreter module is the system's "decision maker", processing data received from the Tracking Manager. Upon receiving a XML document with a detection indication, it makes an immediate processing, followed by the update of its contextual information database. Thus, knowing the object, next to which is the user, will determine what additional information to display and where to do it. With the contextual data determined, a second XML document (XML 2) is created and passed to the Composition Manager (CM) module. This one is responsible for placing a third document (XML 3) in the right folder of the Information Server. A folder for each object/display pair was created in the Information Server, with names according to the corresponding displays names. This is how the CM module knows where to place the generated XML

/

document. Before doing so, it processes the XML document passed by the previous module. It questions the Personalization module to retrieve some data about the detected user and the Objects' Content module to retrieve a portion of information that is essentially text. An element in XML 2 indicates if the additional information has text in its composition, beyond the generic summary that is already included. Content such as image or video will be retrieved from the database only by the Presentation Composer sub-module. Finally, the module automatically refreshes an XHTML file that is in the folder where the XML 3 document was previously placed.

The Composition Manager has one more task, the creation of XML documents with information to be accessed by mobile devices. The document is made available to the Requests Manager, thus, being available to be requested by a mobile device. In case a mobile device does not implement the API JSR-82, it may be placed in the Information Server. The server also has a folder for each mobile device, which using GPRS may request the most recent document.

In this prototype, the **SRCI** module was implemented to complement the Tracking Manager. It can start communicating with one of the discovered devices, but for this application it was programmed only to accept RFCOMM communication requests coming from users. When the mobile application requests a communication, the SRCI queries the Requests Manager database to obtain the XML document that refers to the device.

A. Mobile Application Development

The Mobile Application client is developed in Java (J2ME) for devices that support the MID profile [28]. It has two main modules:

- One with services to interact with the server via Bluetooth (Connectivity Manager with two layers);
- Another one to manage the possible information received from the system (Mobile Manager).

Not all the mobile devices can run the first module to interact directly with the system. To accomplish that, the device must be embedded with the JSR-82 API. If a device does not embed the API, the solution is the direct communication with the Information Server, where the object has an URL address to be accessed through WAP. In this way, the user will be able to receive XML documents to consult later and to store them in the client repository, a Record Management System (RMS).

The module to manage the received information uses the kXML library in its implementation to make the parsing of the XML documents [29]. kXML provides an XML pull parser and writer suitable for all Java platforms, including J2ME. Because of its small footprint size, it is especially suited for Java applications running on mobile devices.

Summarizing, the client application allows the user (mainly, students) to:

- Discover nearby servers and connect to one (JSR-82 dependent). This makes it possible for the user to choose to interact with one from a number of nearby installations, although the existence of only one in the system implemented.
- Send a XML message or keystrokes to the u-learnEST server (via Bluetooth or web server).
- Receive information in a XML structure. This makes it possible for the user to receive personal and private information.
- Store received information.
- Visualize information after "disconnecting" from the system (Fig. 6).

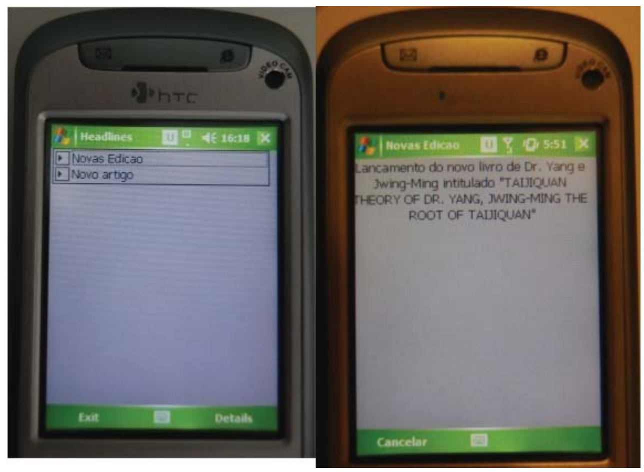

Figure 6. Earlier examples of mobile application screens.

VI. CONCLUSIONS AND FUTURE WORK

The current status of the prototype, using mobile devices and public displays, leads us to think that the system's framework is generic enough to deal with most interactions between the users and the 'laboratory object', even supported by different types of technologies. Although we have not yet carried out thorough usability and functional studies, we believe that the presented framework is also generic enough to accommodate different types of application scenarios, in terms of implementation issues.

The use of m-learning and u-learning tools, if correctly conceptualized and built, constitutes an efficient complementary tool to the traditional teaching methods. Students' information can be dynamically integrated over time and space, broadening and connecting students' understandings, both in the physical world and in classroom settings. Therefore, the u-learnEST project is an important asset to education, because it automatically complements the traditional learning environment without needing special devices from students, the main users of the system.

For future work, we are planning to update the mobile application interfaces with better design and functionality. In relation to interactions with users, we intend to carry out thorough usability, human-computer interfaces and personalization studies. Right now, we are conducting a questionnaire survey among 20 students that tested the system in order to determine their satisfaction and opinions.

Acknowledgment

I would like to thank to Prof. Nuno Correia for the great job coordinating our general work that led to the development of the framework and the system implementation.

Adaptation in a PoEML-based E-learning Platform

Roberto Perez-Rodriguez, Manuel Caeiro-Rodriguez, and Luis Anido-Rifon
Department of Telematics
University of Vigo
Vigo, Spain
rperez@gist.det.uvigo.es, mcaeiro@det.uvigo.es, lanido@det.uvigo.es

Abstract—**In EML-based e-learning platforms for engineering education, adaptation can be focused whether in the EML meta-model or in the run-time environment. In the approach centered in the EML meta-model, adaptation is carried out by advanced modeling and late modeling. In the approach based on the run-time system, it is the run-time system the one that supports the change types that are allowed. This paper presents a conceptual framework and software architecture aimed to support late modeling in an e-learning system based on PoEML (Perspective-oriented Educational Modeling Language).**

***Keywords*— CSCL, adaptation, late modeling**

I. Introduction

In the last years, it has been developed a new approach to e-learning systems design, based on Educational Modeling Languages (EMLs). Those languages enable the definition of a Unit of Learning (UoL) independently from the final system used for delivering the UoL, enabling thus a certain degree of reuse in the design of UoLs [1]. This approach supports the definition of UoLs in a pedagogy-independent way.

Unlike both implicit and explicit models that manage contents, an EML not only describes the static content structure of a UoL, but it also accurately describes dynamic issues such as activities to perform, composition of groups of participants, the order between activities, etc. Therefore, the description of a UoL implies the description of a process. The process described by an EML can be of collaborative nature, that is, several participants collaborate in order to achieve a common goal. That is a difference from languages as SCORM (ADL) [2], which only allows for the definition of processes in which only one participant is involved.

The PoEML language [3] is within this conceptual framework. This modeling language has been designed following a separation-of-concerns approach, encapsulating thus quasi-independent parts of a UoL model in separate aspects/perspectives.

The UoLs described by an EML have a life cycle that can be decomposed into the following phases:

- Authoring: in this phase, the UoL is designed by making use of an authoring tool. This phase is also known as design-time.
- Publication: in this phase, the UoL is imported into an execution engine.
- Delivering: in this phase, the participants perform the UoL. This phase is also known as run-time.

In the Figure 1, it is shown how the author of a UoL publishes it into a Learning Management System (LMS) after the authoring phase.

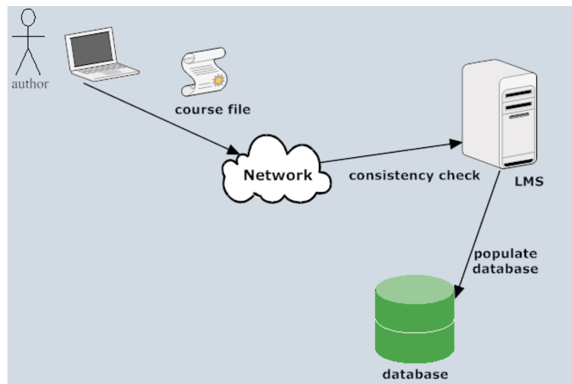

Figure 1. Authoring and publishing of a UoL.

In systems based on EMLs, methods for promoting learning are in the form of structured processes. Collaboration systems based on processes, whose most representative developments are the WfMSs [4], indicate a process specification in which the activities to be performed by the different actors are defined. Due to their characteristics, those systems are very similar to EMLs, and therefore they are relevant for this study.

Some works have proposed to transform processes modeled with an EML to processes modeled with a workflow language [5] [6]. In this work [7], an EML is even used as a true workflow language. Because of the reasons already mentioned, we will refer to EML-based e-learning systems as a type of process-based system.

A main issue in EML-based e-learning systems is that of the adaptation [8]. Late modeling allows designers to leave some parts of the UoL unmodeled until run-time. Often, designers may prefer to model the most relevant parts of the UoL, remaining the rest to be modeled at run-time. Therefore, it is required to support incomplete (or abstract) models, which will be specified during run-time.

This paper introduces both a conceptual framework and software architecture for supporting late modeling of PoEML learnflows.

II. COMMON APPROACHES TO ADAPTATION

From a technical point of view, there are some mechanisms that are used to carry out adaptation. In order to support adaptation in process-based systems, it is necessary to take into account some aspects both from the definition of processes (design-time) as well as from the execution of processes (run-time). Next, we discuss those approaches following the classification in [9]:

- Approach centered in process definition meta-model
  - Advanced modeling
  - Late modeling
- Approach centered in the execution system
  - Type adaptation (evolutionary change)
  - Instance adaptation (ad-hoc change)

A. Approach centered in process definition meta-model

In the approach centered in the process definition meta-model, it is the meta-model the one that determines the structure and the allowed types of changes. The following lines are considered: advanced modeling and late modeling.

Advanced modeling allows authors to consider alternatives during design-time. In this case, the different alternatives (learning paths) that are allowed during execution are modeled in the process definition at design-time. Despite the fact that a UoL has well-defined objectives, those can be achieved by different routes, depending for example on the student's performance. The support of this requisite is more complex if we consider alternatives in every concern that can be modeled (data, participants, time-constraints, etc). Therefore, an EML might allow for the modeling of alternatives in the different concerns involved in a UoL. That modeling of alternatives should be done in a manageable and compact way.

During run-time it should be possible to select one of those alternatives. There are two main ways to do the selection [10]:

- In accordance with the state of execution. Using conditions that are evaluated in specific points (e.g. at the start of an activity) or events that that happen at any time. The state can be related with the characteristics of participants, results obtained in past activities, etc.
- In accordance with the decision of an authorized participant. In traditional education, often teachers make decisions on the best way to achieve learning objectives.

Late modeling allows for leaving some parts of the design without being modeled, in order to be modeled during run-time. Some parts of the process definition are leaved as black-boxes, in order to be modeled during execution. In [10] late modeling is dealt with as a dynamic refining of the models. Often, some parts of a UoL may not have a clear solution and it may be not possible to model them. Designers may prefer to model the most relevant parts and leave without modeling the less relevant ones until run-time. Therefore, it is required to support incomplete (or abstract) models that will be specified during run-time.

B. Approach centered in the execution system

In the approach centered in the execution system, it is the execution system the one that supports the types of change that are allowed. The following lines are considered: instance adaptation and type adaptation.

Instance adaptation is usually named exception management. An exception can be seen as an occasional deviation from the normal behavior of a process. Exception management is needed for dealing with the deviation in run-time from the execution plan foreseen during design-time [11]. In the e-learning field, an exception can be produced when the model is deficient in some realization of the process, as when a certain route (learning path) is over dimensioned respect to other learning paths, causing in this way a competitive disadvantage to the learner that has followed the over dimensioned route. In that case, exception management is in charge of correcting that wrong situation, without need for stopping all process instances, fix the model, and enact all the instances again.

Type adaptation deals with process instance migration during a process execution from an old schema to a new one. One of the main problems in this approach is to make a migration of the process execution state to the new one [12]. Type adaptation can be presented as a dynamic evolution of the model, that is to say, the UoL model described with an EML is able to evolute in time to adapt itself to new situations, for example: the change in a study planning, more learners that expected, a new approach to teach some contents, etc.

III. A LATE MODELING EXAMPLE OF A POEML LEARNFLOW

Educational Modeling Languages such as PoEML have a static view of the world, and they do not support evolutionary and dynamic changes. In the literature, there are many works addressing the lack of flexibility and/or of adaptation in EML-based e-learning systems, such as [13] [14].

Figure 2 shows an example of collaborative practice formalized with PoEML. In this example, it can be seen how the work is divided into three independent activities (corresponding to each one of the Newton's three laws of motion), which are assigned to three different participants. Each activity is reviewed by a different participant. When the reviews of the three participants are positive, the three participants have to edit collaboratively a document that reflects the work performed in the previous three activities. Finally, the teacher makes an evaluation of the last activity, resulting in one of three possible flows (finish, minor revision, major revision). The example learnflow can be carried out just by using a wiki engine for edition and basic HTML forms for assessment by the teacher.

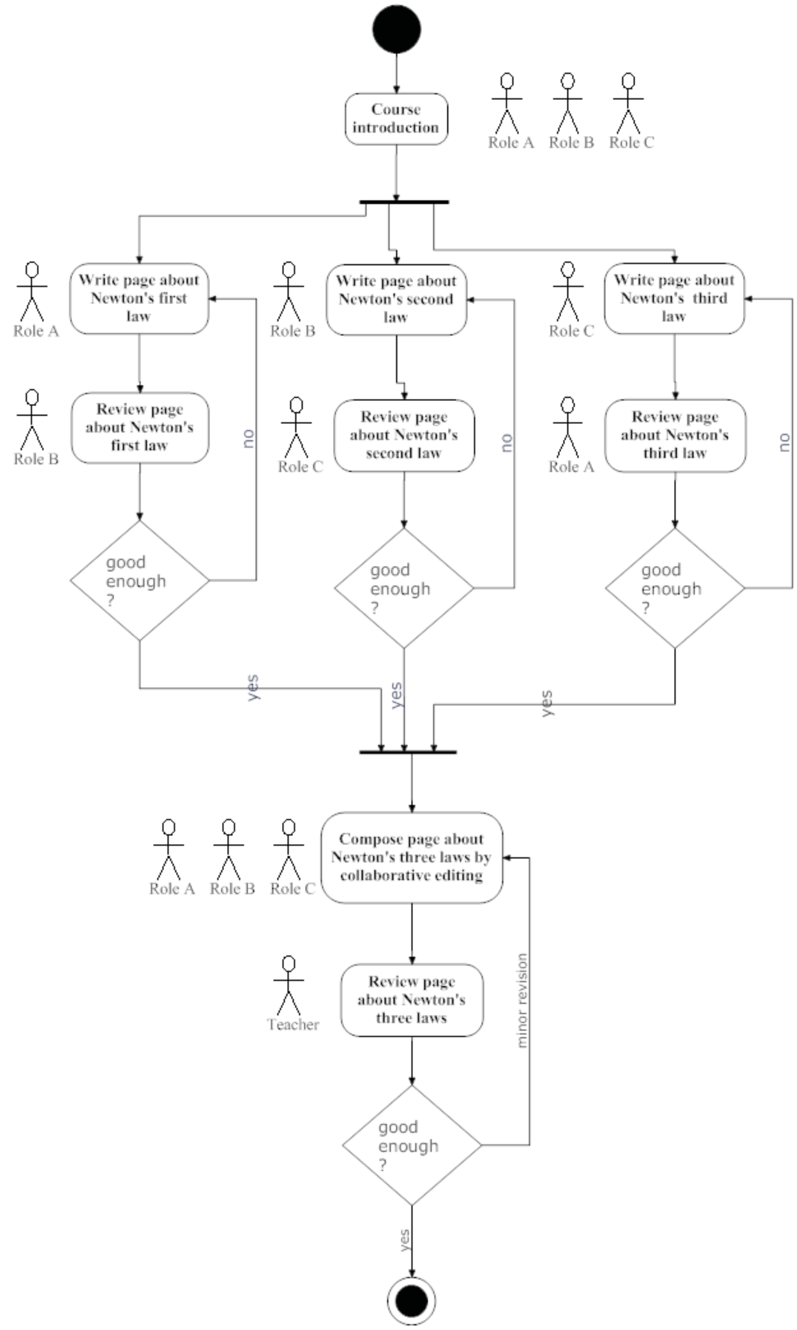

Figure 2 A PoEML learnflow

A collaborative activity is shown in Figure 3. It is worth noting that the edition of a page in a wiki is a kind of activity with no explicit end. In this case the end of the activity will be the temporal deadline. Using PoEML as the modeling language, this collaborative activity is modeled as a `educational scenario` in which there are three roles involved.

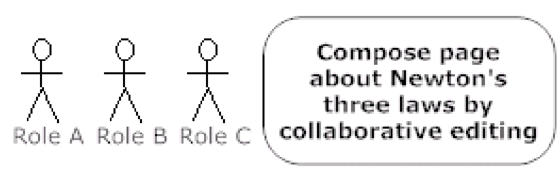

Figure 3. Collaboration at an activity level

The graphical flow-based representation in the Figure 2 is useful to put into manifest the sequencing of operations in a learnflow. Notwithstanding, we will follow an aspect-oriented approach in which the different aspects that compose a learnflow are treated in a quasi-independent way. Thus, in the learnflow of the Figure 2 several aspects can be identified:

The initial `scenario` is shown in Figure 4.

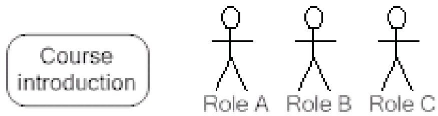

Figure 4. Initial scenario in the learnflow

Once the initial `scenario` is finished, three `scenarios` are launched in parallel. In the Figure 5 it is shown one of those three parallel `scenarios`.

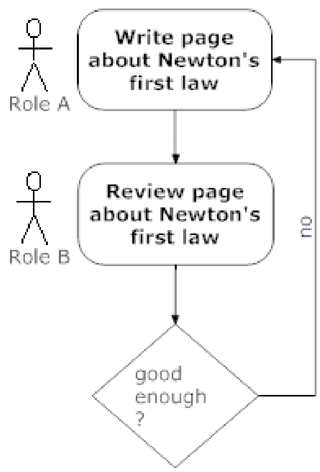

Figure 5. One of the three parallel scenarios in the learnflow

Finally, participants are requested to perform a collaborative activity, which is evaluated by the teacher. Figure 6 shows that final `scenario`.

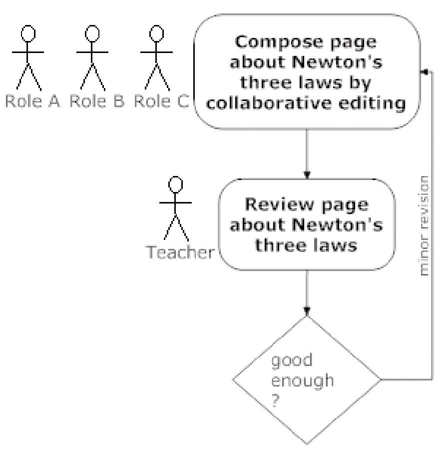

Figure 6. Final scenario in the learnflow

The ordering of `scenarios` is shown in Figure 7.

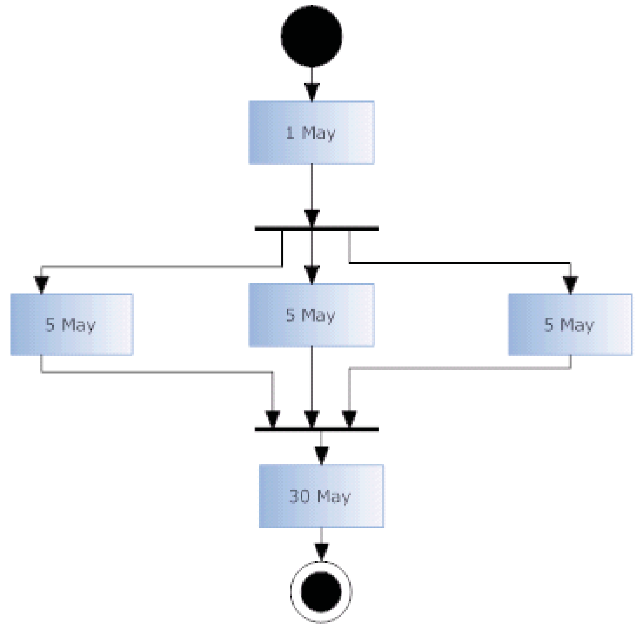

Figure 7. Order and temporal view of scenarios

In the activity *Write page about Newton's first law*, the work for the assigned participant can be specified in more detail. For example, the content of the fist law page might contain: formulation, history, and example of application. In order to leave unspecified the nuts and bolts of the activity *Write page about Newton's first law* in run-time, a *placeholder* activity must be placed during design-time. In this way, the content of the placeholder activity can be specified during run-time, and thus adapted to both teacher's and learners' preferences. With this approach it is obtained a good grade of freedom in design.

In design-time it is just not possible to foresee the behavior of learners. It is necessary to wait until run-time to monitor the learners' reactions and performance. The teacher may want to tune the model in some ways:

- Adding more activities
- Changing the temporal constraints for activity finishing
- Adding/skipping a `goal`, etc.

In the next section we will see the procedure for adding/editing/removing elements of the model.

IV. LATE MODELING OF POEML LEARNFLOWS: AN ASPECT-ORIENTED APPROACH

Following an aspect-oriented approach, the allowed changes in the model can be systematically categorized in *aspects*, each one dealing with a specific concern. In Table 1, it is shown a systematic categorization of run-time changes.

In the literature there are some works such as [13] aimed at providing run-time adaptation in an aspect-oriented way. In the referred works, the underlying model is not aspect-oriented, unlike the PoEML case. So, the PoEML aspect-orientation is a grant for easier aspect-oriented changes during run-time.

A. Situating placeholders in the UoL model

Many times, the complete structure of a UoL cannot be specified during design-time. In that case, it is desirable to count with late modeling support, which provides the needed flexibility to model the remaining parts of a UoL at run-time.

The approach here is to use a special type of construct, named *placeholder*. The placeholder occupies the place of the unmodeled `element` or `specification`. Thus, there will be as many placeholders as types of constructs in the EML at use. In the PoEML case, we identify the following placeholder types (Table 1), in accordance with the `educational scenario` meta-model in Figure 8. This table puts into manifest the aspect composition feature in our approach. The `scenario` placeholder may be composed of placeholders for `goals`, `environments`, `order specification`, and `temporal specification`. In the same way, the `environment` placeholder contains at least a `tool` placeholder.

Placeholder type	Contained placeholders
Scenario placeholder	Goal placeholder, environment placeholder, order placeholder, temporal placeholder
Goal placeholder	
Environment placeholder	Tool placeholder
Tool placeholder	
Order placeholder	
Temporal placeholder	

Table 1. Placeholder classification

The `scenario` placeholder is a black box that reserves space for a `scenario` model. The language constructs will be added at run-time in the space kept by the placeholder.

The `goal` placeholder reserves the space for the definition of a learning objective.

The `data` placeholder is used for reserving the space to add resources and/or activities to a UoL at run-time.

The `order` placeholder keeps the space for adding ordering constraints at run-time.

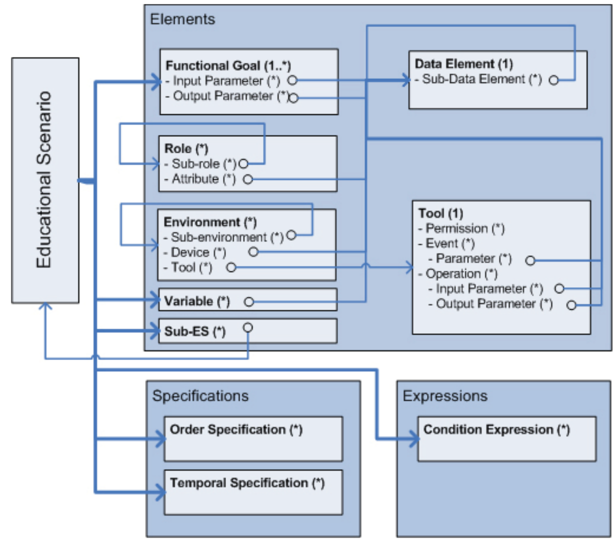

Figure 8. Elements in an Educational Scenario

The `temporal` placeholder enables the deferred definition of temporal constraints in the Unit of Learning.

Finally, the `participants'` placeholder can be situated in the place of the complete specification of `participants'` roles in the UoL.

B. Modeling black-boxes (placeholders) at run-time

When in a learnflow instance the execution flow reaches a black box, the `educational scenario` is instantiated, but it cannot progress to the `accessible` state. Figure 9 shows a view of a learnflow with a `temporal` placeholder in the final `scenario`.

Figure 10 shows the allowed execution states for a `scenario` instance. When a `scenario` contains a placeholder, the scenario instance remains in the `not accessible` state.

At run-time, the teacher can fill the placeholders with activities, temporal constraints, etc. by making use of the authoring environment. When the teacher commits a change (the filling of a placeholder) the related `scenario` can progress to the `accessible` state.

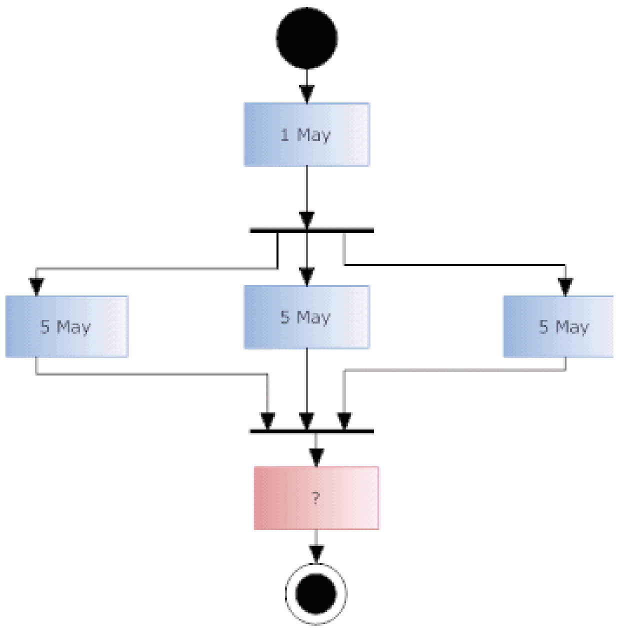

Figure 9. Temporal placeholder in the final scenario

C. *Updating of instances*

The model is the generic/abstract description of a PoEML learnflow; it contains the formal manifest of elements (`scenarios`, `goals`, `participants`, etc.) that make part of a learnflow. Every learner who starts a learnflow enacts a new instance. So, there are as many instances as participants in the learnflow.

Every learnflow instance has its own state, which depends on the state of the `goals` that the instance contains. In the same way, the state of a `goal` depends on the state of its input and output constraints, as well as on its dependent sub-`goals`.

When a teacher commits a change in the learnflow model, every learnflow instance has to be re-evaluated from root to leaves in order to update its state.

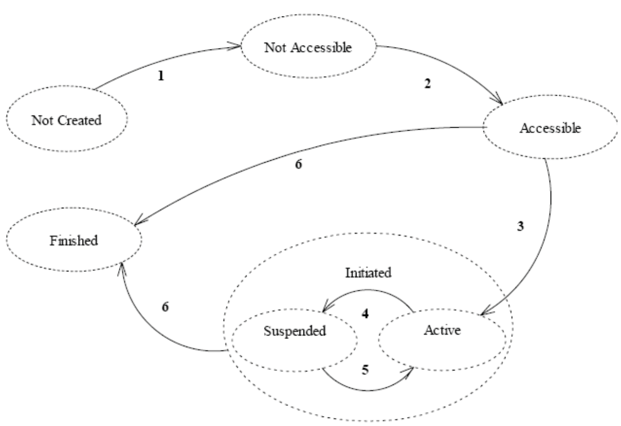

Figure 10. Execution states of a `scenario` instance

V. THE MOODLE EXTENSION

We have developed a Moodle [15] extension that is composed of a new course type with three views: run-time, authoring tool, and monitoring. The focus of this paper is the authoring tool, but for its correct exposition we need to detail the run-time and monitoring views.

In current Moodle course types, there is needed just one database schema to store the course description. In our case, we need a database schema for course descriptions and another one for run-time course instances.

A. *The authoring environment*

The authoring process consists on a series of atomic operations. In the set of possible operations there are ones such as:

- Add/edit/delete a Scenario
- Add/edit/delete a Goal
- Add/edit/delete a resource/activity

Atomic changes are validated in order to assure they are consistent with the overall course design. After verifying its consistency, the atomic change is committed against the database schema that contains course descriptions. The granularity level can be set as desired: an atomic operation may be to add a new Goal with all the required fields, or may be to edit a previously created Goal and change just one field. The authoring process consisting on atomic changes presents some valuable advantages:

- Atomic changes are automatically seen by other co-authors
- There is no need for a complex consistency check like the one needed when importing a previously created manifest file that contains a full course description

The consistency check commented in the last paragraph is yet necessary for interoperability purposes. Course description follows PoEML data model. Therefore, course descriptions can be exported from their database schema into XML manifest files. Hence, a XML manifest file that contains a course description can be imported into another PoEML-compliant Learning Management System.

Several experts are able to work collaboratively on the same design. The co-authors make atomic changes in the course design, and those changes are committed against the database schema for course descriptions. The course design can be tested on-the-fly by creating a new course instance and testing it in the run-time environment. The Figure also shows that manifest files containing course descriptions can be imported and exported into the LMS Engine database.

B. *The run-time environment*

Figure 11 shows a screenshot of the run-time environment for a participant in a course. It consists on tree course views: Structural view, Scenarios tree view, Goals view, and Functional view. We start the exposition with the structural view.

When a participant is enrolled in a course, a course instance is assigned to that participant. At that time, the course structural view is displayed at the browser. The main parts of that page are the navigation bar (Ariadna's thread), the goals, the environments and the sub-scenarios.

The navigation bar or Ariadna´s thread shows at any time the aggregation level in which the participant is. The goals box shows all the goals in the current scenario. The color of each goal is an indication of its state. The possible states are: Not Proposed, Not Attemptable, Attemptable, Pending, Completed, and Failed. Each goal box can be expanded in order to see information about input/output constraints, as well as input/output parameters.

The learning resources and activities are contained into one environment box. An environment contains Moodle-native resources and activities, such as quizzes, forums, and wikis. At the bottom of the page, the sub-scenarios are displayed.

In the Functional view, the participant can see the goals state and a list of all the environments needed to accomplish each goal. Depending on the goal that the participant is working in, the environments are displayed.

The Tree view and Goals View show a map of the current state of the scenarios and goals for a certain course instance. Those two views may be helpful to see which goals have been accomplished and which ones remain pending.

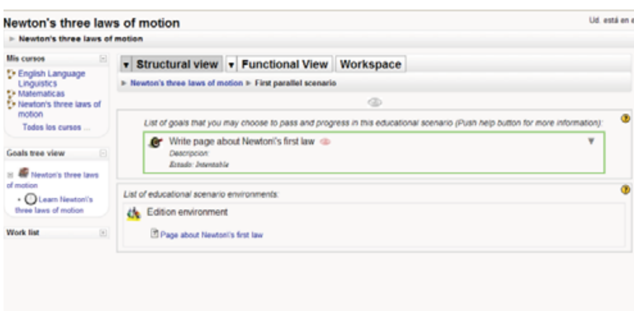

Figure 11 Screenshot of the run-time environment

C. The monitoring environment

The course monitoring feature is available for the teacher's role. This feature is divided into two different views:

- Monitoring per course element (element-driven)
- Monitoring of all elements per student (student-driven)

Figure 12 shows the monitoring of a goal. At the top of the page, we can see the possible states of the goal and the number of students per state. A histogram is used for showing that information in a graphical way. At the bottom of the page, we can see a table detailing the status of the goal for every student enrolled in the course.

Variables and data expressions can also be monitored. Variables may serve to express students' grades in a certain quiz. Data expressions serve to compose decisions that depend on the student's performance, for example, a decision that depends on the grade of a student in a quiz.

The other available view is the student-driven one. That view is suitable for monitoring the student's progression through the course itineraries.

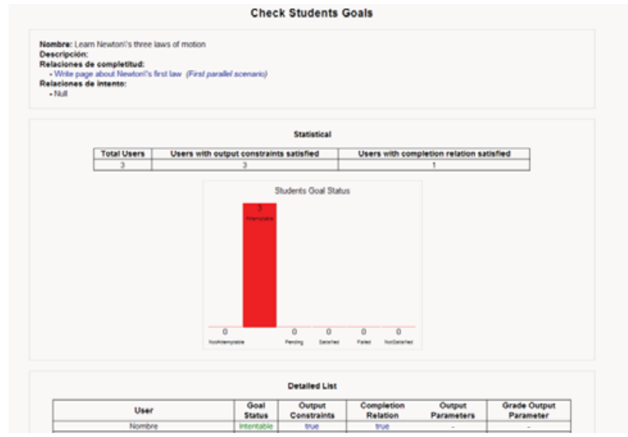

Figure 12 Screenshot of the monitoring environment

VI. IMPLEMENTATION

Figure 13 shows a diagram of the system's architecture. We detail the architecture in the following subsections:

A. *The learnflow engine (authoring, events, and information-retrieval interfaces)*

The learnflow execution engine is the core component in the e-learning system [16] [17]. The engine stores information related to educational scenarios, participants, goals, and rest of elements; and it makes the state of the system to evolute depending on produced events, both external and internal.

The execution engine is integrated into the e-learning system through a well-defined interface, which is based on Web Services, thus guaranteeing the connectivity requirements. At the same time, the presentation components must be as uncoupled as possible from the execution engine. That requirement entails to use a simple set of APIs. Scalability is an important requirement as well, because the execution engine is the central component of the system.

1) *Learnflow Models Manager*

The Learnflow Models Manager is the component that manages the learnflow models. This component maintains the versions of the models, and it also updates the models when required by an authorized user.

Communication from the exterior of the Learnflow Engine is made by making use of the Authoring Interface, which provides the needed service methods for authoring learnflow models. The Authoring Interface is used in run-time for the sake of late modeling parts of learnflow models that have been specified as placeholders during design-time.

2) Learnflow Instances Manager

The Learnflow Instances Manager is in charge of managing the learnflow instances.

Communication from the presentation module is made by making use both of the Information Retrieval Interface as well as of the Events Interface.

Presentation components are able to access the execution engine in a passive way using the Information Retrieval Interface, just to get information on educational scenarios as well as on `goals`. That information retrieval is associated to navigation through `educational scenarios`:

- Get the information related to a `educational scenario`
- Get the information related to the sub-`scenarios` of a certain `educational scenario`

In a similar way, the execution engine has to manage the events from the Events Interface, which are related to the `goals` of `educational scenarios`. A participant may generate try `goal` event, with the possible outcomes of success or failure. That event generates in the execution engine the events of instantiation of `goals` that have a completion relation with the tried `goal`.

Events generated by a participant:

- Start an `educational scenario`
- Finish an `educational scenario`
- Try a `goal`, etc.

Events generated by the execution engine:

- Instantiate an `educational scenario`
- Instantiate a `goal`
- Change the state of an `educational scenario`
- Change the state of a `goal`, etc.

An event that is external to the execution engine, such as the access to an `educational scenario`, may trigger several events that are internal to the execution engine, such as the instantiation of its sub-`scenarios`. At the same time, it is imposed one restriction: the sub-`scenarios` have to contain a `goal` in the `proposed` state. That run-time behavior can be supported with Event-Condition-Action rules [18]:

- Event: a participant accesses a `educational scenario`
- Condition: the sub-`scenario` must contain at least one `goal` in the `proposed` state
- Action: to instantiate the sub-`scenario`

In summary, the interaction between presentation components and the Learnflow Instances Manager may be passive information retrieval as well as the communication of events generated by participants.

B. The middleware layer

In order to make Web Services accessible from presentation modules we make use of the functionalities provided by a SOAP [19] engine. Thus, presentation modules have an uncoupled interaction with the learnflow execution engine.

The functionality that the execution engine provides is published to a WSDL file. The service methods are for the passive information retrieval as well as for the communication of events generated by participants.

C. Presentation modules

The presentation component is composed of three subcomponents, in accordance with the provided functionality. Hence, there are three views: authoring, monitoring, and delivering.

The authoring process consists on a series of atomic operations (in case of a ‘big’ commit, it can always be decomposed into atomic operations). In the set of allowed operations there are ones such as: add/edit/delete a `scenario`, add/edit/delete a `goal`, and add/edit/delete a `tool`.

Atomic changes are validated in order to assure that they are consistent with the overall learnflow model. After verifying its consistency, the atomic change is committed against the database schema that contains learnflow models. The authoring process consisting on atomic changes presents some valuable advantages:

- Atomic changes are automatically seen by other co-authors
- There is no need for a complex consistency check like the one needed when importing a previously created PoEML manifest file that contains a full course description

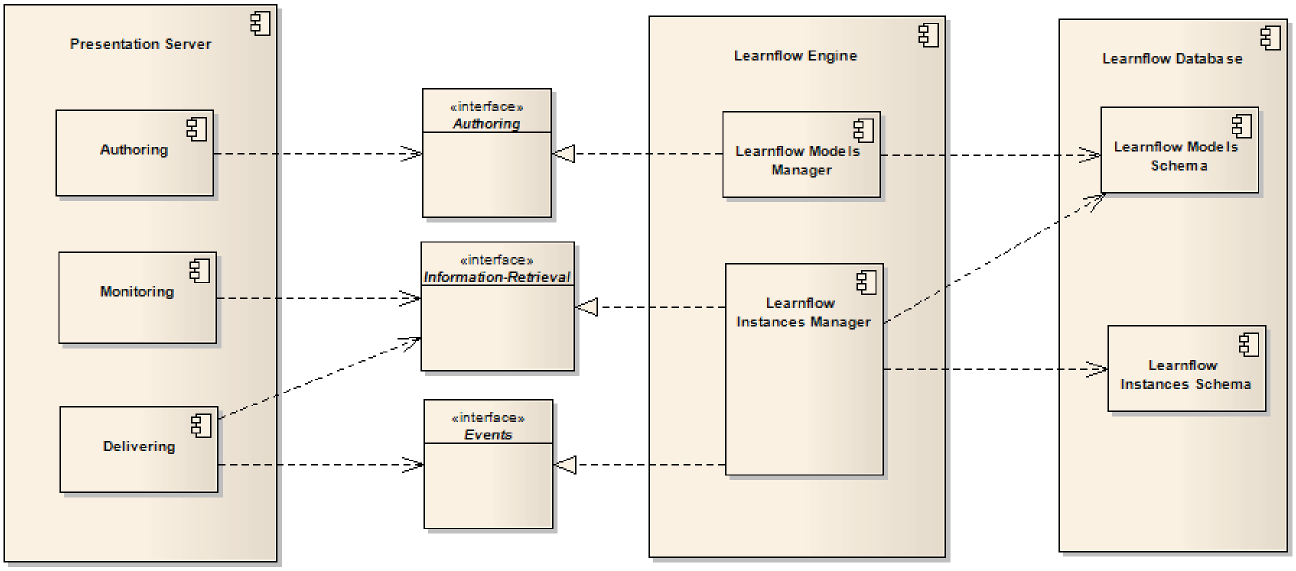

Figure 13. UML diagram of the system architecture

VII. CONCLUSIONS AND FUTURE WORK

With the PoEML-based conceptual framework described in the past sections, and the software architecture that supports it, it is enabled a kind of adaptation known as late modeling. Late modeling allows for leaving some parts of a UoL model unspecified in design-time, in order to be modeled once the learnflow is enacted, that is, during run-time.

The aspect-orientation of the PoEML language is crucial for supporting the positioning of aspect-oriented placeholders in the UoL model, thus enabling an aspect-oriented approach to late modeling.

PoEML supports well a type of adaptation based on the EML meta-model known as advanced modeling. Advanced modeling allows for considering different alternatives in the learnflow execution, known as learning paths, which are modeled during design-time.

The combination of advanced modeling and late modeling enables a high degree of adaptation, since the possibility of defining several learning paths is enhanced with the possibility of modeling parts of those learning paths during run-time.

Our future researching line is focused in the support of the adaptation types that are centered in the run-time environment: instance adaptation and type adaptation. We are currently working on providing PoEML with an execution semantics that allows for changing instances during run-time.

ACKNOWLEDGMENT

This work has been partially funded by eContentPlus program ECP 2007 EDU 417008 (www.aspect-project.org) and by the Spanish Ministry of Education and Science under grant TIN2007-68125-CO-02.

Abstract- The rapid development we have been witnessing for some decades has placed digital information and computer networks at the core of most components of professional and individual life. Learning is one of the crucial fields of activity that have benefited from such technological development. During the last decade, integration of ICT gave birth to what is now called E-learning. The trend towards mobile technologies led to M-learning at the beginning of the current decade. The happening of these two learning environments has raised several research interrogations that revolve around the need to tap the progress by each one of these two environments for the benefit of the other. Our research group deals with this issue too. Coexistence between E and M learning has brought about the need for interoperability, which involves maximum use of technological breakthroughs in both environments and makes it, therefore, possible to build up an educational heritage, regardless of the technological learning tools used. We try to present our approach to create an E&M learning continuum.

Key words: E-learning, M-learning, pedagogy, mobile technologies, MADAR learning, interoperability, standard, IMS LD, adapting standards, modular architecture.

I. Introduction

Learning has always been a fertile ground for research aiming to facilitate access to information and content sharing, so as to provide knowledge, know-how and self management
skills. To this end, researchers involved in learning have striven to tap technological innovation for the benefit of learning.

The rapid development we have been witnessing for some decades has placed digital information and computer networks at the core of most components of professional and individual life. Learning is one of the crucial fields of activity that have benefited from such technological development. During the last decade, integration of ICT gave birth to E-learning. The trend towards mobile technologies led to M-learning at the beginning of the current decade.

The coexistence of these two learning environments, that though they use different technologies, they share the same subject of knowledge and pedagogical approaches, induces a fundamental question concerning how to build E and M learning continuum.

Our research revolves mainly around this question. We are dedicating this article to present our vision of creating the E & M learning continuum. To target this goal, several questions arise: what are the common points between these two environments? What are the different needs behind the exchange and the communication between them? How these needs can be satisfied?

To begin with, we will present the reasons behind creating an M & E learning continuum from a pedagogic and a technologic point of view. We are going to identify, at second place, the different needs' levels of exchanges and communication between these environments. Finally, we will suggest a comprehensive and a general vision of the above mentioned continuum that we name MADAR Learning.

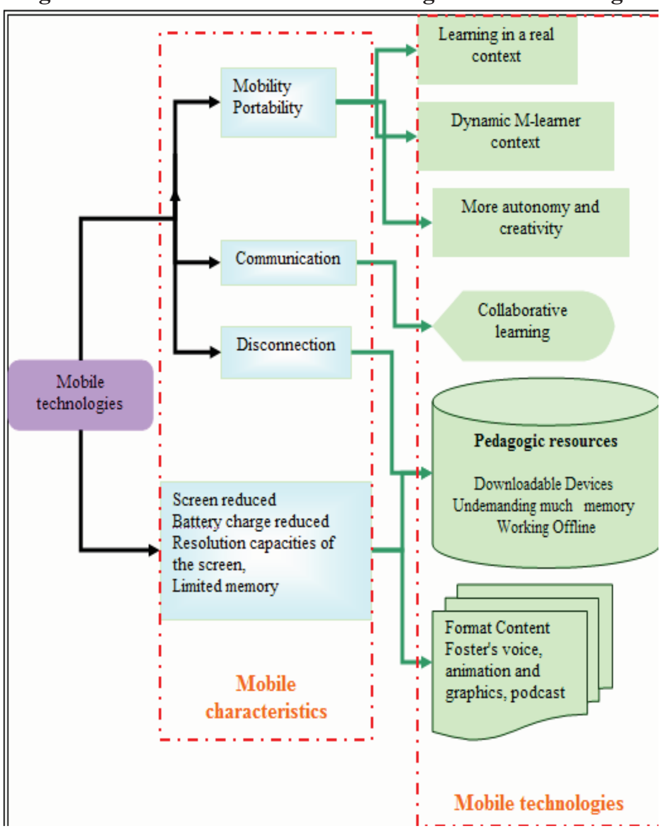
II. Why an M & E Learning continuum ?

A. Pedagogic common points

M-learning and E-learning are both distance learning environments and have, evidently, common features stemming from their context which the aim is their raison of existence . It is thus obvious that these two learning environments share the objects of knowledge that are primarily pedagogic content and support services. In fact, independently of the technological environment, the main actors in a learning situation are: The learner, the teacher, the tutor and the administrator. The process of E-learning will remain the same because it does not depend on the technology used. Consequently, the learning content, the profiles of learners and the E-learning services such as personalization, adaptation, tutoring and administrative management of training sessions are part of the M-learning.

As for the transmission mode, it can be in real time or deferred in both the E-learning and the M-learning. The existence of a virtual environment as a platform for the learning services' provision is essential to allow each actor to perform his/her functions: trainings' monitoring, interactions between different actors and the training administration management. Spaces of discussions on the Web (blogs, wikis, discussion forums, chat and email) are also the same. Thanks to the traceability provided by these tools, they currently represent a learning platform par excellence. The adoption of pedagogic approaches, appropriate to learning pedagogic contexts' objectives, constitutes also a common component of the two learning environments. Currently, several studies have proved the positive impact of classic technology and mobile technology on the learning process. Indeed, in these technologies, a collaborative learning centered on the learner is favored, and that is based primarily on the constructivist pedagogic approach and its successors (socio-constructivist and situational or contextual learning).

Figure N : 1 effects of mobile technologies on M-learning



We can conclude that the components forming a system for managing learning are the foundation of any learning regardless of the technologies used.

B. Technological differences

If the E & M learning share all pedagogic aspects of learning, they use, however, different technologies that influence the learning environment. Indeed, the use of mobile technologies has expanded, in our point view, learning opportunities and imposed new constraints [3] as illustrated in figure N°. 1.

To sum up, we can say that the M-learning can be considered as a new brick that can be added to the strengths of E-learning. Both environments, therefore, need to collaborate so as to guarantee coexistence.

However, we should take into account the specificities of M-learning. That is to say, to consider the parameters of mobile technologies in the adaptation of learning services and E-learning standards and platforms to be able to meet the specificities of M-learning in terms of: mobility, dynamic context of the learner, technical constraints of mobile devices and periods of disconnection.

The collaboration between the E and M learning can be fragmented into several levels (where each level includes the previous level), namely [1]:

- The communication: simple exchange of data;
- The cooperation: Seeking to target a common goal which is the raison d'être of the learning environment that includes the M & E learning;
- The integration: transparent belonging to a same entity. At this level of collaboration, the exchange of data, the sharing of tasks and the going after a common goal, are inherent since environments are integrated within the same learning environment (virtual or real).

To ensure this integration, we are faced by interoperability needs between E & M learning. What is interoperability between E & M Learning? What are the different levels involved? The following paragraphs are an attempt to answer such questions.

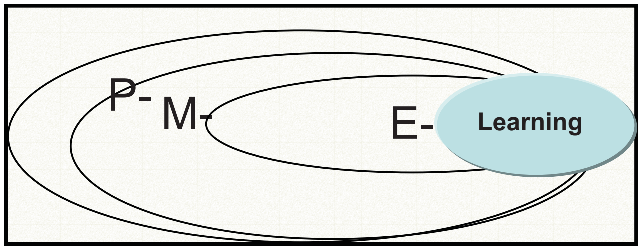
III. Interoperability at three levels for a real M & E learning continuum.

According to IEEE standard computer glossaries (1990), interoperability is the ability of two (or more) systems or components to exchange information and to use the information exchanged.

In projecting that definition in the field of distance learning through conventional and mobile technologies, interoperability involves securing communication and sharing of data, services and learning activities regardless of the development environments and instruments involved.

We have identified [7] three levels of interoperability, namely: lexical, organizational and technological.

Figure N ° 2 : MADAR learning: an overview



A. Semantic Interoperability

The content exchanged in such an environment is extremely important meaning wise, as it is designed to meet specific pedagogical objectives. Semantic Interoperability meets such a requirement. It consists in exchanging and reusing not only contents, but their meaning too.

B. Organizational interoperability

Interoperability between E & M learning is also of an organizational nature. This level corresponds to the need to capitalize on knowledge and past experience in E-learning and use them in M-Learning, in particular, as well as in future learning environments resulting from constant technological progress.

C. Technological interoperability

E & M learning environments require technological interoperability. Indeed, an independent technological environment is needed to support the technologies used by learners, so as to ensure reuse, exchange and communication of learning data, services, activities or processes.

The strategies envisaged to meet interoperability requirements include: the use of standards or families of communicating standards, the external mediator approach acting as an interpreter among components; and the use of a common communication language between modules.

The issue of interoperability between E & M learning is no exception to these rules. Solving it involves mainly: the use of standardization, along with an external mediator and common communication protocols; availing deployment environments that enable portability and mobility functions; suggesting a learning architecture that recognizes M-Learning specificities and takes advantage of E-Learning developments; and, finally, modeling distance learning scenarios in the E&M Learning environment.

In the next section we present our MADAR learning approach that seeks to respond to different levels of interoperability.

IV. MADAR Learning approach for an interoperable E & M learning environment

A. MADAR learning: an overview

MADAR learning is an acronym for 'Mobile ADaptable ARchitecture learning. This is a learning architecture adaptable to mobile technological environments [08 ICL architecture]. It may form the nucleus of an extensible architecture for future technological environments. MADAR means in Arabic trajectory. In the solar system, the course of stars tracks "MADAR" whose perimeter evolve from one year to another. Similarly, MADAR learning tracks, within our team, a continuous evolution stemming from a consecutive integration of advanced technological devices in the field of learning as illustrated in the following figure.

The aim of our approach is to create a core of services, activities and pedagogic content that will serve to create an exploitable educational heritage via various existing and future technologies.

Besides, MADAR learning suggests a management of interactions between the various existing services and the ones specific to the M-learning. However it remains extensible and open to new learning environments, namely the P-learning. That is to say, our approach targets the capitalization of the know and the know-how in the area of learning to meet the needs of three levels of interoperability between M & E learning, at first place, and foreseen learning environments that will emerge in the future (P-learning and others).

B. Pedagogy : the core of MADAR learning

Since the sixties, researches in the field of pedagogic learning approaches have witnessed an extraordinary evolution, ranging from a transmissive learning to a learner-centered pedagogy.

The constructivist approach constitutes the foundation on the basis of which many other approaches, favoring collaborative and contextual work, have emerged.

All the approaches that have emerged tend to provide an appropriate learning to the learner context, while taking into account his/her physical environment and his/her own knowledge. However, in a class environment, it is difficult or even impossible to provide individualized training (depending on the needs of each individual).

Furthermore, it is difficult to create working groups and manage collaboration within the same classroom. Moreover, it is not always possible to implement the theoretical knowledge in a real context for different reasons, namely:

The remoteness of the areas of practice from the learning institutions, the difficulty of making simulations in artificial laboratories, time constraints (practice is time consuming) etc…

Moreover, it is difficult to manage learners' autonomy in the classroom in the sense that the pace of some learners might create psychological weakness problems for the others. In addition, it is impossible for a teacher to follow different rhythms and get adapted to them during a session in the classroom environment. Because of these constraints and being aware of the benefits of ICT and mobile technologies, we suggest in our approach, MADAR learning, a collaborative learning based on the socio-constructivist approach and a contextualized learning based on situational learning [5]

C. Adaptation of E-learning standard for M-learning

The communication and the reuse of content (data, services and activities), in their original senses, are crucial to ensure the success of pedagogic objectives.

The interest in this aspect of interoperability in distance learning is thus legitimate, it emanates from its raison d'être which is the transmission of the know, the know-how and savoir être. To achieve this level of interoperability, metadata are commonly used and more precisely domain' standards or ontology that link the standards of both environments. However, in the absence of specific standards for M-learning, the use of standardization is the only resort in our opinion. We have proposed adaptations of LOM and IMS LD standards in order to use them in M-learning context [2].

D. MADAR learning architecture: The layered model

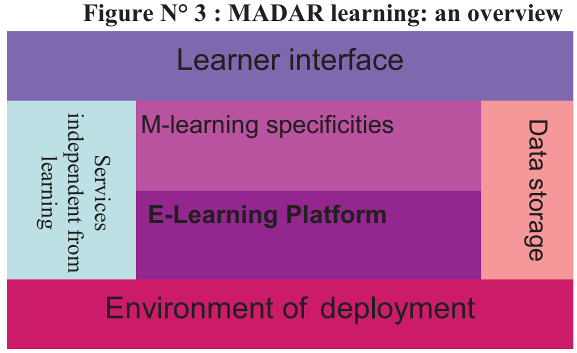
1. Characteristics of MADAR learning architecture

MADAR learning architecture must respond to three objectives, whose the achievement of one can be done only by the achievement of the other, namely: accessibility, adaptability and interoperability [4] . To target these objectives, MADAR learning must be: General, Generic, Open, Modular and independent from access equipment used by the actors.

- General : in the sense that architecture must be able to provide access to all E & M learning activities.
- Generic as far as it must provide a core of basic services common to evolving technological environments.
- Opened : in the sense that it must enable communication, exchange and exploitation of learning content, regardless of their environments of development. To achieve that, learning content should abide by the standards of the domain.
- Modular: as we mentioned earlier, our architecture must respond to evolving needs. To facilitate its extensibility of integrating new technologies, the partitioning into modules seems to be the fitting solution.
- Independent from the technology used by the actors: MADAR learning must provide independent services of access equipments be it used by learners, teachers and tutors or by the administrator.

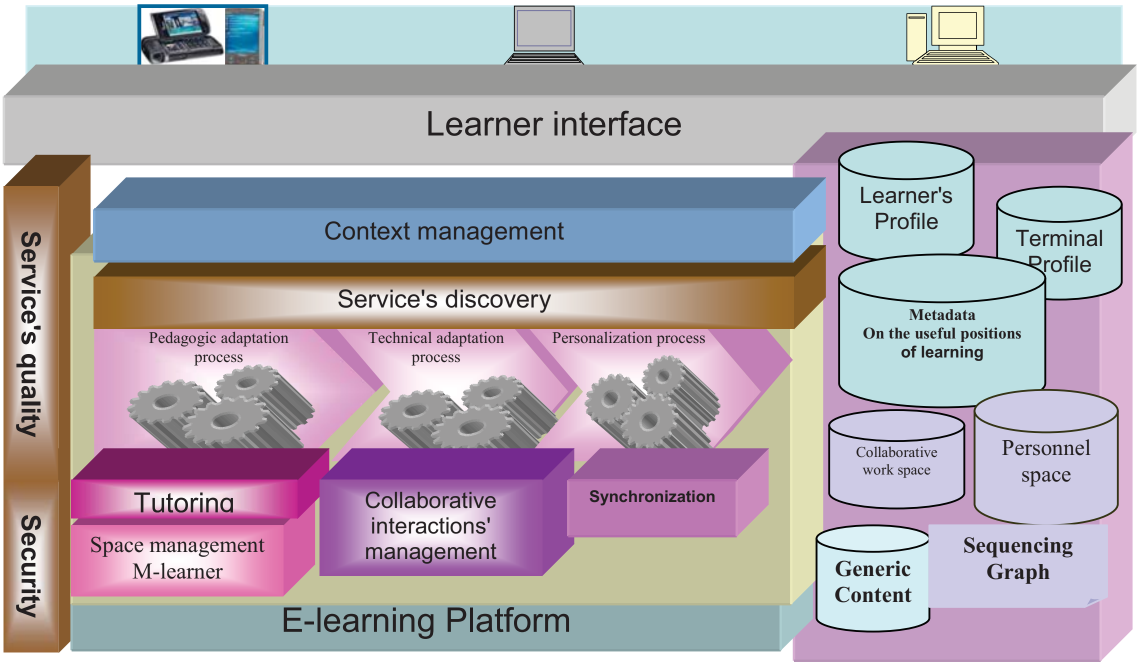
To create the continuum E & M learning we propose a layered architecture. It is based on an E-learning environment and takes into account the specificities of M-learning as well as the needs arising from the use of mobile technologies that are independent from the learning environment. MADAR learning suggests, furthermore, a deployment environment, which aims to ensure the technological level of interoperability between E & M learning. Also it provides a learner interface and a layer for data storage. In general, the functional architecture of MADAR learning is illustrated in the **figure N °3 .**

Figure N° 3 : MADAR learning: an overview



Most services of this architecture have been described in [4]. We limit ourselves in this paper to represent the layered model illustrated in figure N ° 4.

Figure N ° 4 : MADAR learning: The layered model



E. Evironment of MADAR learning deployment

The development of a technological environment conducive to the exchange, reuse of and communication between ELearning and M-Learning are extremely important elementsfor the sustainability of pedagogical materials. In this article, an attempt was made to reach technological interoperability through a deployment environment that recognizes the limitations of mobile terminals and wireless networks, while making the best use of new opportunities offered by these mobile learning technologies. It is therefore proposed that learning activities be presented as web-based services, KSOAP being strongly recommended for use with mobile devices. Taking into account disconnection periods, we have suggested the use of MOM for communications to avoid loss of messages. [3]

V. Conclusion

To achieve interoperability between E-learning and M-learning, we identified three levels of interoperability - semantic, organizational and technological - that respectively meet communication, collaboration and reutilization requirements.

To meet these levels of interoperability we suggested a general architecture MADAR learning which is layer based, modular, general, generic and open. We have also proposed technological deployment environment in order to take into account limited characteristics of small devices. So we opted for Web services combined with MOM in order to take into account the limited capabilities of mobile devices and disconnection periods. And to validate our proposal, we put in place a prototype enabling the user to avail a Web service without losing data, even disconnection happens. The use of KSOAP protocol allowed us to accommodate the limited capabilities of mobile devices. To be able to deploy the prototype, we chose to use open source software. This led us to select Jboss as an application server, and Java technology for learners. We also used Sun's WTK 2.5.2. emulators.

Based on our approach, we do not seek a restrained solution to E-learning and M-learning. On the contrary, we wish it to be open to possible future learning environments. In this vein, we suggested the principle of service encapsulation, whereby any service provided by an environment is to be used in subsequent learning environments, besides the very specificities of the latter. This principle offers the advantage of allowing extension of MADAR learning principle to other learning environments

Abstract—**ESA provides numerous opportunities for university students from ESA Member and Cooperating States to gain practical hands-on engineering experience on real space projects. These opportunities cover a broad spectrum of flight project activities ranging from student experiment payloads on microgravity platforms, atmospheric balloons, and sub-orbital sounding rockets to instruments and small platforms for Earth and Moon orbiting satellites. The education satellite projects range in size from pico-satellites to mini-satellites and are complemented by a global network of education institution and radio amateur ground stations. This paper describes the hands-on space engineering education programme and its setup, the engineering education methods, and the knowledge/skills transferred to the students, in addition to summary technical information on the projects concerned.**

Keywords-space; engineering; education; projects; student satellites.

I. Introduction

The ESA Education Office was established in 1998 with the purpose of motivating young people to study Science, Engineering and Technology subjects and ensuring a qualified workforce for ESA and the European space sector in the future. In achieving this, the ESA Education Office set up a hands-on space engineering education programme comprising a number of different projects underpinned by the principle that students learn engineering skills most effectively by application of their theoretical knowledge to the complete engineering process, from requirements and design, through developing, manufacturing and testing their product, to later flying it in a suitable operational environment in order to analyse the flight data for valuable lessons learned. For space engineering education, the ultimate operational environment is orbital flight (often low Earth orbit), but also sub-orbital flight has proven to be a useful learning ground for many students.

By participating in these projects, students gain the technical/programmatic knowledge and practical skills necessary for entering into the space engineering workforce, and immediately making a solid contribution to the European space programme, thus underpinning and building upon European capabilities in the space domain. The product of these projects is a set of qualified, fully trained engineers covering not only specialist technical disciplines in space engineering, such as structural, thermal, avionics, instrument, propulsion, and ground segment, but also systems engineers capable of developing complete satellites from end to end.

Since ESA hands-on space project activities began in the mid-1990's with the first student parabolic flight campaign, through the completion of three student satellite projects, to present day activities, it is estimated that over 3,600 students distributed over 22 ESA Member and Cooperating States have benefited from it. In implementing the programme, the ESA Education Office works closely with a wide network of engineering faculties in universities across Europe, with space industry companies and with ESA technical experts to ensure that supervision, seniority guidance, mentoring and knowledge transfer is provided to the participating students by experienced professionals. In this context, ESA Education Office, with its partners, also provides the necessary collaboration tools, software, facilities, independent technical reviews, workshops, and internships sponsorship to enable an effective working and learning environment. Crucially, launch opportunities are also provided by ESA in order to actually fly the student-built systems, thus giving high motivation and important post-mission learning experiences.

Past education satellite projects were the SSETI Express micro-satellite designed, built and tested by students, and launched into Low Earth Orbit (LEO) on a Russian Cosmos rocket in 2005; and the first and second Young Engineers Satellites (the latter being an in-orbit demonstration of space tether technology, which was carried on the ESA Foton-M3 microgravity mission in 2007). Ongoing student satellite projects include the ESEO (European Student Earth Orbiter) micro-satellite and the ESMO (European Student Earth Orbiter) mini-spacecraft, both currently under design and development by university students together with industrial prime contractors, and due for launch in 2012 and 2013 respectively. In addition, 9 university-developed "CubeSat" pico-satellites have been selected for launch on Europe's new small launch vehicle, Vega, in 2010. In support of future education satellite missions, the ESA Education Office is leading an international project called GENSO (Global Education Network for Satellite Operations) to establish a world-wide network of university and radio amateur ground stations in order to greatly increase communications coverage. The network commenced early operations during 2009.

Student experiments are developed and flown on a variety of platforms in order to encourage scientific research by students in subjects such as microgravity effects, atmospheric physics and technology demonstration. These platforms include the REXUS sounding rockets and BEXUS stratospheric balloons launched from Esrange in Sweden in collaboration with Swedish National Space Board and the German space agency, and the Airbus A300 Zero-G parabolic aircraft used for the Fly Your Thesis project. These platforms are flown on an annual basis, giving rise to frequent opportunities offered to students.

II. Description of Hands-on Projects

A. European Student Moon Orbiter (ESMO) mini-satellite

ESMO is a mini-satellite mission to be designed, developed, built, tested and operated by students under the guidance and supervision of an industrial prime contractor, with the goal to fully prepare a well qualified workforce for performing challenging future ESA missions in the next decades [1]. Its mission objectives are: to launch the first lunar spacecraft to be designed, built and operated by students across ESA Member States and ESA Cooperating States; to place and operate the spacecraft in a lunar orbit; to acquire images of the Moon from a stable lunar orbit and transmit them back to Earth for education outreach purposes; and to perform new measurements relevant to advanced technology demonstration, lunar science and exploration. In order to achieve these objectives, a miniaturised payload would perform measurements in lunar orbit over a six-month period.

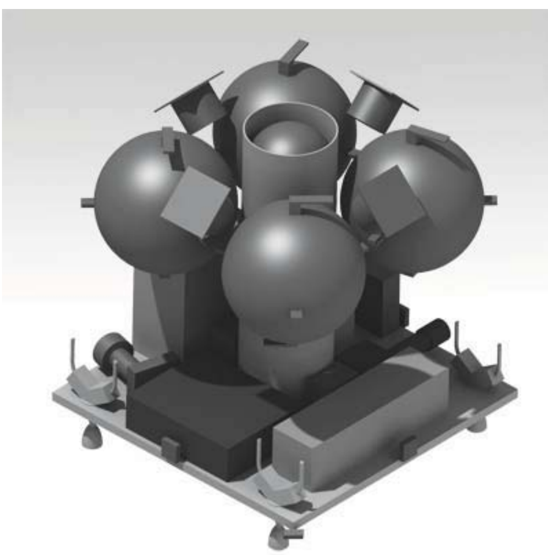

Fig. 1: Interior view of the ESMO mini-satellite (size of 80 cm on a side) showing propellants tanks and other equipment

The core payload is a 2.5 kg narrow angle camera for optical imaging of specific locations on the lunar surface upon request from schools. This will be operated from a highly eccentric lunar polar orbit similar to SMART-1. Other payloads being studied are a small radar payload, a radiation monitor, a 2.5 kg passive microwave radiometer (temperature of the regolith a few metres below the surface), and a telecommunication experiment to test a lunar internet protocol. All may be operated from the same orbit as the camera.

ESMO is planned to be launched into a Geostationary Transfer Orbit (GTO) in the 2013/2014 timeframe, as an auxiliary or secondary payload. The launcher is to be confirmed, but the spacecraft design is required to be compatible with a number of launch vehicles in order to allow flexibility in launch options. Over a period of three months, an onboard liquid bipropellant propulsion system will be used to transfer the spacecraft from GTO to its operational lunar orbit via the Sun-Earth L1 Lagrange point in order to save propellant.

The ESMO spacecraft (see Fig. 1) is designed to have a mass at launch of 190 kg (including propellant) and cubic dimensions of less than 80 cm on a side. It is fully 3-axis stabilized in attitude control and has an end of life power generation of 120 W from the solar panels mounted to the spacecraft body. Communication between the spacecraft and ground stations is performed at S-band frequencies for transfer of commands and telemetry/payload data to/from the mission control centre. Ground stations are located in Malindi, Kenya (10m antenna), Raisting, Germany (30 m), Villafranca, Spain (15m) for nominal operations. Additional stations in Perth/Kourou are envisaged to support the Launch and Early Operations Phase and mission-critical periods such as major spacecraft manoeuvres (e.g. Earth escape, lunar orbit insertion).

The project successfully completed a one-year Phase A Feasibility Study and passed its Phase A Review at a workshop in ESTEC in December 2007.

Surrey Satellite Technology Limited (SSTL), as System Prime Contractor, is managing the ESMO project for the ESA Education Office and providing considerable system-level and specialist technical support to the university student teams during the implementation of the project until launch and early operations. Some 200 students from 17 universities in 10 countries are currently participating in the project. Student work on the first part of the preliminary design (Phase B1) has progressed through 2008 and 2009. The ESMO Phase B2/C/D/E1 contract for the development and qualification of the complete system commenced in October 2009. Contractual relationships are to be put in place between the prime and the universities in order to establish academic supervisors as formal points of contact and local supervisors of the student teams for the purposes of assuring continuity and delivery. Universities are provided with funding for their participation.

The students are expected to provide most of the spacecraft subsystems, payload and ground segment systems under supervision by their universities and the prime contractor as part of their academic studies. The students obtain hands-on training and knowledge transfer by technical experts during internships, in addition to using facilities at SSTL for spacecraft assembly, integration and testing. Flight spare hardware, on-board micro-processor cores, and software is also provided by ESA to the universities where justified to lower project cost and risk.

B. European Student Earth Orbiter (ESEO) micro-satellite

The European Student Earth Orbiter (ESEO) is a micro-satellite mission to Low Earth Orbit. It is being designed, developed, integrated, and tested by European university students as part of their academic studies at university. The education objective of the ESEO project is to provide students with valuable hands-on space project experience in order to prepare a well qualified space engineering workforce for deployment on near-term space projects. The ESEO satellite will orbit the Earth taking pictures for outreach purposes, measuring radiation levels and testing technologies for future education satellite missions.

ESEO is a sub-100 kg micro-satellite (see Fig. 2) currently due for launch into low Earth orbit (LEO) as a secondary payload in 2012. To achieve its mission objectives, ESEO will carry a narrow angle camera for taking images of the Earth. A Tritel-S 3-axis dosimeter will measure the accumulated radiation dose in low Earth orbit, and a Langmuir probe will measure the instantaneous plasma environment. ESEO will also test technologies in orbit, for example, a reaction wheel, and a star tracker developed by students that will be space-qualified for later use on ESMO.

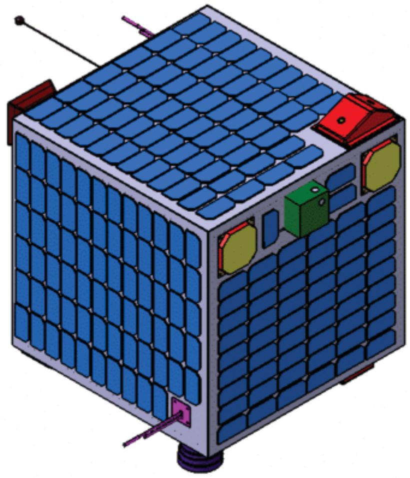

Fig. 2: Exterior view of ESEO micro-satellite (Warsaw University of Technology)

The exact launch opportunity has yet to be confirmed, although ESEO has been selected for launch with the first of the VEGA VERTA flights. However, the design aims at preserving adaptability to other launch vehicles. In LEO the spacecraft will perform its payload operations over a period of six months, with the possibility for mission extension. The orbit will be Sun Synchronous, and the remaining orbit parameters (maximum altitude < 600 km) will be selected to ensure that re-entry occurs within 25 years due to natural atmospheric drag, thus complying with the European space debris code of conduct. The ESEO satellite, as with ESMO, has 3-axis attitude stabilization (principally pointing the camera at Earth) and <100 W of power generation from the solar panels. Communication with ground is provided by an S-band transponder with also an additional transponder provided by AMSAT for communication at amateur frequencies.

As with the ESMO project, an Industrial System Prime Contractor (Carlo Gavazzi Space, CGS, Milan, Italy) is managing the ESEO project and in coordination with the ESA Education Office. They provide system-level and specialist technical support to the university student teams during the execution of the project. The students obtain training and benefit from access to the CGS and ESA in-house expertise, and can use Industry and ESTEC facilities for spacecraft assembly, integration and testing. The student teams are expected to provide most of the spacecraft subsystems, payload and ground segment systems (mission control centre, ground stations) in coordination with their universities and the prime contractor in order to deliver their elements of the mission as part of their academic studies.

The project is currently in Phase B2 (preliminary design activities in order to define the complete system down to component-level), and has recently successfully passed the Mission Definition Review and System Requirements Review during 2009. At the present time about 100 students are actively involved from 13 Universities across all Europe making preparations for the Preliminary Design Review by ESA experts in 2010.

C. CubeSat nano-satellites

A CubeSat (see Fig. 3) is a fully operable nano-satellite developed by a university for educational purposes which measures 10 x 10 x 10 cm in cubic dimensions, weighs up to 1 kg and uses Commercial Off-The-Shelf electronic components. The CubeSat standard was defined in 1999 by Stanford University and California Polytechnic State University [2]. A CubeSat can be built for €50000–€100000 by a university, plus €25000–€50000 is needed for the launch. This very cost has made CubeSats a viable option for universities across the world. Apart from the standard satellite subsystems (power, telecommunications, attitude determination and control, onboard data handling and storage) most CubeSats carry one or two scientific instruments or a technology demonstration payload.

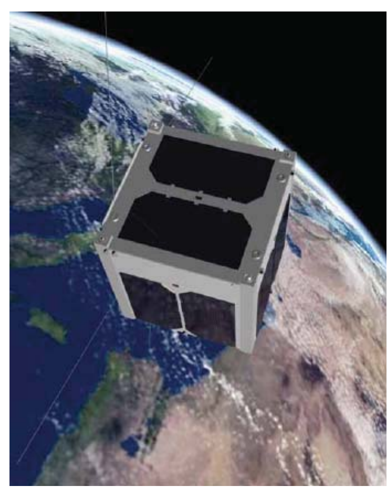

Fig. 3: Artist's impression of a Cubesat in orbit

In May 2007, ESA signed an internal inter-directorate agreement to include an educational payload on the maiden flight of Vega, ESA's new small launch vehicle which is currently under development and presently slated for launch in November 2010. This educational payload consists of nine CubeSats with two back-up CubeSats that can replace the primary satellites should they not be ready in time. The CubeSats that have been selected for the flight opportunity are given in Table 1 below.

TABLE I. UNIVERSITY CUBESATS SELECTED FOR VEGA LAUNCH

Name	University	Country	Mission
SwissCube	EPFL	Switzer-land	Air glow
Xatcobeo	Vigo	Spain	Software-defined radio; solar panel deployment
UNICube-SAT	Rome "La Sapienza"	Italy	Atmospheric neutral density measurements
Robusta	Montpellier 2	France	Radiation effects on bipolar transistors
AtmoCube	Trieste	Italy	Space weather measurements
e-st@r	Politecnico di Torino	Italy	test active 3-axis Attitude Control
OUFTI-1	Liège	Belgium	test D-STAR amateur radio protocol in space
Goliat	Bucharest	Romania	Earth imaging; space environment measure
PW-Sat	Warsaw Uni of Technology	Poland	deployable drag augmentation device

To support the selection of the CubeSats for Vega, a workshop was organised by the Education Office on 22 –24 January 2008. The workshop at ESTEC was the first of its kind at a European level and brought together almost all of the European CubeSat teams for the first time. There are now 35 teams developing CubeSats in ESA Member States and Cooperating States. A second workshop was organized in January 2009 in order to facilitate information exchange amongst this large community and to discuss possible concepts for future CubeSat missions, such as multiple satellite constellations/networks for communications/space weather.

D. Global Educational Network for Satellite Operations

As a complementary hands-on activity to CubeSats, GENSO is a planned network of over 100 small ground stations that is intended to provide global, near-continuous coverage of educational satellites in LEO (see Fig. 4). The network is being implemented under the auspices of the International Space Education Board (ISEB) with CNES, CSA, ESA, JAXA and NASA as member space agencies.

At present, a university typically builds a small satellite (e.g. a CubeSat) and launches it into low Earth orbit. It also builds, or already has available, a ground station to track the satellite and facilitate uplink/downlink telecommunications.

The period of a low Earth orbit is typically about 90 minutes, but the duration of a satellite pass over the ground station is very short and varies from approximately 10 minutes in the best case to no coverage at all for most of the orbits. When supporting only one satellite project, the ground station is not in operation 97% of the time. This is highly inefficient and often, despite onboard data storage capability, a limiting factor in mission return. Moreover, there are sometimes mission critical operations requiring uninterrupted coverage for several hours. However, the situation would dramatically improve if the satellite could be tracked by other ground stations along its ground track.

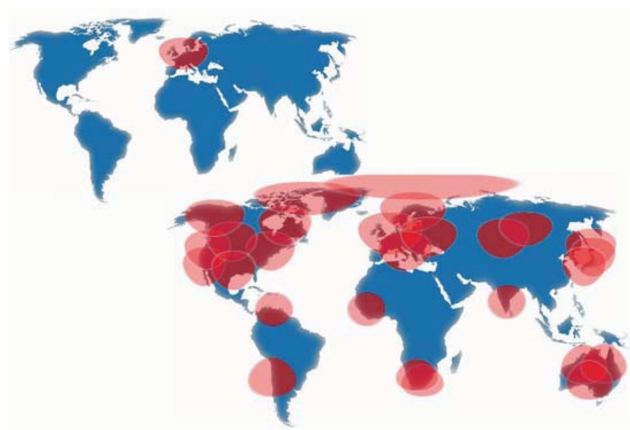

Fig. 4: Coverage of a single ground station in Europe (upper image) compared with envisaged coverage of the GENSO network (lower image)

GENSO provides an attractive solution to these limitations by linking together university/radio amateur ground stations around the world over the internet via the use of standard client software installed in the Ground Station Server (GSS), Mission Control Client (MCC) connected to a central Authentication Server (AUS). Through this network architecture (see Fig. 5) it becomes possible for an operator of an educational mission to transmit commands from its mission control centre to its satellite and receive telemetry from its satellite to its mission control centre even when the satellite is not in view of its own ground station [3].

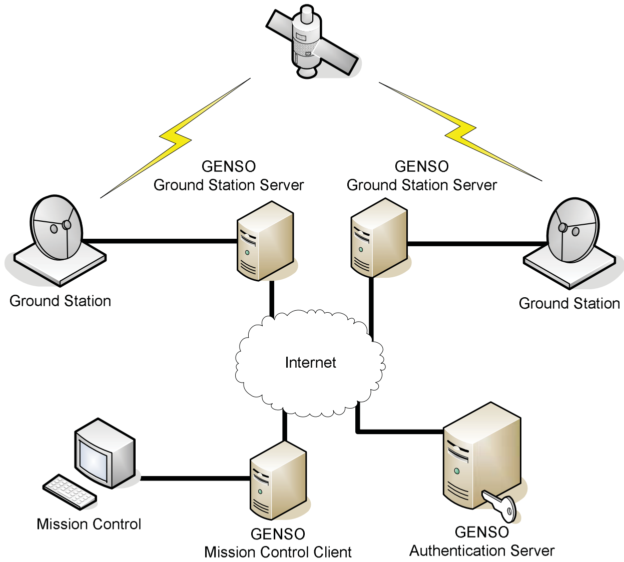

Fig. 5: GENSO network architecture

During a workshop at the University of Aalborg in November 2007, a successful proof-of-concept was demonstrated when an Authentication Server in Austria was connected to the GSS and the MCC software applications installed on the Aalborg ground station. Japanese and American hardware drivers were configured to control the ground station hardware, and telemetry was received from four student satellites – the passes were scheduled, the satellites tracked from horizon to horizon, the radio set and corrected for Doppler, and data decoded. Since then, the GSS application has been installed in five further ground stations in the UK, California and Japan to run tests for tracking satellites and automatically scheduling passes.

In parallel, two dedicated GENSO ground stations have been installed at the European Space Operations Centre (ESOC) in Darmstadt, Germany and at the International Space University (ISU) in Strasbourg. The ISU ground station was installed during August 2008. Installation of a ground station at ESTEC in the Netherlands is currently planned for 2010. These stations are used as nodes in the network but also to test new features and hardware/driver configurations.

ESA is responsible for the overall management of the GENSO project, on behalf of the ISEB. System engineering and technical support is being provided by Selex (Vega) UK under contract. The core software development teams are based at Aalborg University (Denmark), TU Vienna (Austria), Uni. Jean Monnet Paris (France), CalPoly (USA) and UNISEC (Japan). Further teams from Poznan (Poland), Politecnica de Madrid (Spain), and University of Tartu (Estonia) have joined during 2009 to support graphical user interface, scheduling, and driver developments. AMSAT UK is an integral partner in the project on ground station hardware configuration and provides the interface to the radio amateur community participation. University of Vigo (Spain) has recently been selected as the European Operations Node for GENSO to run the Authentication Server in Europe.

The GENSO software applications have been developed and tested to a first release by an international university student development team. An initial operations phase recently commenced in October 2009 with a limited number of ground stations playing an active role (<20 stations are being connected). Operational experience and requests/ideas for extended features will be fed into the ongoing development of GENSO software release 2.0, which is planned to be available in April 2010. At this time, the network will become open to all compatible education/radio amateur ground stations requesting to join through the world, aiming at the widest possible geographical distribution in order to maximize communications coverage for the benefiting satellites.

E. Sounding rockets & balloon experiments

REXUS and BEXUS are five-year programmes providing Swedish and German university students with the opportunity to launch educational experiments on sounding rockets and stratospheric balloons [4]. Three cycles are envisaged during these programmes, each beginning with a Call for Experiment Proposals and ending with the launches. A cycle comprises two rocket launches and two balloon launches. All launches are managed by Eurolaunch and take place from Esrange, near Kiruna, in northern Sweden. On each launch, half of the payload resources are available to Swedish students, the other half to German students. The flights are funded by the Swedish National Space Board (SNSB) and the Deutsches Zentrum für Luft- und Raumfahrt (DLR).

For their share of the payloads, SNSB has decided to invite students from all ESA Member States to participate in the REXUS and BEXUS campaigns. To this end, SNSB has asked the ESA Education Office to make European-wide announcements for the two annual opportunities, select the experiments, manage the interface between the selected experiment teams from European universities and SNSB and Eurolaunch/Esrange, and cover the expenses of European students to attend all of the associated activities (workshops, training week, reviews and launch campaign) [5].

In the REXUS campaign, a spin-stabilised, solid-propellant, single-stage rocket with an 'Improved Orion' motor is used, reaching an altitude of 90–100 km (see Fig. 6). The total available mass for student experiments is about 30 kg. BEXUS uses a 12SF helium balloon from Zodiac (France), which can carry a student experiment mass of 40 kg to a ceiling of 35 km. The floating phase at ceiling altitudes can last up to four hours.

The BEXUS-6/7 flight campaign took place in Kiruna, Sweden, from 3-10 October 2008. Both balloons were launched successfully on Wednesday 8 October, and the following ESA-sponsored experiments were flown:

- TimePiX@Space - Luleå University of Technology, Sweden, Charles University, Prague and Czech Technical University, Czech Republic. Detection of particles in the stratosphere using a hybrid imaging pixel detector developed at CERN [6].
- Stratospheric Census - An international team from the 'Erasmus Mundus' Space Masters course,

currently based at Luleå University of Technology, Sweden. Using innovative nanofilters combined with a strong airflow to gather dust particles from the stratosphere [7].

- Aurora – School of Aerospace Engineering, University of Rome, Italy. A study of the physical properties of the stratosphere, including temperature and magnetic field intensity [8].
- Low Cost Inertial Navigation System (Low. Co. I. N. S.) – La Sapienza University of Rome, Italy. Validation of an inertial measurement unit built with low cost sensors and components [9,10].

All experiments flown on BEXUS-6/7 were successful in collecting data and the teams have since analysed and reported on their results.

The BEXUS-8/9 flight campaign took place on 4-12 October 2009. The five ESA-sponsored experiments flown on BEXUS 9 on 11 October 2009 were:

- COMPASS (Calculating and Observing Magnetic Polar field intensity in the StratoSphere) – University of Bologna, Italy.
- CRIndIons (Measuring Cosmic Ray Induced Ionisation) – Luleå University of Technology, Sweden, Charles University, Prague and Czech Technical University, Czech Republic.
- NAVIS (North Atlantic Vessel Identification System) – Aalborg University, Denmark. A technology test for a student satellite which will receive Automatic Identification System (AIS) signals from nearby ships.
- reel.SMRT – 'Erasmus Mundus' Space Masters course, a collaboration between six European universities. An experimental gravity research platform for high altitude balloons.
- SO-hIgh – Université Catholique de Louvain-la-neuve, Belgium. A 'weather report' experiment using MEMS ((Micro-Electro-Mechanical Systems) built with Silicon-on-Insulator (SOI) technology.

Preliminary analysis indicates that the NAVIS experiment provided excellent coverage at high altitude and was successful beyond expectations. The team received and decoded 24,000 AIS packets from ships in the area. The COMPASS, SO-hIgh and CRIndIons experiments also performed well, though the reel.SMRT experiment experienced breaks in the line attached to the deployed microgravity platform and was only partially successful.

The three experiments flown in the REXUS-5/6 sounding rocket campaign on 3-11 March 2009 were:

- Nordic Ionospheric Sounding rocket Seeding Experiment (NISSE) - University of Bergen, Norway, University of Oulu, Finland & Finnish Meteorological Institute. Detection of ionized water by the EISCAT radar to study particles dynamics in the polar magnetic field [11].
- Itikka - Castor Space Club of the Tampere University Of Technology, Finland. A test of an inertial measurement unit.
- Vibration effects on biphasic fluids (VIB-BIP) - Universitat Politecnica de Catalunya, Spain. Study of the behaviour of a biphasic fluid (a liquid containing gas bubbles) in a low gravity environment under vibrations.

Unfortunately the NISSE experiment failed to function correctly. Although the rocket was clearly detected by the EISCAT radars, a malfunction in the spraying system prevented the water from leaving the spray nozzles, so no ionized water cloud was detected. The Itikka experiment was successful in acquiring acceleration data. The VIB-BIP experiment was a partial success with images of the fluid obtained, but unfortunately no vibrations in the fluid during the low gravity phase of the flight.

Fig. 6: Used in the REXUS programme, the Improved Orion M112 is an unguided solid-propellant single-stage rocket, launched from Kiruna in Sweden (SNSB)

The REXUS 7/8 launch campaign is scheduled for 22 February to 5 March 2010 when three ESA-sponsored experiments will be flown. The Call For Proposals for the next REXUS and BEXUS flights was completed during November 2009 and the selection of experiments is ongoing.

F. *Parabolic flight experiments*

Parabolic flights were proposed by ESA with the intention of fostering university student interest in microgravity research all over Europe. The Student Parabolic Flight Campaign, started in 1994, was the first hands-on activity offered by ESA. The last full ESA student campaign was held in 2006.

Thereafter, the whole programme was subjected to a thorough review, resulting in several managerial and safety recommendations for future campaigns. Following these recommendations and specific interactions between the ESA Education Office and the ESA Directorate of Human Spaceflight, a new programme concept called "Fly Your Thesis! – An Astronaut Experience" (FYT) was launched [12].

This programme offers European students the unique opportunity to design, build, and eventually fly a scientific experiment for microgravity, as part of their last year of University, i.e. for their Master or PhD thesis.

Fig. 7: Airbus A300 'Zero-G' aircraft, operated by Novespace, used by ESA for its Microgravity Research Campaigns (credit: Novespace)

Teams composed of two to four students and supported by an endorsing professor can apply, each year, by submitting a Letter of Intent to ESA Education Office. A Review Board composed of experts from the European Low Gravity Research Association (ELGRA), the ESA Directorate of Human Spaceflight and ESA Education Office pre-selects up to 20 teams who are then invited to develop detailed scientific and technical proposals with the support of an ELGRA scientific mentor. At the end of this pre-selection phase the student teams present their projects to the Review Board during a dedicated workshop held at an ESA centre. Following evaluation by the Review Board, up to four teams are finally selected to build and fly their experiments in an ESA Microgravity Research Campaign. The students accompany their experiments onboard the Airbus A300 Zero-G aircraft (see Fig. 7) for a series of three flights, each consisting of 30 parabolas of about 20s duration each. During this campaign, they work in close contact with renowned European Scientists carrying out their own research. ESA Education Office financially supports the cost of the flights, part of the hardware development, as well as necessary travel and accommodation.

For the first edition of this programme, the Review Board selected four student experiments to participate in the ESA 51st Microgravity Research Campaign which took place on 3-5 November 2009 in Bordeaux:

- *Complex* - a team of three students from the Norwegian University of Science and Technology, in Trondheim, Norway. They studied the flow birefringence of a solution of clay particles in salty water, allowing them to have a deeper understanding of the self-organisation of those small particles.
- *The Dust Side of the Force* - a team of five students from the Institute of Planetology at the University of Münster, Germany. The experiment was about the greenhouse and thermophoretic effect, which can lift particles off the ground in low gravity conditions. This effect is thought to be important in planet formation and the formation of dust storms on Mars.
- *AstEx* - a team of three students from the Open University in the United Kingdom and the University of Nice-Sophia Antipolis, France. Their experiment investigated the behaviour of granular material under shear stress, with the possibility of using their results in the design of future asteroid sample return missions.
- *ABCtr MicroG* - a team of four students from the Autonomous University of Barcelona and the Polytechnic University of Catalonia in Spain. Their experiment investigated the behaviour of particular biological agents involved in the assimilation of drugs by the human body. The results could help to improve treatments in space.

A second call for the FYT programme was launched in April 2009 and a preliminary selection of 12 student teams has been announced at the beginning of September 2009.

G. Drop tower experiments

The ESA Education office is endeavouring to extend the range of hands-on activities by developing student programmes for other microgravity ground-based platforms. This year, a new hands-on activity called "Drop Your Thesis!" (DYT) has been launched. The aim of this educational programme is to give European students access to the ZARM Drop Tower, in Bremen, in Germany. Each year one university student team will be offered the opportunity to drop, a few times, a microgravity scientific experiment as part of their Masters or PhD thesis. This facility is composed of a 146 m tall steel tube, designed as a vacuum unit, which houses all technical parts to handle the drop capsule. Below the tower, a chamber of 11 m depth contains the catapult system. The installation delivers 4.74 s of microgravity in dropping mode and 9.3 s in the catapulting mode. The first call for proposals was launched in November 2009 and a first campaign will be held in autumn 2010.

H. Large diameter centrifuge experiments

In parallel to the FYT and DYT programmes, the ESA Education Office has launched a complementary gravity-related programme called "Spin Your Thesis!" (SYT) to provide European students with access to the Large Diameter Centrifuge facility, in Noordwijk, in the Netherlands. This centrifuge has a diameter of eight meters and is composed of four arms which can support up to six gondolas (see Figure 8). In order to perform the experiments, the acceleration of the facility varies from 1 to 20 times Earth's gravity within at least

60 s. The objective of this educational programme is to have, each year, a two-week campaign with four university student experiments. The first call for proposals was made during autumn 2009 and first campaign should take place in spring 2010.

Fig. 8: Picture of the ESA Large Diameter Centrifuge (ESA)

I. CanSat activities

A CanSat is a mock 'satellite' accommodated within the volume and shape of a regular soft drink can (see Fig. 9). The CanSat concept was introduced in 1998 by Professor Robert Twiggs from Stanford University. Just like a real satellite, a CanSat consists of a 'bus' and a payload. The bus comprises the structure (the aluminium soft drink can, antenna, circuit board), power (battery), telecommunications (transmitter), onboard computer and the recovery system (parachute). The payload may consist of sensors for measuring accelerations, the ambient air temperature, pressure and humidity, a differential GPS, a camera (pictures or video), attitude determination sensors or a mini-rover.

A CanSat is launched by an amateur rocket to an altitude of 500–4000 m. Balloons have also been used as release platforms. After release from the rocket at apogee, a parachute or parafoil opens and 5–20 minutes later the CanSat makes a soft landing. The drop time, during which it transmits telemetry, is comparable to the horizon-to-horizon pass of a satellite in low Earth orbit. Their advantages are that they can be built at very low cost, typically under €1000 and can be proposed, designed, built, tested and launched in six to nine months.

The building of a CanSat usually involves participation in a competition for university and high school students. Such competitions are organised regularly in different parts of the world. The competitions are in generally two categories:

- the standard CanSats (370 g)
- the Open Class' (over 1 kg), which often includes a mini-rover.

Over the past three years, there has been growing interest amongst European countries for CanSat activities. In The Netherlands, a pilot demonstration was organised in 2007, followed by national competitions for upper secondary school students in 2008 and 2009. Further pilot competitions took place on a national level in Spain, France and Norway in 2008 and 2009 and these activities look set to continue in the future.

Fig. 9: Typical Cansat deployment with parachute (CanSat Nederland)

Based on the objectives of the ESA Education Office and its existing profile of hands-on activities, ESA's first priority for supporting CanSat activities is to encourage the set-up of activities in more of its Member States, focusing in particular on secondary schools. A workshop was held in October 2009 to brainstorm possible collaborations with the organisers of national competitions and other interested parties. Several possibilities are under consideration, including the establishment of a common website for European CanSat activities, the development of a CanSat kit and the organisation of a European-level competition.

III. ENGINEERING EDUCATION METHODS

Focusing students on real world engineering problems in the space domain, by allowing them to work hands-on to ultimately design, develop and build space-related hardware and software systems capable of functioning successfully as required in their operational environments has proven to be a very powerful engineering education tool. The 'learning by doing' approach has been underpinned and reinforced by a number of formal education methods, introduced as a result of lessons learned on the student project activities, which have led to increased success in the educational and operational/mission outcomes.

A. Mentoring by senior technical experts

Where possible within the scope of the project, the work of the students has been closely followed by a senior expert in the relevant technical field. This has been done both remotely (expert and students not co-located, communication by phone or internet) and locally (student and mentor co-located, communication largely through daily face-to-face meetings). Remote mentoring has had limited effectiveness, whereas local mentoring has proven to be highly effective in all cases. It has been most effective when students are embedded in the core system team of the project on internships. Such a daily contact with expert advice has led to strong motivation, deep understanding, high quality work output, and resulting engineering products either meeting or exceeding requirements and expectations. Quick progress is made due to mentors allowing students to explore the trade space whilst properly bounding it and guiding them towards the best solution to the problem, often based on their past experience with the appropriate rationale behind.

B. Training courses to increase practical skills

For the majority of the project activities, regular workshops are held either at ESTEC or the prime contractor (in the case of the micro-satellite projects). These are one week events where representatives from each team of students working on the particular project gather together to coordinate their interfaces/dependencies with each other, and to complete group tasks required by the project team (ESA or prime contractor) to make significant progress on project milestones. Whilst this is also an occasion for the students to meet their mentors (typically for half a day or more), additional education is given to students in the form of training courses. This has been particularly useful in increasing practical skill levels in advance of upcoming relevant project work. Courses in such areas as requirements definition, structure/electronics/thermal design & analysis techniques, and manufacturing of PCBs/cables through soldering and crimping have benefited the overall quality of workmanship achieved by the students. This is also foreseen to reduce the number of defects that need to be remedied later on, saving time and effort.

C. Immersion in the project environment

Considerable effort and investment has been made to allow students to be fully involved in the project activities, through regular contacts, meetings and internet-based tools for the exchange of key information, particularly technical data. System engineering tools are accessible to all students and capture all requirements and design data at all levels and all originators on the project. Licences for industry standard analysis tools (e.g. NASTRAN/PASTRAN for structural analysis) are provided to participating student teams in order to facilitate design decisions down to the lowest level. Furthermore, project management related aspects such as schedule, work breakdowns and task descriptions are provided at the start of the project activity (or phase of the activity) in order to give a clear path ahead to follow. A web portal is used to clarify points of uncertainty and to track tasks and project events on a continuous basis.

D. Independent reviews of design

All project activities undergo formal project reviews at key milestones in the project lifecycle, such as requirements reviews to agree on the requirements for students to follow, or preliminary or detailed design reviews to check that their designs comply with the requirements agreed. Later on in a project, post-test reviews are conducted in order to qualify the design or accept student-built flight hardware for system/platform integration. These reviews involve ESA technical experts not directly participating in the project, and have been an extremely useful learning experience for the students (as they learn more about quality standards and trying to meet those standards), as well as raising overall quality levels. It is also an important verification of their work if it passes an ESA review.

IV. Knowledge/Skills Transfer to Students

Across the different project activities, the knowledge transfer to the students varies according to the strategy of the Education Office to meet the needs of a well qualified workforce.

A. Micro-satellites

These larger projects involve tens of different universities working on different subsystems of the overall system over typically 3 or 4 years in the development cycle. Here, students gain significant specialist experience and deep insight into a particular subsystem, and learn to define and adhere to interfaces with other subsystems. This satisfies the needs to produce specialists in Europe in particular competency areas known to be in short supply in the workforce. Student system engineers are also trained and a knowledge of complex space systems is developed. However, due to the long duration, students typically only experience part of the engineering process (either design, development or manufacture/testing), and knowledge transfer between generations of students in each team is crucial. This continuity must be provided by the supervising professor locally at the university. The involvement of space industry is expected to also give students a working knowledge of how to apply and meet minimum product assurance standards.

B. Nano-satellites

Being contained within a single university and short enough in duration to have the development cycle fitting within one generation of students, these smaller projects produce specialist engineers and system engineers with a working knowledge of space systems with moderate complexity, but with stronger system engineering process and full project lifecycle understanding than the micro-satellite projects. Students appreciate a high degree of interdisciplinarity due to the vertical integration of the project team in one location, but as a result they tend not to strongly experience interface definition activities which are relevant to larger space projects. A moderate level of innovation is enabled where students can explore and demonstrate new concepts/technologies.

C. Student experiments

As these are highly focussed short-term activities where the full development cycle lasts for a year or less, they are an excellent introduction to the space project lifecycle and an opportunity to gain excellent and relevant hands-on practical skills in a less challenging flight environment than Earth orbit. These opportunities offer students the possibility to be creative in design, perform scientific/technology research and test their ideas/concepts with a specific experiment development. They still gain experience of interdisciplinarity (to a lesser extent) since structural, electronics and software engineers need to work in the same team to achieve their objectives. Engineering as well as science students benefit from these programmes, and the experience gained can lead to a career path suited to instrument/payload engineering.

D. Ground segment

The GENSO project in particular is targeted at producing the ground segment, software and operations engineers of the future workforce. Students gain knowledge in ground station networks, mission control centre functions, real-time communications links and mission planning/data exploitation activities. Whilst specific protocols are not widely used in ESA missions, the underlying principles remain the same, so the students can gain a deep understanding of the ground segment elements.

E. High school hands-on activities

These activities, with CanSats in particular, give children their first contact with the space domain and serve to attract the next generation of youngsters into engineering faculties at university where they can then build satellites and flight experiments prior to graduating and entering careers in ESA or industry. The opportunity to build, program and fly a CanSat under the supervision of their teacher, then compete against other schools to win a prize can give inspiration to children and spark their interest in space, thus leading to increased take-up in science, technology, engineering and mathematics subjects at school and an increase in the pool of potential (space) engineers.

V. CONCLUSIONS

Over 3,500 European students have been involved in the various hands-on activities announced, managed and funded by the ESA Education Office to date. They have been able to visit ESTEC and participate in workshops, project reviews, integration and test campaigns. They have prepared the required documentation according to professional standards, followed formal engineering processes and participated in communication and outreach activities. They have developed flight and ground hardware and software, benefited from the support by ESTEC/industry staff on these projects, and from detailed discussions with these experts. Throughout all these processes they have met fellow students from other European countries, learned how to work successfully as a team, and established valuable contacts at ESA and in the space industry. Several hundred Masters and PhD theses have resulted from these projects, and the active involvement in one of the projects of the Education Office has often been the first step towards a successful career in space.

VI. ACKNOWLEDGEMENTS

The ESA Education Office wishes to acknowledge the high cooperation of its international/European partners, contractors and participating universities in conducting the abovementioned education projects activities.

Furthermore, several past and present Young Graduate Trainees working in the Education Office have contributed significantly to the progress made in these hands-on projects. They are too numerous to name, but their support is well appreciated.

A competitive collaborative learning experience in chemical plant design

Santos Galán
Department of Chemical Engineering
Universidad Politécnica de Madrid
Madrid, Spain
santos.galan@upm.es

Abstract—**This paper reports on the experience of using collaborative learning techniques in a competition environment, which can be a proper approach in the traditionally highly demanding and competitive engineering courses, avoiding most of the drawbacks attributed to collaborative learning methods. The students were organized in contractor "companies" with several technical departments and a project manager, competing at every stage of the design process. The final result included some of the usual documentation of a professional basic engineering project. The results were good technically and well accepted by the students, but not all the drawbacks were removed.**

Keywords--collaborative learning; engineering course; design project; chemical engineering

I. INTRODUCTION

In recent years, the collaborative learning paradigm has been increasingly incorporated in modern engineering courses. The term collaborative learning is one of the names (e.g., cooperative learning, study groups, etc.) that encompasses a variety of learning/teaching techniques where students work together in small groups. It is frequently presented in opposition to competitive and individualistic learning, sometimes in such an enthusiastic way that forgets or even neglects [1] the benefits of the other approaches, as well as self-criticism.

Some of the advantages of this learning strategy are more comprehensive learning, lower failure and drop-out rate and a better understanding through peer discussion. Collaborative learning is said to foster creative thinking as members in a group generate new ideas, strategies, and solutions more frequently than working individually [2].

Disadvantages include (time) inefficiency, unclear hierarchical structure and unfairness in grading. Also, active resistance to collaborative methods in science and engineering courses has been reported [3].

Since the benefits of the technique have been extensively praised in the literature, in the following section we will focus on the disadvantages and false attributions that the experience described in this paper tried to avoid.

II. DRAWBACKS OF COLLABORATIVE LEARNING

One of the reasons adduced to apply collaborative learning strategies in engineering instruction is that professional engineers must interact with other engineers and professionals, requiring communication, leadership and teamwork skills that are not effectively instilled by traditional teaching techniques [4]. This is true, but the statement needs qualifying:

- Apart from pathological individuals, students have been acquiring and developing social skills since they attended the kindergarten, mainly not at the school.
- In professional life, teamwork is organized around specialized personnel with a clear hierarchy where leaders have got the authority to remedy low achievement or improper behavior. This is not the case at the university, where the students are forced to deal with potentially uncooperative members.

Working in a group requires not only social skills but also organizational and management effort, what is generally not recognized enough at grading. Even when these abilities can be taught, they are built over the knowledge of what has to be managed, so young students are not the best candidates. Also, in the extremely demanding engineering courses, the managerial effort has to be detracted from other learning activities: It is generally recognized that group work usually means covering fewer topics, what should be balanced in every case against the benefits gained.

A common negative comment from students is that not all the members spend the same amount of effort in group work but they are awarded a group mark [5]. The apologists of the collaborative learning methodology would likely answer that positive interdependence has not been achieved or that task assignment was unequal, what can be solved. Those professors would possibly understand better the students' point of view by just suggesting them to get paid (only a fraction of their salary) on a department group basis.

It is difficult to find a professor that confess it, but frequently, group work means less correction work. Finally, the author cannot forget what an instructor for collaborative learning techniques told in one seminar he attended: Collaborative learning was a necessity because of our current, less motivated and less prone to effort, students.

To summarize, collaborative learning is not the panacea: It does work for some students and it does not for others, (especially at engineering schools), and it has got advantages and disadvantages. Learning, as responsibility, is always individual and collaborative learning strategies cannot be used in a general and naïf way, but are the appropriate tool for some courses and subjects. At engineering schools, they have to be carefully tuned in order to be efficient and accepted. The experience that follows, applying a competitive orientation, tried to do it.

III. THE DESIGN PROJECT

Design projects are a classic tool in engineering teaching that induces learning through doing and where collaborative learning can be applied.

The experience this paper deals with was implemented in a Separation Processes course in parallel with the development of the common topics: distillation, column trays design, liquid-liquid extraction, leaching and crystallization. The assignment was the design of a chemical process and plant based in a (part of a) real-world project for ETBE production.

A. *Organization of the work*

The students were organized in four groups (contractor companies) of five students, each one responsible of one of the five typical departments of an engineering company: project management, process design, mechanical design (columns and heat exchangers), instrumentation and piping. The project managers were the top students as by the qualifications of the tests of the first two weeks of the course. Then they have to negotiate with the rest of students to complete the company. There was no need for the professor to intervene.

The contractors received only the design basis specification and letters from the client (the professor) asking for the development of a stage of the plant design, usually affecting mainly to only one department. At the department level, at every stage of the design the four groups competed and the best solution was adopted for all the groups, providing the same starting point for the evaluation of every department. The students applied the knowledge of the course and were provided with additional information and examples for the auxiliary tasks.

The first milestone was the process flowsheet, to be developed by the process engineering departments. It implied the design of two distillation columns with eleven components, not having information about the separation sequence. The students used for the design the standard professional process simulator Aspen Plus. This is a difficult problem and the professor provided some additional orientation via e-mail and discussion meetings. The project managers of three groups assigned their best performers to this department, probably because this one is the only task directly related to the topics taught in the conventional course and it was expected arduous. The process flowsheet with the stream table is shown in figure 1, just as an indication of its complexity.

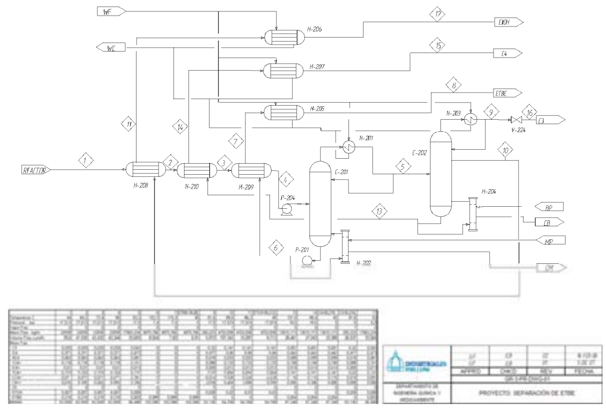

Figure 1. Process flowsheet

With the process information the rest of departments did begin their work:

- The control and instrumentation section developed an outline of the control strategy, the P&I diagrams (figure 2), the list of instruments and a preliminary study of the process safety system.
- The mechanical departments did a thermal calculation of the heat exchangers and a basic engineering design of the columns using KG-Tower, the program supplied by the company Koch-Glitsch. For every item in the list (of equipments) a specification sheet was written.
- The piping department determined de dimensions of the pipelines, drawn the plot plan and the isometric diagrams (see a sample in figure 3).

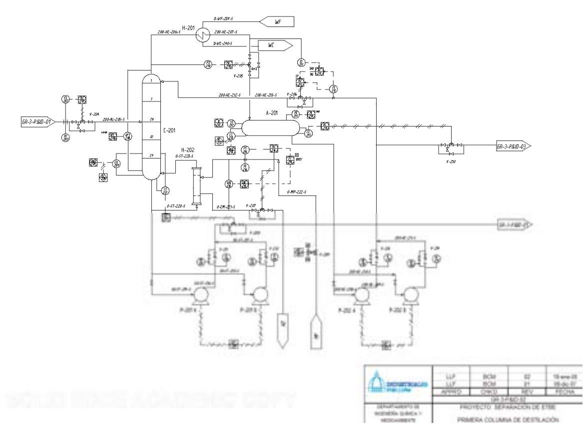

Figure 2. P & I Diagram

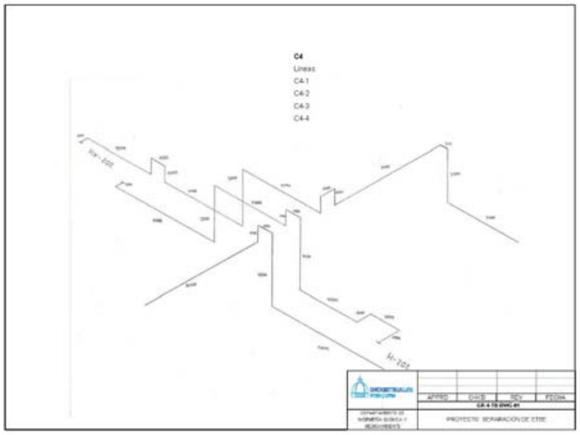

Figure 3. Piping isometric

As these tasks have to be developed almost simultaneously, there were some intermediate milestones for homogenization. The elaboration is really an integrated process were the role of the project manager, coordinating the work of his departments as well as, sometimes, the work with other groups at homogenization, was critical:

- Additional process data, as physical properties, are required for the piping and equipment design.
- The instrumentation department needs to discuss the control strategy with the process department.
- The equipment data are needed for the P&ID, the piping design and the plot plan. Note that isometric diagrams are the 3D routes of pipes in the real plant. You need to know the dimensions of the equipments and its positions in the plant.
- The piping dimensions determine the nozzle diameters of the equipment.
- Instrumentation induced connections in equipments and pipes.

Apart from the coordination function, project managers wrote an operations manual, formatted the design basis and detailed the utilities. They also collected an organized all the documents of the project.

All the documentation generated was included in a basic engineering ("black") book with around 30 documents (reports and drawings).

B. Grading policy

The general idea behind the grade structure was to avoid the drawbacks of the collaborative learning methodology, in particular the usual conflicts in groups of students that, apart from trying to learn, have to deal with the negotiations in a team where the hierarchy is diffuse or inexistent. As mentioned above, collaborative learning is generally presented as an imitation of actual professional life, but the interests and consequences of actions in the real world configure quite different scenarios.

Grading included individual and group results:

- Students that did not acted as project managers got their individual marks from the professor, their project manager and department peers at the other groups, but they only knew the final result.
- Project managers got their individual marks from the professor, their departments and project managers at other the groups, just knowing only the final result.
- The group mark was decided by the professor and a poll where all the students participated. Of course, they could not vote themselves.
- Every student got his grade by combining the group and individual marks.
- Additionally, a poll was filled by the students at the end of the project.

By letting the departments to grade the project manager and the project manager to grade the departments it was expected that a reciprocal sense of interdependency appeared, but it did not happen. The authority of the project manager was ignored several times, requiring the intervention of the professor.

IV. RESULTS

Not all the groups completed all the tasks (it was difficult) and one student abandoned in the middle of the project, but the results from the technical and instructional points of view were very good. The projects were sent to a real world international contractor company for evaluation and their comments were very positive, mentioning an "almost" professional work.

In the poll, many students answered that it was the first time that they participated in such kind of design projects, so related to professional life. That they really liked it, but they encountered the work extenuating. It was extenuating for the professor as well. The suggestion of creating a new course only for the design project was accepted and will be (hopefully) offered next year.

Some of them cited that it was unfair that there was only a winner at every stage when usually the work was quite similar, what is a criticism on the competitive orientation of the project. Actually the difference in the qualification was only extra points over the conventional mark, but they did not like the comparison.

The inclusion of incentives to keep the compromise of the students within the group was asked. Some students opined that several members of their group did not work enough, and that the mechanisms to deal with the problem were not sufficiently effective.

Almost all of the students encountered painful the change of specifications in the middle of the project (a real life problem) and asked for more information on the design methods and procedures.

The key factor for the success seems to have been the work of the project managers. The winner group was the best only at two milestones, but the final result was significantly better than the others because of the coordination and involvement of the project manager.

One of the curious issues of this learning experience is the variety of approaches and styles developed by project managers to lead their teams to achieve project goals. As it was mentioned before, project managers were the only members of the contractor groups selected applying an objective criterion. One of them, showing a surprising authoritative attitude, was partially ignored by his departments, and got a relatively bad punctuation from them. Another, using a cooperative style, was also partially ignored, but received an excellent mark from her departments. At the end, the cooperative managers got their groups develop the best projects.

V. CONCLUSIONS

The collaborative learning techniques that have been progressively incorporated in modern engineering curricula are just one of the methods that can be applied in the instruction by professors, but are not "the method". There are serious drawbacks in using collaborative learning strategies and the suspicion that some of the better results attributed to those techniques could be caused by a downgrading of the courses (at least there are less topics covered).

The experience presented in this paper tried to avoid many of the cited drawbacks, finding an appropriate case for the use of the collaborative learning methodology connected to actual professional work.

The result was good at the technical level and was well accepted by the students, but not all the goals were attained: the control of uncooperative members by the project managers using the grade policy was insufficient, and the competitive part of the design, that in part was possibly stimulating for reaching so good results, was considered unfair by some students.

Abstract— **The capstone design sequence in the Electrical Engineering Program at Western Kentucky University is a two semester sequence. Student teams design and execute a solution to an industrial or applied research problem during the academic year. In order to improve the capstone sequence, project management techniques have been introduced into this sequence. These techniques include acquainting students with project management theory and teaching students to manage the projects more effectively. This paper will present the basic structure of the sequences, discuss the assessment results which led to this new focus in the sequences, describe the project management techniques incorporated into the courses, and explain the impact the new emphasis has had on the capstone design sequence.**

Keywords- capstone design, senior project, project management

I. Introduction

The Electrical Engineering (EE) program within the Department of Engineering at Western Kentucky University (WKU) has a project rich curriculum. Our students take a design course each academic year that provide opportunities for completing projects. As the students mature through the curriculum the amount of work effort, design, and project size increases, until the capstone sequence of their senior year. As our student numbers have increased, the effort of managing these projects has become a difficult task for the EE faculty. To address these problems, the faculty of the EE program has utilized conventional project management techniques to create a design process to manage and asses the project teams for our senior capstone experience. The subsequent work describes the capstone design sequence our senior EE students complete. Next, the assessment data alluding to the difficulty in managing these projects is presented. In an effort to address these problems, the revitalized design process is presented with much detail. This work is completed with some concluding remarks. The utilization of this design process is new within our program. As the faculty assesses its performance in helping the student complete their projects there is room for adjustments so the process has the right balance of control and flexibility such that the students are successful.

II. Design of EE Capstone Design Sequence

Students entering their final year of study in the EE program at WKU take a two semester capstone design sequence comprised of EE 400 (EE Design IV) and EE 401 (EE Design Project). In these courses, students are placed on teams and assigned projects which include industrial and applied research projects. The students design and execute a solution to the design problem during the academic year. The courses must be taken sequentially in an academic year. The first course in the sequence is EE 400. During this course, students focus on design methodology and decision-making. The course includes ethics, professional issues, and the planning and design phase of the project culminating with oral and written reports. The objectives of this course are to further develop design skills, develop teamwork skills, learn to deal with situations in an ethical manner and write the senior project proposal.

The second course in this sequence is EE 401. This course is constructed so that the student design team will assume the primary responsibility for the completion of the project. At the end of this course, students have completed a major capstone design experience and can demonstrate their ability to design, build, and test a system to meet specified criteria. Also, students exhibit their capability to communicate their project design and results in a written format and in an oral presentation.

The design sequence has multiply opportunities for faculty to provide feedback to students regarding project progress. Mandatory status meetings occur weekly in which the design teams meet to update the faculty on the status of the project and deliverables. Prior to each progress meeting, the team must submit a status report. Also, several design reviews are scheduled for each team during the academic year. At the design reviews, the teams present the status of their project. During the design reviews, the faculty evaluates team progress toward the established project milestones. Failure to meet the milestones will affect the final grade.

III. Improving Capstone Courses Through Assessment

The WKU EE program is a relatively young program producing the first graduates in May 2004. Prior to engineering programs, WKU was home to three engineering technology programs from which the new engineering programs grew. The three engineering programs at WKU (civil, electrical, and mechanical) received ABET accreditation in 2004. The capstone design sequence is heavily assessed by the WKU EE faculty in support of the ABET Criterion 3 A-K program outcomes. [1] In fact, all eleven Criterion 3 outcomes are represented by these courses. The EE program assessment plan uses several rubrics to determine if the program outcomes are being met. Also, the faculty discusses this course heavily during the course review process in which each course taught in the curriculum is examined. The major assessment results are listed in Table 1 below.

TABLE I. SUMMARY OF ASSESSMENT RESULTS FOR CAPSTONE DESIGN COURSES

Year	Assessment Result
2004	Gantt chart developed in fall semester, project driven by timeline
2004	Students noted progress in logbook through year. Logbooks found to be ineffective.
2005	Faculty noted the need for more formal project milestones through the year
2005	Students submitted weekly progress reports rather than logbooks
2006	Established monthly design reviews as well as continued weekly meetings.
2007	Course restructured with firmer deadlines so that students had a better understanding of their final grade.
2008	Incorporated three design reviews and project deadlines into requirements
2009	Include project milestones in fall and spring semester
2009	More emphasis placed on project and time management

Over the years of offering these courses, the student performance has continued to improve. However, it is noted that students continue to struggle with setting project milestones and faculty have not given adequate intermediate feedback to students during the year. Therefore it was determined through the course assessment that more formal milestone development and appraisal should be incorporated into the courses.

IV. REVITALIZING THE CAPSTONE DESIGN SEQUENCE

In an effort to teach project management as it applies to an engineering project and to create a more manageable assessment tool to gauge project progress, the faculty of the EE program at WKU has introduced a new design process for its EE400 and EE401 design sequence. The following outline known as the *Workbook Table of Contents (WTOC)* best describes the new design process. Details of each heading will be described below.

Workbook Table of Contents

I. Project Management Plan
II. Requirements documents
III. Execution and Closing

Figure 1: Workbook Table of Contents

A. Project Management Plan

In the Project Management Plan (PMP) shown in Figure 2, the students are tasked to define all attributes of the project in an effort create a detailed statement of work. The WTOC plan should be flexible enough to meet the needs of projects of varying scope and scale. As the faculty assesses possible projects at the beginning of the academic year, it is imperative that the projects have enough creative content so that the students are able to fulfill the tasks described within the PMP. If students were not able to develop the PMP for a specific project for whatever reason, the project may not be a good fit for our sequence due to a lack of learning opportunities. An additional benefit of this PMP is to force the project sponsor to agree to a written statement of work describing the project to be completed, thus driving the development of acceptance criteria. Once this is established, the student design team and the sponsor have agreed to the components of a successful project. If for any reason during the execution of the project the deliverables change or the student design team fails to meet the stated criteria, both parties will fully understand the work did not meet the sponsor's expectations. It is often the case that due to time constraints many engineering project require that the project scope will change, or the student design team will be drawn to a different solution which results in only partial project success or project failure. Through this PMP document, all parities are focused on meeting the written goals of the project.

1) Project Requirements

To create a PMP for their projects, students are asked to complete outline items A: Project Requirements, B: Scope, and C: Project Planning, seen in Figure 2. The Project Requirements is composed of the high level project overview and definition of stakeholders. This section is the first documentation the students are asked to complete once they are assigned their projects. The students are tasked with developing an understanding of the big picture of their work as it relates to their project sponsor. It is very important that the student design team understand the impact as to why they are doing this project. There could be possible safety or financial implications that if the student design team where unaware of, the task may seem meaningless. Through this task, the students can better work to meet the organizational goals the sponsor hold very important. Also, within this section of the PMP, the student engineers determine and document all the important people that are affected by their work. Often the students will list the project sponsor and their faculty sponsor who are both working to make sure the students complete a successful project. The student will need to identify all of their team members as well.

I. Project Management Plan

- A. Project Requirements
  1. High level overview of project
  2. Identification of stakeholders
     a. Technical sponsor
     b. Faculty sponsors name
- B. Scope
  1. Product description
  2. Product acceptance criteria
  3. Project deliverables
  4. Project exclusions
  5. Project constraints
  6. Project assumptions
  7. Preliminary budget
  8. Project risks identified

9. Change control plan
10. Patent search

C. Project Planning
1. Work Breakdown Structure (WBS)
2. Activity Sequencing
3. Gantt Chart
4. Roles and responsibilities

Figure 2: Project Management Plan of WTOC

2) Scope

The next phase of the PMP after the students identify the stockholders and come to have a "big picture" view as to the "why" of their project, the students begin to develop their project scope. As can be seen in Figure 2, the Scope section contains ten items which the students generate with consultation of their project sponsor. At the beginning of the project the faculty sponsor facilitates the initial meeting between the project sponsor and the student design team. Once this has occurred, the expectation for the students to gain the information from the sponsor in a convenient, non-burdensome way is paramount. In some instances the sponsor may not be able to give information to the student engineers for all of these items. For these cases, the students are asked to make decisions and strive for agreement with their sponsor. In practice, it is common for sponsors to have unclear requirements and it is often the engineer's task to help them decide some of the finer details.

From this list of ten items some of the most important items will be described. The Project description is a lower level statement of the project, similar to that in the Project Requirements section. As stated previously a key result of the Scope is the Project Acceptance Criteria. This criterion is vital in keeping all parties focused on the goals of the project. The project deliverables are an important list of the items to be completed or created as a result of this project. This list of deliverables is used to focus the stakeholders and students on the goals of the project. Within the scope, the constraints are documented in an effort to describe what parts of the projects will not affect existing systems that interact with the project items. When completing any project, it is good practice to list the fundamental assumptions that frame the context of the engineering work. This effort is completed by listing the project assumptions. The next item in the scope is to identify and detail the project budget. In most cases the budget is a limiting item as to what tasks can be completed through the project. This PMP is flexible enough to deal with many budgetary situations.

As the student design team comes to know more about their project through the steps of developing a project scope the students are also asked to evaluate the project risks. This can be a difficult task for some projects as it may not be clear as to what risks exists for the student's success. In most cases assistance by the faculty and project sponsor helps the students in completing this task. These risks can fall within many categories. Some risks are technical risks such as a challenging design task or a nonexistent solution. There are also manufacturing risks that could impact the outcome of the project. Some projects could have human or environmental risk to be considered. For this PMP, the assessment of risk for now is open to all categories which allows for a great degree of flexibility.

It has been alluded to that over the course of an engineering project change is enviable. There are many reasons as to why there is change to the scope of a project. With this in mind, the PMP has been designed to account for this reality. The students are supplied a change control plan by their faculty sponsor. With this plan administered, the student design team and sponsors can purpose and notify one another of scope changes with the opportunity to accept and reject the proposition. Due to the complex nature of these projects, there are numerous aspects of the project that could be affected by the smallest of changes. The team can manage these changes and the affects to the project that will take place as a result.

The student design team must also understand the intellectual property landscape that exists for their project. When designing a solution to an engineering problem, it is necessary to understand what solutions are patented as to make sure there are no legal implications to possible solutions. At the same time this knowledge can help to form a valid solution that introduces new intellectual property with the possibility of new patents. Avoiding infringement is paramount when design solutions to open engineering projects.

3) Project Planning

The last component of the PMP is Project Planning, as seen in Figure 2. This section of the PMP has four items to assist in developing and documenting the time management planning stages of the project. Student engineers are introduced to some common project tools that are widely used in both industry and academia. The first of these tools is known as the Work Breakdown Structure (WBS). Through this tool, the team graphically displays and categorizes all the significant project tasks as shown in Figure 3. The creation of this document forces the students to analyze and breakdown how they will accomplish tasks to meet the documented project scope.

Robot Platform Project Work Breakdown Structure

1.0 Old Robot
1.1 Disassemble
1.2 Draw schematics of robot
1.3 Reassemble with improved wiring
1.4 Fix program glitches

2.0 New Robot
2.1 Prepare vehicle
2.1.1 Purchase vehicle
2.1.2 Remove parts on old vehicle/disassemble
2.2 Redesign robot
2.2.1 Define specs for redesign
2.2.2 Develop design
2.2.2.1 battery location
2.2.2.2 junction box location
2.2.2.3 linear actuator location

2.2.2.4 DAQ's/circuit board
2.2.2.5 onboard computer location
2.2.3 determine current component list
2.2.4 order components
2.2.5 mechanical components
2.2.5.1 draw new components
2.2.5.2 order components
2.2.6 electrical wiring plan/ power budget
2.2.7 circuit boards
2.2.7.1 draw circuit boards
2.2.7.2 order circuit boards
2.2.7.3 build circuit boards
2.2.8 refine and modify software
2.3 build robot
2.3.1 steering, starting, stopping
2.3.2 electric components
2.3.3 power
2.3.4 software integration
2.4 testing

Figure 3: Sample Work Breakdown Structure

From this list of tasks, the team first sequences the activities and then applies a time scale to meet the overall deliverable of the project, as defined in the Scope. These documents are used in conjunction to estimate the length of time each activity is to take. The scheduling tool used in this sequence is the Gantt chart which is shown below in Figure 4. Within a project, there are many technical and non-technical tasks that are equally important. The purchasing and procurement of components is a non-technical task that can be very time consuming and greatly impact the timeline of a project. Once an order is placed, some items take only days to process and receive while other items have significant lead-times and can drastically impact the timing of a project. Using the tools of activity sequencing and Gantt charts can be used at this early phase to determine the length of the project tasks such as design, analysis, experimental verification, purchasing, procurement, assembly, testing, and final assembly.

	Week						
Task	1	2	3	4	5	6	7
Define specs for redesign	■	■					
Determine component list		■					
Order components			■	■			
Design and make circuit boards					■		
Software integration					■		
Test and Troubleshoot						■	■

Figure 4: Sample Gantt Chart

The final element of the PMP Project Planning section is to list the roles and responsibilities that address each of the WBS items. With this agreed upon by all the team members, the individual contributors can start to focus and take ownership of their items with a clear understand from the Scope as to their deliverable. By including a document that clearly lists the WBS item and the team member assigned, confusion about which team member will complete various tasks is avoided.

B. Requirements Documents

At this point in the WTOC, our student design team has a clear understand of the project scope and team member responsibilities from the WBS. The Gantt chart drives the timing and sequencing of each task. With a clear vision of what is to be done to complete a successful project, the individuals are ready to begin execution of the project. Referring back to Figure 1, the second phase of the WTOC is developing the Requirements documents as shown below in Figure 5. In this section of the WTOC the student design team completes the design and analysis task associated with meeting the project deliverables. The items from the WTOC are an example set of tasks required for most engineering projects. The list is meant to be flexible such that not all projects will require all of these tasks, or the tasks required will be similar, but not exactly as listed in this WTOC. The project and faculty sponsor can work to modify this list as best suited for that particular project.

II. Requirements documents
A. Functional block diagram (hardware and software)
B. Hardware and Embedded System Tradeoff Analysis
1. Three possible solutions
2. Pugh Matrices
C. Software Design
1. Software requirements specifics
2. Software design document including flow chart
3. Justification of embedded system solution
D. Proof of Concept (Schematics)
E. Agency Approval Requirements
F. ABET Documentation
G. Risk Management Plan
H. Final Budget
I. Demonstration of Design
1. Test plan
2. Test equipment requirements

Figure 5: Requirements Documents of WTOC

The first item in this section has the students to develop a functional block diagram of their project solution, an example is shown in Figure 6. This diagram provides a graphical representation for the design and can be very helpful in explaining the solution to sponsors, team members, and those interested in the project. From this diagram, all parts of the system should be representative and the connections from system block to system block should be clear. A good functional block diagram should speak to a mid-level project description and be more informative than the high level overview, but not as detailed as an engineering drawing or schematic.

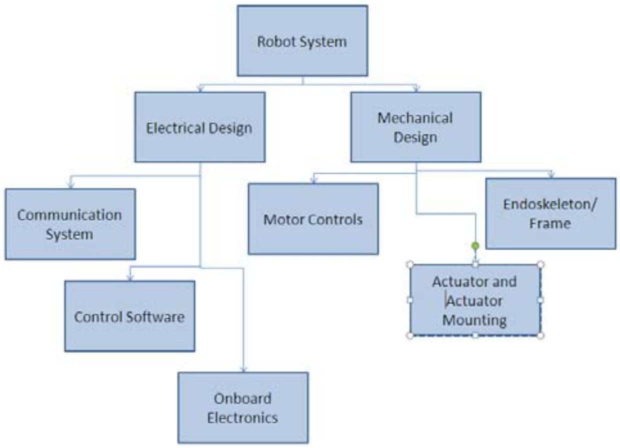

Figure 6: Functional Block Diagram

Since the focus of the course sequence is electrical engineering projects, the majority of these tasks are focused on providing the design, or the use, of an electronic embedded system to meet the project deliverables developed within the project scope. This electronic system will normally have a hardware component as well as a software component. Some project may have one and not the other, but for the WTOC both are listed for generality. In this section, the selection criterion of the embedded system is presented and the reasons the embedded system was chosen are explained.

When software is required, the student engineers are to deal with the software design as a system which includes the appropriate level of documentation is required to drive the design. With this approach the students are asked to develop a Software Requirements Specification (SRS). This document is to clearly specify the function of the software. With the SRS in place, the engineer can then design their software, and this document is called the Software Design Document (SDD). From the SDD the code is created very quickly and the team members can reference back the SDD in creating this code. With the SRS and SDD, the software task can be broken up into parts with multiple people coding in parallel all the while making sure the software meets the specification laid out in the SRS.

The remaining items of the WTOC are focused on managing constraints based on project specifics. Some projects will be approved by third party, or in house requirements. Due to this constraint, the teams document the requirements and define in their analysis and design the "how" and "why" their design will meet these constraints. These constrains may also drive tests required in the subsequently described Test Plan. As the students are completing a course, either EE400 or EE401, to meet their degree requirements, they must fulfill ABET requirements which include the documentation of how their project "meets desired needs within realistic constraints such as economic, environmental, social, political, ethical, health and safety, manufacturability, and sustainability." [1] While the students are completing their design, special attention is paid to the identified risks that where identified within the Scope and an effort is made to ensure the design meets those constraints.

With the design maturing and meeting the project deliverable in the presence of constraints, the hardware schematics, SRS, SDD, and final budget of the proposed project solution is realized. With these documents created, this information is formalized and presented. It is imperative that the design team reviews their requirements from the Scope to make sure all deliverables are meet in light of the pass/fail criteria such that the proposed solution will be successful.

The student design team is asked to provide some type of design demonstration to validate their analysis. This could be a software-based simulation using a tool like Matlab or Multi-Sim, but more likely will be a partial mock up of the purposed system. This system is referred to as their Revision 0 (Rev.0) system. Using their Rev.0 system, the team is to present and complete a test plan. This test plan should represent all the constraints as defined from previous sections of the WTOC. With their Rev.0 system passing their purposed test plan, the student teams will have confidence their final design will meet all project deliverables.

C. Execution and Closing

With the Rev.0 system successfully completing the test plan, the team is ready to move to the third and final stage of WTOC, Execution and Closing. The outline of this phase is shown below in Figure 7. In this phase the team finalizes the design by fixing any problems found through the initial testing phase. At times there will be sufficient problems with the initial design that the teams will need an additional revision of the system and testing trials. The project sponsors are asked to make that decision as to when the design team is ready to move forward. When they are, the team will finalize their design and documentation. These results are flexible to the given project and the items listed in the WTOC can be modified based on recommendations from the sponsors. Normally, these items will include their design and analysis documentation, proof-of-concept simulations, hardware schematics, the software documentation (SRS, SDD, Code), testing data as defined in the test plan, list of Scope changes agreed upon by design team and sponsors, the modified Gantt Charts with actual project timing, final project budget, along with any other pertinent documentation.

III. Execution and Closing
- A. Final design
- B. Design Results
  1. Input/output data, power requirements, ect.
  2. Statement about compliance with recognized safety codes if appropriate
  3. Statement of problems encountered in design and how problems were resolved
  4. Discuss design changes
  5. Schematics
  6. Actual schedule of events
  7. Cost of project
- C. Results of testing

D. Conclusion
E. User's manual
F. Final presentation
G. Spec sheets
H. Status reports
I. CD (includes all documentation, code, schematics, presentations, etc.)

Figure 7: Execution and Closing of WTOC

If the project requires a user manual, this would have been identified within the Scope. To meet these requirements the student design team would be asked to create this manual based on the specification of the final design. There would be acceptance criteria as defined by the project sponsor as to the completion of this task. The manual would be present in any closing documentation.

The student design team is tasked to create a report to close out their course sequence requirements which contains the project information as described previously. The students are tasked to give presentations throughout the project sequence as well as a final presentation to summarize the results of the project in closing. All of these presentations should be included within the closing documentation. The design team is asked to make a CD or DVD of all project material with a section clearly presenting the project report and presentations.

V. Conclusion

The capstone design sequence in the EE program at WKU is a successful culminating sequence which prepares students for challenges they will meet in their professional careers upon graduation. Through a variety of assessment means, the EE faculty determined that these courses would be a richer and more effective experience by the incorporation of project management topics and practices into the courses. A detailed project management approached described in this paper has been incorporated into the capstone design sequence. As a result, the student projects are better managed and the students are more effective in meeting their design objectives.

Abstract—**Information Technology has always been a popular choice among high-school graduates when deciding on a field of study. Despite the comparatively high education levels among Latvian employees, there is still a lack of knowledge and practical skills crucial for competitiveness in a market based economy. In order to ensure relevance of the qualifications and adaptability in the fast changing environment, active learning and teaching have a special importance. Recent developments in information technology call for a serious reconsideration of the actual teaching methods and provide opportunities for developing a new educational methodology. This paper focuses on experiences of application of information technologies within the course of Logistics Information Technology for developing students' practical skills and abilities. Experience shows, that social emotional skills and abilities of nowadays students have better response on interactive collaboration, especially on active methods of teaching. Therefore, the necessity for an active teaching and learning e-environment is highlighted, and its possible realisation with application of Web 2.0 technologies is discussed within the course of Logistics Information Technology.**

Keywords—active teaching and learning, information technology, logistics information technology, web 2.0

I. INTRODUCTION

Information Technology has always been a popular choice among high-school graduates during the last decades. Admissions statistics of Latvian higher schools shows that Computer Science and Information Technology are always on top among fields selected by enrolees as their future career. However, despite a comparatively high education level among Latvian employees, there is still a lack of knowledge and practical skills critical for competitiveness in a market based economy, and namely on logistics. The current paper focuses on application of IT within the course Logistics Information Technology (LIT) for developing student practical skills and abilities. In fact, information technologies within LIT are not only the subject of teaching, but rather part of didactical tool aimed at demonstrating the power of IT in every field of application, such as logistics, education, entertainment and others. The possibility of learning information technologies/systems by applying them in studies allows students (1) to understand the basic principles of IT in Logistics (which is the aim of the course), and (2) to evaluate the variety of its applications for different solutions (which is the outcome of the course). This, according to Bloom's Taxonomy of Educational Objectives, can be explained as student growth through development of their intellectual skills and abilities.

Ten year experience of teaching LIT and researching students social emotional characteristics shows the necessity of reconstructing LIT teaching methods and learning platform in a way to support active teaching as much as it can be possible within the course. The dramatically fast growth of Information Technology, which is the main subject of the course, does not allow lecturer to stay passive without updating all teaching and didactical material monthly. Moreover, students' background in information technologies and their professional skills are always the challenge for the course lecturers. The lecturer has always to be able to give professional answers to questions which are out of studying programme and actually covers just up-to-date information technologies issues.

The objectives of the paper are formulated as follows. First the experience in teaching Logistics Information Technology is shared pointing out development milestones of the course. Then, the necessity for applying active training and teaching within the course is summarized. Finally, main specifications for learning management system within LIT are pointed out leading to a conclusion of necessity of applying Web 2.0 technology into the course. According to the objectives pointed, the rest of the paper is structured as follows. In the beginning, introduction to the subject of Logistics Information Technology is presented and the necessity of developing the course is highlighted. The syllabuses of the course, as well as some pedagogical notes are discussed.

II. INTRODUCTION TO THE COURSE LOGISTICS INFORMATION TECHNOLOGY

A. LIT milestones

The symptoms of necessity for the course Logistics Information Technology in the Master Curriculum on Information Technology were pointed out firstly during participation in the European project „INCO Copernicus AMCAI 0312 (1994 – 1997) "Application of Modern Concepts in the Automated Information Management in Harbours by Using Advanced IT – Solutions"". The project results showed a great lack of logistics specialists having efficient knowledge in information technology [1].

The course of LIT was developed for the post graduate students of the Department of Modelling and Simulation in 1998. The course curriculum became an outcome of the project LOGIS LV-PP-138.003 "Long-distance tutorial network in "Logistics Information Systems" based on WEB technologies" (2000-2002). As well, the lectures and training book "Logistics Information Systems" book was published covering the main topics of the LIT course [2].

The enhancement of the course curriculum continued within participation in the next project LOGIS MOBILE LV/B/F/PP-172.001 (2004 – 2006) "Competence Framework for Mobile On-Site Training in Logistics Information Systems". The novelty of it was the use of mobile telecommunications in learning and training in the area of LIT, combining them with m-training and e-learning methodologies [3].

In the LOGIS MOBILE project usual training methods are changed fundamentally, from e-learning to m-training, together with reducing the amount of study material. Instead of comprehensive lectures and a training book it was decided to prepare, as compact as possible, a concise training dictionary in LIT. The most frequently used terms in LIT are grouped in the dictionary. There is a control question at the end of each term explanation, which would let users to check their knowledge. Mobile phones could access this study service. Computers would no longer be necessary.

In 2005, the course materials were located on the Web at http://www.logis-edu.com. Since 2007 the description of the curriculum has been located on the ELA-LogNet website. The ELA-LogNet site is a logistics education network of universities and non-academic training organisations interested and involved in initial and further education and training in logistics to promote all types and levels of logistics learning by means of all new technologies in pan-European collaboration. In 2008, co-funded by the European Social Fund, a text book in Latvian on Logistics Information Systems was published covering basic topics of the course, as well as lab descriptions. In 2009, the course curriculum was re-viewed and some critical improvements were made. The current syllabus of the course is presented in the next section.

B. LIT syllabus

The LIT course is aimed at providing students with high level knowledge, skills and competencies in Logistics Information Technology through the integration of theory and practice. The course focuses on the application of information technologies to logistics management. It is divided into two parts: Logistics Information Technologies and Logistics Information Systems. Due to the high correlation between both of them, information technology applications in logistics management should be first explored before going deeply to the subject of Logistics Information Systems, which in turn are applications of appropriate information technologies to the realisation of logistics functions. However, the important point is to observe information technologies in the context of logistics management. Fig. 1 explains the LIT course main components.

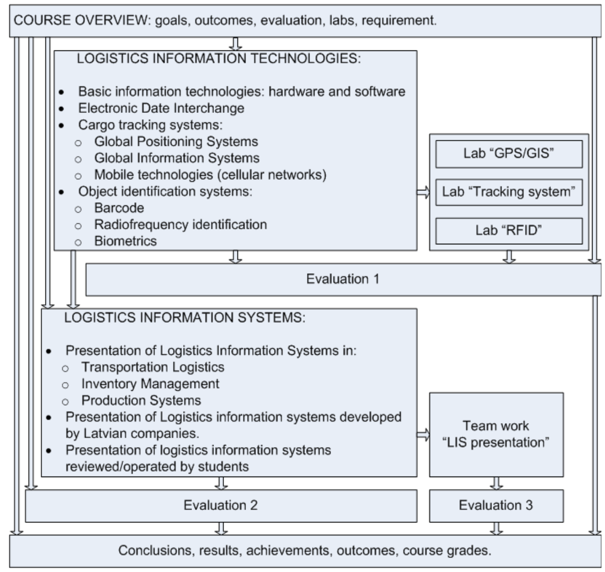

Figure 1. Main Components of LIT Courss

As shown in Fig. 1, the course is structured into several blocks. It starts with a course overview block. According to the first principle of andragogy which states that, as the learners need to know why learning is important and how learning will be conducted, the course structure, goals, outcomes and requirements must be discussed first. Moreover, a response to IT professional standards should be provided underlining the role of the LIT curriculum for getting a professional diploma of Master in Information Technology. This is normally done in interactive discussion sessions, if the number of students is not too great. Finally, the lecturer outlines the course structure, its goals and outcomes.

The second block of the LIT course covers the main topics in Logistics Information Technologies, such as Cargo Tracking Systems, Global Positioning Systems (GPS), Geographical Information Systems (GIS), Methods of Automotive Identification (Bar codes, RFID, Biometrics), Industrial Networks, Electronic Data Interchange, Mobile Technologies in Logistics etc. Actually, they all are sub-blocks within the main Logistics Information Technologies block. The sequence of the sub-block through the course is not precisely defined, and is flexible to any lecturer/students requirements. Along with this theoretical block, students should improve their practical skills performing several tasks during three labs, descriptions for which will be provided in the next section. The evaluation test finalises the block of Logistics Information Technologies and allows students to summarise and analyse it during preparation for the evaluation.

The next block of the LIT course is aimed at both exploring and introducing the variety of information systems in the context of logistics management. Several solutions are discussed in the fields of transportation logistics, inventory management, warehouse logistics, production etc. In each case the focus is on the functionality of the system for supporting related logistics functions. However, besides exploring the functionality, technical solutions are also discussed in order to underline the correlation between information technologies and information system. For example, when discussing every logistics information system, the following questions are debriefed: hardware (not only the common use like computer, fax, or whatever, but also GPS tracker, or RFID scanner), software, data transmission solutions (local network, Wi-Fi, mobile network, EDI etc.), and information technology (GPS, GIS, Biometrics, etc.). In parallel with lecturer's (and invited industrial partners' as well) presentations, students make their own presentations of different logistics information systems. This task is performed as team-work and is aimed at both enhancing students' professional competence and their group working skills. The block is finalised by evaluation tasks (see the section on evaluation for detailed explanation).

C. Labs

Although there are many different modern approaches to enhance learning by students through e-learning and m-training, the lab-based approach has gained popularity in recent years. It is recommended that labs should form an integral part of the undergraduate IT curricula. In the context of this, two lab assignments in LIT curriculum were developed and implemented in 2003, namely "The analysis of e-commerce systems" and "GPS and GIS application for object positioning monitoring". Lately, in 2007 "E-commerce" was replaced by the new one, namely "Cargo Tracking Systems Analysis", and in 2009 a new lab on "Radio Frequency Technology applications in Logistics" was added to the LIT curriculum. At the time of the preparation of this paper, the course consists of three lab assignments aimed to develop and enhance students' practical skills and competences in LIT. Table 1 provides a description of the lab exercises:

TABLE I. DESCRIPTION OF LIT LABS IN 2009

Lab	Lab description	Outcomes
"GPS and GIS systems"	Students learn the basics of GIS and GPS. They use GPS receivers to collect data (geographical coordinates) of the defined route and then analyse collected data using geographical information systems (learn how to calibrate maps, read GPS receiver data and analyse data).	Understanding the principles of GPS; Understanding GPS accuracy errors; Map calibrating skills; GPS data importing skills; GPS data analysis ability.
"Cargo Tracking Systems"	Students work with cargo tracking systems. A student team is separated into two groups. The first group makes a route outdoors while the second group follows their movements by means of the tracking system.	Enhancement of GPS principles by using mobile technologies; Tracking software operational skills.
"Radio Frequency Identifica-tion"	Students make experiments with RFID tags; write/read information; test influence of different factors (magnetic field, water, metal etc) on RFID operational capability.	Understanding RFID physics; Ability to write/read RFID tags.

D. Student Evaluation

The student evaluation process is a critical challenge for every academic course. It should be realised in a way which:

1. allows adequate evaluation of student knowledge;
2. is effective for learning and in fact is part of learning;
3. covers students personal character traits (for example, some of them perform better on tests, some benefit more in oral examinations, others do better writing essays).

Initially, the evaluation of students was conducted at the end of the course and was organised as an examination. In this, students choose a topic for discussion at random from a number of cards. After a brief preparation period, students present their topics and receive a grade. However, the shortcoming of this method is the limited number of questions students may answer in a limited time period. Due to that, since 2004 the examination processes has been supported by an on-line test which consists of more than 500 questions covering the main points in LIT. Students answered about 40-60 questions in a one hour time frame. This allowed the evaluation of a wider range of student knowledge and avoided any claims of unfair assessment. However, the main shortcoming of this is that examination at the end of the course usually leads students to postpone their studies to a few days before the exam.

To improve the evaluation by making it an assessment-for-learning, in 2009 a new evaluation system was implemented. The final grade for the course is derived from these three components: (1) a first evaluation after the "Logistics Information Technologies" block, (2) a second evaluation after the "Logistics Information Systems" block, and finally (3) a third evaluation for team-work at the presentation of the LIT system.

Each evaluation has its own weight and allows students to complete their final grade points during the semester. This can be called a portfolio assessment, in which students gather artefacts that illustrate their development over time. If a student is not satisfied with a final grade, it is always possible to improve the grade by taking a written examination which covers all course questions. The evaluation portfolio in the LIT course consists of:

- An on-line test with 60 questions which covers the block of Logistics Information Technologies (Evaluation 1 in Figure 1);
- Written essays on three questions in the context of block Logistics Information Systems (Evaluation 2 in Figure 1);
- Team-work and lecturer presentations of the Logistics Information Systems (Evaluation 3 in Figure 1).

While there are still some shortcomings in the current evaluation, the new way of assessing students provides the following benefits:

1. motivates students to study during the course;

2. minimises psychological stress during the assessment, by providing opportunity to improve the grade during next evaluations;

3. provides a variety of assessment methods way for students. This is an essential point for discussion in a pedagogical context, because there is no just one 'best' way of examining the students. Some of them being "slow-thinkers" would feel a lot of pressure due to time limitations during the test (in evaluation 1). Others might feel more comfortable going deeply into the subject (as is necessary in evaluation 2), and some like to give direct answers to precisely-defined questions;

4. supports both individual student work (and responsibility for the outcome) and team-work (where the responsibility for the evaluation is spread among all team workers).

The evaluation portfolio components may have differential weights which can be easily updated by the lecturer before the course is started.

III. PEDAGOGICAL NOTES IN LIT

There is little difference between the terms 'teaching' and 'learning' in the current paper. 'Teaching' is explained as part of educational process, where an active position (or role) is taken by a lecturer who presents (teaches) some material to students using different methods. Illustratively, a didactic lecture is a trivial method of teaching. In contrast 'learning' can be explained as part of an educational process, where students actively construct their own knowledge by absorbing, understanding and analysing information provided by the lecturer. We can assume that the student's role in teaching is more passive compared with the lecturer's, however learning is driven more by students (with some support and coordination from the lecturer's side).

In LIT, the main focus now is on supporting students in active learning and, if possible, in student-centered learning. By active learning we understand "instructional activities involving students doing things and thinking about what they are doing". Active learning is the idea that different people learn in different ways. Understanding how learning can be realised, which is the better method of learning for each student and to provide different learning styles for students is one of the pedagogical objectives of LIT. Teaching aids include text books, slide-show presentations and different video materials etc., see Fig. 2.

Every teaching process consists of three components: students, teacher, and an environment. In teaching, the role of the lecturer is dominant and usually performed by a trainer (instructor, lecturer). In learning, the main components are students and the learning environment. The lecturer's function here is to support students with a variety of methods, tools and environments. In this section, we consider the LIT course audience and discuss some teaching methods and tools specific for students doing studies in technical fields.

Despite plenty of traditional didactical teaching aids, the actual focus now is on improving the quality of educational process applying different IT solutions, especially at the Faculty of Computer Science and Information Technology of Riga Technical University. Academic personnel point out the great importance of using modern technologies in teaching. Illustratively [4, 5, 6, 7] describe the application of IT solutions in developing effective e-learning and evaluation methods.

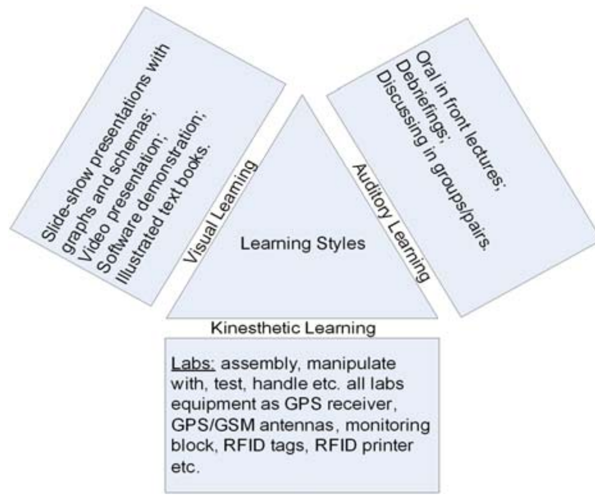

Figure 2. Supporting learning styles in LIT

A. *Course audience*

The understanding of the students taking the course is a quite essential point in any educational process. Prior experience of the learner undoubtedly impacts on the process of learning, partly because students get their experience not only at university. The LIT course is developed for postgraduate students doing full-time Masters Studies in the field of Information Technology, so prior knowledge in information technologies and computer science is preferable. This cannot be regarded as a challenge because (1) professional competence in information technologies is presumed, when one is a student in the Faculty of Computer Science and Information Technology, and (2) the course in Logistics Information Technology is a logical enhancement of the course of Logistics Information Systems Basics which is part of the Bachelor's Curriculum.

The LIT course consists basically of postgraduate students whose average age is 22-24. Almost 90% of LIT students are employed either in private companies or in government organisations, which makes them to be extremely high demanded for qualitative learning and teaching processes. Most of the students work in the IT field, which gives them deeper professional skills. For that reason, lecturers need to be able to adjust course material to suit students experience and prior knowledge. Some features of LIT students noticed during the teaching experience are:

- students ask for concise information;
- need more practical illustration;

- share their own experience about subject;
- prefer debriefing sessions to lessons;
- prefer labs to lessons.

B. Teaching methods

According to our experience, a lecturer must organise the course providing a balanced learning experience using different learning methods, i.e., lectures, labs, discussions etc., see Fig. 3. To illustrate, during typical classroom lectures, conceptual and theoretical information (intuitive learning) should be supplemented with concrete, practical information (sensory style) expressed through lecturers comments and explanations. Pictures and diagrams of slides presented to visual learners must also be explained orally for verbal learners who seek explanations having words. Active learners prefer to do physical experiments and to learn by expressing themselves working in groups. They appreciate conducting lab exercises which can promote the students cognitive activities. For reflective learners, however, we provide tasks, such as evaluating different options (i.e., different cargo tracking options in the second lab exercise) and making analysis (of the data acquired in Lab 1).

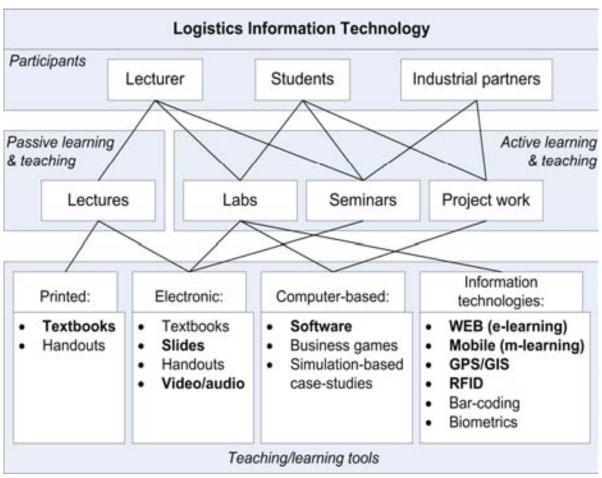

Figure 3. Teaching components in LIT

LIT employs lectures as the most used teaching method. This can be called a passive teaching method, where the lecturer has a major role. Lectures are mostly used in the Logistics and Information Technologies block; however it still has some active learning elements such as debriefing, discussions and 5-minute activities done in pairs. The Logistics Information Technologies block is organised using workshops, seminars and team-projects. Here, both lecturers and students have active roles, so this block can be characterised as an active learning support block.

Laboratory exercises are traditional method of active learning. Labs can be used to facilitate the exploration and illumination of difficult concepts. Most importantly, labs can enhance the cognitive learning process, which is often referred to as the integration of theory with practice.

In fact, information technologies within LIT are not only the subject of teaching, but rather part of didactical tool aimed at demonstrating the power of IT in every field of application, such as logistics, education, entertainment and others. The opportunity to learn information technologies/systems by applying them in studies allows students (1) to understand the basic principles of IT in Logistics (which is the aim of the course), and (2) to evaluate the variety of its applications for different solutions (which is the outcome of the course). This, according to Bloom's Taxonomy of Educational Objectives, can be explained as student growth through development of their intellectual skills and abilities.

IV. Teaching / Learning Environment in LIT

The application of information technologies for the purpose of education in LIT started almost directly after the course had finished (see table 2.)

TABLE II. IT IN LIT LEARNING

Year	IT Solutions	Pedagogical goals
Since 2004	On-line test	Student final evaluation, using on-line test
Since 2006	Mobile training	Student self-evaluation of main logistics information systems terminology, precise vocabulary
In 2007	Moodle	publishing announcements for students, providing lecture materials & handouts, giving assignments for practical work; communications
Since 2008	ORTUS education e-environment	publishing announcements for students, providing lectures materials and handouts, giving assignments for practical work; communications; evaluation desktop; course evaluation by students

Application of modern information technologies for teaching/learning purposes in LIT started firstly with using on-line test as evaluation. Lately, m-learning elements were included for student self-evaluation in main terms of LIT.

Application of Information Technology as an environment started in 2005, when all course materials were located at Learning Management System Moodle. Application of Moodle was aimed to facilitate educational process and make it more efficient and interactive, as well as for distance learning purposes. Moodle provided different means for educator and students that allow performing day-to-day operations in a much more efficient way, for instance publishing announcements for students, providing lectures materials and handouts, giving assignments for practical work and labs. In this case students were able to access all necessary materials and information from anywhere at any time when Internet is available. Also it is possible for students to stay in a permanent contact with their lecturers, which is important when personal communication is impossible (for instance, in the case of distance learning). The next step in enhancing a learning environment took place in 2008 in overall way for all RTU students. ORTUS is an environment created on the basis of LMS Moodle as a single electronic educational environment of RTU. It provides high-quality support for an educational process. However, ORTUS does not allow the use of objects, to be placed inside the educational modules repeatedly; or the use of materials, created by lecturers and students, to remain in a study programme, so that in the course of time a student loses access to them. Also, using ORTUS it is not possible to organise a comfortable educational space for active co-operation between students working on team solutions to educational tasks.

Despite plenty of benefits being provided by above mentioned solutions (mostly related to the possibility of using them outside of class), there are still some shortcomings. The following can be mentioned as main issues:

- There is no single e- environment that co-ordinates both learning methods and tools in one single platform. The on-line testing system is physically located at another website, the ORTUS structure is formed by RTU IT department and, in fact, provides only limited functionality for active learning.
- None of the mentioned solutions provides an environment for active learning. Actually, all of them serve as storage for keeping such teaching material, as slides, video/audio, handouts etc. The only active processes are forums and on-line tests.

All the above mentioned leads to the final conclusion concerning the necessity of re-designing the e-learning environment in order to satisfy the following requirements for active learning:

1. to implement active learning tools and methods;
2. to maintain learning activities like communication, discussions, team-working;
3. to support both collaborative and co-operative learning;
4. to support the lecturer's role as an active participant and co-ordinator, rather than as promoter;
5. to allow students to create valuable cooperative, collaborative and individual products, (for example, project works), which can later be used by students in their professional carriers.

When analysing applications of IT for teaching purposes, it is possible to select a number of influencing factors. In our opinion, the most important of them are the increased amount of information related to the permanent development of technologies and entrepreneurial activity, and the mass introduction in teaching the technologies on the basis of the Internet, including Web 2.0 technologies. The first factor causes changes in knowledge of the specialisation, and determines the main requirements of the environment for teaching, the rapid transmission of knowledge and abilities of the students and researchers from different geographical regions. The second factor allows an increase in the creative potential of students, provides joint creation and use of information resources and collaboration and expansion of functional possibilities for teaching. Contemporary students want teaching in the form of an active dialogue and to be in a position to have an impact on the course of events, that is, they want to be competent participants in a teaching process, the authors and reviewers, as the student-centered model foresees it.

Following the definition of Tim O'Reilly [8], Web 2.0 is the technology for designing systems which, through network co-operation continue to develop as more people use them. The main feature of Web 2.0 is to attract the users to create knowledge by introducing home page content and to use the principle of frequent verification. In the base variant of Web 2.0, every person could easily create and spread content in the World Wide Web. It could include records in weblogs, pass video information through YouTube, place pictures in Flickr, help in the creation of content in wiki, as it is actualised in Wikipedia, and also create social networks of the Myspace type. Thus, contrary to Web 1.0, which makes service to a vertical «Teacher-Student» relationship, the Web 2.0 technology is characterised by development of horizontal connections and works on the basis of social ties and relations.

The high popularity of Web 2.0 in social environment asked to its serious analysis as a tool which can be applied as teaching and learning platform. There are plenty of researches on Web 2.0 benefits as a pedagogical tool. Illustratively, [9] shows a significant reason for educators to turn to Web 2.0 as it seems fit with certain experiences emphasized in contemporary theories of learning and modern thinking. The research presents a response of Web 2.0 within the psychology of learning, namely four influential but overlapping frameworks as behaviourism, constructivism, cognitivism, and the socio-cultural perspective. It is concluded that Web 2.0 technology makes possible individual efforts of knowledge construction; it provides tools for more probing self-reflection; and, most significantly, Web 2.0 stimulates the experience of learning as interpersonal and communal in nature.

The key components of Web 2.0 are easy-to-use instruments and general or social relationship systems having the expected results. One of the most interesting results of the use of Web 2.0 is the phenomenon which is often named 'Collective Intelligence', describing the situation when the potential influence of information between the users of World Wide Web grows very quickly. It is very important, that this index increases with the increase in the number of persons actively contacting each other through World Wide Web that provides people with possibility of joint search, creation and the exchange of information. The research of McKinsey [9], Forrester [10] and other authors in the area of the application of Web 2.0 technologies, shows recently growing active interest in the phenomenon of Collective Intelligence. It has also resulted in an increase in the amount of investment in Web 2.0 technology. Researchers point out that for effective creation of new decisions and knowledge it is necessary to aggregate the possibilities for users of the input of information, methods of joint activity, and also modern technologies of collection and processing of information (wiki, weblogs, widgets, mashups etc.).

As a result of research on improving LIT teaching, the main conceptual requirements were formalised for the developed environment of e-learning with the use of modern approaches and IT technologies. It is necessary to provide the e-environment having the following basic functionality:

- permanent development of educational materials, with the possibility of their modernisation by authors and teachers and by students. Traditional electronic courses serve only as base information sources;
- generalisation of existing knowledge and the creation of new knowledge – students create materials themselves and communicate with other students through technologies, enabling the distributed creation of materials and division of responsibility in the process of forming and the use of resources;
- use of large sections of the aggregated information sources in the process of teaching, which includes in itself all possible formats of files and methods of their transmission;
- the study of materials takes place at any time and at any place: all information sources can be used not only by computers but also by mobile telephones, MP3 players etc.

The development of these new possibilities for e-learning environment will be based upon the instruments of Web 2.0 technology, such, as weblogs, wiki, podcasts etc.

Articles written on weblog technology form an analogy of the classical concept of scientific theses and create electronic home pages of a persons or organisations on which the collection of information is made on a concrete topic or topics, including regular updates of this information. Information can be written down in a weblog by a proprietor. It can be re-written from other weblogs. The readers of a weblog can also supply information, make comments on themes and discuss different questions. Automatic creation of templates is thus possible for theses published in a weblog, using information from the pages of wiki and personal notes associated with them. A weblog can be integrated with other weblogs. The results of continued experiments, current results of work and newly synthesised ideas, can be written down in a weblog.

It is possible to select the different forms of weblogs for the teaching of LIT, firstly as a means of communication between students concerning organisation of the course, the performance of tests and home tasks, and the support of different student initiatives, secondly, for additional discussion of course themes, conducted by a teacher and the encouragement of students to make independent analyses of the information received. In such weblogs, teachers will formulate questions and tasks for students, and also give references on additional materials and resources for the topic. Thirdly, for the students, using weblog on a research theme can become the method for bringing in comates and teachers to make comments, and to criticise and correct the method of preparation.

The addition of the use of weblogs for teaching LIT can be a forum – a traditional asynchronous mechanism of communication. A forum can be related to any theme, document, person, or weblog. A forum provides bilateral connections and enables both comments on the theme and the comments of other users.

For the personal base of knowledge modern technology of wiki is appropriate. Wiki is a home page which, in the asynchronous mode, is filled with information from a group of people and can be used as a mean of accumulating knowledge on a certain topic in the process of collective work. The basis of wiki is represented by a graph, where knots are noted by keywords (terms) and vocabulary entries associated with them. Personal wiki can be integrated with other wiki's, for example in Wikipedia and other dictionaries and encyclopaedias.

In teaching LIT, the use of wiki is assumed for the joint performance of laboratory exercises and course projects, and also for group discussions having a possibility of giving references on additional materials. Upon completion of every block of the course themes, students apply the acquired knowledge in practice and by wiki resources to collect new ideas, descriptions of interesting decisions etc. relating to this block of themes. In the future, they can be taken into account in a new modification of the course or to create independent educational content themselves.

To provide the course with a great number of aggregated information sources, it is possible to use podcasts. It will be used in the teaching of LIT for distribution among students by audio and videotape recordings including courses or comments on a study programme. Creation of podcasts is also planned by students themselves, summarising the results of their research in LIT course.

Conclusion

Recent developments in information technologies and telecommunications facilitate the development of new training and educational methods and tools, as described above. This provides possibilities for organising educational processes not only in the traditional way, but also by means of active learning, combining IT technologies with modern pedagogical approaches. This is of special importance for LIT teaching, where IT is the main subject of the course.

Current improving of LIT teaching relates to redeveloping course context, structure (using module-based structure), and appropriate student evaluation method. Special attention is paid to developing laboratories with modern IT equipment like GPS navigators, tracking software and Radio Frequency identification technology hardware and software. The interest among students grows up dramatically with inventing labs, moreover, they became more active not only in labs, but in lectures as well. This helped to make usual lectures to be more interactive and student-oriented with debriefing sessions at the end of every lesson. However, making those essential steps toward active learning, the importance and necessity of teaching platform became obvious. Four years experience of Moodle as learning management system showed both its benefits and shortcomings. The analysis of shortcomings leads to the conclusion of necessity researching Web 2.0 in the context of LIT.

By using Web 2.0-based LIT e-learning environment, both lecturers and students will be able to create individual centres of teaching and researches on the different themes of LIT. Moreover, the designed e-environment will provide opportunities to form student personal portfolio achievements in studies and research, by submitting them in an electronic form for discussion and debriefing with co- students and lecturers.

Abstract— **This paper describes a fingerprint identification system (FIS) developed to be integrated in learning management system (LMS). Hence, a middleware is necessary to connect any LMS with our own FIS, which will provide us a scalable, robust, easy integration in any LMS. This project aims to solve the problems of identity authentication of users in remote or virtual environments whose use has spread both in distance education and traditional universities. It seeks its integration into traditional and remote environments, and in the remote environment in exams as well as virtual labs. The project aims to cover all the weaknesses that traditionally have the password or user name. The implementation starts from the own fingerprint identification system developed to its final integration in the LMS.**

Keywords-evaluation; fingerprint identification system; learning management system; middleware; virtual labs)

I. Introduction

Nowadays, there are many precise solutions for the security in physical access and even in processes online. Into the higher education is becoming a need using new security systems. Student cards with just bar code are not enough to assure the identity. In the same way, new virtual communities manage different courses, contents and tools such as: forum, chat, calendar, etc. but what refers to identification still uses user name and password to let enter to the system. Hence, it can see the necessity of developing new application that complement and intensify the learning management systems.

In higher education there are several systems and utilities that provide robustness for both teachers and students. One example is smart cards that give access to both physical buildings and specific applications of a college. However such systems do not guarantee the identity of the person in the building, in the lab or using resources of a subject. So, we need a solution for the identity of the people that access to physical building or Web applications.

The starting point of the research is to develop a biometric system [1] which has the requirements that are demanded today in higher education. The initial challenge is to deal with a branching structure, which is our university case. As a distance Education University has different centers throughout the country and even beyond our borders. This branching structure is completely transparent to the student. The student attends at his nearest center for tutoring or exams. The documentation or logistics behind a subject are hidden.

Our university has made great changes, automating the entire process, leading to what we call "virtual package". A barcode reader identifies students who access an examination room. After checking if the student is allowed to do an exam, it prints in real time a customized exam for that student, indicating the place in the classroom where the student must sit.

The new assessment model aims to use the resources of educational communities and add a new identification module. As advantages are:

- Use of resources and applications that offer the learning management systems
- Structure applicable to any LMS
- Elimination of the process of sorting and delivery of exams
- Biometrics [2] could resolve the problem of identification

Therefore this new model instead of printing the test, the test will be done by computers in the examination room. The prints just only will indicate on a label where a student must sit. Every post will have a computer along with a USB biometric reader which will identify the student and then will show his test, Fig. 1.

II. New Evaluation Approach in Local Environment

A. Biometric Technology

The new assessment model aims mainly to verify the identity of all students in both local and remote access. The choice of technology should be based on something that characterizes each individual from the rest; therefore biometrics can provide a reliable answer to our problem.

However, a 100% secure system [3] is impossible. While biometrics can minimize the risks involved in an examination, these cannot disappear altogether. Graphically the reliability [4] of a biometrics system could watch in what is called The

Biometric Solution Matrix [5] that is based on five key points: urgency, effectiveness, exclusivity, receptivity and reach. A study of biometrics in our application and our specifications required obtained two matrices: one for local environments and another for the remote, Fig. 2.

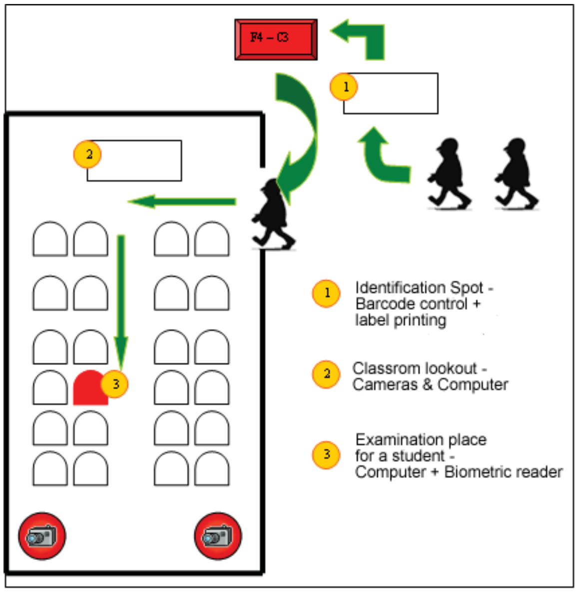

Figure 1. Schematic of the new local examination environment

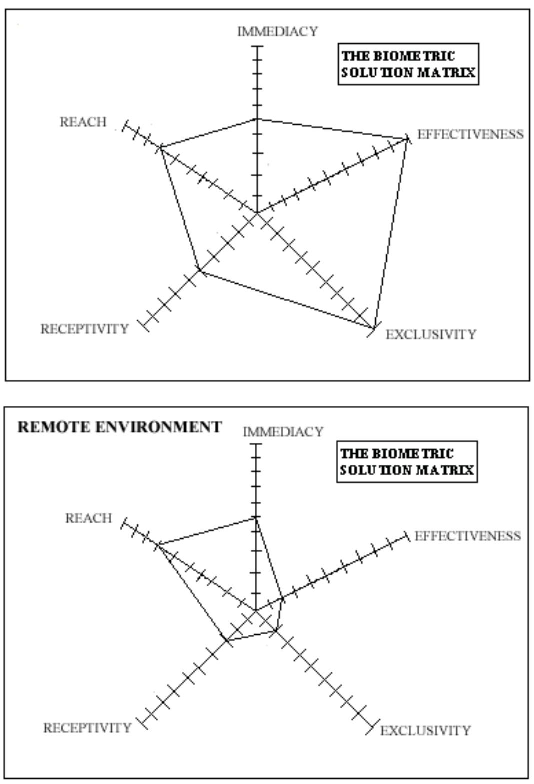

Figure 2. The Biometric Solution Matrix: Local and Remote Environment

As shown both matrices have the same levels of immediacy and reach. The immediacy show us how important are the data and whether development is needed immediately or not. In local enclosure, there is already a manual version to verify identities by ID card and in remote enclosures as they are not yet developed, hence the immediacy should have a moderate value either because there is a workaround or because data are not so important for endanger human life. The reach defines the amount of people where the biometric solution must be implemented. An application of verification for a small group would not make sense in relation use-cost, biometric systems take place in medium-high groups of students. Our university is of this kind, it handles a large volume of students every year.

The effectiveness, exclusivity and receptivity take different values in both environments. The effectiveness show us how well the system solves a problem of authentication, in local enclosure through the use of biometrics can solve perfectly the problem of identification. In remote enclosure, it is true that biometrics will give some support to the implementation, but these uncontrolled environments will have many problems to be covered.

The exclusivity present to biometrics as the only solution for an application with the need to verify identities. In local environment to our current design, the biometrics technology is presented as the best applicable technology and unique to these enclosures. In the remote environment, having a not very high effectiveness and needing other devices to control the enclosure, it is presented as a not exclusive solution needing some other methods for identification to take place at the same time.

The receptivity of students using biometrics has a moderate value in local environment, as it presents a new control that could have malfunction or give an excessive feeling of data collection. In the remote environment, the situation even worse since the implementation of biometrics must be done in a room that usually use students; the perception of intrusive technology becomes more noticeable.

Following this study we see that biometrics is a solution that fits better into the local environment, since it gets a better solution improving the current model. But in the remote environment it is insufficient and requires additional technology. Regardless of this matrix widely used to define solutions, our two environment demand greater emphasis on feasibility and costs relationship.

B. *Phases in the implementation*

The access to a class in the LMS with open permissions is done by a user name and password, which are data that can be easily acquired by others. Which puts into discussion the resources and content that must be shared with this ambiguous security.

The new service stems from the challenge of ensuring that identification. In other words ensure that the person is really the person access to such rights. This is done for a double identification using the username and password along with a new biometric application that interacts with the LMS and contents such as web exams, virtual labs, and so on.

As shown in the Fig. 3, an LMS provides the following services basically for the identification:

- Login (user/password)
- Access to Management Groups and Profiles, which gives a specific role
- Access to the resources for that role

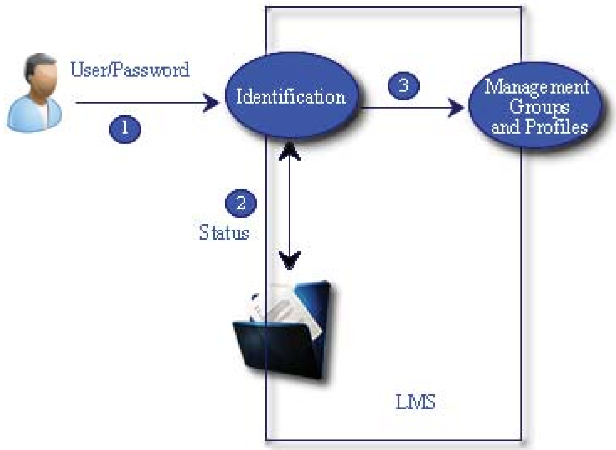

Figure 3. Basic Identification in the LMS

The new model, Fig. 4, involves adding resources that do not exist in the learning management systems. Our project should design a module applicable to any LMS, such as dotLRN, Moodle, Sakai, etc.

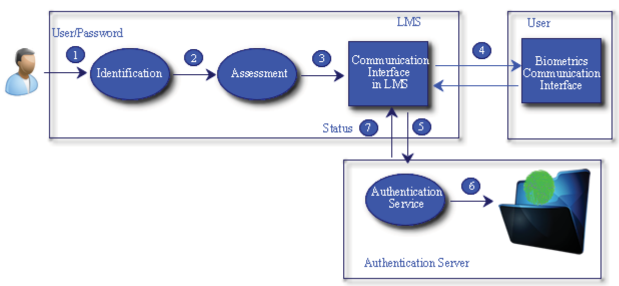

Figure 4. Block diagram of the new security model

The learning management system offers range of services among which is the option to do tests. When a student accesses to the assessment package in LMS it will start the communication between the LMS and the biometric device on the user.

The communications interface in LMS will request the capture of a biometric sample. Then, the biometric interface will send a captured sample. The next step will be to communication between the LMS interface and the authentication server.

The captured sample will be verified in the database of the Authentication server. This database will contain all the samples of students with personal data, so that the biometric matching [6] will be 1:1 from a password.

The methodology of the double identification will be:

1) The user is identified in the LMS by user name and password, which is the basic and general identification of any LMS.

2) Access to the Assessment portlet

3) As a result, it starts the communication between the LMS interface and Biometrics interface.

4) The biometric communication interface will capture the fingerprint's user and return it to the LMS interface.

5) The communication interface of the LMS provides the fingerprint captured to the authentication server.

6) In the authentication server the new sample is compared with the fingerprint database.

7) It returns the approval (status) to continue the evaluation process.

Transparent manner could envisage a repeat steps 4 to 7 during the test. This would ensure that the user does not change during the test. This check can load the system and would only be done if the examination is conducted on-line remotely, that is not performed in specialized classrooms of the UNED.

III. Design of the Fingerprint Identification System (FIS)

The fingerprint identification was the first identification system that was developed, is widely introduced in the market and consequently there is great availability and variety of devices and prices. For the implementation of an automatic fingerprint recognition system in learning managements systems, it was developed a priori in a standalone environment in order to move into LMS after some test.

This system involves an image processing, study and extraction of useful information from the fingerprints. Therefore it requires a previous phases before the extraction of information, these will be a pre-processing phase and an enhancement of the image phase. The total phases generated are as follows [7]:

- Image acquisition: Firstly, it used a database of fingerprints of free distribution accessible from the website of "Fingerprint Verification Competition, FVC". Therefore we used the database FVC2002. In this database for each user was taken 8 different samples, which was enough to test false acceptance and false rejection.
- Enhancement the image. The possible noise introduced in the capture can cause distortions in the information in the fingerprint. It is therefore important to undertake a phase of enhancement [8] of the image.
- Minutiae extraction and post-processing. This is the study of discontinuities in the fingerprint, such discontinuities are called minutiae. In this phase these points are extracted and are verified that they are not spurious points.
- Comparison of data. In the last phase of the identification system compares the new captured sample with the stored samples in a database.

The block diagram of the automatic fingerprint identification system is shown in Fig. 5.

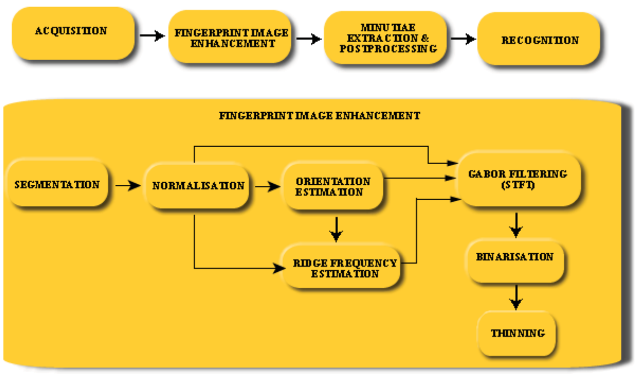

Figure 5. Block diagram of the fingerprint identification system

A. Enhancement of the Image

Some basic concepts that will be used are: ridges, valleys and minutiae. The ridges are simply the present lines in the fingerprint, so the valleys are the groove between adjacent two lines or ridges. The useful information will be the discontinuities in the pattern of ridges in a fingerprint, which are called minutiae.

Within the minutiae are different but the most general classification is to discriminate between ridge endings and bifurcations. The endings, as its name suggests the line simple simply ends and bifurcations will be a line divided into two. The minutiae points are the targets for the next phase, but the elimination of false information will do in this phase.

The enhancement phase includes various blocks, there are: segmentation, normalization, orientation and frequency of the ridges, filtering using Gabor filters, conversion to binary image and thinning. Following, it explains each block to obtain an overview of the achievements in this phase.

1) Segmentation. It selects the image area where there is useful information, also called area of interest. The result is an image with only the foregrpund of the fingerprint. It uses a variance method [9].

2) Standardization. It adjusts the intensity values in grayscale in a certain range, mean and variance desired. This does not change the structure of the image. This phase facilitate the implementation of the successive stages in the identification process

3) Orientation of the ridges. This phase is necessary because of the type of filtering is done in the following stages. Gabor filters or also known as STFT (Short-Time Fourier Transform) are selective in frequency and orientation. For the calculation of the orientation, the image is divided into blocks and each block is calculated gradients using the Sobel operators for the direction x and y. Then we calculate the local orientation of a block centered on pixel (i,j), $\theta(i,j)$.

4) Local frequency ridges. The calculation of frequency follows the same methodology as in previous stages. It divides the image into blocks projecting all pixel values in the direction orthogonal to the orientation of the ridges, which has been calculated in previous step. Such projection has almost sinusoidal shape, which minimum points correspond to the crest of the fingerprint. Thus we can calculate the distance between the first and last peak obtaining the frequency of a block.

5) Gabor filters. Gabor filters (Fig. 6) [10-11] consist of a sinusoidal waveform to a particular frequency and orientation modulated by a Gaussian envelope (1-2). As it is selective in frequency and orientation, works effectively on the ridges without affecting its structure while reducing the noise level.

$$G(x, y; \theta, f) = \exp\left\{-\frac{1}{2}\left[\frac{x_\theta^2}{\sigma_x^2} + \frac{y_\theta^2}{\sigma_y^2}\right]\right\}\cos(2\pi f x_\theta) \quad (1)$$

$$x_\theta = x\cos\theta + y\sin\theta,\ \ y_\theta = -x\sin\theta + y\cos\theta, \quad (2)$$

Where: θ is the orientation of the Gabor filters; f is the frequency of the cosine; σ_x^2 and σ_y^2 are the standard deviation of the Gaussian envelope along the x and y axis respectively; x_θ and y_θ define the axes of the filter x and y.

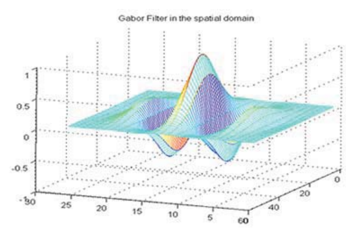

Figure 6. Gabor Filter in the spatial domain

The enhanced image is obtained from the convolution of the Gabor filter and the normalized input image. Applying this filter results an image with noise reduction, smoothing and reconstruction of the ridges.

6) Conversion to binary image. Because of most algorithms for extraction of minutiae operate with binary images, it requires the conversion of binary from grayscale. This process provides a greater contrast between ridges and valleys, where the pixels 1 are ridges.

7) Thinning of the image. In this last phase, which will be the input of the successive blocks in the fingerprint identification process, consists of thinning the width of the lines. Iteratively [12], the width of the lines will be reduced lines until one pixel width lines. As a result we have the skeleton of the input image without affecting the structure of it.

B. Minutiae and post-processing

In order to extract the minutiae point it uses the Crossing Number (*CN*) [13-14] algorithm. Such algorithm consists of scanning the values of neighboring pixels to a particular pixel P. It takes a window of 3×3 and calculates the sum of the differences of a pixel value minus the value of next pixel counterclockwise. As a result of this algorithm yields a value of *CN* which corresponds to a pixel type (Table I).

TABLE I. CLASSIFICATION OF PIXELS ACCORDING TO THE VALUE OBTAINED CN

CN	Property
0	Isolated point
1	Ending ridge
2	Continues point
3	Bifurcation
4	A crossing point

Only the ending and bifurcation ridge will be interesting to discriminate fingerprint. So the pixels with values of *CN* 1 or 3 will be stored in a database. For each minutia will be important to keep: the coordinates (*x, y*) point, local orientation and its distance to the next distance to the next minutia. Such information will be required in the matching phase.

After using this algorithm it gets some false minutiae points, which are not real information of the user, Fig. 7. This false information can be introduced by noise on the image that has not been eliminated at earlier stages and by the thinning process that could generate some random points. Then a post-processing stage is implemented, where the extracted information is analyzed. In our project was carried out following the algorithm of Tico & Kuosmanen [15], which has a common initialization phase for both the analysis of bifurcations and endings, then two alternatives: for false bifurcations or false endings.

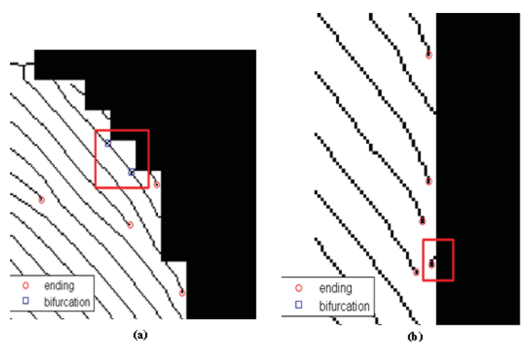

Figure 7. Results of the extraction of minutiae points: (a) Detail of the false bifurcations extracted; (b) Detail of false ending extracted.

C. *Fingerprint matching*

In this last phase of the identification algorithm is comparing an input fingerprint against the database. As we said, in the database there is local information which was extracted in the previous phases. Comparing local information [16] we will observe the relationships between points will not change. So any shift or rotation will be proportional in the both images.

Graphically all the phases of the design of our FIS can be appreciated in Fig. 8.

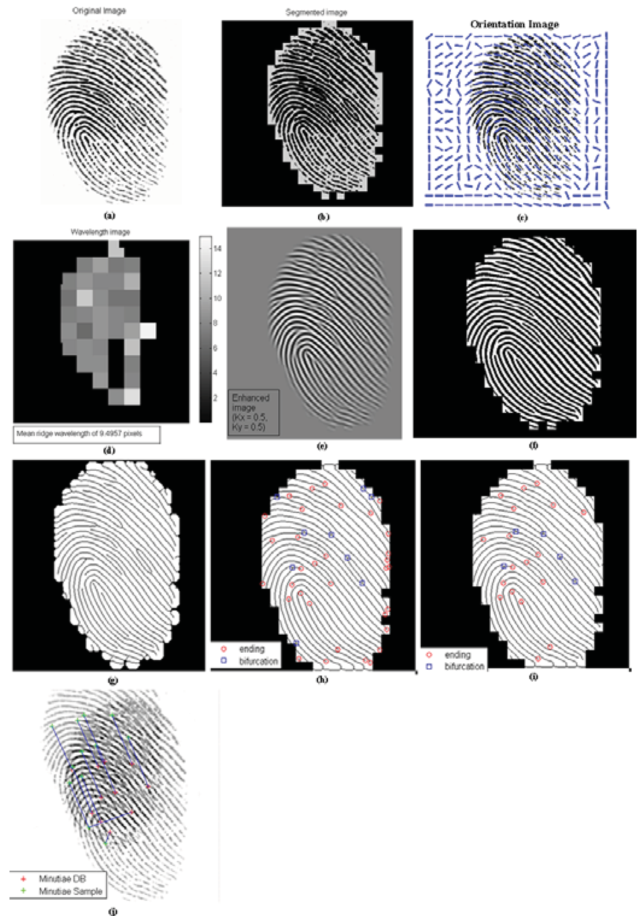

Figure 8. Fingerprint Identification System. Results: (a) Original image; (b) Segmented image; (c) Orientation image; (d) Wavelength image; (e) Enhanced image; (f) Binary image; (g) Thinning image; (h) Minutiae extraction; (i) Post processing image; (i) Matching.

IV. FIS IN ALF

The UNED uses an educational community, called aLF, to develop different contents of their courses, offers a range of services that allow a living relationship between students and teachers. It's a friendly environment. It is also an intuitive environment that requires no prior training course at the user level. That means UNED uses dotLRN as the LMS, which is an application of OpenACS, and in which aLF is based on.

OpenACS, Open Architecture Community System, is a free Toolkit, open source, which provides a fast Web application development with GPL. OpenACS architecture is based on a Web server AOLserver and as database Oracle and PostgreSQL. OpenACS provides a large set of applications that can be used to develop Web sites and is particularly useful for those who are collaborative. Some of the most important applications are dotLRN, dotFolio, Workflow, CMS, Blogging, e-commerce, forums.

It has a great set of APIs and services to rapidly develop new applications. Its data model follows the philosophy of object-oriented with standard SQL and methods with PL/SQL and support different databases (PostgreSQL and Oracle).

OpenACS is developed by TCL code and is widely used in a number of universities, institutions, companies and freelance developers.

DotLRN is a fully featured LMS-type software, open source and has a sophisticated portal system that integrates tools for managing courses, content and collaboration tools. As we said dotLRN is a system that is based on OpenACS. OpenACS is the Web Framework and dotLRN is its e-learning system and management of communities. It is scalable, robust, extensible, and with the SCORM standard. OpenACS data model implements an object-oriented that developers can modify. Users or system administrators have a Web interface that allows them to create departments and schools within which the courses are distributed.

Figure 9 shows the home screen of a course "*Pruebas del CSI"* in aLF. This is the screen to find any student in a subject.

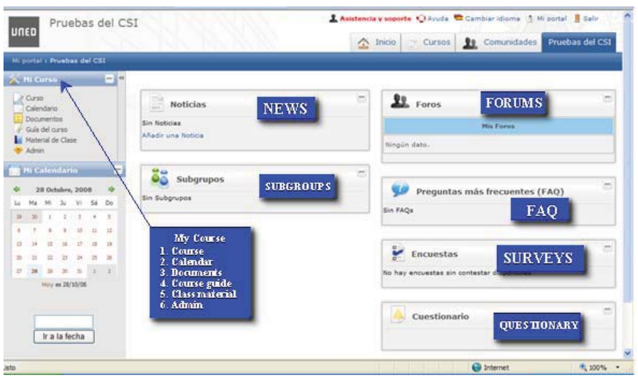

Figure 9. Start Menu for a Course in aLF

As shown on page layout is three columns with the first column narrower. In this column we present the tools, clicking on *"Material de Clase"* (Class material) one can find different exercises to be performed or documentation, subsumed under *"Tareas, Proyectos and Exámenes"* (Tasks, Projects and Exams). In this example there is an exam, called *"Prueba 1",* see Fig. 10. At this point, the LMS Communication Interface requests the capture of the fingerprint to provide access to screen or Web site of the exam.

The creation of a test by the teacher of that subject is simple; it can create a multiple-choice test or submit a URL to another page.

V. STUDY: REAL CASE IN LABS EXAMS

Evaluation is a necessary process in any training activity. If no assessment, the potential for improvement of the learning processes are not significant. The assessment helps to know the strengths and weaknesses of the training activities developed. It allows us to implement mechanisms of correction.

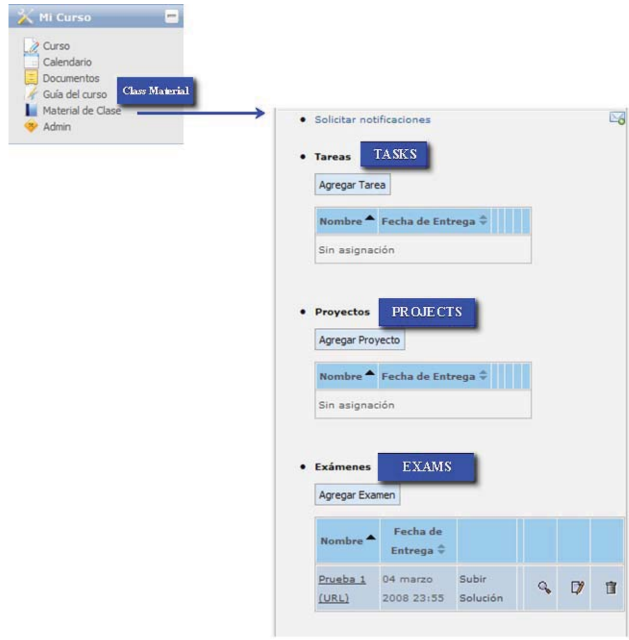

Figure 10. Class Material Options: Tasks, Projects and Exams in ALF

Three moments must be evaluated in this project:

- The design, content and strategies
- The development of the system during tests or access to virtual or remote laboratories
- The results once exams or practices in labs are over

Then, we seek a pedagogical evaluation covering the educational aspects of introducing our FIS into the LMS, including its planning, development and results.

It should be noted that levels of reaction generates the new model. Referring to the assessment that students make the quality of the new model, based on their impressions. This is an assessment of the degree of user satisfaction. Notwithstanding the evaluation results will also be important, i.e. the consequences of the new model at the level of quality for students.

So, on one side is to assess the application itself, technological, and on the other side the educational impact on student learning [17]. Table II can be seen these two lines of assessment based on the three occasions, already cited, where one must evaluate the project.

Once the module Fingerprint Identification System is created, the next step is to test its real utility in higher education. The student profile in these tests will be engineering careers. This is an advantage at the technical level, as the acceptability of introducing new technologies and ease of use is high. Users are familiar to new emerging technologies, and the use of different devices is common in their day to day. This causes the learning of another new application is fast and reduces the associated training failures.

TABLE II. EVALUATION MODEL

DESIGN	
Technological	**Pedagogical**
-Accessibility -Usability -Technical functionality of the module	-Organization (student orientation) -Objectives -Contents -Training strategies -Learning activities -Resources -Evaluation
DEVELOPMENT	
-Information / Introduction -Resolution of technical problems -Synchronous communication -Asynchronous communication	-Tutoring -Task-Management -Evaluation / feedback -Combination local / Online
FINAL	
-Acquisition of new knowledge and skills -Usefulness	

Our university has both profiles of students, sciences and arts. But the FIS module tests are intended for use in the department of Electrical, Electronics and Control engineering for industrial engineering students. At first this module is designed to apply in the subject *"Digital Electronic"* for local environments in real labs. This subject handle around of 80 students and the tests are conducted over 5 days, which means an average of 16 students per day.

After the tests of this new module to see its advantages over a traditional model is important to get values of the false acceptance rate (FAR) and the false rejection rate (FRR) as well as the measured of acceptability of users. That is the perception that they were inspired by this new module.

A questionnaire [18-19] example of parameters to be measured and which depend on the response and opinion of the students are shown in the Table III.

TABLE III. SURVEY ON THE EFFECTIVENESS OF FIS IN THE LMS

Item	1	2	3	4	5
1. Use only passwords and user name					
2. Use of biometrics in college					
3. Fingerprint is a technique intrusive					
4. Suitability of biometrics in college					
5. Improvements in the conduct of examinations Web from the traditional					
6. Integration of Web tests in the LMS					
7. Ease of online examinations					
8. Delayed LMS resource usage by FIS					
9. Improved identification after integrating FIS					
10. The identification can be faked even after FIS					
11. Enrollment difficult for biometrics					

Where: 1. Very Inappropriate, 2. Some Inappropriate, 3. Neutral, 4. Some Suitable, 5. Very appropriate

Similarly it must keep in mind that the results of the questionnaires are based on:

- Sample of 80 students
- Advanced technical knowledge
- Average age: 30 years
- Second career or professional experience for over 3 years
- Degree: Industrial Engineering

VI. CONCLUSION

The integration and testing of fingerprint identification system in the learning management system and its development during online test is the line of research that we want to continue and evaluate the advantages and disadvantages in platforms increasingly extensive and highly diverse. As well as studying the responses of students to new technologies in learning platforms.

This new module is targeted for technical profiles with advanced knowledge in emerging technologies. This provides initially greater acceptability and low skepticism about its value. After the test of the module in real exams must do a deep study about the results, producing a feedback and improving to achieve low failure rates as well as a broad acceptance and a possible extension to other technical areas within the university. As the initial approach is oriented to conduct tests online, it is intended that this resource can be integrated as middleware between protected resources, so it is attractive to think of integration in access to virtual and remote labs.

***Abstract*—This paper describes the design and implementation of a virtual laboratory for photovoltaic power systems based on the Cadence PSpice circuit simulator, which is intended to be a complement to the traditional physical laboratory in undergraduate photovoltaic engineering courses.**

Keywords-component; photovoltaic power systems; laboratories; simulation; engineering education; pspice;

I. INTRODUCTION

Virtual laboratories are recognized as an attractive complement to traditional engineering laboratories. Among other advantages, they do not require expensive and dedicated equipment, reduces the required time for instruction, and promote student involvement and learning [1]-[2]. This paper describes the design and implementation of a virtual laboratory for photovoltaic (PV) power systems based on the Cadence PSpice circuit simulator. For this purpose, a library of PV components has been developed, which allows simulating the behavior of PV components and systems.

The use of PSpice is very common in industry, research, and also for training and teaching electronics [3]-[5]. Besides, despite PSpice is a circuit simulator, it has been also used for simulating other kind of systems [6]-[8]. Its application for the simulation of PV systems begins in the nineties [9]-[10], and there is even a textbook on this field [11]. The simulation tool described here was former designed for research purposes [10], but it has been updated as educational software that can be integrated into PV systems engineering courses, which are every day more frequent in the university curricula.

Regarding its implementation, the virtual laboratory is intended to be a complement to the traditional physical laboratory. In this approach, students can be firstly tasked with virtual pre-laboratory assignments, which provide adequate background and preparation before performing actual experiments. Secondly, just in the physical laboratory, students can compare measurements and simulations during the experiments. And finally, the virtual laboratory can also support post-laboratory tasks allowing the repetition of experiments or the completion of unfinished laboratory exercises. Besides, in any of these steps, students can gain a deeper understanding of the matter through the design, simulation and analyses of their own experiments.

Among the prerequisites that should have evaluated before the adoption of computers for instructional use [12], accessibility and student computer background have received special attention. Regarding the former, a free version of the PSpice simulator is readily accessible to students without the need of purchase the license. Besides, the full license software is usually available in departments that teach courses on PV power systems. Regarding the second prerequisite, students of electrical engineering usually have learned PSpice before boarding the PV laboratory. Anyway, the required technical skills for the students are basic and they could be taught at the beginning of the course.

II. LABORATORY DESIGN

This section presents an overview of the virtual laboratory design and the simulation procedure. Later, several examples of application are shown.

A. Symbol library

A symbol library of PV components, so-called Sisifo, has been created in PSpice using a two-level hierarchical design and following a bottom-up method [13]. At the bottom level, PV components are described by mathematical models. Next, a schematic is created for each mathematical model by means of equivalent electric circuits using the Analog Behavioral Modeling feature provided in PSpice [14].

For example, the current-voltage (I-V) curve of a PV generator can be expressed with a good approximation by a single exponential model [15]:

$$I = I_{SC}\left(1 - \exp\frac{V + I R_S - V_{OC}}{N_S V_t}\right) \qquad (1)$$

Where I_{SC}, $V_{OC,}$ R_S and N_{SM} are, respectively, the short-circuit current, the open-circuit voltage, the series resistance, and the number of cells connected in series in the PV generator. The thermal voltage V_t is equal to mkT_C/q (where m, k, T_C and q are, respectively, an ideality factor, the Boltzmann's constant, the temperature of solar cells, and the electron charge).

A simplified bottom schematic that describes the electric behavior of (1) is displayed in Fig. 1, which is composed of a current source (IL) equal to I_{SC}, a voltage-controlled current source (IDIODE), and a series resistor (RS). The schematic has two output terminals (VG+ and VG-), and two inputs (irradiance, G, and ambient temperature, T) that define the operating conditions of the PV generator, of which depend the variables I_{SC}, $V_{OC,}$ and V_t that appear in (1).

This work has been supported by the UPM 2009 Program on Educative Innovation.

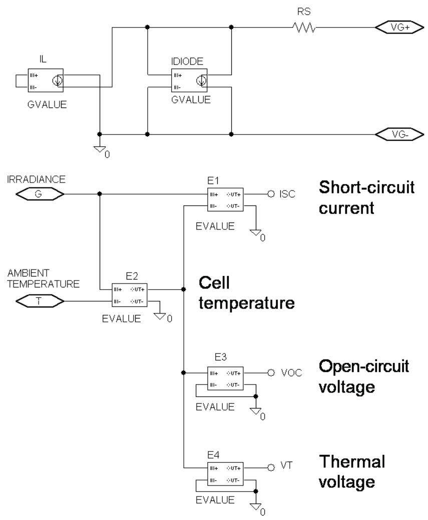

Figure 1. Bottom schematic for the PV generator.

At the top level, each schematic is associated with a hierarchical symbol that can be electrically connected in a photovoltaic system. For example, Fig. 2 displays the symbol of the PV generator associated with the schematic of Fig. 1. Each symbol has a set of attributes that define some parameters of the mathematical model, which can be modified by the students. For example, table 1 shows the attributes of the PV generator, which can be directly obtained from manufacturer's datasheet.

Besides the PV generator, other system components have been created from mathematical models using the Analog Behavioral Modeling: ON/OFF series charge regulators [15], lead-acid batteries [16] and DC constant power loads [17], whose detailed description can be found elsewhere [10]. For example, Fig. 3 shows all the Sisifo symbols arranged for simulating a Solar Home System.

The two-level hierarchical design of Sisifo allows using the simulation tool in beginning, intermediate and advanced laboratories. In the first ones, students can simulate experiments previously designed by teachers, as in Fig. 3. In intermediate laboratories, students can simulate their own experiments only at the system level considering each component as a "black-box" represented by its hierarchical symbol, without the necessity for a deep knowledge of the underlying mathematical model. In advances laboratories, students can move down in the hierarchical design in order to analyze the models or even fit model parameters as a function of the experimental measurements. Besides, advanced students can also create new models and symbols for enlarging Sisifo.

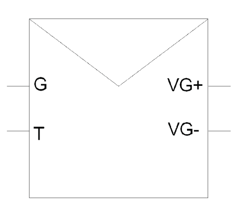

Figure 2. Hierarchical symbol for the PV generator.

TABLE I. ATTRIBUTES OF THE PV GENERATOR SYMBOL

Attribute	Definition	Units
ALFA	Short-circuit current temperature coefficient	$ºC^{-1}$
BETA	Open-circuit voltage temperature coefficient	$ºC^{-1}$
ISCM	Module short-circuit current	A
NOCT	Nominal Operation Cell Temperature	ºC
NPC	Number of cells in parallel (per module)	
NPM	Number of modules in parallel	
NSC	Number of cells in series (per module)	
NSM	Number of modules in series	
PMM	Module maximum power	W
VOCM	Module open-circuit voltage	V

B. Simulation procedure

Once Sisifo has been created, it is added to the list of symbol libraries available in the Cadence Schematics environment, which allows designing and drawing PV circuits, as in Fig. 3, simulating them using PSpice, and analyzing the waveform of simulated data using a graphical interface called Probe [13].

Regarding the simulations, PSpice supports three different types of analysis that are very useful for the virtual PV systems laboratory:

- DC sweep analysis. It allows varying the value of a source (voltage or current) or a parameter through a specified range, which can be used for plotting the current-voltage curve of a PV component, for depicting the variation of a model variable as a function of a given parameter (e.g., I_{SC} versus G), and so on.
- Transient analysis. It allows the simulation of a PV circuit response as a function of time, from an initial state (time=0) to a specified time.
- Parametric analysis. It repeats one of the two previous analysis (DC sweep or transient) several times varying the value of a source, or a parameter, in each iteration.

Next section shows some examples of simulation with PSpice using these types of analysis.

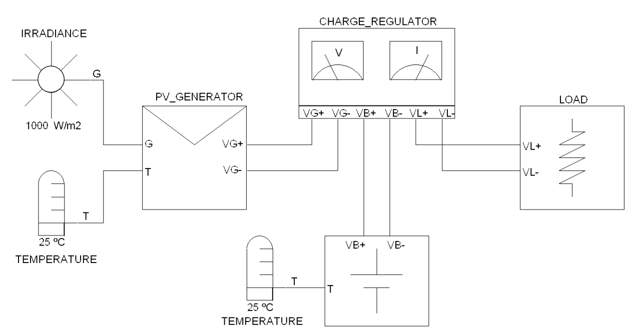

Figure 3. All Sisifo symbols arranged for simulating a Solar Home System.

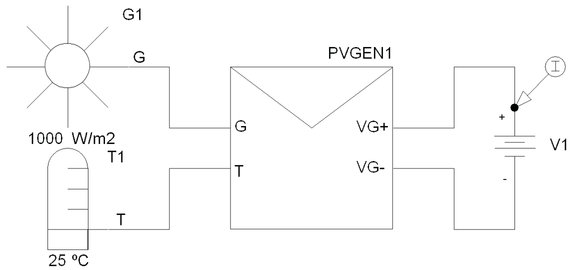

Figure 4. Circuit for simulating current-voltage curves of a PV generator.

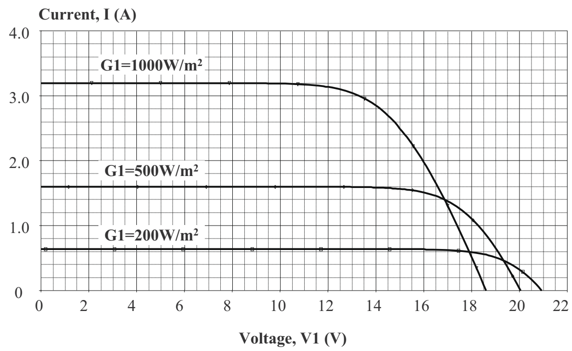

Figure 5. Current-voltage curves from the circuit displayed in Fig. 4.

C. Simulation examples

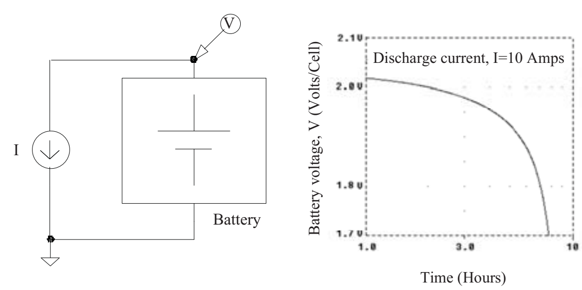
This section illustrates some of the possibilities of the virtual PV power system laboratory through several examples of simulation.

1) PV generator current-voltage curves

Figure 4 shows the circuit for simulating the current-voltage curve of a PV generator. Figure 5 displays the simulation results after performing a DC sweep analysis of the voltage source V1 (from 0 to 22V) and a parametric analysis for three irradiance values of G1 (200, 500 and 1000W/m^2).

2) Battery voltage-time discharge curve

Figure 6-a shows the circuit for plotting the voltage-time curve of a 2V/100A·h lead-acid cell, which has been simulated for a constant discharge current of 10A using a transient analysis. Figure 6-b displays the simulated curve.



(a) (b)

Figure 6. (a) Circuit for simulating the discharge curve of a battery. (b) Voltage-time curve at a constant discharge current of 10A.

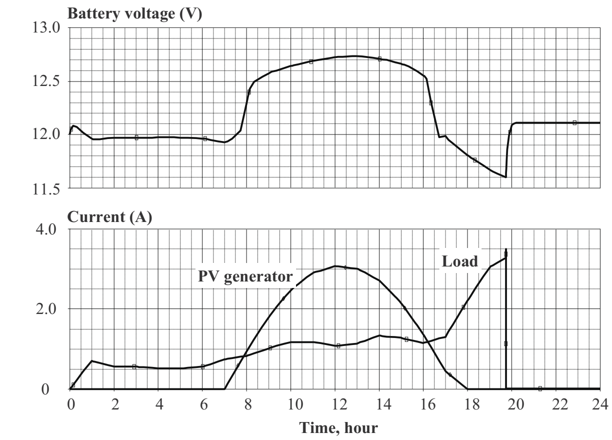


Figure 7. Evolution of the battery voltage, PV generator and load currents, after performing a transient analysis of the circuit displayed in Fig. 3.

3) Transient response of a photovoltaic system

Figure 7 displays the evolution of the battery voltage, as well as PV generator and load currents, after performing a transient analysis of the circuit shown in Fig. 3.

III. IMPLEMENTATION

In general, it is agreed that computer simulations can not completely replace physical experiments [18]. Following this approach, the virtual laboratory has been constructed as a complement to the traditional laboratory. This section describes the application of the virtual laboratory in supporting pre-laboratory and post-laboratory assignments. Despite the virtual laboratory could be also used during the physical laboratory session for comparing measurements and simulations, this application has been not considered here because the available time for hands-on experiments is usually scarce.

A. Pre-laboratory assignments

Exercises of simulation within the PV virtual laboratory can be introduced in pre-laboratory assignments required to students. Such exercises may provide a theoretical background to the behavior of PV power systems before performing hands-on experiments.

Pre-laboratory assignments may include not only a set of simulation tasks but also quizzes that should be given to the instructor at the start, or before, the physical laboratory session, which can be employed for identifying points of confusion or individual student problems.

Obviously, the designed of the set of simulations should be adapted to the student level. In their basic form, simulations may be performed on straightforward circuits previously designed by instructors, as in Fig. 4 and Fig. 6-a. Students should just push a button and the results of simulation appear in the screen, as in Fig. 5 and 4-b. Students can also modify some parameters of the circuit, for example changing the discharge current in the circuit of the Fig. 6-a, repeat the simulation, and analyze the results. A simple, but essential, application of these circuits is analysing the current-voltage curve of a given component, for example, as in Fig. 5.

Pre-lab simulations can also reproduce the behavior of hands-on experiments, which may provide an adequate preparation to students before starting the physical laboratory. Anyway, students must be aware that simulations are based on simplified mathematical models, which have their limitations in terms of accuracy, and therefore they only provide an approximation to the behavior of real PV components and systems.

B. *Post-laboratory assignments*

The virtual laboratory can also support post-lab tasks allowing the completion or the repetition of hands-on experiments, which is one of the main limitations of the physical laboratory.

Simulations also allow performing experiments that are very difficult of carrying out in the physical laboratory because they require a lot of time. For example, the measurement of one battery discharge curve, as in Fig. 6-b, lasts several hours or days, depending on the battery capacity and on the discharge current. Other experiments are simply impossible of performing in the physical laboratory. For example, determining the variation of the battery capacity as a function of the discharge current requires the measurement of several discharge curves, which would last weeks or even months.

Besides, in both pre and post-laboratory assignments, students can gain a deeper understanding of the matter through the design, simulation and analyses of their own experiments. Finally, it is worth mentioning that simulations can also play the role of assistant for answering pre and post-laboratory quizzes, which can be linked to simulations for this purpose.

IV. CONCLUSIONS

A virtual photovoltaic power systems laboratory based on PSpice has been developed and presented in this paper with the aim of promoting and improving student learning in this engineering field. For this purpose, a PSpice symbol library of PV components, called Sisifo, has been constructed, which nowadays includes the following components: PV generators, ON/OFF charge regulators, lead-acid batteries and DC constant power loads. The current version of Sisifo allows the simulation of these individual components as well as stand-alone PV systems created with them, and it is free available in Internet [19].

The virtual laboratory is intended to be a complement to hands-on experiments and can be used in supporting both pre-laboratory and post-laboratory assignments. Pre-lab exercises may provide theoretical background and preparation before performing hands-on experiment, and they can also be employed for identifying points of confusion or individual student problems. Post-lab tasks allow the repetition of hands-on experiments or performing those that are very difficult of making in the physical laboratory.

An evaluation of this virtual laboratory will be implemented in order to assess the students perception of its effectiveness on their learning process, whose results will be presented in a future work.

Lab2go - A Repository to Locate Educational Online Laboratories

Danilo Garbi Zutin, Michael E. Auer, Christian Maier, Michael Niederstätter
Center of Competence in Online Laboratories and Open Learning
Carinthia University of Applied Sciences
Villach, Austria

Abstract— **This paper discusses the creation of a common framework to describe online laboratories according to the semantic web technology. The so called Web 3.0 technology is actually growing daily and is proposed to be one of the leading Web technologies within the next years. Improved search mechanisms and facet based browsing are only some key features which enhance the data handling within the repository. Online laboratories are interactive experiments which are available over the Internet and can be divided into two main groups, software simulations and laboratories made up of real hardware equipment. Technology-enhanced learning is becoming a new important trend in higher education worldwide. In particular, engineering education is becoming an exciting emerging field of research because it involves a multitude of disciplines which aim to resolve the pedagogical problems that arise with the advancement of technology. With the help of the semantic web technology a significant step forward can be made in terms of a general description model for online laboratories and the location of laboratories with requested properties.**

Online Laboratory; Semantic Web; Ontology; Web Repository

I. INTRODUCTION

With the excessive supply of broadband Internet at the end of the last decade many research groups all over the world have started the exploration of ways to support and facilitate the learning activities of students by using new possibilities. Important outcomes of these efforts are online laboratories. Since nowadays many modern universities, schools and other organizations started programs to offer, in addition to their traditional laboratories, a wide range of online laboratories in different scientific fields. Like traditional laboratories this type of laboratory provides students with particular engineering experience and allows them to explore systems and their real behaviors. Online laboratories are fundamental for home experimentation because they are especially designed for distant learning students to acquire introductory hands-on experience and familiarize themselves with real-life phenomena. These online experiments can be found in different fields, including electronics, mechatronics, informatics, etc [1].

In traditional laboratories most of the equipment is not efficiently used because of the fact that the laboratories are used for other experiments or very specific equipments are only used for a very short time period of the year. Online laboratories are a suitable instrument to solve these problems by sharing the labs. Since some years there are a number of initiatives to share laboratories among different institutions by the use of a common architecture such as the iLab Shared Architecture from the MIT (Massachusetts Institute of Technology) [2].

Currently, available online laboratories are often hidden from the public education community. The most significant reason for this problem is the current lack of information about online laboratories that provides potentially interested parties the ability to search for adequate laboratories. This lack of information regards almost everyone in the online laboratory community such as students, administrators as well as lecturers even if this influence them in a different manner. The fundament of this problem is the lack of information which describes the resources. This is not a specific problem of online laboratories but rather a general problem of the current Web and concerns many content types of special interested communities. A solution to solve this problem can be realized by using Semantic Web technologies to describe these content types, establish a framework and create a base for new searching mechanisms. This paper discusses the creation of an online laboratory portal in the form of a repository, where information about specific properties of these laboratories is collected. The basic idea behind the Web portal is a semantically linked repository for the e-learning community that reduces the efforts of researchers as well as lecturers and students to find and share information about online laboratories all over the world.

II. ONLINE LABORATORIES

Online laboratories are interactive experiments that are provided over the Internet. Online laboratories can be divided into two main groups, software simulations and laboratories made up of real hardware equipment.

Figure I describes the classification of laboratories in general. Our focus is the right field of the depicted.

Software simulations are often used in the field of mathematics and in particular simulations where either the setup of hardware is too expensive or the setup of a laboratory is too difficult or even impossible, due to security reasons. Simulations help students to improve their knowledge and an approximate idea of the behaviour of the "real" world [1].

A large amount of currently used software simulations are already Web based and thus allowing learners to get access to these laboratories at any time and from any place[1] .
Web-based software simulations are so called "Virtual Laboratories" and differ from remote laboratories in that way, that they only use software while “Remote Laboratories” consist of real hardware equipment. In comparison to “Virtual Laboratories” remote laboratories allow persons to manipulate real hardware. Because of the fact that laboratory experiments and instruments are becoming increasingly sophisticated and expensive for universities to purchase and maintain remote laboratories is getting more and more interesting. Remote laboratories

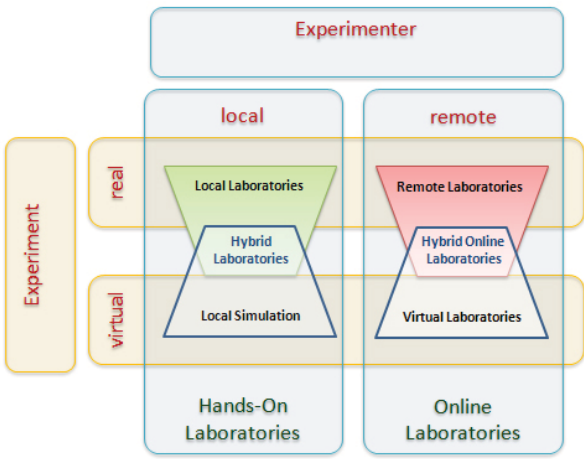

Figure 1. Classification of Laboratories

offer a solution and represent a practical alternative through which students may conduct experiments online, regardless of time and space limitations. Compared with traditional laboratory practice, remote laboratories offer flexible learning in time and place, access to a wide number of distributed experiments and cost-cutting strategies. Furthermore, as collaborative educational strategies become more widespread, remote laboratories offer great possibilities for students to interact as they work towards a common goal.

III. SEMANTIC WEB

At the beginning, the Web consisted basically of many Websites containing only unstructured text. Web 2.0 extended this traditional Web with a few extremely large Web sites specialized on certain specific content types like YouTube for Videos and Flickr for pictures. The transition from Web 2.0 to Web 3.0 implies a growing transition from receiver to producer of information, from static to dynamic content, from control of the few to the wisdom of the crowds. In contrast to Web 2.0, in Web 3.0 many Web sites will be hosting arbitrarily structured content what will be realised by using Semantic Web technologies.

The fundamental characteristic of the Semantic Web is the description of various content or information with metadata. In the traditional Web anyone can write a page saying whatever they please and publish it to the Web infrastructure. In the case of the Semantic Web, it means that our data infrastructure has to allow the individual to express a piece of data about some entity in a way that it can be combined with information from other sources. This sets some of the foundation for the design of RDF (Resource Description Framework) [3]. It means also that information is not managed for a large corporate data center.

The Semantic Web standards have been created as a medium in which people can collaborate on models that they can use to organize the information and share models that can be used to advance the common collection of knowledge.

The Semantic Web also uses the idea of class hierarchy for representing commonality and variability. Differently to OOP (Object Oriented Programming), Semantic Web is not focused on software representation, classes are not defined in terms of behaviours of methods, although the notation of classes remains and plays much the same role. Higher level classes represent commonality among a large variety of entities and lower level classes represent commonality among a small, specific set of things [4].

This is the essence of modelling in the Semantic Web: providing an infrastructure where not only can anyone say anything about any topic, but an infrastructure that can help a community work through the resulting chaos that is present on the Web concerning different viewpoints about a determined subject [4]. A model can provide a framework (like the described classes and subclasses) for representing and describing commonality and variability of viewpoints when they are known. But, in advance of such an organisation, a model can provide a framework for describing what sorts of things we can say about something.

The Resource Description Framework (RDF) is a W3 Consortium recommendation used today as a general method of modelling information by different syntax formats. The idea of RDF is a metadata model that describes Web resources in the form of subject – predicate – object expressions. This form is called triples in the RDF terminology. The subject denotes the resource and the predicate denotes the aspects of the resource and express a relationship between both.
Another important document of the W3 Consortium recommendation is the RDF – Schema (RDFs) which enables the description of so called lightweight ontologies.

IV. BASIC DEFINITIONS OF THE ONTOLOGY

One of the first steps to make use of the semantic web technology is to create an ontology, or in other words a generalized, formal representation of the domain. This general model consists of various properties, data types and relationships representing various types of online laboratories in a generic model. To develop a model, which is accepted by the end users it is essential that the model is easy to understand, well structured and a very close representation of the real world situation. At this point several discussions about various general states have to be made to ensure that the model is really applicable to the current real-world-situation.

When starting with the model definition, a lot of questions about very principal things come up. For example how is an online laboratory defined? Should we differ between an experiment and a laboratory? These fundamental questions are very important and only with the right definitions of the basic description model, it can maturate in the right direction.

Because of the various possibilities and terms to describe this domain, a general definition of the basic terms and principles in an online laboratory grid is required. In our general definition the following terms and definitions are used to describe an online laboratory:

TABLE I - PROPERTIES OF AN ONLINE LAB

Property	Description
Access URL	Every online laboratory has a URL (Unique Recourse Locator) which gives access to the online laboratory directly or via a middleware. In the last case, different laboratories can have the same access URL if they are connected to the same middleware and one laboratory can have one or more access URL if it is connected to different middleware.
URI	The property URI is the Unique Identifier of the Online Lab.
Name	The property title describes the name of an online laboratory which has not to be unique. (An online laboratory can represent in different languages).
Experiments	The property experiments represent virtual and real experiments of online labs.
Owner	The property owner represents a person or an organization (like universities or companies) which offers the online lab.
Administrator	The property Administrator represents a person which is responsible for the online lab.
Creator	The property Creator represents a person which is the developer of the online lab
Description	The property description is a textual description about the online laboratory without semantically linked data which is available in different languages.
Languages	The property language represents the available languages of the online lab.
Release date	The property release date represents the release date of the laboratory
Access Requirements	The property access requirements will give information about the access of the online laboratory (open access, access upon request, restricted access)
Lab Status	Defines whether the laboratory is online or offline.
Costs	This property represents the access costs
Technical Data	This property provides information about the technical background for the online laboratory developers
Client Requirements	This property provides information about requirements for the clients. (Client Technology, Runtime engine, Client OS, Browser)
Documentation	Documentation of the online laboratory including Hardware and Software
Architecture	This property describes the architecture that a specific laboratory belongs to.

/

Online Laboratory

An online laboratory is an environment which allows a person to perform experiments and or simulations over the Internet. Online laboratories consist basically of software based simulations or hardware based experiments.

An online laboratory can be divided further in the following three types of labs:

Remote Laboratory

A remote laboratory is an online laboratory which provides real experiments. This definition implies the control of real hardware and the realization of real measurements.

Virtual Laboratory

A virtual laboratory is an online laboratory which provides software simulations or applications.

Hybrid Laboratory

A hybrid laboratory is an online laboratory which combines virtual laboratory and remote laboratory technologies. It provides real hardware experiments and software simulations as well. All types of online laboratories have several properties, which are described more in detail in Table I.

As already mentioned an online laboratory can have one or more experiments. An experiment is defined as follows:

Experiment

An experiment in the current domain is defined as the smallest enclosed unit of an online laboratory. It provides the execution of virtual or real experiments to observe the behavior and output of a system. An online laboratory consists of one or more experiments in different fields of science and engineering.

Moreover according to the interactivity between experiment and experimenter an experiment can be categorized further:

Observation Experiment

The experiment parameters as well as the experiment environment are fixed. This kind of experiments allows users only the observation of an experiment.

Fixed Experiment

The experiment environment is fixed but the experiment parameters are remotely tunable. Furthermore it is possible to control one or more measurement instruments also remotely.

Adaptive Experiment

The experiment parameters as well as the experiment environment are remotely changeable. This definition includes for example the modification of a circuit.

Every experiment of an online laboratory is described by certain properties which are defined in Table II.

V. TERMINOLOGY

For the terminology existing vocabularies and bindings were inspected more in detail. The focus was on several well known standards such as Dublin Core [5], LOM [6], SKOS [7], vCard [8], FOAF [9] and WGS84 [10]. With the analysis of the various standards it could be seen that mostly only parts of the standards can be adopted and that a definition of various new terms for the definition of an online laboratory model is required.

TABLE II - PROPERTIES OF AN EXPERIMENT

Property	Description
URI	The property URI is the Unique Identifier of the online laboratory.
Name	The property title describes the name of an online laboratory which has not to be unique. (An online laboratory can represent in different languages).
Type of Experiment	The property type of experiment describes the type of the Experiment (Virtual experiment or Real experiment)
Description	The property description is a textual description about the experiment without semantically linked data which is available in different languages.
Scientific Field	The property field represents the division of the experiment like engineering, science as well as their subdivisions like electronics, mechatronics …
Educational level	The property educational level represents the current educational level (primary, secondary, tertia, research)
Creator	This property represents a person which is the creator of the experiment.
E-learning material	This property informs about additional e-learning material for the experiment
Difficulty level	This property represents the level of difficulty of the experiment.
Online lab	An experiment is part of one online laboratory. This property represents these online laboratories.
Documentation	Documentation of the experiment including Hardware and Software
Duration	The time a user needs to complete the remote experiment.

After the evaluation of the different standards it was made the decision to adopt basic terminology and data types from Dublin Core to the model. Examples for adopted terms are such as *title*, *description* or the *type* data which are also defined in Dublin Core.

It is not planned to make use of SKOS and LOM in the online laboratory description because only small parts are fitting to the current model and can be used to describe the online laboratory domain.

It was therefore decided to adopt some basic terminologies from the not included standards. An example here is the property difficulty from LOM [6]. This property describes very well the difficulty level with a pre-defined range [Very Easy, Easy, Medium, Difficult, Very Difficult].

Besides describing all technical aspects of the laboratory itself, a model to describe persons, organizations and projects has to be found. This will be used for properties like creator, administrator or rights holder. As already mentioned vCard and FOAF were inspected more in detail. The decision was to make use of the FOAF ontology because on one hand it allows more possibilities to define relationships between agents and on the other it is much more used as vCard in RDF representation. Within the portal it would be very useful to see which person knows whom. It facilitates then the organization and establishment of connections with other persons and groups of researchers more easily.

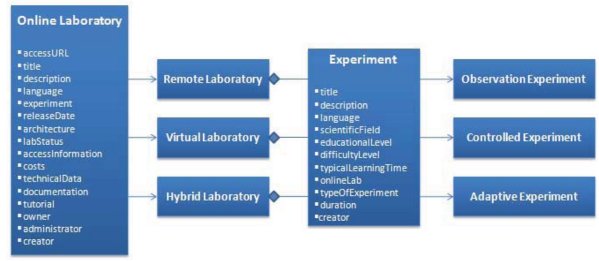

Figure 2. Classification of Laboratories

VI. ONTOLOGY DESIGN

The first milestone is to develop an ontology which is easy to understand and to apply. Right now for the first approach the ontology includes only fundamental descriptions and properties which are not too detailed. It is advisable not to implement a too detailed description at the beginning, so that the users have some freedom and the model can grow with additional user's feedback regarding inputs and terminologies. With this practice a creation of an ontology which can't be understood and would not be accepted by the end-user could be avoided. It is a very important point in defining a description model for a domain, as it could help users to get in touch with the description model and gives them also the possibility to contribute to the model development, what might increase the acceptance of the model by the users.

According to the basic definitions which are described in section IV and on the use of standard vocabulary described in section V the first draft of the ontology was made. Before starting to build the ontology a class diagram for the model was designed.

As can be seen in Figure 2 we used two main classes to describe an *Online Laboratory* and an *Experiment*.

The online laboratory class contains all properties which were defined in table II. The different types of laboratories are designed as subclasses of the online laboratory class. Depending on the type of experiment each subclass is linked to one or more experiments of a specific type. Furthermore, a class of type remote laboratory can be linked only to experiments where the property *typeOfExperiment* is set to "Real experiment".

The *Experiment* class contains all properties which are described in table II. Additionally three subclasses were created to determine whether the experiment is an observation, a controlled or an adaptive experiment. With this further division it is easier for users to differ between the interactivity types of experiments. To differ trough various interactivity types also a further property in the class *Experiment* could be used, but in terms of model readability and the implementation of facet based browsing it is much better to make use of subclasses.

Afterwards the software Protégé [9] was used to design the ontology itself. Protégé is a freely available tool to design ontologies. It has a lot of useful plug-ins and extensions such as the reasoner *Pellet* to check the ontology's consistence and the *Property Matrix* plug-in make the ontology design easier. That plug-ins will help through the development process.

As already mentioned above, the idea is to let the ontology grow together with user inputs. It is now questionable how this can be realized? We assume that users would not send e-mails or insert various comments in a forum if they have any improvements. Therefore next to the definition of the properties in our ontology the user has the possibility to add additional information. This will be realized similar as in Wikipedia. The user could write additional descriptions by setting tags. The evaluation and analysis of these tags will give the developer very useful hints to find out which additional properties are desired by the end users. Afterwards it is apparently which tags can be adapted to the model as a new property or also which properties can be renamed that they are used in the proposed way.

VII. The Aims With the Lab2go Repository

The basic idea of the Web portal is a repository that offers a common framework to collect and describe laboratory data from different laboratory providers located all over the world turns out to be necessary to continually foster the development of laboratories and exchange of knowledge among interested parties. This Web portal will host information about running research projects, researchers, organisations, existing state of the art technologies, etc, in order to strengthen the collaboration in this field of science as well as providing knowledge about the laboratories and their operating institutions.

To solve this problem this paper shows the fundamental problems that exist today and the resulting requirements which are necessary to implement a successful platform. One objective of the platform is the improvement of the search process for online laboratories with the use of Semantic Web technologies. Due to the particular way used by the Semantic Web to describe resources, not only full-text search can be supported. This kind of description enables new ways for the implementation of search mechanisms like facet based browsing which allows the user to search information according to the properties of a special object. Furthermore it is possible to query resources based on specific criteria. To outline the differences between the well known Web 2.0 methods and the Semantic Web a typical information searching scenario can be used:

- A user wants to search for all online laboratories which contain experiments in a specific filed, have a specific difficulty level and are freely available.

Using today's available Web searching tools such a query is not possible as these tools make use of keywords to perform a search. On the other hand such a scenario is perfectly supported by the Semantic Web. This new possibilities provided by the Semantic Web is one of the important keys to advance the information exchange in the community.

The fundamental concept of this project is based on the idea of making use of already existing solutions. Therefore the semantic collaboration platform OntoWiki which was developed by the research group AKSW at InFAI (Universität Leipzig, Institut für Angewandte Informatik) was chosen. OntoWiki is an open-source Platform which can be installed by any Web space and accessed by an ordinary Web browser [11] and is easily adjustable by writing customized plug-ins. Differently to MediaWiki [12], the base platform of Wikipedia, where the metadata can be directly included into the text, OntoWiki is completely based on tags and can be called as a data wiki.

OntoWiki is the base for the portal and provides a framework for the development of Semantic Web application and was therefore used to create a customized solution for online laboratories. Mostly users are not familiar with the concepts of Semantic Web or are not willing to spend time writing the metadata manually. For that reasons Lab2go is also a tool to create metadata for the online laboratory resources.

VIII. Ontology Design

The focus of this chapter is to figure out the main functionalities which will be available within the lab2go repository.

Every user has the right to browse through the repository content and search information about online laboratories. With a free registration a user gets the rights to add, edit and evaluate content. When creating or editing a contribution, the user can set group policies to control the level of access other users have over it. In terms of evaluation there are the possibilities to rate and to comment a resource. With this functionality a user gets a better feeling of the relevance of a resource.

A significant new functionality is the searching possibility. As already explained in the previous chapter by using facet based browsing customized views can be generated. Property values can be filtered out from a list of resources. This so called filtering can be applied to any type of resource and also to any relation within the description model. With a combination of two or more filters the list of results becomes more precise. Another possibility is to display various properties directly in a resource list that the property values can be recognized very quickly.

To manage the data easily an editor and additional plug-ins were developed. It looks like a common html-form when entering new laboratory data or changing some contents. In the backend the data is converted automatically to metadata and then saved in the store. Features like auto complete for pre-defined property values or resource names (if already existing) make the data input more comfortable. Also visual inputs like a calendar or the possibility to add multiple values of a property makes the editing of resources easier.

Additionally to the pre-defined description model a user can set individually tags for each resource. This has the advantage that in case a user wants to describe his laboratory with a specific term or property he has the freedom to do this without any limitation. In a second stage exactly these tags can be inspected and evaluated. The result represents a significant input for the ontology development. Misuse of terminology and need for additional terminology could be detected easily.

Not only searching, evaluation and data management tools were implemented in lab2go. One of the most important key points remains as in so many applications the data handling. Filter out data which is not interesting for certain views; finding the right order of the displayed information and make use of an impressive style are only a few considered key points. The developments in this field are going on continuously.

CONCLUSIONS

Semantic Web technology is a very broad field that can be applied in many distinct areas. In this paper very specific use-case scenarios are mentioned. There exist however many other possible extensions beyond the main scope described here. It proposes an approach on how to provide such specific type of information using Semantic Web technologies, and comprehends a first implementation attempt of an open source platform.

Summarizing this paper shows an overview about the Semantic Web (Web 3.0) and the most important differences to Web 2.0. Furthermore it covers the problems of lack of information channels for online laboratories and presents a potential solution in the form of an online portal.

***Abstract*—This panel session proposal describes an introduction of the technical activities carried out by some of the Telefionica University Chairs along Spain in a whole view of activities inside the social working of Telefonica and their associated chairs.**

Keywords-Technical networks, Corporative identity.

Abstract

Telefónica University Chairs Network focuses on the social impact of Information and Communication Technologies (ICT) in the public agenda issues and especially in some of the principal areas of interest for Society, such as: the impact of ICT in education, health, inclusion, climate change, security or productivity. In 2009, its strategic plan includes: research projects, prospective studies and surveillance technology, workshops with experts and knowledge transfer activities. Currently, there are 16 Telefónica University Chairs in 13 Spanish universities.

Under this programme, Telefónica has promoted a knowledge portal that aggregates information coming from different universities sources belonging to the Chairs network. The objective is to create and develop a community of experts belonging to both, the academic and the business worlds with the aim of opening the conversation and disseminate the contributions to the community. In the website can be found, for example, information about the use of new technologies in education, advances in telemedicine, analysis about how to improve the industry productivity or how the use of ICT can help with climate change challenges.

Telefónica University Chairs Network provides a channel for knowledge transfer among universities and also between universities and Telefónica. Specialised workshops are periodically organized with the participation of business and university experts to discuss and share knowledge about the current state and the future of some strategic topics. Some of them are: the new architecture and the challenges of the next Internet generation, IPv6, intelligent sensors networks and security in electronic commerce.

Abstract— **Information and Communication Technologies have enabled us to gather much more information, to process it better and to disseminate it to anybody in the world. So, these technologies appeared to be one of the most powerful tools for educators. The experience or the University of Deusto in applying a Competence-Base Learning Model supported in an LMS and the results of the adoption of this Learning Model to a new Open Source LMS give us the lights of LMSs experience in University. The adoption of 2.0 technologies in the classroom through an initiative of the Telefonica Chair has result in a test bank and a very useful experience for educators interested in applying these technologies so as to know the lights and the shadows of this tools.**

Keywords-component; education; LMS; Web 2.0; Learning Cycle; Competences; e-Learnine.

I. New Technologies in Education: a Mirage or a Miracle?

Are Information and Communication Technologies bringing any good to Education? This was the question which UNESCO began with its Newsletter on Education in the end of 2003. They wanted to pinpoint that it was a chimera to trust in any single technology to transform education [1], more than that, we would like to add that a bunch of well chosen technologies could hardly produce any good result if they are not properly backing an effective pedagogical framework.

In fact, having the best means and the best technologies does not always turns out in obtaining the best results if those means and technologies are not guided in the right direction.

Most of the experts would agree with us in thinking so. Information and Communication Technologies have enabled us to gather much more information (and under some conditions, to transform it into knowledge), to process it better and to disseminate it to anybody in the world (of course, if that one has granted the access to the net). But technologies, by themselves, will not give us a place in heaven.

II. MAUD: The Pedagogical Framework of University of Deusto. A Competence-Based Learning Model

The University of Deusto, a pioneer in this field, has been developing and implementing a unique pedagogical framework during the last ten years, known by its acronym MAUD (University of Deusto´s learning model) [2], which has been the foundation of the Tuning Project [3], now spread not only around European Universities (and supported by European Commission) but to the United States and South America ones as well. MAUD is based in autonomous and meaningful learning and centered in students´ skills and competences development as advocated in the European Higher Education Area.

The development of a competence-based model found in ICT a natural ally allowing teachers and students bear part of their interaction and monitoring of their learning process in an Learning Management System platform.

The Chair of Telefónica has been involved over last two academic years in several projects related to the use of information technology as supporting tool in the learning process, two of which are presented in this paper.

III. MAUD: Learning Cycle

MAUD encourages students´ personal development and meaningful learning. Meaningful learning cannot be based merely on the acquisition and repetition of information that has been delivered by someone else. To this effect, meaningful learning should involve thinking, combining activities of observation and contextualization with activities of reflection that help to understand situations and contents. Thus, MAUD [4] defines a structured learning cycle organized in five stages, as shown in Figure 1.

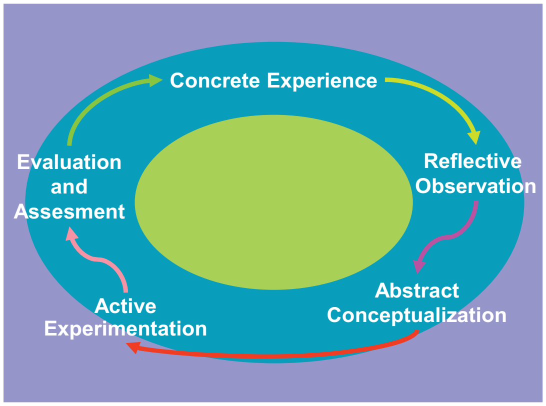

Fig.1 Learning Cycle Stages

A. Concrete Experience

To sum up, this first step tries to put the student in relation with the topic to be learned/studied starting from her knowledge and experienced got beforehand. People do not begin learning form point zero, but from the standpoint of their own knowledge and experience. Therefore, the model seeks to motivate the student through his own experience and context to come close to the idea of the topic. During this step, defining or describing the problem under study and sharing the objectives of the training process between professor and student are key issues.

In this first phase of rapprochement there can be introduced various strategies to assist the person to ask the proper questions to contextualize a particular subject: Linking to other contexts, experiences, future expectations, questions of how to learn, questions on the subject, common perceptions.

B. Reflective Observation

This phase is an essential step in meaningful learning. Reflective observation involves knowing how to see, opening our eyes to look at the reality that surround us and, secondly to question through reflection the considerations that this observation, in the form of ideas, objectives, goals, experiences, contents or conducts, really means.

It is the student who takes the responsibility of linking ideas, feelings and values with their own reality and way of seeing the world. Learning materials are the basis of student work, and must represent a challenge for them to transform their knowledge and previous experience in new and deeper understandings.

This phase should help learning things and concepts, their use and applications, their effects on others, and so on. The purpose of this phase is the person to ask questions, be concerned, as no significant learning can occur if individuals do not question about what they are learning and their circumstances. Evidence shows that students have great difficulty in asking questions and questioning about themselves and their surroundings. This is a clear indicator of excessive dependence from their teachers.

C. Abstract Conceptualization

Abstract Conceptualization follows Contextualization and Reflection. Then, the purpose is to learn as deeply as possible the theoretical positions on the issue, bringing the student the theory that from a specific scientific area has developed. Conceptual learning is based on the acquisition of knowledge, scientific terminologies, facts and data, methods and strategies, principles and theories that shape scientific knowledge of each subject.

This is a learning process based on the use and application of cognitive skills such as understanding, analytic-synthetic thinking, critical opinion and divergent thinking, enabling integrated and meaningful learning.

The conceptualization phase allows the scientific mainstream and, at the same time, it is a phase that helps the mental structuring of ideas, principles and theories, linking them with other ideas and thoughts that help to embed information and especially to produce knowledge.

The conceptualization of coping may be an individual at an early stage and later as a team. The contribution of intellectual styles and individual characteristics of each member are the basis for enrichment of the group.

D. Active Experimentation

The fourth phase concerns the linking of theory and practice. It includes any activity that promotes development of skills and abilities of students in applying concepts, theories or models with the aim of further strengthening them. There can be included drills, exercises, projects, or research designs.

It is an especially appropriate stage for collaborative work, learning to cooperate and develop social and interpersonal skills. This individual and social nature of learning has the potential to create powerful learning environments that use traditional and virtual experience as a resource for collaborative learning and to integrate academic and social life. In this regard the contribution of an LMS and, as discussed in subsequent experience, Web 2.0 happen to be a very powerful element.

E. Evaluation and Assessment

This final evaluation of the results achieved in the learning cycle has several perspectives. A staff assessment for the students to reflect on what they learned. A formative dimension that is based on the consideration of feedback as the key to student progress. Finally the evaluation of work and study of each student as an accountability process.

IV. ICT IN EDUCATION: LEARNING MANAGEMENT SYSTEMS AND WEB 2.0 TOOLS

As everybody knows, the boom in ICT has fostered the development of virtual education or e-learning, above all, to gain efficiency in the new paradigm of Higher Education as it is been promoted by most states in Europe. Among them, Learning Management Systems –or Content Management Systems- and those architectures related to the Web 2.0 are the most popular tools to make virtualization in education possible [5].

But these advances in information technologies have produced, as well, great controversy in the education community about the ideal model, whether it is a LMS or anything based in Web 2.0 architectures, to support in the most appropriate way the learning model. Deusto was not outside of this discussion and that is why from the Chair of Telefónica some projects in both directions were proposed in order to provide tools and guidance on their use that were helpful to teachers and students in developing the learning process.

V. A LMS TO REINFORCED MAUD

According to a recent study carried out by the California State University (23 campuses, 450.000 students, 47.000 people in staff) about "The state of Learning Management in Higher Education Systems", at least in USA, LMS based in proprietary software are, to a large extent, the most used solutions to virtualize the learning-teaching process. [6]

Maybe because of the same way of thinking, maybe because human being likes to create new things, the first development of MAUD at University of Deusto was based on an e-learning platform built ad-hoc for the University, called "ALUD". The decision of developing a specific tool, based in proprietary software, rather than adopting an existing one (even under Open Source Code) was due to the primary objective to adopt of an e-learning platform perfectly adapted to the conceptual framework of the own learning model so that it would guide and support the work of educator, not only in development, but in the very conceptualization of her subjects.

More recently, the opportunity of adapting the well-known Open Source Learning Management System, Moodle to the MAUD was analyzed. It should offer educators a platform widespread in the educational community, and therefore it should be easier for them to share and to exchange courses and materials while a suitable environment to learn the conceptual model they use.

The aim of this project was twofold. For one hand, University of Deusto took advantage of this process to rethink the whole tool (ALUD 2.0 was born) and for the other, it was agreed that the new solution should be an Open Source based Learning Management System; so, in this way, it was Moodle the new LMS chosen.

It is to be said that, from the perspective of the University of Deusto´s Model of Learning (MAUD), two key elements should be added to Moodle in the customization process of the new platform: the format of the courses according to the definition of the learning cycle and competency assessment.

A. Format and Structure of Courses

The previously stated Learning Cycle makes up the different learning units, so the five phases described before define the structure of each learning unit. To accomplish to the model, Moodle Themes were used to support the learning units.

In this way, every instructor could use the new LMS platform without having to renounce to any characteristic of the Deusto´s pedagogical framework. Another aspect that was no of less importance was the fact that, achieving a structured model, it would give higher coherence and solidity to the whole educational system as everybody would have to adopt the same strategy in the teaching-learning process.

Besides of that, the use of Moodle for the new ALUD 2.0 platform offers educators a variety of compatible resources through the incipient/vast community of teachers that are developing courses with it, so that they can exchange units, courses and, even, teaching strategies with the rest of the users of Moodle based LMS.

A special effort had to be made in order that all the previous educational material, the one designed under the first proprietary platform, could be automatically migrated to the new one as no teacher wanted to lose her work. This was a key issue for the success in the adoption of the new platform.

B. Competence-based Assessment

As Delors´ report proposed [7], during the last years, a special attempt has been made to redefine education as a process to acquire and develop some general and specific competences instead of following with the old paradigm which defended to learn (memorize) a lot of different contents. As explained before, this is the main foundation of MAUD.

Competences are the cornerstone of Deusto´s pedagogical model. By competence, MAUD understands: "the set of acquired knowledge, capacities, abilities and skills leading to a good level of development and action" [8].

Twenty one competences comprise MAUD´s framework, each of them split in three progressive levels of achievement and for every level several indicators and descriptors have been established to offer a complete vision of students´ performance.

Being the development of these competences the main goal of the MAUD, assessment plays a fundamental role in the whole model. As most users know, Moodle contains a special module to assess outcomes which could be used, if not as it was, for this purpose.

Moodle´s "standards" offer some sort of indicators and descriptors to define somehow competences. Nevertheless, these resources were not sufficient to back competences as they are defined in MAUD up.

So it was necessary to adapt the new LMS to MAUD´s requirements. To accomplish it, the arranged module allows to structure competences in different levels, indicators and descriptors. It is platform administrator's or each educators job to define and concrete each of those aspects for the given competence or competences that should be developed through the particular subject. After this work of systematization, evaluation could be done to know the real level achieved by each student related to every worked competence.

The result of this work has been a new platform that has integrated the knowledge accumulated in a decade of research and experimentation in a competency-based model over an Open Source platform widespread in the educational community.

Currently a pilot experience is been developed for a score of ALUD experienced teachers who are evaluating the functionality of the new platform, its adaptation to the latest innovations in the model as well as the migration process.

First impressions are excellent and the experience has been so positive that some of the technicians who have been involved in the adaptation of Moodle have decided, encouraged by the university itself, to create a startup to use the knowledge gained in the project and, in this way, to extend it to the broader community of Moodle users.

In this process, there has been an important contribution of some professors associated with the Chair of Telefónica not only through their technological knowledge of Moodle developments but the experience in applying Moodle and The Pedagogical Framework of University of Deusto. Finally, complete content and organizational editing before formatting. Please take note of the following items when proofreading spelling and grammar:

VI. LMS VS WEB 2.0 : TWO OPPOSING POINTS OF VIEW

During the last decade, LMS deployments have been consolidated in most of the traditional educational institutions [9], not only to replace face-to-face instruction (e-learning), but also to combine it with computermediated instruction (b-learning or "blended learning") [10]. No problems have been found by teachers and students adapting to this change -apart from the usual technical difficulties- because these systems mimic most of the concepts used by traditional education: order, arrangement, standardized evaluation, etc.

At the same time, the popularity of Web 2.0 [11] has brought a slew of new interaction styles, boosting participation (collaboration), customization (flexibility) and immediacy (real-time). Such a radical shift has determined the development roadmap for other available platforms, forcing their adaptation to the new communication demands.

Unfortunately, traditional e-learning platforms are too lined up with the conventional education structure. They haven't been able to follow flexible 2.0 applications' fast pace. Some teachers, fascinated with this new conception of the web, have decided to rebel against the imposed LMS and embrace the Edupunk movement [12]. Edupunks criticize the stifling rigidity of the archaic and closed LMS systems, reclaiming more open, agile and flexible platforms, focused on the learner instead of the content, by using a DIY ("Do It Yourself") approach. Despite the critics, Edupunks are not alone in the crusade against LMS.

Recently, Bush and Mott stressed this point [13] with a "Post-LMS Manifesto". Are we witnessing a shift from formal to non-formal education? From education institutions to education experiences? In the late 90's Gatto complained about many absurd and anti-life situations related to traditional education systems [14]. Nowadays, many authors reclaim a ubiquitous education [15][16], on-request and nonformal[17], an "expanded education" [18]. As Stephen Downes stated [19], "learning is not based on objects and contents that are stored, as though in a library. Rather, the idea is that learning is like a utility -like water or electricity- that flows in a network or a grip that we tap into when we want". Is this just another top-down versus bottom-up endless debate? The Cathedral versus the Bazaar? [20] Or an intergenerational conflict caused by different views of the world and the learning process? [21] It remains to be seen whether the Web 2.0 Connectivism will oust the Constructivism, theoretical principles of popular LMS like Moodle.

VII. EDUCATION 2.0: A POSITIVE EXPERIENCE

Despite the successful experience of the University of Deusto in the use of an LMS as a tool in which support their learning methodology, the Chair of Telefónica, true to its goal of exploring the opportunities offered by new technologies applied to education, could not stop the implementation of 2.0 technology in the classroom.

That is why we chose to prepare and offer students a course based on knowledge of these technologies and, in turn, developed the intensive use of them as an educational tool.

After two years promoting them, we could conclude that using Web 2.0 applications at classroom has been a very positive experience. The main advantages of this change are the following:

A. Less lectures, more collaborative work

Unidirectional communication and the lack of spontaneous interaction are common situations when teaching large classes (above 50-60 students). This trend can be broken easily with social software: prompting students to comment their opinions in blogs, following each other in microblogging networks or using them to interact with teachers. Education 2.0 is more than just adding technology to education. Teachers have to become DJs [22], combining miscellaneous sources and keeping their students on the dance floor. Content can be self-made, remixed -using someone else's material- [23], or even created by the students themselves.

B. No textbook

Instead of working with just a sole information source, several diverse resources are used: blogs for group work, microblogs for communication, RSS feeds, multimedia clips linked from a wide range of platforms (e.g. Youtube, Flickr, SlideShare) and a wiki to gather them all in a common place and support collaborative work (see Fig. 2).

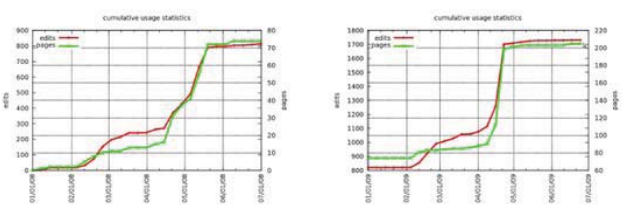

Fig.2 Wiki use during Spring Semester 2008 and Spring Semester 2009

Personal blogs or tumblelogs are used as virtual portfolios to store all subject-related resources created by teachers, students or any other online content service provider. Students can organize these Personal Learning Environments (PLE) freely, without being evaluated.

C. Beyond physical boundaries

Education extends beyond the spatial and temporal boundaries of the classroom. Interaction is not limited to teachers and students, it is virtually global. This new scenario brings back the old question quoted by McLuhan and Leonard

[24]: "Why should I go back to school and interrupt my education?". Forty years later, we can solve this problem.

Moreover, two interesting consequences arise:

- The teacher is not the only yardstick anymore: aside from their evaluation within the classroom, students also receive feedback from other users interacting with the contents.
- The teacher is not the only available data source anymore: collective intelligence of social networks [25] replaces the expert's role. Not only students are the subjects of their own learning, but also the sources of learning, functioning as the perceptual input for the wider network.

D. Non-formal communication, non-formal learning

Not every student is able to discuss a topic in public, but they are usually experts on texting and sending thoughts by mobile phones. Microblogging platforms such as Twitter are based on a similar idea. Therefore, not much training is needed to use them and increase spontaneous interaction. Microposts can be shown during the class, in a less formal way of real-time participation. If lack of privacy is a problem, less public services like Yammer or EdModo can be used instead.

As we can see, it is not casual that many teachers are gradually introducing Web 2.0 tools in their learning processes [26], due to their multiple advantages.

VIII. NOT EVERYTHING IS SO POSITIVE

Web 2.0 features can also be considered problems in certain contexts. Where some see flexibility, others see lack of control; where some see cooperation, collaboration and syndication of several sources, others see confusion.

These are the main problems detected during our experience:

A. Lack of order

Course content is not stored in a centralized and static location anymore. Instead, the content generated by teachers and students is scattered over the Internet, and may be compiled. Not being able to find and organize these resources will result in a limited vision of the whole working material. Therefore, developing this digital competency becomes mandatory [27], mastering RSS aggregation and social bookmarking platforms. In our case, we consumed RSS feeds created with Yahoo! Pipes, using blog widgets as clients, for aggregating all subject-related content.

B. Lack of control

Teachers lose control at two different levels:

- Technical level: control over technical infrastructure is usually lost using Web 2.0 platforms, because most of them rely on "cloud computing" based free services. Although is possible to deploy them "in-house", both Google and Microsoft are offering free professional services to academic institutions (regarding email, IM, VoIP, blogs, microblogs, sites, documents, etc.). The bad news is that service providers disclaim any liability or responsibility for any loss. Recently, popular Web 2.0 services experienced temporary failures, being some of them fatal to their users. [28]
- Social level: the etiquette of the Internet cannot be controlled by teachers. Their authority means nothing outside the academic institution. Spam, Internet trolls or even cyber-bullying can disrupt teachers' efforts, without an easy solution.

C. Privacy and arbitrary limits

Web 2.0 platforms promote participation and new content publication, but they usually forget about privacy issues. Mediocre or incorrect information can remain accessible on the web for years, lasting after the end of the author's academic career, and becoming a problem during professional life. Out of context blended-learning activities or teenagers' opinions may lead to similar problems. Besides, these platforms can add arbitrary restrictions to their Terms of Service (TOS), blocking some uses that can be considered legitimate by teachers. A clear example of this problem is the arbitrary age limit for some social networks, preventing their use in lower grades.

D. Scope confusion

Analyzing students' preferred social networks (e.g. Facebook, MySpace) and using them to deploy educational content is very tempting for many teachers, but such strategy doesn't seem to be very effective for some reasons:

- Teachers are not students' best option to share spare time with. They may take it as an invasion of privacy, so it is not recommended to try to be best friends.[29]
- Such an environment specifically designed for leisure, hyperconnected with procrastinating friends, full of silly tests, chats, etc., is not the best place to work on educational content. Moreover, previously defined digital identities within each social network can alter online teacher-student relation.

IX. RECOMMENDATIONS FOR WEB 2.0 ADOPTION AS EDUCATION SUPPORT TOOLS

There is no specific solution for the problems mentioned before, but different tools can be combined to achieve a good trade-off among them. The solution we would like to propose is based in a combination of content-centered tools, typically managed by teachers, and learner-centered tools, managed by students:

- Course wiki: installed on a local web server, with restricted access for students (control, privacy). Teachers and students use them to support collaboratively generated content, in a structured way, compile links to remote resources and practice with wiki syntax (Wikipedia contributions sandbox).
- Group blogs: created in a public service and merged together in a blog planet. Students use them to create and share subject-related content.
- Personal blogs or tumblelogs: used as virtual portfolios or PLEs. Students freely choose their favourite service

to develop them, and select the RSS feeds generated by the rest of the tools.

- Microblogs: mostly Twitter (public, universal) and Yammer (private, under control), to encourage spontaneous participation and real-time communication inside or outside the classroom. Generated microposts are easily added to blogs through RSS widgets.

Since there have been no previous similar experiences in our Faculty, some confusion is understandable at the beginning of the semester, but students should be able to understand the dynamics of the work after a few weeks.

The use of more homogeneous systems could be another solution to the problem. The structure of the content can be hold in a LMS supporting Web 2.0 features (e.g. Moodle), managed by teachers, and integrated with a virtual portfolio platform (e.g. Mahara). In such systems students can organize, discard or add resources in a relevant way to their own learning process, interacting with a wider community and adapting the structure of the network as their experience varies [30].

X. Some Conclusions

As previously stated, there is a serious debate when it comes to selecting appropriate tools to improve the e-learning platforms.

From University of Deusto´s standpoint, there are some consequences that have come clear during our experiences. First of all, our efforts to develop our own pedagogical framework pay off; not only to improve the previous teaching-learning process, but to design the proper tools to implement it from the technological point of view.

From University of Deusto´s standpoint, there are some consequences that have come clear during our experiences.

First of all, our efforts to develop our own pedagogical framework pay off; not only to improve the previous teaching-learning process, but to design the proper tools to implement it from the technological point of view.

Secondly, Learning Management Systems still can provide a variety of good results for professors and pupils and keep things "structured". cbconc

Thirdly, Moodle –the Open Source Solution- has provided a proper environment for our LMS ALUD 2.0. It is flexible enough to be adapted to our own needs and requirements.

Fourthly, Web 2.00 tools have happened to be a good mate in this journey. Being clear about the objectives, one can use both approaches and tools instead of choosing between both of them.

Nevertheless, there is nothing that lasts forever. For us, it means that from the Chair of Telefónica and, of course, following the path we are building up, we will keep on experimenting, implementing, and fortunately, developing suitable tools and technologies to help education to be the process that any student deserve and every teachers need.

Acknowledgment

The findings and conclusions presented here are the result work of many professors and lecturers from Deusto and especially to the Vice Rector for Innovation, Aurelio Villa, and people from the Institute of Educational Sciences at the University of Deusto. The support of Telefonica through the Telefónica Chair has allowed parts of this work to be carried out and news experiencing been developed nowadays in the adoption of new technologies into the classroom.

Abstract—**In the developed countries vocational demand for scientific and technical studies is a serious concern for government, universities and companies and different analysis and programs are promoted to try to compensate the steady decrease of their demand. In this communication the phenomena for Spain, with an spatial emphasis in Catalonia, will be reviewed in the European context, and some clues for promoting new engineering vocations will be given.**

Keywords-component; engineering vocations, engineering studies promotion

I. INTRODUCTION

The Catalan Government concerned by the decreasing number for engineering vocations in the context of a foreseeable mid term increase on engineering graduates demand to sustain the so called knowledge-based society new challenges decided to promote a plan to foster engineering vocations in Catalonia, through the EnginyCAT initiative. Progress and output figures for high school and university have been analyzed and compared at international level and more significant insights on youngsters' vocations and clues for attracting vocations have been studied.

UPC-Telefonica Chair on Future Trends on Information Society focuses its activity on the analysis of the Information Society evolution and in its impact on the different significant social fields and in particular on education, health, administration and competitiveness. Special attention is devoted to the national and international best practices and indicators at both national and international levels. The research approach for the different fields is based on the analysis on the general trends at global level and its projection at local level based on specific regional studies that allow extracting robust indicators. One of the main topic consists on studying the evolution and future trends of the scientific and technical education at the different educational levels and more particularly in high education at both national and international perspective

EnginyCAT and the UPC-Telefonica Chair have joined efforts to study the main professional fields and factors for engineering practice are to draft the main professional tendencies. Basic trends for job market will be analyzed at international level and projected into the national and regional Spanish levels. Specific and differential parameters for the job market corresponding to the different main disciplines: civil, industrial and ICT, is a central field of research.

II. ACADEMIC AND PROFESSIONAL CONTEXT

In order to have a consistent perspective about higher educational demand on engineering and technology it seems convenient to take a look at the preceding pre-university secondary education, Fig. 1, [1-2], data in science and technology areas.

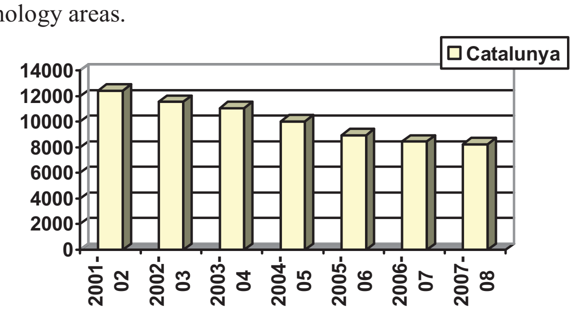

Fig.1 Number of technology junior-year high school students in Catalonia

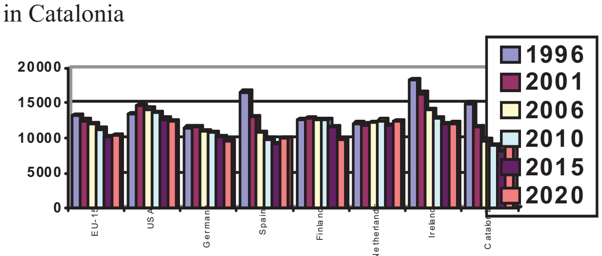

Fi

Fig. 2. 18-year old population evolution per million of country inhabitants.

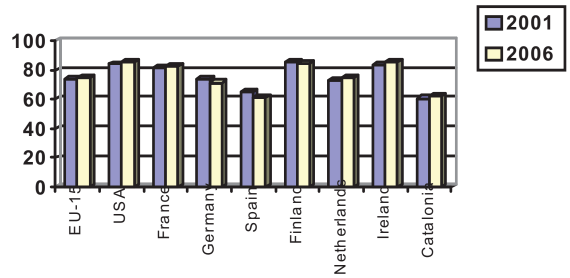

Fig. 3 Percentage of population successfully completing secondary school

At Catalonia (and similarly Spanish level) data show, [3], a steady yearly decrease of about the 5% (2% due to the demographic decrease and the 3% due to the percentage decrease with respect to its population of age). In absolute terms the population has passed from 12.400 youngsters in 2001-02 to 8.243 in 2007-08 academic year. When looking at the evolution into the international context, it may be seen, Fig. 2, that demographic decrease will still add pressure to the total demand decrease at least until 2015. An additional factor stressing the number of students entering at higher educational level is the percentage of youngsters completing secondary school. It may be seen in Fig. 3 how these percentages for the Spanish and Catalan cases are 15-20 percentage point below European averages.

Finally a last significant aspect contributing to the engineering studies vocation shortage is the percentage of women going into Science and Engineering studies. It may be seen, Fig.4, how the percentage of women is around 25-30% far below the "natural" 50%. If some studies as Biology and Architecture are extracted, the percentage fall below 20%.

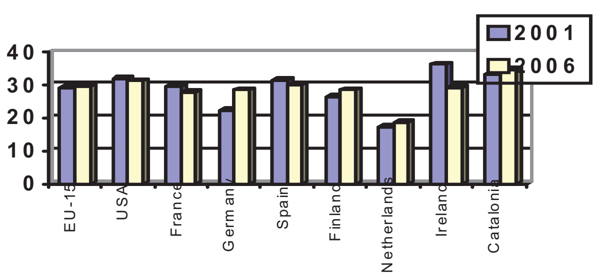

Fig.4 Population percentage Science and Engineering higher education women presence

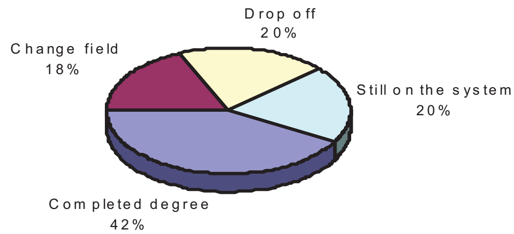

Fig. 5. 2000-07 follow-up of 8.700 university engineering students in the Catalonia University system

Once entering into the higher education, [4-7], engineering studies tend to be relatively difficult studies and the graduation rate is in some cases really low. Fig. 5, shows the academic evolution of a cohort of students entering into engineering studies in Catalonia and their evolution after 7 years (largely enough to have completed their studies). Results show, that eve entering with good marks in general, in average 60% of the students will probably complete their degree (20% probably with a quite longer time than necessary), 20% will switch to different university systems and 20% will drop off from the university system. In Fig. 6, comparative international results show that the situation in quite similar in mostly of the countries except in very well organized systems as the Ireland (Anglo-Saxon) and France systems.

When looking at the occupational job market, Fig. 8, it may be seen that in general the number of necessary professional engineers and technicians to attend the so called knowledge based society is normally above academic output and this shortage will foreseeably increase in the coming years. As an example, for the Catalan case, Fig. 8, the actual number of existing professionals (98.000) is slightly below companies demand (110.000) this makes a shortage of 12.000 graduates (10%. approximately). With the actual number of yearly graduates 7.600 out of 13.000 students entering the university this shortage will increase up to 25.000 when compared to the average EU-25 or up to 55.000 when compared to the number of professional engineers and technicians of the top European countries.

It is then clear the urgent need for reducing the gap.

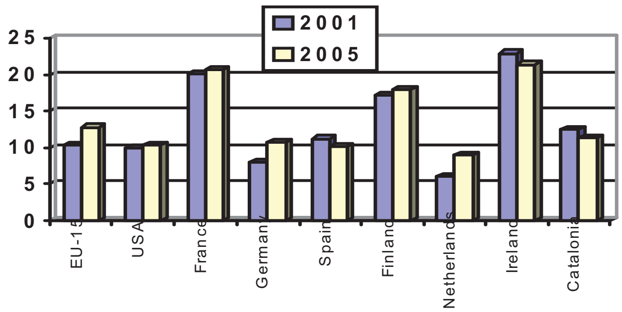

Fig. 6. Science & Engineering university graduates per 1.000 20-29 year old inhabitants

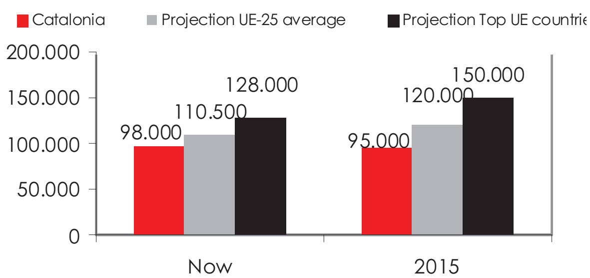

Fig. 7. Number of professionals now and 2015 projection for the engineering professional occupational market in Catalonia. Source CEDEFOP and EnginyCAT processing [8]

III. ENGINERING YOUTH PERCEPTION

In order to act over the system it is necessary to understand the factors behind the vocational shortage phenomena. Mostly of the factors are qualitative perceptional elements [9], Fig. 9, shows the more significant reasons expressed by the European youngsters to explain their lack of interest towards the Science and Technology studies.

Among the different aspects: atracttivity, difficulty, salaries and interest express their perception of a low return for a significant effort. In short they do not feel the social return (not just or especially in terms of salary) is consistent with their personal investment.

In order to contextualize this question, Fig. 9, shows the perception comparison for different professions.

It may be seen for example as Medicine studies even when having many common threats in terms of effort with engineering studies are perceived much more positively than the engineering studies.

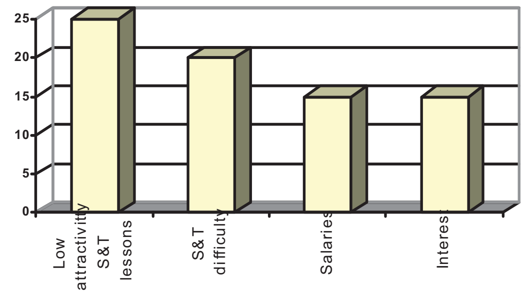

Fig. 8 Percentage of European youngsters marking the different reasons to express their lack of interest towards Science & Technology studies.

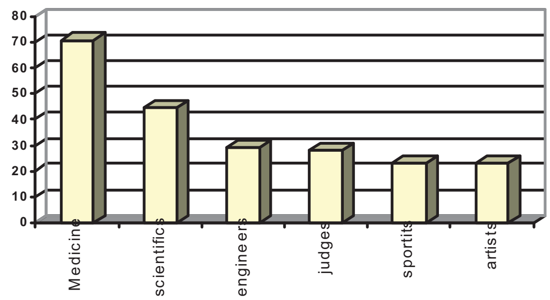

Fig. 9. Percentage of European youngsters positive perception of different professions.

IV. ENGINYCAT A PLAN TO PROMOTE THE ENGINEERING STUDIES IN CATALONIA

To balance this situation different aspects will need to be addressed. Three points will be critical: to attract more youngsters to the S&T studies, to improve the graduation rate at both secondary and university levels, and specially to improve the matching between the graduate expectations and the social return. Starting late 2008 the Catalan Government, through the University and Research Department created a plan, EnginyCAT, to promote engineering studies among Catalan youth. The goals of the program, Fig. 9, where addressed towards three main focus:

- To improve the scientific education among secondary education.
- To increase the number of youth vocations to pursuit science and technology studies, addressing a special attention to the women presence.
- To contribute to he improvement of the graduation rate at university level, with a special effort towards the engineering and technology curricula modernization.
- To improve the matching at both quantitative and especially qualitative levels between the engineering and technology graduates and the professional demand.

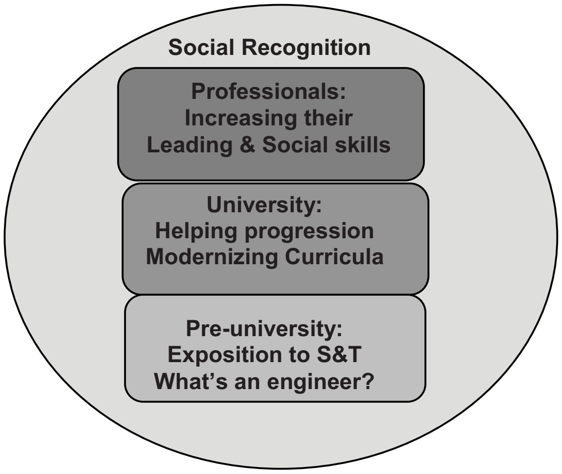

Fig. 9. The main goals of Promotional Plan EnginyCAT

The different actions need to be strongly coordinated with the different agents already operating in the system as universities and higher education institutions, professional charters, companies, etc, to create synergies and avoid duplicities.

The program consists on a broad scope limited number of actions to cover the three main areas of interest, pre-university youngsters, higher education (engineering and technicians) and professional insertion as described in Table I.

	ACTION 7: Designing future projects
LÍNE 5: Get involved!	
	ACTION 8: Engineering 2020. Curricula modernizing
LÍNE 6: Your future: Innovation!	
	ACTION 9: Leading and Communication skills

Table I. EnginyCAT Program basic lines and actions

V. ENGINNERING CHALENGES AND PROSPECTIVE JOB OPPORTUNITIES

On of the main actual social concerns is job market in general, and youngster's job market in particular. One of the ways to give a clear vision about engineering is through their professional and job new opportunities. The basic point is to translate to the society a fresh idea of the engineer role, not just from its parts but mostly from the point of view of the problems that may solve, Table II, and the job opportunities it may create.

The reasons to become an engineer
Leading a sustainable economic development to solve the emerging social XXI century new challenges
Increasing number of job opportunities and professional outputs
Innovative designs to promote new projects, ideas and companies

Table II. The engineer vision

VI. CONCLUSION

From an attentive analysis of the different academic and professional parameters it comes clearly the need to increase engineering attractiveness among youngsters. Science and technology proficiency will become of the leading economic development factors.

The key element is to generate a clear, positive and realist vision of the future engineering professional role. It is then necessary to interact with the k-18 pre-university kids and youngsters to let them know the new engineering challenges, (energy, water, health, environment, education, mobility, entertainment, aging people, etc), to increase the design and problem-solving component in our higher level studies, and to promote the innovation and entrepreneurship culture among our graduates to contribute too create a new generation of high-added-value companies able to hire very talented and motivated people.

ACKNOWLEDGMENT

This work has been possible through the EnginyCAT program of the University and Research Department of the Catalan Government and the support of the Telefonica_UPC Chair on New Educational Trends of the Information Society.

Abstract—**Many universities use free software applications as tools for theoretical teaching and for resolving practical exercises. In many cases they are software package,s in the development of which many users collaborate, in constant evolution and adaptable to different teaching needs. In Latin American universities there is a growing tendency to use it and there are communities highly committed to its development.**

As an attempt to compile those applications most used in Latin American universities, the LULA Project (Linux para Universidades LAtinomericanas) is about favouring the integration of this software and the exchange of educational material amongst universities. It is a non-profit initiative coordinated by the Telefónica Chair of the University of Extremadura, in which the integrating universities of the Virtual Latin American Campus (CAVILA) collaborate.

Keywords-component; Educational software; LINUX Distribution; LULA Project.

I. Introduction

The Junta of Extremadura (the regional government) was a pioneer in committing to open source software in Spain and, since then has coordinated different initiatives, at both regional and national levels. From the Junta of Extremadura, despite there not being any policy or specific strategy for the implementation of open software sources, it promotes and uses it in many institutional servers. In recent years it has been observed that open source software is being incorporated in different ambits of the Uex. From software used for practice, teaching platforms or web servers and e-mailing. Within the University of Extremadura, the Telefónica Chair of the University of Extremadura (UEx) [1], aimed at teaching and research in Communication and Information Technologies in Universities, is coordinating the LULA project for the creation of a Linux distribution oriented towards the educational ambit.

The idea of this project emerged from the cooperation of the Telefónica Chair of the UEx with AULA [2], an association of Latin American universities (the UEx among them) founded in 2007 and aimed at coordinating the creation of an ambit of higher education in which cooperation and the exchange of knowledge and experiences amongst public universities and research groups Hill be encouraged.

II. The virtual latin american campus as the basis of the LULA project

The Virtual Latin American Campus (CAVILA) is the main initiative of the Association of Latin American Universities (AULA) to boost teaching, research, and Latin American identity by means of cultural diffusion. In this virtual space, the different universities of AULA offer graduate and postgraduate subjects. It is a project which in the last two years has been financed by the AECI (Spanish Agency of International Cooperation).

The Action of the Virtual Latin American Campus aims, in its first phase, at the formation of a joint Teaching Organisation Plan, which is the basic tenet for the overall training of the student, with professional and social relevance, by means of professional crosscutting values training, adapted to the specific problems of their environment. The target group is, initially, the 500,000 students that comprise the Campus of AULA Universities which potentially and directly can benefit more immediately, although an ambitious offer of life-long teaching also exists, for workers and people who, for reasons of distance or lack of sufficient economic resources cannot have access to teaching requiring attendance. In this sense, millions of Spanish-speaking emigrants are being contemplated for whom this could be a great opportunity; women and other isolated indigenous groups could access business training, training or specific retraining courses for employees from their places of residence without the need to travel.

The overall aim of AULA is the creation of a Euro Latin American Virtual Campus of “innovation with social relevance”, with the aim of training committed “workers of knowledge”, as citizens, with human rights, peace and government, along with the solution of regional problems of the surrounding area and business innovation. Thus, it deals with the construction of of virtual space of higher education, with the necessary teaching and research quality, which is possible to achieve sharing the scientific and technical excellence of each university and with the corresponding professional and social relevance.

As for the specific objectives, it should be pointed out that with this virtuality it is hoped that borders will be overcome and the integration of a Euro Latin American university space will be achieved, with multiple human and economic synergies.

Taking these objectives of integration, training, innovation and social improvements as principles, AULA Universities have decided to collaborate in the compilation for the diffusion of open source educational software which is being used in these universities, as an integrating and exportable model for other universities.

III. Components of the LULA project

The LULA initiative is being coordinated by the Telefónica Chair of the university of Extremadura, with the help of those in charge of education and technology at the seven universities which are currently members of CAVILA: Federal University of Santa María (Brazil), University of Guadalajara (Mexico), the National University of Entre Rios (Argentina), the Nacional University of La Plata (Argentina), the University of Porto (Portugal) and the University of Santiago of Chile (Chile). The initial diffusion of the project was to those in charge of these universities, but the news extended in a question of days over the internet to such an extent that other universities and user groups have joined the initiative.

IV. Development of the linux distribution

To create the Linux distribution, teachers of the participant universities, and those which have later joined the project, indicate the educational applications based on open source software which they use daily in theoretical and practical teaching classes. The Telefónica Chair of the University of Extremadura compiles these software packages and studies their suitability and compatibility in order to include them in the LULA distribution.

Since May 2009 the official website http://lula.unex.es is operational with the aim of facilitating communication amongst teachers during the different stages of the project, informing on its present state and offering support services and consultancy to the future users of LULA. This website will also serve as a centre for downloads where any user who desires to may obtain and use a copy of the distribution free of charge, without technical or legal restrictions.

The project has been planned in three phases. Initially, contributions and suggestions are being gathered in relation with the set of applications which will form part of the distribution. The following step consists of creating a preliminary version which can be tested by the teachers who collaborated in the previous phase. Finally, the definitive stable version will be created which will be distributed amongst Universities of CLAVILA and published on the web-site. Three phases are outlined below along with the predicted time span:

Phase 1: Compilation of applications

In this first phase, the participant universities indicate the educational applications based on free software they wish to incorporate in the distribution. An application request service has been set up on the website using web forms as shown in figure 1. Those teachers who wish to apply for the inclusion of applications should previously have a user account. The user register is free of charge and is carried out merely for statistical reasons, in order to know the level of participation and identify the requested applications better.

Figure 1. Application form for LULA applications.

The LULA project is an open project not exclusively limited to the ambit of CLAVILA universities. Any registered user belonging to another university, group of users or private user may suggest the inclusion of additional applications. For this first version of LULA, the application selection process gives greater priority to those applications requested by teachers belonging to CLAVILA universities when necessary.

On compiling applications, the Telefónica Chair will proceed to study and evaluate the suitability and compatibility of requested applications. For each application indicated, the technician will revise licences of use and will carry out installation, functioning tests and a study of their compatibility with the other applications that make up the distribution. The updated list of applications can be consulted in one of the sections of the LULA site (http://lula.unex.es/index.php?seccion=lula). The development of this phase is programmed from 1 June to 30 September 2009.

Phase 2: Creation of trial versions

The aim of the second phase is the development of one or several trial versions of the distribution, commonly termed 'beta' versions. During this phase, the applications indicated by teachers will continue to be evaluated and will give rise to the preparation of specific repositories of the distribution.

The beta versions generated will allow each teacher to see whether the distribution really adjusts to their needs in accordance with the requested applications, or whether, some sort of modification is required before the final version is published. It will also enable any user to try out any one of the educational packages and those of general purpose and check there are no errors or incompatibilities.

Many of the applications included in LULA have binary packages with ready-to-use programmes; however, some requested packages lack these packaged versions, making manual packaging necessary. The integration of LULA specific software in the package management system allows users to easily install and uninstall applications in the system, centralised and with no need to worry about the dependencies that each application requires. The package format *.deb* and the package management system *dpkg* have been opted for in the development of LULA, both of which are characteristics of the Debian GNU/Linux distribution [3].

The launching of the first beta version of LULA is forecasted for 30 October 2009.

Phase 3: Creation of the final version

The aim of the third and last phase is to obtain the final version of LULA, stable, and completely functional. As teachers try out the trial versions and inform on their experiences, the technical team will proceed to carry out any necessary modifications. The causes for change could be related to the repair of errors or *bugs*, the substitution of applications, updating of versions and inclusion of new libraries, dependencies, or preconfigurations. The incidences derived from the use of the distribution's beta versions can be reported by users via the personalised online support service available at the LULA website, or at the email address lula@unex.es. The launching of the final version of LULA, namely, LULA 2009, is forecasted for 15 December 2009.

V. Why create a distribution?

From a technical point of view, all the Linux distribution is made up of a common element, the Linux kernel, surrounded by libraries and applications in the user's space which provides complete functionality to the operative system. One of the main characteristics which differentiates one distribution from another is precisely, the set of applications or packages which comprise it. Originally, each distribution includes a more or less predefined set of packages to satisfy the needs of a particular group of users, giving rise to classification according to purpose.

The general purpose distributions, for example, are usually aimed at home users and include applications of frequent use to carry out basic routine tasks, such as editing documents, surfing the web, watching films, listening to music, downloading contents or sending emails. On the other hand, there is a group of distributions created with specific purposes focussing on concrete aspects such as security, education, entertainment or optimum benefit of the machines resources. The fact of having a wide range of options at our disposal does not guarantee finding the ideal solution for a particular scenario. Moreover, on their being such variety often the task of choosing the best option is made more difficult.

General purpose distributions are very attractive from the point of view that they provide a wide range of packages, the handling of which is relatively simple for home users. What is more, there are normally a considerable number of users or businesses that back and support them. However, a gap may still exist made up of a group of applications not contained in the original distribution and which are required. An initial attempt to solve this consists in integrating the appropriate personal technician in the community of developers of the official distribution, in such a way that it means covering the needs for our concrete scenario from within. Although this is a viable option, the process could prove to be too complex and, more importantly, exceed the deadlines set for the project.

These are just some of the main reasons which raise interest in and the need to create a personalised Linux distribution based on a general purpose distribution. In addition to providing extra required packages, similarly, it would be possible to modify those which are considered to be unnecessary. Many organisations, businesses and user communities find an adequate solution in personalised Linux distributions to cover their needs and objectives. Given the characteristics of the LULA project, it seems that adopting this solution is a suitable option and at the same time justified. However, awareness exists that from nearly any Linux distribution a user with an average working-knowledge of Linux could install the packages that make up LULA but, with the Telefónica Chair having done this previous compilation, selection, running and compatibility tests, this time is saved and enables less experienced users to try out this software.

VI. General characteristics of the LULA distribution

In this section some of the most relevant general characteristics and technical aspects are presented of the Linux LULA 2009 distribution. Given that the project is presently in full development, the possibility of making small changes during the third phase is not ruled out.

- *Base system Ubuntu 9.04 'Jaunty Jackalope' (x86) updated until the launch date of LULA.* In the remasterization of Ubuntu [4] services and applications unrelated to the specific purpose of LULA installed by default have been eliminated in an attempt to reduce the final size of the distribution and improve the overall performance of the system.
- *Execution in Live mode with the possibility of permanent installation in the hard disc.* Currently, the development of an installer called LULA-Installer is being developed, however, its inclusion in LULA 2009 has not been confirmed as yet. The second candidate for installer is Ubiquity [5].
- *LULA specific software packaging*. Manual packaging of applications and libraries in Debian format is generally carried out when the software requested by teachers is not available in the base distribution, or the software version is not that required.
- *Creation of own repositories.* The manually packaged applications will go on to form part of its own software repository kept in the infrastructure of the Telefónica Chair within the University of Extremadura.
- *Java Virtual Machine OpenJDK installed by defect.* This is a free solution which has undergone rigorous compatibility tests, guaranteeing the correct running of the Java applications [6].
- *Wine integration*. Not all the applications that a LULA user could need possess a version for Linux or sufficiently powerful alternatives to replace proprietary

solutions in a given moment. Wine will allow an execution of a great number of native applications of Windows operative systems, in this way favouring the gradual migration from said proprietary platform.

- *Desktop virtualization with VirtualBox*. This software allows operative systems to be installed in virtual machines which can be easily administered.
- *Incorporation of new options in the menu to facilitate the control of certain services.*
- *Visual aspect of LULA. Desktop subjects and icons have been created from original material and resources available on the net under free licences.*
- *Universal and Free technical support service*.

VII. Support and advice service/helpline for LULA users

As element of added value, the Telefónica Chair of the University of Extremadura will offer a support and advice service for LULA users free of charge. The catchment of the service is considerable, given that it would mean approximately half a million pupils that presently make up the universities of CAVILA, plus all those users who wish to use the distribution.

The support and advice service will be offered through a section of the site created specifically for this purpose. Registered users will be able to send all their doubts and queries related to the installation of the distribution and its software packages via web forms. Each query, once resolved by the technician assigned, will become part of the publically accessible data base. The queries resolved will be categorised to help users with silmilar problems find solutions.

VIII. Present state of the project

The Project is developing as foreseen following the content and planning indicated in section IV. The second phase is currently being started. After the call on behalf of the Telefónica Chair to the rectors and other academics in charge of CAVILA universities for collaboration in diffusing the initiative, to date the LULA site has 140 registered users and almost a hundred requested applications during the first phase to be included in the distribution. The number of IP addresses that have visited the site is more than ten thousand.

It should be stressed that, since the beginning of the project, a spontaneous diffusion has been produced through news sites, forums and blogs principally related to Free Software. This has brought about interest in collaborating at other Latin American universities, groups of users and private users. In fact, more than half of registered users identify themselves as being from universities that do not belong to CAVILA.

IX. Some statistical data of collaborations

A total of 95 applications were requested in the first phase, amongst which predominate programming tools, mathematical applications, statistical analysis applications and general purpose applications related to office applications, multimedia and communications. Below, some specific/concrete figures are shown which can provide us with an approximation of the type of application required by teaching staff:

- General purpose applications: 6,3%
- Programming tools: 43,2%
- Mathematics and statistical analysis: 21%
- Educational tools: 7,4%
- Servers: 5,3%
- Other software tools: 14,8%

The nature of the tools requested (listed in figure 2) and the additional information supplied by the teaching staff during the first phase, indicates that a large majority are mainly directed to the teaching and practice of subjects related with programming, ICTs and mathematics.

Figure 2. List of applications requested by users.

According to collected data, 82% of users affirm to be familiar with the use of the proportioned free applications, and 66% currently use free applications in their teaching. Another interesting piece of information is the 41% of users who state that they replace some sort of private software for free solutions. The main applications that are replaced correspond to those belonging to Microsoft (Microsoft Visual Studio .NET, Microsoft Office y Microsoft IIS).

X. Conclusions

From the Telefónica Chair of the University of Extremadura, we understand that activities and initiatives that are developed should result in a direct reward for society. In this sense, we relieve that the LULA Project could be of great interest to Latin American university communities in several aspects:

- Students of these universities will have in a single DVD all the compiled software they need for their teaching practice. It is actually relatively easy for a new user of Linux to download and install different educational packages that they may need in their subjects. However, with LULA, as well as saving installation time, they will not need to identify each application one by one and try them out to see if they work correctly, as they will be already installed and ready to use. On the other hand, it is also possible that a percentage of the students and teachers may never have used Linux. In this sense, the LULA Project tries to encourage and facilitate the first encounters with this type of software.

- As for teachers, the fact of knowing what applied education software alternatives for teachers exist could be advantageous and enriching. On compiling all this software in a single distribution, teachers have the opportunity to compare these packages with those they normally use in their teaching. It is hoped that in subsequent versions of LULA work groups will be formed for the exchange of educational material amongst universities.
- Universities which opt for the distribution could benefit from savings in operative system licences and proprietary applications. This philosophy is already being successfully applied in universities and administrations in several countries.

It is still early days to evaluate the results and repercussions of the Project; however, the involvement on the part of teaching staff is good and requests to collaborate are still being received to date. After the first experience, it is foreseen that in 2010 new services and resources in the LULA portal will be incorporated where universities and groups of users of applications or types of specific applications participate in the exchange of material, guides,and experiences, enriching their knowledge and , consequently, of future versions of LULA- For the next version of the distribution the setting up of the most common resources of collaboration in communities of free open code software, such as wikis, forges, mailing lists and, follow-up of task lists.

***Abstract*— Most E-Learning projects tend to separate learning activities from everyday work. This paper presents an approach where closer integration between learning and work is achieved by integrating multimedia services into manufacturing processes.**

The goal of E-Learning services integration in manufacturing is, through the development of new multimedia solutions, to accelerate and enhance the ability of manufacturing industry to capitalise on the emergence of a powerful global information infrastructure. In this paper we suggest to combine the areas of media streaming services and manufacturing processes, by providing electronic learning offerings as collections of media streaming services. The key components of our approach are 1) an xml based streaming service specification language, 2) automated configuration of distributed E-Learning streaming applications, 3) web services for searching, registration, and creation of E-Learning streaming services.

***Keywords*— just-in-time learning; media streaming services; web services; manufacturing processes**

I. Introduction

Manufacturing processes involve the control and management of manufacturing systems ranging from basic assembly processes to the high-tech manufacture of pharmaceutical, telecommunications and electronic equipment. Categories for such manufacturing processes are assembly line / flow shop, and cellular manufacturing / group technology. E.g., in case of assembly line based processes a line of dissimilar machines are grouped in the line (sometimes more than one to balance flow). Innovation, productivity, flexibility, and continuous improvement are key ingredients to success in the constantly evolving world of manufacturing.

A major challenge to which companies must respond is the integration of advanced E-Learning technologies. What is actually needed is a learning "on demand", embedded into work processes, responding to both requirements from the work situation and from employee interests, a form of learning crossing boundaries of e-learning and performance support.

The goal of E-Learning services integration in manufacturing processes is, through the development of new IT solutions, to accelerate and enhance the ability of manufacturing industry to capitalise on the emergence of a powerful global information infrastructure.

Multimedia networking services support monitoring, controlling and supervising production processes in order to achieve high levels of efficiency and environmentally friendly production. The new flexibility of workers and work environments makes traditional conceptions of training in advance, in rather large units and separate from work activities, more and more obsolete. Manufacturing scenarios where E-Learning services can be integrated are shown in Fig. 1.

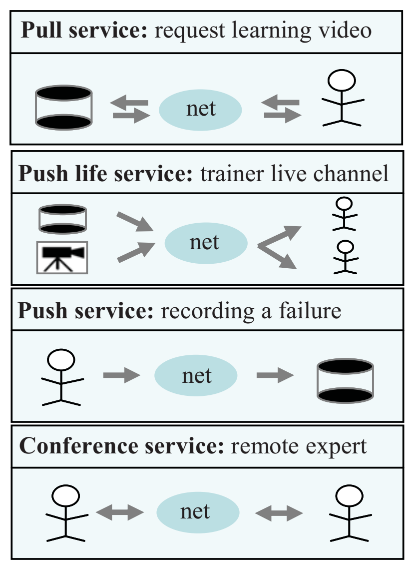

Figure 1. E-Learning services in manufacturing processes

The following streaming services can be identified:

- Pull (on demand) service: allows on demand access to remote E-Learning content, e.g. video content illustrating configuration of a CNC machine.

- Push service: e.g. a push channel from a remote expert to the manufacturing personal (“how to configure / operate a machine”). Live audio and video (expert) as well as media files can be delivered (see Fig. 1).
- Push service: for recording a failure scenario during a manufacturing process by recording the comments (voice) of a worker and by recording the machine status by video. This documentation can be used later to analyse details.
- Conference service for maintenance and remote diagnosis: teleoperation and remote diagnosis and maintenance of distant plant and production equipment can be achieved by using peer to peer E-Learning streaming services.

The remainder of this document is as follows. Section II makes a comparative digest into related work in this field of interest. In Section III we discuss a xml based language which allows specification of E-Learning streaming services while section IV outlines the architecture and describes the major components and technologies to solve the problems stated in section I. Finally, section V gives a brief summary and concludes with a note on future work.

II. RELATED WORK

[1] presents a framework for an on-demand E-learning management system that make use of broadband network for the delivery of distributed "educational activities" such as distributed courses, tutoring sessions, lectures, workshops, etc. The developped scheme is tailored towards personalized learning using distributed information in a dynamic and heterogeneous learning setting, i.e. a connected network of learning management entities and educational systems where learners are individually supported in accessing distributed resources. However it is restricted to on demand scenarios and multimedia files.

[2] introduces a framework for design and development of an interactive multimedia E-learning system for engineering training. The main goal of the project is to encourage low cost developing of effective and customized e-learning systems for engineering training by using popular and inexpensive software tools especially for **virtual simulation of engineering system operations.**

The Venice [3] project proposes a web services based framework for VoIP applications. By using a service oriented architecture, the authors aim at easing the integration of supplementary services, the compatibility between different signaling layer protocols for call control and the installation of software updates on client devices. However, the Venice project is specifically tailored to VoIP scenarios, i.e., the authors do not address reusability between different multimedia applications nor provide a generic platform for the development of these.

Based on a distributed messaging middleware, the Global Multimedia Collaboration System (Global MMCS) [4][5] provides a framework for an audio/video collaboration system, which bridges the gaps between nowadays multimedia applications by providing a common signaling protocol with gateways to existing protocols like SIP or H.323 [9]. However, the authors do not address other multimedia applications and the reuse of components between these.

In [11] a mobile streaming media CDN (Content Delivery Network) architecture is presented in which content segmentation, request routing, prefetch scheduling, and session handoff are controlled by SMIL [12] (Synchronized Multimedia Integrated Language) modification. The approach concentrates on the segmentation aspect, which is important for mobile users. In [13] also an XML based specification technique for streaming services is introduced. However, it does not enable the specification of quality of service attributes and distribution policies.

In [6] an approach is suggested to combine the areas of e-learning and Web services, by providing electronic learning offerings as (individual or collections of) Web services as well. It elaborates on this by showing how content providers and content consumers (i.e., learners) can communicate appropriately through a Web service platform with its common description, publication, and retrieval functionalities. However, it does not support live channels.

The JSR 309 [16] is designed to provide server-based Java applications with multimedia capabilities. It targets a large range of applications from simple ring-back tone applications to complex conferencing applications, by providing: media network connectivity to establish media streams, IVR functions to play/record/control multimedia contents from file or streaming server, ways to join/mix IVR function to network connection to create, conferences and call bridges. However the proposed API approach is restricted to Java based applications and it does not support enhanced VoIP functions, e.g ring groups or call queues. It mainly provides low level objects like players, recorders, mixers and connections that developers can manipulate or combine together to obtain all the multimedia capabilities.

[17] presents a generic framework for multimedia applications consisting of a set of reusable Web service components, a modeling language based on finite state automata and a compiler. The authors concentrate on the signaling plane protocols, especially their similar structure and purpose, i.e. the definition of possible states for both, client and server, and the transitions between these states via the exchange of messages.

[10] describes a service-oriented communication (SOC) paradigm based on Web services for real-time communication and converged communication services over IP. This approach extends Web services from a methodology for service integration to a framework for SOC. In particular, it introduces the generic Web services-based application session management (WS-session), the two-way full duplex Web services interaction for communication, and the development of Web Services Initiation Protocol.

III. SPECIFICATION OF E-LEARNING SERVICES

A. Model

Manufacturing processes are composed of manufacturing resources, e.g. manufacturing automation devices, equipment & machinery, material & manufactured parts, and manufacturing personnel. E-Learning streaming services are related to such manufacturing processes and / or single manufacturing resources. E.g. for a single machine a video on demand can be requested by the manufacturing personal to study the detailed configuration steps for such a machine.

The class diagram in Fig. 2 represents a model of our E-Learning streaming services (UML class diagram). Different fundamental components of the system are shown in the form of classes and relationships.

An E-Learning service can be described by its media objects, related manufacturing resource, distribution and replication policy, and the quality of service used for content delivery. Media streams can also be categorized according to how the media objects are delivered. In pull services data delivery is initiated and controlled from a client whereas in push services a server initiates data transfer and controls the flow. Conference services support scheduled and ad-hoc conferences. Such conferences contain the following attributes: date and time when the conference will take place, the invited participants and as an optional part the leader, the agenda as well as conference documents.

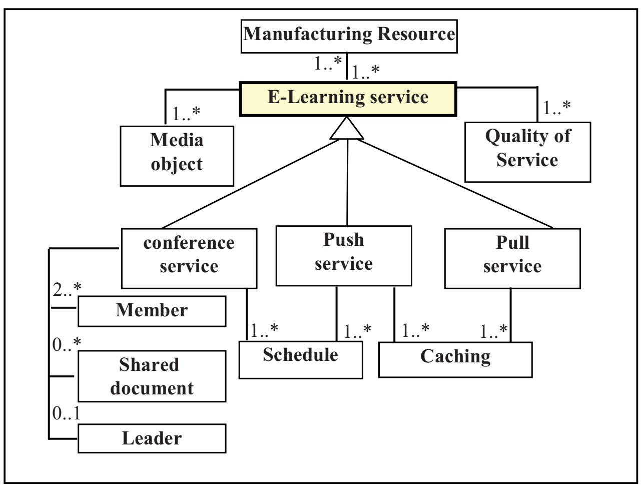

Figure 2. E-learning service model

B. Use Case: Life training

The following scenario (Fig. 3) illustrates one of our implemented use cases, a technical training (how to configure and operate a machine) for a computerized numerical control machine (CNC) as the related manufacturing resource: The operator shows the handling of a machine to the distributed audience. A background speaker (in a separate location, e.g. office) explains the configuration steps. To enable the interaction between the speaker and the learning community, each participant is offered an audio back channel. In the scenario there are different QoS requirements, e.g. for the video transmission showing the manufacturing machine a high resolution and frame rate is required.

The specification of media objects is based on SMIL [12]. SMIL (Synchronized Multimedia Integration Language) is an XML-based language, which facilitates the construction of accessible multimedia applications for the internet and mobile devices. Collections of XML elements and attributes can be used to describe the temporal and spatial coordination of one or more media objects.

In addition to SMIL, the type of media objects (live / file), the delivery policy and the roles which consume and supply media objects can be specified.

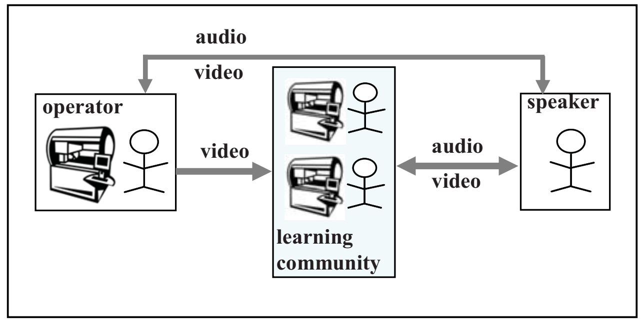

Figure 3. Example scenario

C. XML Specification

A specification of an E-Learning service is a structured composition of autonomous objects (see Fig. 4):

- resources or manufacturing processes (category, type, keywords)
- a collection of media objects, e.g. audio and video objects (life or files)
- distribution policy, e.g. push or pull
- roles and related media objects, e.g. speaker

This information can be used later, e.g. by the manufacturing personal, for searching and accessing E-Learning services.

Fig. 4 illustrates the specification of the life training scenario introduced in subsection A. The first part contains the description of manufacturing resources related to the E-Learning service. The list of media objects which are used in the service is part of the section "MediaObjects" together with the type, bitrate and source. The media streams are delivered based on a push policy. This includes also the definition when the media objects must be delivered (date and time), together with the available bit rates. Finally the roles, e.g. a speaker role or a operator role are introduced together with a list of media streams which are consumed and supplied by each role. E.g. the speaker consumes and supplies video as well as audio objects referenced in the section MediaObjects.

```
<StreamingService>
<ManufacturingResources>
   <resource  category = "num control machine" />
   <keywords>live training </keywords>
</ManufacturingResources>

<MediaObjects>
  <video id = "v1" type = "live"
                bitrate= … src =  … />
  <audio id = "a1 type = live"  src = …/>
  . . .
</MediaObjects>

<DistributionPolicy>
  <push codec="MPEG4" date= …  time=…
        recording="yes"
  </push>
</DistributionPolicy>
<Roles>
   <role name="Speaker"/>
     <consumerOf>
        <video id=… />
        <audio id=… />
   </role>
   . . .
</Roles>
. . .
```

Figure 4. E-Learning service specification

IV. SERVICE ORIENTED ARCHITECTURE

A service-oriented architecture (SOA) is basically a set of services interacting with each other and coordinating some activity. Service providers and service consumers are the two main entities acting on behalf of a user. The Web service technology additionally addresses a standardized description of a service's functionality using an XML dialect [14]. Using the Web Service Description Language (WSDL) [7], a service provider describes the functionality (interface) of a service in a platform, language, and operation system neutral way while a service requestor talks to these services using SOAP over HTTP (or other transport protocols).

A. E-Learning Streaming Services

Streaming services are managed by a set of web services (see Fig. 5). Such a web service is a URL-addressable software resource that performs operations and provides answers. In our case, the operations offered by the service interface are:

- searchStreamingService: allows searching a streaming service (based on the elements and attributes which form the xml service specification (e.g. category of a manufacturing resouce, type of media object, distribution policy, etc.).
- registerStreamingService: enables validation and registration of new streaming services.
- createStreamingService: instantiates streaming software components and establishes interconnections between components.
- startStreamingService: the operation start is typically invoked by a scheduler (in case of push based services, driven by date and time values).
- subscribeToStreamingService: allows users to subscribe to (future) streaming services (e.g. a remote video based training related to a certain CNC machine). When a new media streaming service is registered or started, a user will be notified automatically by the service manager (as soon as such a service has been registered to the xml database).

After searching a streaming service, the client (e.g. RTSP media player) sets up three network channels with the RTSP server when media data is delivered using the RTP over UDP, as shown in Fig. 5. A full-duplex TCP connection is used for control and negotiation. A simplex UDP channel is used for media data delivery using the RTP packet format. A full-duplex UDP channel called RTCP is used to provide synchronization information to the client and packet loss information to the server. RTSP initiates and controls delivery. The XML service description includes references to media streams, using the URL method rtsp.

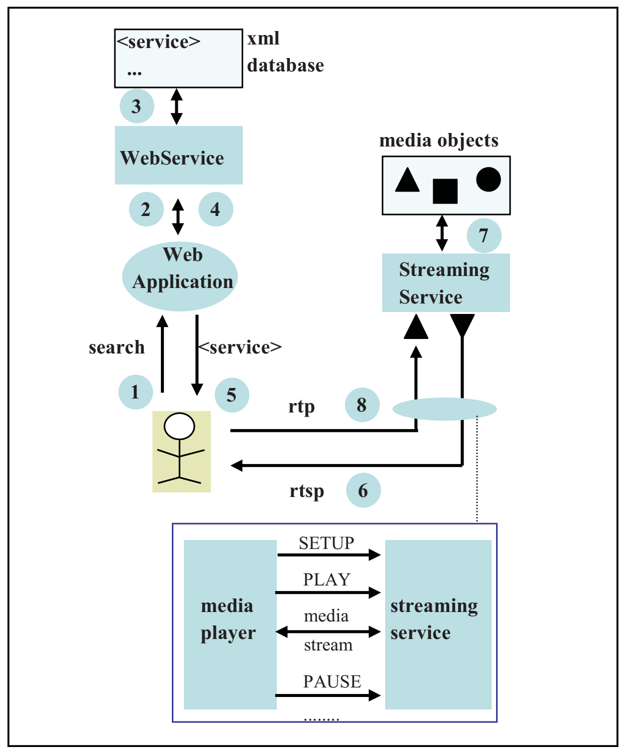

Figure 5. E-Learning Web services

According to our service specification language, the following properties of E-Learning services can be used as part of a query:

- manufacturing resources, e.g. category or keywords
- media objects properties, e.g. recorded live training
- distribution policy, e.g. on demand service

- QoS properties, e.g. bitrate, used codec
- Date / time duration attributes

B. *Prototype*

Our approach is based on a clear separation of a streaming service specification - and its implementation by a distributed application and can be used for different streaming paradigms, e.g. push and pull services.

The following figure (Fig. 6) illustrates the user interface and the management interface. The services are managed by a service manager, which provides in the current implementation a simple interface to search, and start (request) services. Moreover, a management interface enables creation of new services, and deletion of existing services. Service specifications are stored as XML documents in a XML database.

A new e-Learning streaming service specification is first analyzed by a web service (operation create) . Driven by a component library which contains existing streaming components, such as encoders, media servers, etc., and a set of configuration rules, a web service creates a distributed streaming application configuration. Based on such a service specification, the service manager also supports retrieval of existing services.

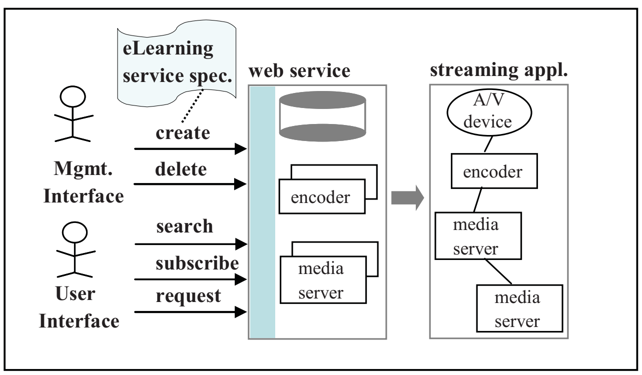

Figure 6. User interface and management interface

Push services are started automatically according to the specified date and time values. Starting a service means to create the required streaming components, e.g. an encoder and a media server component as well as to establish the communication relationships. Before a new service is created, a consistency checker is responsible to test the availability of nodes, and media objects according to the definition as part of a service specification. A service specification is then analyzed by a web service, which will select appropriate streaming software components.

Multimedia services are stored as XML documents in a XML database. We use Apache's Xindice, which is a database designed from the ground up to store XML data or what is more commonly referred to as a native XML database. Advantages are: faster for XML than other databases, no mapping to relational required, quick fragment retrieval provided, and optimized XML querying supported.

The prototype has been implemented using the PHP programming language and the PHP Web Services Development Pack nusoap [8] for the creation of and access to web services. We use the existing media server components from RealNetworks, and the OSS software Asterisk [15] as a VoIP server. The first (subjective) test results based on implementation of push and pull services as well as conference management are very promising. However, the used OSS VoIP system Asterisk does not offer scheduled conferences, i.e. a direct mapping to the Asterisk conference management functions is not possible. Information related to scheduled conferences are stored in a xml database. As the prototype is still under development, an objective measurement of processing time and delay has not yet been made.

C. *User Experience*

In a production environment robust and easy to use search functions are one of the key requirements. Our original search functions had to be improved. Context-driven search results, driven by the concrete manufacturing resources which are part of a single work place are regarded to be important for the machine operators. E.g. depending on the available machine(s) which are part of a single work place, the search functions have to offer the "right" E-Learning services related to the given local manufacturing resources.

The most accepted E-Learning streaming services are on demand video services. From the production management point of view, push services are essential for quality improvements. Such services allow a "just in time" documentation of occurred failures, during runtime of a machine by ad hoc video and audio recordings. These recordings can be analyzed later and appropriate solutions can be developed to improve manufacturing processes.

V. Conclusion and Future Work

In this paper we have presented a service oriented architecture for E-Learning streaming services – realized using web services technology. The major contributions and extensions of our approach aim to provide a high level specification of E-Learning services in terms of user roles, media objects, distribution policies, etc.. Based on such a service specification, a web service supports automated creation of tailor made media streaming applications, based on existing software components, e.g. media server or VoIP software components.

We report the current status of our prototype. The prototype has shown that our XML based language is well suited for automatic generation of implementations. At implementation level, the different aspects are integrated in a general object-oriented architecture supporting modularity and reuse of software. The deployment of new service operations is very easy to accomplish due to the modular structure of the service oriented architecture and the well designed and easy to use PHP development pack nusoap.

We do not use JMF [18], because it is not stable enough, especially for long running streaming applications. Instead, we use existing media streaming components (e.g. media server from RealNetworks).

Future work will concentrate on the extension of the service model to support additional functionality, e.g. application sharing. Another important aspect will be the integration of authentication services (authentication of users).

The proposed framework is part of a multimedia project, financed by the state government of Baden-Württemberg in Germany.

***Abstract*— when practical classes are not properly planned and organized, students tend to see them as a mere requirement in which they should spend the minimum amount of time and effort. As a consequence, the aim of these practical classes is completely distorted. A solution to this problem is the well-known project based learning approach (PBL). In this paper, the influence of practical classes, each one organized as a small PBL activity, is analyzed in the field of a microcontroller-based system design course. When the results obtained in different years are compared in order to analyze an educational methodology, some variables of this analysis change (e.g.: the group of student, the difficulty of the exams, etc). Instead, in this paper the marks obtained by students that faced the practical classes correctly are compared with the marks of the students that considered them just as a requirement that needs to be fulfilled. In this way, the analysis is not distorted by the change of some variables.**

Keywords- PBL, microcontroller, digital, practical

I. INTRODUCTION

The Bologna process has highlighted the overly theoretical aspect of some courses in Spanish technical degrees [1, 2]. Also, when practical classes are not properly planned and organized, students tend to see them as a mere requirement in which they should spend the minimum amount of time and effort. As a consequence, they lose the opportunity to put into practice what they are taught in lectures. Hence, they tend to acquire this new knowledge in an excessively theoretical way, without promoting the skill at applying it to the real situations they will face once they graduate. Another consequence of these wrong-planned practical classes is that skills such as collaborative work, task management, critical thinking, etc. are not properly promoted.

The project-Based Learning (PBL) is a useful approach in order to eliminate this two negative consequences [3-5]. Not only students are given the opportunity to put into practice what they learn in lecture classes, but also they work in an environment in which collaborative work and other important skills are needed (public presentations, etc.). As a consequence, the knowledge acquired in lectures is not simply memorized; it becomes a tool for solving the problems that students will face in their future jobs. This is even more evident in courses in which, due to their thematic, students have the opportunity to use real equipment in the practical classes [6-8]. This is only possible when there are enough workbenches, which usually implies low-cost equipment, and also when some autonomy can be given to students, which usually implies that there is no risk for equipment or students if they work without direct lecturer's supervision.

In this paper, the influence of PBL on a microcontroller-based-system design course is analyzed. The main objective is determining how the learning process of students is affected depending on the way they face PBL-based practical classes. Without any change in the lecture classes, each practical class is organized as a small PBL activity: alarm with hysteretic levels for controlling an analog measurement, chronometer controlled by matrix keyboard, thermometer with temperature record, etc. One of the key issues of this paper is the way in which the results are analyzed. Instead of comparing the results obtained this year with the results obtained in previous ones, in which the practical classes were not PBL-oriented, the analysis compares the results obtained by students that tried to benefit from practical classes with the results obtained by students that considered them as a requirement. In this way, there is no variation of certain variables in the analysis, such as the group of student, the difficulty of exams or the group of lecturers.

The organization of this paper is as follows: firstly, a brief description of the course is given in order to have a complete framework (section II). In section III, the new practical classes approach, based on PBL, are described. The way in which the dedication to practical classes is measured is described in section IV. In this section, the analysis of the results is also presented. This is completed by the test results explained in section V. Finally, some conclusions will be presented (section VI).

II. COURSE DESCRIPTION

The PBL approach analyzed in this paper is applied to an annual course of telecommunication engineering degree. The course is centered in the design and development of microcontroller-based systems and is given in the third academic year. Evaluation is done by means of two exams. The first one is set at the end of the first semester and the second one is set at the end of the academic year. In these exams, only practical questions are done, trying to avoid contents memorization by students. In the final evaluation, the results obtained in practical classes are also taken into account (the evaluation of practical classes is explained in the next section).

The number of students is approximately one hundred, divided in two groups for lectures and five groups for practices. This means that the number of students per practical group is twenty. This high number of students has a very important influence on the way practical classes are organized, as it will be explained later.

Another important aspect related to practical classes is that the topic of the course implies, on one hand, low-cost equipment and, on the other, no risk for students when solving each project on their own [9, 10]. Hence, it is possible to have enough number of workbenches and to leave the laboratory open for the students without lecturer's direct supervision (see Fig. 1).

III. PRACTICAL CLASSES DESCRIPTION

Practical classes, as has been mentioned, are PBL oriented. The aim is that students do not simply memorize what is explained in lecture classes. Instead, they should acquire the skill of using it for solving the real-life problems they will face in their future jobs. Also, other skills demanded by companies in their new workers are promoted (e.g.: collaborative work, public presentation, etc.).

Firstly, it should be taken into account that the number of lecturers for the whole course is only two, what makes the number of students too high for a traditional PBL to be done. Hence, each practical class is organized as a small PBL activity rather than developing a larger one for the whole academic year. In this way, the supervision task is simplified and can be done by the reduced number of lecturers in charge of the course (see Table I). Nevertheless, the main reason that justifies this organization of the practical classes is another. Each of this small PBL activities is related to one (or two) of the topics of the course. In this way, students have the opportunity to put into practice what is explained in lecture classes, improving their skill of applying their new acquired knowledge to real problems, rather than simply memorizing it. To help this approach, a special effort is done in giving each practical class once the corresponding topics have been explained in lectures and once the students have had time to prepare and study them. In this way, the idea of practical class as a mere requirement tends to be blurred.

Figure 1. a) Laboratory with 12 workbenches for the practical classes; b) Workbench for every working group of 2-3 students; c) elements for debugging/testing the solution implemented for each project.

8	Alarm with hysteresis for controlling an analog voltage value which needs to be shown every second on the LCD display.	CCP module (PWM and comparison) AD converter
9	Data-logger of the information sent by the PC (serial communication)	USART module (asynchronous communication)
10	Temperature measurement (sensor controlled by I2C) and storation of the results in an external memory. The stored data will be sent to a PC when demanded (serial communication)	SSP module (I2C) USART module External devices (temperature sensor, EEPROM memory,…)

In order to promote the acquisition of certain skills such as team work and task management, students were organized in working groups of two or three members (hence, in each practical class there are seven or eight working groups). In principle, a higher number of students per group would increase the development of these skills. Nevertheless, it should be taken into account that one of the key issues for PBL success is avoiding passive member in each group. Considering that each practical class is organized as a small PBL activity, a higher number of students per working group would lead to a reduced amount of work per student and would favor the passive attitude of some of the members.

Evaluation of each activity is also planned so that students acquire and develop certain skill like, for instance, oral expression, public presentation or technical writing. When a working group has finished one of the proposed projects, its members explain their solution to lecturers, justifying the design decisions they made. Also, they have to answer the questions asked by lecturers, who act as contractors of the working group. Besides, a report has to be handed over by every student. In this practical report they have to explain their solution and answer to a questionnaire with practical and theoretical questions related to the corresponding topic (but not necessarily to the project proposed for that topic). In this way, students need to study what has been explained in lectures in order to do the practical report. Hence, not only the mentioned skills are promoted, but also copying is prevented or, at least, is easily detected and the appropriate measures can be taken [11].

An important aspect that should be highlighted, and that later will be discussed as a possible improvement of the proposed approach, is the absence of a limit date for handing over each project solution. Nevertheless, it was strongly emphasized by lecturers that practical classes would only be useful if each project is done immediately after the related topics are explained in lectures and before the next topics are finished. This leads to a two-week period of time for doing and finishing each project. The aim was improving the self-management of each student and of each working group.

IV. Analysis of the Proposed Methodology

The effectiveness of the proposed method is going to be analyzed comparing the results obtained by students of the same academic year. In this way, the influence of certain variables that change from one year to another (students, exam and lecturers) is neglected. Specifically, in this analysis the results obtained by students who respected the proposed date of handing over are compared with the results obtained by students who did not. That is, a relation between the results obtained in the course (final mark) and the dedication degree to practical classes is established.

A good measure of the dedication degree to practical classes (rather than the mark obtained in their evaluation) is the date of handing over. In this way, students that try to benefit from practical classes have earlier dates if compared with students that only try to 'fulfill the requirement'. Obviously, it is possible to consider that the opposite situation may happen: students that do not see the proposed projects as an opportunity to improve their knowledge have earlier dates of handing over as they try to finish as soon as possible. It should be taken into account that each practical class needs a previous studying of the concepts explained in lecture classes (something characteristic of PBL). As a consequence, the students who try to observe the recommendations of the lecturers usually have the earliest handing over dates. Also, these students have the higher marks in the practical evaluation (nevertheless, this variable is not considered for measuring the dedication degree).

Considering this, the handing over date of each student was taken down in order to measure the dedication degree. In this way, it is possible to calculate an average handing over date for each practical session at the end of the academic year:

$$HOD_i = \frac{\sum_{X=1}^{N} HOD_{X\_i}}{N} \quad (1)$$

in which HOD_i is the average handing over date of project number i, HOD_{X_i} is the handing over date of student X for project number i and N is the overall number of students.

With this average value, it is possible to determine the dedication degree of each student to each practical class (DD_{X_i}) by means of the following equation:

$$DD_{X\_i} = HOD_i - HOD_{X\_i} \quad (2)$$

in which positive values means that the student presented the solution before the average date and negative values after the average date. That is, positive values means high dedication degree and negative values means low dedication degree. Calculating the average value of the ten practical sessions for each student, it is possible to obtain a numerical value that measures the dedication to practical classes:

$$DD_X = \frac{\sum_{i=1}^{10} DD_{X\_i}}{10} \quad (3)$$

in which DD_X represents the dedication degree of student x considering that the total number of practical classes is ten.

The other variable analyzed is the mark obtained in the course. In this mark, it is taken into account not only the results in the two exams, but also the evaluation of the practical classes. In this way, the final mark represents the success not only in knowledge acquisition (mainly evaluated by means of the two exams), but also in skill acquisition (mainly evaluated by means of practical classes).

In Fig. 2, the relationship between the two variables is shown. The x-axis represents the dedication degree, in which positive values represent a high degree of dedication whereas the negative values represent low ones. This variable has been normalized to the maximum positive value. The y-axis represents the mark obtained in the course. The pass is

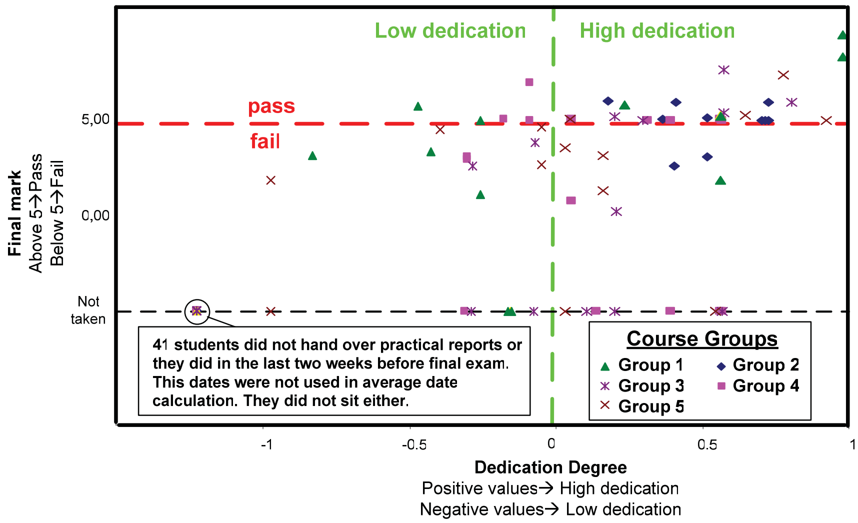

Figure 2. Comparison between dedication degree and the final mark of each student. The five practical groups (or course groups) are differentiated.

achieved with a minimum mark of five and the maximum mark is ten.

The first important result that should be highlighted is that the number of students that did not sit the exam is considerably lower in the group with a higher degree of dedication. Specifically, 9 students with a positive degree of dedication did not sit the exam, whereas in the negative-dedication group this number rises to 47. This means that only 16% of the students that did no take the exam had a positive degree of dedication. This result is even better if it is taken into account that some of those nine students were closed to a passive attitude in their working group, taking advantage of their mates but without being clearly detected during the presentation of each small project. This is something that should be corrected with the improvements proposed later.

The analysis of the results obtained by students that took the exam also validates the proposed methodology. The best marks are obtained by students with the highest degrees of dedication. In fact, in this group the number of students with a mark above five is 26, whereas the number of fails in this group is only 9. This means that 75% of the students that faced practical classes in a correct way passed the exam. On the other hand, only 5 students with a negative degree of dedication passed the exam, which is a low number if compared with the 12 students that failed. This means that only 29% of the students that did not take into account the proposed handing over date passed the exam.

It should be noted that 41 did not hand over all the practical reports or they did in the last two weeks before the exam. Their handing over date was not taken into account for determining the HOD_i. If these dates had been considered, the analysis would have been distorted as these students did not even assist to lectures. That is, they gave up the course before the first semester ended. This fact will be deeply discussed in the next section, as it has a very close relation to the absence of a mandatory handing over date.

V. ANALYSIS OF THE TEST RESULTS

At this point, it is only possible to ensure that a relation between high degree of dedication and satisfactory knowledge and skill acquisition exists. Nevertheless, it is not possible to ensure that these good results are a consequence of the proposed method. It is possible to consider that good student would have obtained higher marks independently from the approach employed in practical classes. In order to clarify this point, at the end of the academic year a test with several questions about the proposed method was done by every student. The results obtained for each question are shown in Fig. 3, in which a value of ten means *'I totally agree'* and a value of zero means *'I totally disagree'*.

The first two questions of the test were:

- Question 1: The practical classes helped me in understanding the theoretical contents of the course.
- Question 2: Complementing every topic with a practical class helped me in understanding what is explained in lecture classes.

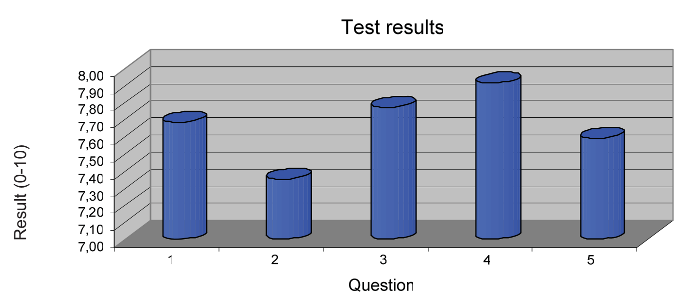

Figure 3. Results of the test done by every student.

As can be seen, the results show that the proposed methodology, in which each practical session is organized as a small project, helps students in acquiring the knowledge as a useful tool, rather than simply memorizing it. This is the main objective and it has been fulfilled.

Other objective was the improvement of certain skills such as collaborative work or public presentation, strongly demanded for new engineers in their jobs. This aspect was analyzed by means of the following question:

- Question 3: The practical classes allowed me to practice certain skills such as collaborative work.

The result shows that this point was also covered by the proposed methodology.

Finally, the last two questions asked in the test were:

- Question 4: Practical classes have shown me that a real project is more complex than solving a problem 'on the paper'.
- Question 5: Practical classes have shown me that a real project involves numerous related topics (analog electronics, common sense, etc.)

The objective of showing the students that the new knowledge is not only theoretical contents that have to be memorized is also fulfilled (these two questions have close relation to the first two).

If all the results are considered (not only the test results, but also the comparison between dedication degree and final mark), it is possible to infer that the proposed methodology satisfies all the goals pursued by lecturers. The knowledge is not simply memorized; it is acquired by students as a tool for solving the real problem they will face in their future jobs. Also, other very important skills (oral expression, critical thinking and technical writing) are also promoted by this methodology. The main drawback for PBL to be implemented in this course was the high ratio students-lecturers. Nevertheless, the results show that this problem can be avoided if small PBL activities are planned all along the course duration instead of a single and more complex project.

There are some aspects that can be improved. The handing over limit date was only a recommendation. As a consequence, only 44 students had positive dedication degrees. Also, 41 students did not sit the exam. Considering that the method has proven to be effective, the suggested handing over date should be turned into a mandatory date, as a trial for decreasing the number of students giving up the course. This involves some difficulties. The most important one is: What happens if a student does not present a project solution before that date? The easiest option would be that student failing the whole course. Nevertheless, this would not necessarily increase the number of students with positive dedication degree. Possibly, this would increment the number of students copying from classmates or, even worse, incrementing the number of fails just due to a delay of a few days. This is a typical problem of PBL and there is not any easy solution: bonuses in the final mark for those students that presented all practices on time, reducing the mark obtained in a practice for every day of delay, etc. All possible solutions have merits and flaws. Lecturers should select the one which better suits the course, the PBL activity and the theme of the course.

Another remarkably aspect that should be highlighted is that the PBL approach demands more dedication not only from students, but also from lecturers, whose availability for the students can not be limited to the practical classes timetable. Students work in the proposed projects all along the two weeks between each practical class. Sometimes, they get stuck and need some help in order not to lose excessive time. This does not mean that every problem needs to be solved by lecturers in the instant that it appears (students have to deal with difficulties trying to find the solution on their own or the PBL loses its benefits). Nevertheless, if they have tried several possible solutions and they did not work, students should have the possibility of asking for "immediate" lecturer's help in order not to lose excessive time and fall behind. As a possible solution, the two lecturers in charge of practical classes organized themselves so that there was always one of them available for students during teaching hours (not in the practice's laboratory, but in their office or research laboratory). Nevertheless, the best option for this proposed methodology would be incrementing the number of lecturers from two to three or four, something that does not depend on them but on the University organization.

VI. Conclusions

In this paper, evaluation of a PBL approach applied to a microcontroller-based system design course has been analyzed. Due to the reduced number of lecturers in charge of practical classes, the PBL methodology was applied by means of small projects rather than a more complex single project. The analysis of the results tries to eliminate the influence of certain variables (group of students, difficulty of the final exam or group of lecturers) that may change if the analysis is done comparing the results obtained in different years, in which some of them the old methodology was used and, in the rest, the new one. These results show that the proposed methodology helps student in acquiring the new knowledge not as theoretical concepts that have to be memorized, but as a tool for solving real problems. The efficiency of PBL is already perfectly known, but the proposed PBL-based methodology is an option to be considered when the number of lecturers available is low for a typical PBL.

Abstract— **Providing a communication aid is a complex issue which requires a deep insight on the theoretical backgrounds, the technological basis and, specially, the problems faced in bringing together the expectations and needs of users, teachers, speech therapists, families... and the perspectives and knowledge of linguists, teachers, engineers and speech pathologists. In this on-going project we intend to develop and implement helpful tools for students with communicative impairment by means of communication boards based on icons, pictures or conventional characters.**

Keywords-Augmentative and Alternative Communication, Communication Boards, Special Needs, Accessibility

I. INTRODUCTION

The development of a human being depends a great deal on the ability to communicate. Not only social aspects are involved, but also those related to psychological stability and cognitive development.

History is full of examples of great people who made their way through communication difficulties. Hellen Keller, deaf-blind was the first person gaining a Bachelor Degree of Arts, a great author. Political activist and lecturer, she would have been lost without Anne Sullivan's determination.

In 1995 Jean-Dominique Bauby, editor-in-chief of French Elle magazine suffered a rare kind of stroke who left him in a locked-in syndrome (a condition in which a perfectly agile mind is trapped in a useless body). He could not walk, eat or even breath. All he could do was blinking his left eye. He dictated an entire book on his experiences by having the alphabet told and blinking to select a letter. His story inspired the film *Le Scaphandre et le papillon* (The Diving Bell and the Butterfly).

It is also inevitable to mention Stephen Hawking, whose colossal efforts allow us to enjoy the ideas and theories of one of the most influential physicist nowadays.

This colossal efforts are made at an outstanding personal cost, and here is where technological aids may provide that extra-help needed to forget about communication methods and to focus on communicative content.

Digital aids have proven helpful in getting the message from those unable to speak or even write through conventional methods. If we do not help every student to effectively communicate and develop their minds to the maximum we would never know how many great minds are we leaving behind, locked in dysfunctional bodies.

Readiness as a key aspect in a communicative act. It is important, not only to provide with an effective way of communication, but it also has to be a quick one. This way we allow the user to keep pace of a conversation. Otherwise the hole speech would result in a monologue.

Personal assistants dictating the alphabet have been replace by scanning switch activated keyboards. The former went through all the available characters following, in most cases, the conventional alphabetic order. As for the latter, the standard is the QWERTY display. None of the sequences has been set with a scanning approach in mind.

This project is aimed to explore and optimize the scanning sequence implementing a frequency based sequence (recently used by communication assistants), thus reducing time waste and allowing more fluent communicative exchanges.

We will set the basis of augmentative and alternative communication to analyze conventional communication boards used with students and adults. The TICTAC approach will be presented to have a better idea of the whole communication strategy behind the project. Finally we will go through the main features of TICTAC virtual keyboard.

As it is a work in process final results are yet to come, but there are indicators showing a lot of people may find this keyboard useful, making a difference in their everyday lifes.

II. AUGMENTATIVE AND ALTERNATIVE COMMUNICATION

A. Defining AAC Systems

According to the American Speech-Language-Hearing Association (ASHA):

Augmentative and alternative communication (AAC) includes all forms of communication (other than oral speech) that are used to express thoughts, needs, wants, and ideas. We all use AAC when we make facial expressions or gestures, use symbols or pictures, or write.

People with severe speech or language problems rely on AAC to supplement existing speech or replace speech that is not functional. Special augmentative aids, such as picture and symbol communication boards and electronic devices, are available to help people express themselves. This may increase social interaction, school performance, and feelings of self-worth [1].

There are many types of AAC but they tend to fall into two main groups:

- Unaided communication systems, such as gestures, sign language or traditional communication boards. They do not provide voice output and no electronic hardware is involved.
- Aided communication systems which are the trend nowadays:

[...]electronic devices that may or may not provide some type of voice output. Devices that provide voice output are called speech generating devices. These devices can display letters, words, and phrases, or a variety of symbols, to allow the user to construct messages. Messages can be spoken electronically and/or printed on a visual display or strip of paper. Many of them can connect to a computer for written communication. Some of them can be programmed to output different spoken languages [1].

B. AAC User

The first difficulty we come across with when we try to identify the potential user is the lack of patterns in this population. They come from all age and socio-economic groups; appear in all backgrounds, have all sort of health conditions and show different levels of communication performance.

The ASHA gave us the most commonly used definition of this population.

Individual with severe communication disorders are those who may benefit from AAC -those for whom gestural, speech, and/or written communication is temporarily or permanently inadequate to meet all of their communication needs. For those individuals, hearing impairment is not the primary cause for the communication impairment. Although some individuals may be able to produce a limited amount of speech, it is inadequate to meet their varied communication needs. Numerous terms that were initially used in the field but are rarely mentioned include speechless, nonoral, nonvocal, nonverbal, an aphonic [2].

A number of studies [3] suggest that 8 to 12 people per 1.000 may experience severe communication impairments that require AAC.

C. Ethiology

We must assume there is no typical AAC user, even given the same primary cause for the lack of communicative exchange.

Nevertheless disabling conditions that may require AAC have been categorized into four types [4]: congenital conditions, acquired disabilities, progressive neurological diseases and temporary conditions. Cerebral palsy, mental retardation or autism are examples of congenital conditions. Acquired impairments that may lead to the use of AAC include traumatic brain injury, cerebral vascular accident, laryngectomy or glossectomy. There is a number of progressive neurological diseases with an impact on communication such as multiple sclerosis or Parkinson's disease. Finally, we must consider those cases in which the restriction in communication is temporal (e.g. intubation or severe facial burns).

III. Communication Boards

A communication board is a technical help for AAC users consisting in a surface where the communication facilitator displays a variety of icons, symbols, letters, words... for the person to point, stare at, or select by any means available (such as automatic scrolling for scanning).

A. Traditional

These are hand-made custom boards. The facilitator decides on the concepts included and their display. Then, he places them on the board (a piece of wood, cardboard, plastic...) either manually or setting the display with the aid of a computer program such as Boardmaker [5] and printing the complete board to stick it to an appropriate surface.

These, though very popular both in primary and secondary school, highly limit the communicative competence of the individual and basically avoid any possibility of a conversation.

B. Electronic

We include here most commercial communicators. Some of them barely differ from the traditional ones except for the fact that the selection triggers an action (generation of artificial voice, playing an audio file or printing a message on the screen or paper). The level of customization varies considerably among them. Some may be designed from scratch while others are predetermined by default with little room for customization.

Their readiness and the supporting role of the company selling the product to solve eventual problems is to be taken into account.

But a careful *cost-benefit* study must be carried out from a long-term perspective as they are not so useful with this idea in mind. It also limits considerably the vocabulary available and the structure of the sentences, which becomes more and more important as the studies approach to a university level.

Cátedra de la Infancia. U. Vigo

C. Digital

Communication Boards based on digital environments are becoming less scarce. Although most commercial digital boards are simply unaffordable for most families or institutions; the efforts of professionals in bringing together their IT skills with their AAC mastery are laying the foundations of an exciting new way of approaching AAC.

People with severe impairment are especially vulnerable to separation from the mainstream society. Technologies applied to AAC systems may help to bridge that gap [6].

IV. Digital Communication Board

In order to help people (particularly students) showing communication impairments, we are currently working on a set of two digital communication boards aiming two radically different problems. Both of them draw the limits of the issue according to the "ability to write" criterion. This ability should be assessed in 'cognitive terms' rather than 'motility terms'.

An cognitively impaired person who is, as a result, unable to read or write needs a communication system capable of easily transmit basic needs and feelings. They do not feel the urge to communicate and just do as they please with a very low tolerance to frustration. They interact with a limited number of people (therapist, teachers, etc), normally trained *ad hoc* to understand their jargon. In other words we need to focus on simplicity in terms of access, meaning and use: a simple message followed by a quick response. Iconic communication serves this cause effectively.

On the other hand, physically impaired users preserve all the intelligence (average or gifted) and have the need to express themselves in complex ways. They have a better frustration handling and are able to deal with delayed responses. They are also able to enrich their message with a variety of paralinguistic resources. Their social network is wider and may benefit extremely from the use of written language.

A. AAC Systems Board

The first board has been completely developed as an icon/picture based board intended for AAC Systems in individuals without the ability to acquire a written code. A basic form of A.I. allows it to continually adapt itself to the needs of the user, as well as being proactively adapted by speech therapists and caretakers. It includes built-in functions to improve basic communication skills. It has also been partially implemented and tested by a pilot user.

This board has been already described [7] and will not be discussed here as it is highly improbable for one of its users to reach engineering studies (either vocational or university), given the cognitive impairment associated to the communicative problem. We can not rule it out completely, though as we are discovering interesting capabilities particularly in mathematics an physics in certain individuals, e.g. autistic savants may be unable to read or write but could understand and express complicated formulas and equations given in mathematical notation.

B. Virtual Keyboard

The second board is being developed and expected to be implemented and tested by pilot users by the second term of this academic year. It is intended for those physically impaired and thus, unable to hand-write or use an adapted keyboard but who are cognitively able to write. It consists of a virtual scanning keyboard optimized using cryptography algorithms activated through any standard or custom-made push-button.

This is, due to its characteristics and features, the communication board most likely to be used by engineering students with special needs, and unable to make use of conventional virtual keyboard; thus, demanding a scanning system to select the different characters and symbols.

Writing through a scanning device is somehow similar to playing scrabble, only here you have an specific message to deliver. Given this situation you would rather get an 'j' than a 'w' when writing in Spanish (or exactly the opposite in English). This approach sets the basis of the virtual keyboard.

Scanning programs like Kanghooru (http://www.xtec.cat/~jlagares/f2kesp.htm) allow setting the optimal computer screen scanning order for each individual case. This type of programs may be used in conjunction with TICTAC keyboard to operate a computer. Bearing this in mind, four 'keys' have been left blank (e.g. launching software).

The keyboard is also able to speak when used with Llegir (http://www.xtec.cat/~jlagares/f2kesp.htm), a text-to-speach program specifically designed for physically impaired users.

V. Virtual Keyboard analisys

A. Display

This board is set as a conventional virtual keyboard, displayed on screen and maximizing the character area to enable students with visual impairment or difficulties in staring at a particular point to go through the board with following the scanning.

There is a number of differences which outstand against the traditional QWERTY keyboard in terms of display:

- All conventional function keys have been removed.
- All symbols have been grouped under the symbol category.
- The upper line is used for the compacting categories: vowels, consonants, capital letter, number, symbol, control, end.
- Vowels come first, they are colored distinctively and ordered within their category according to frequency criterion, this is, the more used the vowel in the language selected, the earlier will be scanned.
- Consonants are the next category, also distinctively colored, and again ordered according to their frequency in the language selected.

- *May* turns the letter selected into a Capital Letter. There is no Capitals Lock.
- Numbers are ordered conventionally.
- All symbols available are displayed and have been reduced to the ones which are essential for communication. E.g. we only include closing question and exclamation marks, because those are the ones required in many languages, and enough in Spanish to give the intention implied in the message.
- The .com extension has been included as a facilitator given its importance and prevalence in on-line communications, and its difficulty to be written by scanning.
- b_t / b_p/ b_l are accessed through the control button and stand for delete_ everything /delete_word / delete_letter (borrar_todo, borrar_palabra, borrar_ letra, in spanish) respectively.

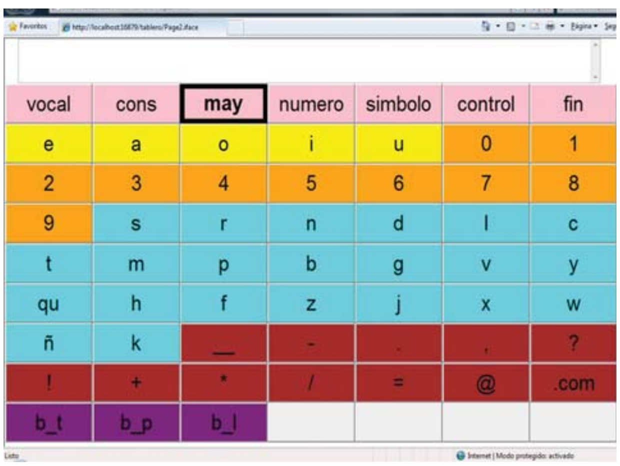

Figure 1. Keyboard display

B. *Letter frequency*

As we have mentioned earlier, all vowels and consonants have been arranged within the keyboard to follow their frequency order in the language used.

A lot has been discussed [8] on the QWERTY letter distribution but contrary to the urban legend (assuming the display slowed the typist), this was developed according to statistical evidence on letter frequency in English but intended to be use with both hands (ten fingers) at a time. This means it is a very fast display if you can use ten fingers moving over the keyboard. Scanning through a QWERTY keyboard distorts the benefits derived from a careful design. Much of the same applies to following the Latin alphabet on its conventional order.

There are two languages available in this keyboard: Spanish (Castilian) and Galician.

Letter frequency is available for Spanish [9], but it had not been determined for Galician. To confirm the information found for Spanish as well as to establish the letter frequency in Galician, a statistical analysis was run using *Make Character (Letter) Frequency Count Software* by Sobolsoft, based on long texts (above a million characters)

Nevertheless the frequency of the letters in a language depends a great deal on the type of text used (e.g. a legal text tends to the use of particular verb forms increasing the prevalence of 'r' or 'd' or 'n'. That is why, instead of using one single text, the letter frequency has been determined using different texts from a variety of sources. Further field tests need to be done to adjust the order of the letters to everyday use. As *practice makes perfect*, it is clear that once determined an order, the user should keep it as practice gained increases speed much more than any eventual modification to fit minor statistical differences.

C. *Technical Issues*

This virtual keyboard is a web application. It has been developed in Netbeans 6.5 and the application server will be Sun Glassfish v. 2. The programming language used is Sun Java EE5 with IceFaces framework. This framework applies Ajax (Asynchronous JavaScript + XML) transparently to the programmer. Using this technology we avoid flickers and reloading screens as well as making the program less bandwidth demanding and enhancing the user experience.

D. *Keyboard Access*

To select a character from the keyboard while it is been automatically scanned, the users must provide a click by any means available to their mobility. This could be pressing a push-button, blowing on a microphone or using any other click emulator.

To facilitate learning and adapting the keyboard to users expertise and mobility the scanning speed can be adjust to:

- Very slow: 10 seconds
- Slow: 8 seconds
- Normal: 5 seconds
- Fast: 3 seconds
- Very fast: 2 seconds

These categories have been determined through observation and practice and might be subject to revision.

Figure 2. Configuration Screen

ACKNOWLEDGMENT

We would like to recognize the work of Álvaro Novo Quiza, who made, a useful contribution to communication in severely physical impaired students, but otherwise as smart as a teacher could desire. They can now express themselves and show what they are capable of. Thank you for contributing with your End of Degree Project.

We would also like to thank the teachers and students in CEIP Seis do Nadal, particularly Ángeles, for been so welcoming and giving us an opportunity to try our virtual keyboard.

***Abstract*—In recent years, the possibilities for distance teaching in engineering education have increased tremendously. The widespread availability of the Internet has allowed the use of rich media over long distances. As visual connectivity improves, an opportunity to enrich and rethink the place of learning design in on-line and distance education is presenting itself. This paper presents a case study of development of digital video to be used in e-learning postgraduate engineering courses. Videos should be used in autonomous DVD or embedded in hypermedia learning objects. Multilingual, interactive questionnaires and mixing use of animations and real images are some features of the video. The use of these video is put to the test in a postgraduate course on Solar Energy and other Renewable Energies in Buildings**

Keywords-component; Video teaching media, solar energy, engineering education.

I. Introduction

Some studies in the field of engineering education [1], [2] point out that one of the future trends will be the greater utilization of information and communication technologies (ICT) in ways that improve teaching and learning. It is expected that such ICT will increase accessibility of students to engineering programs and allow students greater flexibility in terms of how, when and where they study. These ICT would be used in undergraduate programs as well as in postgraduate programs and engineering lifelong learning, as long as this technology can be used to accomplish pedagogical goals. The only theoretical presumption is that educational outcomes would determine the selection of teaching delivery media. That means that the introduction of the ICT must be accompanied by improvements in the understanding of learning and teaching [3], [4]. Thus, the explosion of ICT has presented teachers with the opportunity of revisit the whole question of teaching and learning and to explore new forms of deliverables that supports students' creativity.

Besides electronic books and links to technical web sites, ICT aided engineering courses frequently involves multimedia presentation with interactive exercises and questionnaires, technical video and hypermedia tools, included to promote active learning.

This paper presents a case study of development of digital video to be used in e-learning postgraduate engineering courses. Videos should be used in autonomous DVD or embedded in hypermedia learning objects. Multilingual, interactive questionnaires and mixing use of animations and real images are some features of the video. The use of these video is put to the test in a postgraduate course on Solar Energy and other Renewable Energies in Buildings, within the framework of an international e-learning project. The pilot experience was designed to answer, amongst other, the question about what would be the students' usage during the course and what would be the implications of this experience for further developments.

II. Digital Video in Education

The applications and potential benefits of the use of video in teaching and learning started with the analogue videotapes in the early seventies [5, 6]. In some cases, video technology was used to improve practical teaching by developing simulated laboratory sessions [7]. In others, video-taped lectures were used in distance courses as a substitute of traditional lectures [8]. Nowadays, with the broad use of digital technology, video can be considered as a powerful medium that, first, can provide narrative visualization, and second, can engage multiple senses of learners simultaneously. Educational applications incorporating videotapes, digital video and on-line video can be found in disciplines as diverse as management, language teaching, physics and mathematical sciences, medical education and engineering.

Traditional forms of educational video include film, broadcast television and video cassette playback. Analogue video disks allowed video resources to be integrated into computer-based learning, but this technology was relatively expensive and did not become widespread. With the advent of digital video, video resources can be distributed to students via CD-ROM or DVD, on-line via the Internet, and embedded within other computer-based learning resources. Compared to traditional forms of video which are viewed primarily in a linear sequence, digital video permits more effective interactivity and control, as video elements can be quickly selected by the user, or controlled by a computer program, in any desired sequence. Although, while the technical requirements for digital video production may now be less demanding, the production of quality learning content still requires appropriate expertise [9-10].

The first question that arises is that the role of video clips should be considered more an addition to other teaching materials than a replacement of the same. This question becomes important depending on the audience: while on-campus students are more likely to consider the video resources useful as extra information on the topic, off-campus students are more likely to consider that the video resources are useful in helping them to understand the issues involved in the topic [8, 11]. This may be due to the fact that on-campus students have easy access to lectures and academic staff, while off-campus students receive only printed or electronic study materials, and the availability of video resources may provide alternate viewpoint on the topic of study.

Another relevant question about the use of video resources is the format of the video. The format of the video can be considered in two ways: the length of the video and the recording setting. It is noted that the literature [10] recommends short video segments to maximize learners' concentration. Previous experiences reported in the literature [8] confirm this trend: it is preferable four segments video of 11-12 min duration than a video of 45 min of a full lecture. Respects the recording setting, two options are the most common for distribution: a) streaming video from a web site (for example, the university learning content management system) via broadband Internet access; and b) supply of CD-ROM or DVD version. Practical playback of the on-line video resources requires a broadband Internet connection, which on-campus students have access to in the university computer laboratories. However, due to a combination of price, technical availability and geographic factors, the uptake of home broadband Internet connections is comparatively low; hence CD-ROM or DVD would be expected as the preferred playback source for off-campus students.

When searching for video clips for teaching purposes, you can consider television broadcaster on-line resources, or websites such as YouTube, TeacherTube or BUFVC, which can be very useful. However, high level technical and/or educational videos are very scarce, and direct use of streaming videos for teaching could be inefficient for the learner if the video resource is not integrated in a comprehensive teaching approach. Further, though the use of videos is a move forward, passively observing a video is not cognitively engaging and challenging, and therefore learning is not as effective as it can be. Some interactivity should be desirable in video resources, promoting engagement and active involvement.

Most common use of integration of video resources in teaching engineering courses are related to on-campus experiences, but are very scarce when referred to e-learning, off-campus experiences. E-learning has recently become a promising alternative to the traditional classroom learning, helping society move toward a vision of lifelong and on-demand learning. Thousands of on-line courses are now being offered. Recent advances in multimedia and communication technologies have resulted in powerful learning systems with instructional video components. The emergence of non-linear, interactive digital video technology allows students to interact with instructional video. The concept is not new but is taking on new forms. However, the effect of interactive video on e-learning is still not well understood. Reference [12] describes a research mainly focused on investigating the impact of interactive video on e-learning effectiveness through an empirical study. A multimedia based e-learning system was used to teach a Management Information Systems course to freshmen, undergraduate students. Results of the experiment showed that the value of video for learning effectiveness was contingent upon the provision of interactivity. Students in the e-learning environment that provided interactive video achieved significantly better learning performance and a higher level of learner satisfaction than those in other settings.

But e-learning has also a great potential of use in life-long, postgraduate courses. It is the most frequent case for current professional engineers or architects. E-learning is partially a response to the demand for reduction in time-to-competency in the knowledge-based economy. Companies need to offer effective training to employees and business partners to ensure that they acquire new skills in a timely manner. The number of international e-courses is also increasing nowadays, due to the increase of professional mobility and the global economy. When using video resources in international courses, multilingual facilities are an added requirement for their integration in multimedia based e-learning systems. At present, none research on learning effectiveness of using video resources in teaching international, postgraduate e-learning engineering courses has been reported. This work is intended to carry out a study of the effectiveness of video resources on learning outcomes and learner satisfaction in e-learning engineering courses.

III. CASE STUDY OF INTEGRATING VIDEO IN AN E-LEARNING ENGINEERING COURSE

This paper presents a case study of development of video teaching materials for international, postgraduate engineering courses. The video will be put to the test in a postgraduate e-course entitled Solar Energy and other Renewable Energies in Buildings, within the Higher Polytechnic School of the University of Burgos. The pilot experience is designed to answer, amongst other, the question about what would be the students' usage during the course and what would be the implications of this experience for further developments.

During the period from November 2009 to March 2010, the University of Burgos will teach an international, full on-line course on Solar Energy and other Renewable Energies in Buildings, as partner of a European Union project. The project, entitled Novel and Integrated Model of Sustainable Energy Communities (NIMSEC), is focused on improving and surpassing the local level energy efficiency, and increasing the overall share of renewable energy production, especially in public buildings and/or industry and agriculture. Based on an analysis of the local framework conditions and on data collected in energy audits, concrete pilot actions are planned and implemented towards building integrated model of sustainable communities. Training courses on energy efficiency and renewable sources of energy will aim at university students on one hand and at technicians (energy auditors) and installers or distributors for renewable energy sources on the other hand.

The staff of the University of Burgos has previous experience in teaching international e-learning engineering courses, described in detail in the literature [13]. The present course will be addressed to engineers and architects who wish to become specialized in the field of the small Renewable Energy Sources applications in buildings. The learning content management system (LCMS) of the University for on-line teaching, UBUCampus-e, will be used for the delivery of the course. That implies a high grade of technical contents focused on renewable energy engineering topics. Besides electronic books and links to technical web sites, some multimedia presentation with interactive exercises and questionnaires, technical video and hypermedia tools will be included to promote active learning. In the previous experience [13], some technical or informative videos on renewable energies were included in the multimedia teaching tools. These videos, as obtained from free and public websites, were only partially related to the topics of the course, and, as a consequence, their use was considered only as complementary information on the topic. Locution was only in English language and no interactivity was allowable.

In this work, the authors have developed a pilot experience of a video on Solar Thermal Systems for Domestic Hot Water production to be used as teaching material in the next postgraduate e-learning course. When planning the teaching materials, some requirements of the video were established:

a) The video should be editted in several languages, accordingly to the international nature of the project.

b) The video should enable random access to its different parts, which is expected to increase learner engagement.

c) As a solar thermal system has no visible moving parts when fonctioning, some animations should be included to increase the visual impact of thermal concepts in the video.

d) Some kind of interactivy was desired, in conection with the learning outcomes and the assessment of the course.

e) Two versons of the video will be needed: first, one version with full facilities which will be distributed vía DVD and, second, an on-line streaming version of the video to be included in the LCMS of the University for those students with broadband Internet access.

Respect the video languages, it was decided to use only Spanish for the locution, because of the high costs of locution recording in other languages. Optional subtitles in English, French and also Spanish were then adopted as a solution to offer a multilingual video. Availability of subtitles has also a secondary benefit, thus this feature of the video increases the accessibility of the video for disabled people (deaf people).

In order to provide interactive video, logic segmentation of the instructional video into seven chapters was performed. If the learner does not interact, the whole video will automatically 'flow' from beginning to end. However, the learner can perform interactive operations at any time by pressing the control buttons of the media player used, going forward or back to the next/previous unit. The user can also directly jump to any particular video chapter by clicking the correspondent sub-topic in the menu tool-bar of the media player (i.e., random access to video content). As a result, interactive video eliminates the linearity of traditional video.

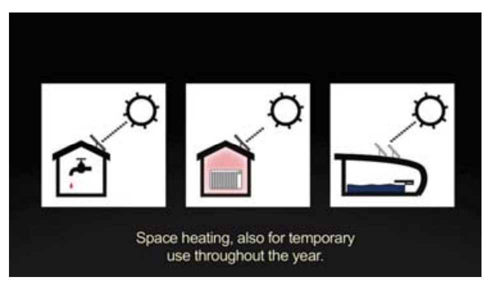
2D and 3D animations have been included as a dynamic approach to some critical thermal concepts of solar thermal systems, such as the energy balance and the green-house effect of the solar collector, or the explanations about the alternate uses of the low temperature solar thermal energy systems in buildings.

As a novelty of the instructional video, interactive questionnaires in Spanish, English or French languages are available in the main menu of the video. These questionnaires consist in multiple choice questions tests. The user clicks on the selected answer and the video offer an answer (correct or wrong) to the user. The question/answer process is visually reinforced with the change of the related picture appearing at the left side of the screen. These questionnaires are intended to be used as self-assessment exercises by the learner. The topics included in the questionnaires are related to the questionnaires and exercises that will be used in the assessment of the course.

Fig. 1 shows some examples of the features of the video described in the precedent paragraphs.

(a)

(b)



(c)

(d)

Figure 1. Examples of several features of the Solar Thermal System multilingual interactive video: (a) main manu page in Spanish language; (b) video footage with English subtitles; (c) 2D video animation with English subtitles; (d) interactive multiple choice questionnaire in French language

Recording of the video was produced in full HD quality with a camcorder. An experimental low temperature solar thermal system for on-campus teaching at the Higher Polytechnic School was used for the recordings. 2D animations were designed with After Effects CS3·software, while 3D Studio Max was used for 3D animations. Full HD plus 2D and 3D animations were integrated into video linear edition by means of Final Cut Studio2 editor.

Interactive questionnaires were first edited with Photoshop to combine pictures with text-boxes including the questions. Finally, encoding of video, questionnaires and all the facilities was done with Adobe Encores CS3, which manages all the menus and options of the user.

Codification in MPEG-2 was used to produce the DVD with full facilities described, of about 1 GB in size. In this format the video can be played in any commercial DVD player or in computer.. However, for distribution through the Internet, a version with compressed codification in MPEG-4, with no optional menus and only English subtitles, was produced.

Finally, a text file in pdf format has been also included in the DVD. This text is a printed version of the script of the video, so the learner can use it as a reinforcement tool during or after the video use. The text is available in Spanish, English and French.

Author's previous experience in e-learning engineering courses [13] is that self-study materials (including self-assessment procedures) are used frequently by the students during the course and receive, in general, a very high valuation as helping tool for learning. Usually, students that achieve a higher level of mastery in the topics of the course use more frequently and during more time the self-study materials than the rest of students. At the same time, their valuation of the self-study materials is directly related to the course assessment criteria and methods, activity where they will put their extra time and effort. Therefore, we expect that the effectiveness of the proposed video resource is higher respect the use of commercial, non-interactive videos or the use of no videos.

The streaming video will be included in a hypermedia tutorial conceived as a helping learning task in the corresponding module. The editor of these learning objects (exe.exe, eLearning XHTML editor) is a desktop authoring environment to assist teachers and academics in the creation of web content. The editor includes a range of pedagogical forms, e.g. objectives, advance organizers, and learning activities (text, videos, questionnaires, wikis, etc.), which constitute the equivalent of the 'teacher talk' in content resources designed for online learning. Some features of the hypermedia tutorial are presented in Fig. 2

(a)

(b)

(c)

Figure 2. Hypermedia tutorials on Renewable Energies in Buildings: (a) Objectives and pre-requisites to follow the tutorial; (b) Multiple choice test; (c) Reproduction of a linked scientific video.

The learning objective of the set of hypermedia tutorials is to broad the scope of each module and to present the information in an attractive and interactive way, in order to engage the student with the correspondent topic. Though the relevant engineering content of the course is included within the licensed e-books (texts of reference), the hypermedia tutorials are intended to allow students to go more deeply into the specific topic.

It is expected that 25 engineers or architects coming from 5 countries of the European Union will be involved in the course. It is very probably that, for many of them, this will be the first time they will follow a full internet engineering course; also, that they probably will have to use extra time after their current job to study the course.

A survey on the effectiveness of the video as teaching material and its integration in the e-learning course will be performed. Some data about the student engagement with the video will be collected by means of a perception test. The information will be gathered by the presentation of statements to which students were invited to respond on five-point scale ranging from ‘strongly agree’ (5) to ‘strongly disagree’(1). The questionnaire is conceived in order to elicit information about three dimensions of student’s engagement with the video tutorial: learning outcomes, technical matters and easiness of use. A preliminary perception test will be posed to each student at the early beginning of the course, when he has just got an overview of the course but not still begun with the required tasks. A second test will be posed at the end of the course, when the student had finished it, in order to compare changes in the student’s perception of the quality of the video tutorial, before and after using them. Scores of both pre- and post-tests will be examined through descriptive statistics. For students using the on-line streaming video distributed through the UBUCampus-e LCMS, the tracking facility of this system will be used to check every learner-content interactive operation with the interactive video

IV. Conclusions

A European postgraduate program on renewable energies in buildings, developed in an international cooperation project, is oriented to improve engineer’s ability to design and construct renewable energy systems in buildings and communities, along the period 2009-2010. The international course, with a high grade of technical contents focused on renewable energy engineering topics, is addressed to engineers and architects who wish to become specialized in the field of the Renewable Energy Sources applications. The LCMS of the University of Burgos for on-line teaching, UBUCampus-e, will be used for the delivery of the course.

A multilingual, interactive video on low temperature solar energy systems, conceived as a helping learning task, has been developed by the teachers, and is included within the course contents. The learning objective of this video is to present the information in an attractive and interactive way, in order to engage the student with the correspondent topic. Being of elective use, the video include technical description of the solar system, interactive questionnaires and additional text documents for self-study, aligned with the expected outcomes and the assessment of the course. Design criteria for learning effectiveness of the video are based on literature and previous experiences of the authors.

The pilot experience will be put into force during winter 2009 and spring 2010, using the interactive video within an e-learning engineering course on renewable energies. It is expected that 25 students from several European countries will be involved. A survey will be conducted to study if the video, which provides individual control over random access to content and offer optional self-assessment of learning, may lead to better learning outcomes and higher learner satisfaction.

Acknowledgment

The authors thanks the Energy Intelligent – Europe program, (project NIMSEC, grant EIE/07/221 SI2.467621), for supporting this work.

Abstract— **The domain of traditional hypermedia is revolutionized by the arrival of the concept of adaptation. Currently the domain of Adaptive Hypermedia Systems (AHS) is constantly growing. A major goal of current research is to provide a personalized educational experience that meets the needs specific to each learner (knowledge level, goals, motivation etc...). In this article we have studied the possibility of implementing traditional features of adaptive hypermedia in an open environment, and discussed the standards for describing learning objects and architectural models based on the use of ontologies as a prerequisite for such an adaptation.**

Keywords: e-learning, learner modeling, , adaptive educational hypermedia, ontologies, RDF, IMS LIP

I. Introduction

E-learning is a very dynamic domain, constantly growing, which refers to educational content or learning experiences delivered or made through digital technologies. The development of this domain has a direct impact on teaching quality and reducing costs. E-learning today is dominated by Learning Management Systems (LMS) such as Blackboard, Moodle, ATutor or Claroline, which are integrated systems that provide support for a wide area of activities in the e-learning process. Thus, teachers can use the LMS for course creation and test suites, to communicate with students, to monitor and evaluate their work. Students can learn, communicate and collaborate through LMS.

The problem is that LMS does not offer personalized services, presents the same educational resources to different learners, regardless of different levels of knowledge, interest, motivation and objectives. As Morrison [1] stated:"Just as people differ in many respects, so do ways in which they learn differ". Some of these differences are evident in the types of experiences that each person needs to learn. It is therefore essential to start the process of planning, attention to the characteristics, capabilities and experiences of learners - as a group and as individuals. "Adaptive Educational Hypermedia Systems (AEHS) try to provide an alternative approach to non-individualized, providing various services, tailored to the learner profile. The purpose of this adaptation is to maximize the subjective satisfaction of the learner, the learning speed (efficiency) and assessment results (effectiveness).

There are two basic questions in AEHS:

- What can we adapt to? The answer includes several learner characteristics, such as knowledge, goals, tasks or interest, background and experience, learning style, context and environment.
- What can be adapted? The answer includes the presentation (adapting the actual content, the presentation of that content, or the media used) as well as the navigation (adapting the link anchors that are shown, the link destinations, and the overviews for orientation support).

In addition, Adaptive hypermedia systems (AHS) for e-learning represent a continuously growing research domain, involving knowledge from several fields (adaptive systems, adaptive hypermedia, learning management systems, user modeling, educational psychology, instructional science).

Adaptation can take 3 forms [2]:

- Adapted systems: in which adaptation is hard-wired by the application designer; in this case, the system is customized to a particular user profile, which is defined beforehand, at design time.
- Adaptable system: in which adaptation is explicitly required by the user. More precisely, the user can specify her/his own preferences, by manually creating her/his profile; thus the system is dealing with a fixed profile, which can only be modified by user's intervention.
- Adaptive systems: in which adaptation initiative belongs to the system itself, based on continuous observation of user preferences and needs. The user's profile is no longer static, it is dynamically updated by the system, after tracking and analyzing user behavior.

II. ADAPTIVITY IN E-LEARNING

A conceptual definition of adaptivity in e-learning refers to the creation of educational experiences that adjust based on various conditions (personal characteristics, pedagogical approach, user interactions, learning outcome) during a certain amount of time in order to improve performance indicators (e-learning efficiency: results, time, costs, user satisfaction). The functional definition refers first of all to the main characteristics provided by the system. An adaptive system must be capable of managing learning paths adapted to each user, monitoring user activities, interpreting them using specific models, inferring user needs and preferences and exploiting user and domain knowledge to dynamically facilitate the learning process [3].

We can identify three major development paradigms in Artificial Intelligence in Education:

- Intelligent Computer-Assisted Instruction, using classic mainframes and mini-computers as platforms. The main goal of these systems was the transfer of knowledge to the student, therefore the learning material consisted mainly of presentations and also some exercises and problems. Correspondingly, the most popular technologies were curriculum sequencing and intelligent solution analysis [4].

- Intelligent Tutoring Systems, using personal computers as the support platform. The main goal shifted from educational material presentation to supporting the student in solving problems and procedural knowledge formation. Consequently the core technology became interactive problem solving support.

- Web-based educational systems, having the WWW as support platform. The goals of these systems became more complex and diverse, including at the same time content delivery, problem solving support and collaborative work support. Consequently multiple technologies were employed, ranging from adaptive curriculum sequencing, adaptive hypermedia, adaptive information filtering, intelligent solution analysis, intelligent collaborative learning, class monitoring.

Our research is oriented towards the adaptive and intelligent Web-based educational systems. Adaptive systems are those systems that try to behave differently toward each student, based on the information accumulated in the student model, while intelligent systems apply artificial intelligence techniques in order to comply with the needs of their users.

III. ADAPTATION COMPONENTS

In what follows, we present the components of adaptation, to examine briefly adaptation levels and technology, adaptation models and ways of representing adaptation knowledge.

A. *Adaptation Levels and Technologies*

A method is defined as a notion of adaptation that can be presented at the conceptual level. A technique is a way to implement a specific method. Techniques operate on actual information content and on the presentation of hypertext links. It may be possible to implement the same method through different techniques and to use the same technique for different methods [5].

According to the most recent classification there are two levels of adaptation:

- Adaptation to the level of content and presentation adaptation
- Link level adaptation navigation or support adaptation.

Indeed, by abstracting hypermedia as a graph, we can either adapt its nodes (content level adaptation) or its edges (navigation level adaptation). Figure 1 provides a summary of the adaptive hypermedia technologies.

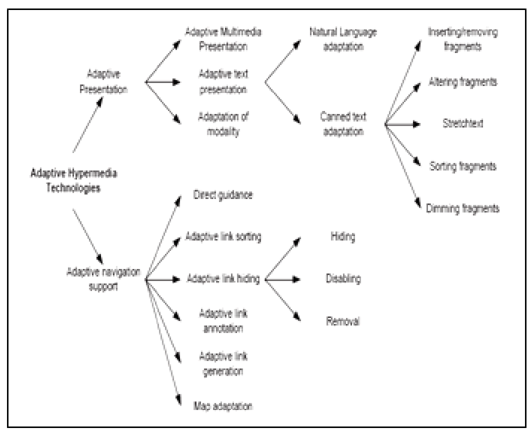

Figure 1. Updated taxonomy of adaptive hypermedia technologies [6]

While the distinctions of the taxonomy are important for identification and classification of adaptive systems, the implementation of these techniques can be achieved using a small selection of fundamental data structures that can be combined to create powerful AH systems.

B. *Adaptation Models*

The Adaptive Hypermedia Application Model (AHAM) provides a framework to express the functionality of adaptive hypermedia systems by dividing the storage layer into three parts that specify what should be adapted, according to what features it should be adapted, and how it should be adapted.

The Munich Reference Model preserves the three-layer structure of the Dexter Model describing the network of nodes and links and the navigation mechanism. It extends the functionality of each layer to include the user modeling and adaptation aspects. The Run-Time Layer, the Storage Layer and the Within-Component Layer are represented as UML subsystems as it is illustrated in Figure 2.

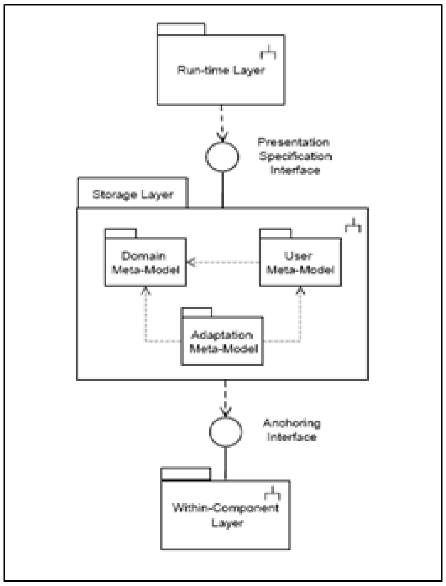

Figure 2. Architecture of Adaptive Hypermedia Applications

The Run-Time Layer contains the description of the presentation of the nodes and links. It is responsible for user interaction, acquisition of user behavior and management of the sessions.

The Storage Layer has more functionality than just storing information about the hypermedia structure. To support adaptation the Storage Layer is divided into three sub-models:

- The Domain Meta-Model that manages the basic network structure of the hypermedia system in terms of mechanisms by which the links and nodes are related and navigated. The nodes are treated as general data containers.
- The User Meta-Model manages a set of users represented by their user attributes with the objective to personalize the application.
- The Adaptation Meta-Model consists of a set of rules that implement the adaptive functionality, i.e. personalization of the application.

The content and structure within the hypermedia nodes are part of the Within- Component Layer, which is not further detailed as its structure and content depend on the application. The functionality of adaptive hypermedia systems is specified by three types of operations included in the classes of the reference model:

- Authoring operations are needed by adaptive hypermedia systems to update components, rules and user attributes, e.g. to create a link or a composite component, to create a rule, to add an user attribute to the model, to delete components or rules.
- Retrieval operations are required to access the hypermedia domain structure and the User Model, e.g. to get a component, to get all rules triggered by a user's behavior or another rule.
- Adaptation operations are used to dynamically adapt the User Model content to the user behavior and to adapt the presentation to the current state of the User Model, e.g. the adaptive resolver, the constructor or the rule executor.

The remainder of this paper presents the visual specification (slightly simplified) of the layers of the reference model and includes a few constraints of the formal specification out of a total of seventy constraints that comprise the complete specification of the Munich Reference Model [7].

C. Representation of Adaptation Knowledge

We can identify several ways of addressing the issue of procedural knowledge, for more detail see [8]; in our case we are interested in the use of ontologies. Because, from our point of view, different types of knowledge relevant to the adaptive learning could be represented using ontologies based on the use of Resource Description Framework (RDF).

There are several authors that propose the use of ontologies, such as Cristea [9] (appropriate ontologies for each layer of the LAOS model, namely: domain, goal and constraint, user, adaptation, and presentation ontologies), Henze et al.[10] (domain ontology, user ontology, observation (interaction) ontology and presentation ontology).

IV. Integrating Adaptive Hypermedia Techniques

In this section we discuss the possibilities of using standardized metadata to describe and classify information stored in a Resource Description Framework database to describe the knowledge, preferences and experiences of users accessing that information. In addition, we will illustrate how to implement features of adjustment with the ultimate goal of implementing a personalized access to learning.

A. Using RDF Metadata

Resource Description Framework (RDF) is a graph model for formally describing Web resources and their Metadata, to enable automatic processing of such descriptions. Developed by the W3C RDF.

A document structured in RDF is a set of triplets. An RDF triple is an association: {subject, predicate, object}

- The subject is the resource to describe;
- The predicate is a type of property applicable to this resource;
- The subject is given one or another resource: the value of the property.

To annotate resources, we have identified a subset of best practices of 15 elements which are summarized in Table I, using the categories defined in the LOM [11]. It was found that these 15 attributes are enough to annotate and query our resources, and represent a compromise between sets of annotations more abstract and more detailed. Annotations of an entire course can be included in a single RDF file. All RDF triples are then imported into a relational database to customize the display of resources and to ask others.

TABLE I. THE 15 ATTRIBUTES TO ANNOTATE AND QUERY OUR RESOURCES

General	Title	**dc:title**
	Language	**dc:language**
	Description	**dc:description**
Lifecycle	Contribute	**dc:creator** with a **lom:entity** and the author in vCard format "name surname" dcq:created with the date in W3C format
Rights	Description	**dc:rights**
Relation		**dcq:hasFormat** **dcq:isFormatOf** **dcq:hasPart** **dcq:isPartOf** **dcq:hasVersion** **dcq:isVersionOf** **dcq:requires** **dcq:isRequiredBy**
Classificatio n		**dc:subject** for content classification. This attribute links to an entry in a hierarchical ontology, that is an instance of **lom_cls:Taxonomy** (see next section)

B. *Topic Ontologies for Content Classification*

Personalized access means that resources are tailored according to some relevant aspects of the user. Which aspects of the user are important or not depends on the personalization domain. For educational scenarios it is important to take into account aspects like whether the user is student or a teacher, whether he wants to obtain a certain qualification, has specific preferences, and, of course, which is his knowledge level for the topics covered in the course.

Taking user knowledge about topics covered in the current account is complicated, because it requires Cognitive Styles (see also [12]). The general idea is that we annotate each document by the topics covered in this document. Topics can be covered by sets of documents, and we will assume that a user fully knows a topic if he understands all documents annotated with this topic.

To be more general, we use ontologies that are already part of classification systems are internationally recognized.

ACM CCS as a topic ontology for learning objects. The ACM Computer Classification system ([13]) has been used by the Association for Computing Machinery since several decades to classify scientific publications in the field of computer science. On the basic level, we find 11 nodes that split up in two more levels.

To classify a resource, the IEEE Learning Object RDF Binding Guide ([14]) suggests the use of *dc:subject* with elements of a taxonomy that must be found on the Internet. Such a taxonomy hierarchy is an instance of *lom-cls*:*Taxonomy* and must be formatted in a RDF file where the topics and subtopics are separated using *lom_cls*:*Taxon* and *lom_cls*:*rootTaxon*. As discussed, we used ACM CCS, The main structure is as follows (Figure3):

```
<dcq:SubjectScheme rdf:ID= ACM CCS >
<rdfs:label>ACM Computer Classification system</rdfs:label>
</dcq:SubjectScheme>
<lom_cls:Taxonomy>
  <lom_cls:rootTaxon>

C. *Describing Users*

In recent years there have been some efforts to standardize the information about a user, which should be maintained by a system.we choose the IMS Learner Information Package [15].

IMS LIP is a structured information model. An XML binding is included but is not meant to exclude other bindings. The information model contains both data and meta-data about that data. The model defines fields into which the data can be placed and the type of data that may be put into these fields. Typical data might be the name of a learner, a course or training completed, a learning objective, a preference for a particular type of technology, and so on.

The Learner information is separated into eleven main categories (as shown in Figure 4). These structures have been identified as the primary data structures that are required to support learner information. This composite approach means that only the required information needs to be packaged and stored.

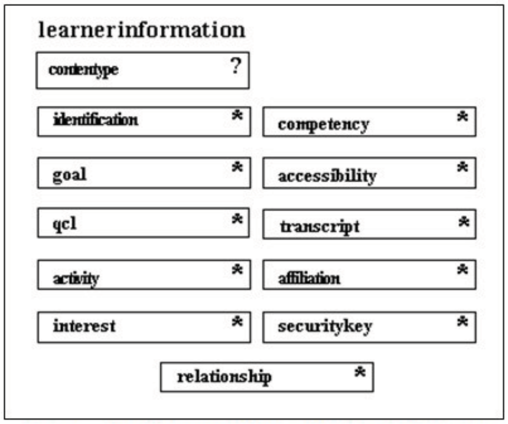

Figure 4. The IMS Learner Information Package (LIP) core data structures

An example of accessibility category data is represented in Figure5.

```
<learnerinformation>
  <contentype><referential>
      <sourcedid><source>
          IMS_LIP_V1p0_Example
        </source>
        <id>basic_1001</id>
      </sourcedid></referential>
  </contentype>
  <accessibility>
    <contentype><referential>
        <indexid>accessibility_01</indexid>
    </referential></contentype>
    <language><typename>
        <tysource sourcetype="imsdefault"/>
    <tyvalue>Frensh</tyvalue></typename>
      <contentype><referential>
          <indexid>
            language_01
          </indexid>
      </referential></contentype>
      <proficiency profmode="OralSpeak">
        Excellent
      </proficiency>
      <proficiency profmode="OralComp">
        Excellent
      </proficiency>
      <proficiency profmode="Read">
        Good
      </proficiency>
      <proficiency profmode="Write">
        Poor
      </proficiency>
    </language></accessibility>
</learnerinformation>
```

Figure 5. An example of LIP Accessibility information.

The *identification* category represents demographic and biographic data about the user. The *goal* category represents learning, career and other objectives of the learner. The *QCL* category is used for identification of qualifications, certifications, and licenses from recognized authorities. The *activity* category can contain any learning related activity in any state of completion. The *interest* category can be any information describing hobbies and recreational activities. The *relationship* category aims for relationships between core data elements. The *competency* category serves as slot for skills, experience and knowledge acquired. The *accessibility* category aims for general accessibility to learner information by means of language capabilities, disabilities, eligibility, and learning preferences. The *transcript* category represents institutional-based summary of academic achievements. The *affiliation* category represents information records about membership of professional organizations. The *security key* is for set passwords and keys assigned to a learner.

V. System Description

Our system is under development, we present here a primary prototype interface. (Figure 6)

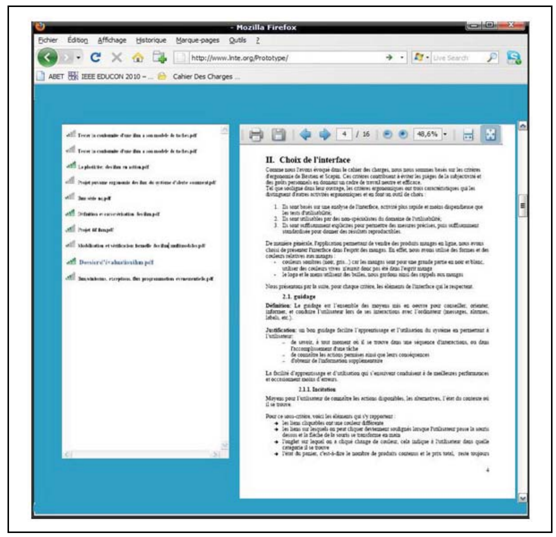

Figure 6. Protoype of the user interface

Information will be presented in two different frameworks. The left frame displays the course structure based on metadata. The user can navigate through this structure and can open documents in the right frame. Each resource is annotated according to the current user profile to express its relevance to the user. For annotations, we use a metaphor of wireless connection.

VI. conclusion

In this article we have studied the possibility of implementing traditional features of adaptive hypermedia in an open environment, and discussed the standards for describing learning objects and architectural models based on the use of ontologies as a prerequisite for such an adaptation.

We discussed how this information can be expressed as RDF metadata and how we can use queries over this metadata. We also discussed the architecture of our hypermedia all based on the Munich Reference Model. We finally present our system (adaptive hypermedia), which has been implemented as a prototype.

In our work, we will continue to improve links RDF. We will also experiment with compositions of resources and techniques of presentation and adaptation of different types of applications tailored functionality.

Applying an Inductive Method to a New, Multidiciplinary, Management of Innovation & Technology Course: Evidence from the University of Nicosia

Despo Ktoridou
Department of Management & MIS
University of Nicosia,
Nicosia, Cyprus
ktoridou@cytanet.com.cy

Abstract—Managing **Technological innovation is one of the most important aspects of business for management, business, management information systems (MIS), engineering and science students to learn. Academics and practitioners, who teach topics related to technology innovation to multidisciplinary classes, usually they do so deductively, that is the lecturer introduces the general principles and continues with applications of those principles. A common observation is that University students do not see any motivation knowing that someday they will need those knowledge and skills. A *Student-centered teaching method* on the other hand shifts the focus of activity from the lecturer to student including *inductive teaching* and learning.**

The new, elective "MGT370- Management of Innovation and Technology" course was to engage students from different specializations in a collaborative environment in which students have access to assignments based on real-world case studies and problems. After a group open-discussion a preliminary analysis of students' perceptions towards technology innovation content knowledge faced a significant contradiction.

This paper presents a review of the unique features of the main inductive methods, describes the new elective Management of Innovation and Technology course, presents assessment outcomes, reports the learning outcomes after the employment of inductive learning strategies in the course and gives recommendations on how assessments are being used to deploy, manage and improve the course.

Keywords-problem-based learning; technology innovations; student-centered method; inductive teaching and learning method;

I. INTRODUCTION

Academics and practitioners who teach specializations such as MIS, and Science traditionally do so deductively. Students are introduced to theory and mathematical models and then are given exercises from the textbook and possibly some real-world cases/applications to analyze. A general observation is that teaching technology innovations to multidisciplinary classes generates questions on whether any real world cases could be explained; can any practical problems be solved; does all this knowledge meet the interests of a multidisciplinary class; and finally is it really a motivation telling students that they will need certain knowledge and skills someday [1]. Is it really motivating to know that what they are learning will be useful for their curriculum and further for their careers? Based on references [2] and [3] the most common reason for students to leave sciences is the lack of connecting the course material to the real world.

A student-centered approach where the student is responsible for his/her own learning by building his/her own version of reality is an alternative approach to learning. Specifically a student-centered approach includes inductive teaching and learning where students are primarily presented to a precise challenge, like a real-world case study to analyze, seek a solution to a complex illustrated open-ended real-world problem or interpretation of experimental data. While dealing with these challenges, students realize that they lack skills, knowledge, facts and conceptual understanding and they request the help of the lecturer, who plays the role of the facilitator. Based on references [4], [5] and [6] it is demonstrated that inductive methods encourage students to adopt a deep approach to learning that lead to further intellectual development. Inductive teaching and learning incorporates the following learning methods: inquiry, problem-based, project-based and discovery as wel as case-based teaching and just-in-time teaching. Prince and Felder [1], one of the few who have examined these methods as a group, have reviewed several of the most commonly used inductive teaching methods defining each method, highlighting commonalities and specific differences, and reviewing research on of their effectiveness for and science education.. This paper presents a review of the unique features of the main inductive methods, describes the practical applications of: inquiry learning, problem-based learning, and case-based teaching in the new elective course MGT-370 Management of Innovation and Technology and discusses practical issues of implementation specifically in meeting the needs of a multidisciplinary class. Finally it attempts to evaluate the effectiveness of the various activities. Recommendations are given to academics and practitioners for designing their curriculum based on a student-centered approach using inductive methods for: the development of critical thinking and creative problem-solving skills, a deeper understanding for formation of positive attitudes and confidence in knowledge or skills toward the course [1].

II. LITERATURE REVIEW

A. *Student Centered Teaching Methods*

During the last few decades, education literature presents a broad variety of student-centered teaching methods and presents evidence that a proper implementation of a student-centered method could lead to: rise of motivation towards learning with more positive attitudes toward the subject, greater retention of knowledge and deeper understanding [8,9,10,11].

Student-centered teaching methods shift the focus of activity from the teacher to the learners. These methods include active learning, competitive learning and inductive teaching and learning placing the emphasis on learning instead of teaching. Academics and practitioners are continuously seeking ways to enhance, enrich their classes as well as motivate their students. More specifically, in higher education, for an elective Technology course, taken by business, management, management information systems (MIS), and science students, one approach is to be such targeting to an assessed short-term mastery, a depth of course material understanding, critical thinking acquisition, creative problem-solving skills, formation of positive attitudes toward the subject, and level of confidence in knowledge or skills.

B. *Inductive Methods*

Inductive teaching and learning include a range of instructional methods: inquiry-based learning, case-based instruction, problem-based learning, project-based learning, discovery learning, and just-in-time teaching. All these methods are all student-centered; are initially presenting to students challenges (questions or problems) and continue with studying the course material in the context of addressing these challenges. In class students are actively involved in discussing questions and solving problems (*active learning*), while in and out of class the work is done in groups (*collaborative learning*). [1] have summarized in a table the features of common inductive teaching methods Table I.

TABLE I. Source Journal of Education 95(2), p. 124

Method► / **Feature▼**	**Inquiry**	**Problem-based**	**Project-based**	**Case-based**	**Discovery**	**JITI**
Questions or problems provide context for learning	1	2	2	2	2	2
Complex, ill-structured, open-ended real-world problems provide context for learning	4	1	3	2	4	4
Major projects provide context for learning	4	4	1	3	4	4
Case studies provide context for learning	4	4	4	1	4	4
Students discover course content for themselves	2	2	2	3	1	2
Students complete & submit conceptual exercises electronically; instructor adjusts lessons according to their responses	4	4	4	4	4	1
Primarily self-directed learning	4	3	3	3	2	4
Active learning	2	2	2	2	2	2
Collaborative/cooperative (team-based) learning	4	3	3	4	4	4
1 – by definition, 2 – always, 3 – usually, 4 – possibly						

The differences among the above mentioned inductive methods are obvious. In the literature each method has its own research base, history, guidebooks, supporters, and critics, and is not clear what the methods are and how they are interrelated [1]. Lohman [12] claims that similarities of case-based and problem-based learning are obvious; however, in problem-based learning students are confronted with poorly structured problems driving to acquisition of new content knowledge while in case-based learning students analyze hypothetical situations, well structured, detail context-rich, involving solutions to problems and/or decision making. Katsikitis *et al.* [13] comparing case studies to problem-based learning found no significant difference between the two methods as far as performance or knowledge acquisition. The following paragraphs summarize definitions and applications of inquiry, problem-based and case-study learning methods that have been implemented in this paper.

Inquiry Learning- The focus of inquiry learning is on answering questions, solving problems, or explaining a set of observations [14]. Lee [15] in his work states that students should learn to "formulate good questions, identify and collect appropriate evidence, present results systematically, analyze and interpret results, formulate conclusions, and evaluate the worth and importance of those conclusions" only after an effective implementation of the method. Similar outcomes could derive after an effective implementation of a problem-based learning as well as certain forms of case-based instruction.

In this paper *inquiry learning* is implemented *as an instruction tool* using questions and problems providing contexts for learning strategies in ways of using strategic management of innovation to enhance firms performance.

Problem-based Learning – This approach to teaching offers students opportunities to learn via contextualized problem sets and situations. Through the group work and independent investigation, they achieve higher levels of comprehension, develop more learning, knowledge-forming skills and social skills. Lessons may be designed using different scenarios such as: a) entire class discussion b) group of students reporting their progress on earlier learning issues and listing their present learning issues and future plans of work, (c) short lectures on group work, aiming to keep class up-to-date on general issues, clarify common difficulties, as well as suggest additional learning issues [16].

According to meta-analysis of the effectiveness of problem-based learning done by a group of scientists [19], 43 empirical studies were identified having effects on problem-based learning, knowledge acquisition and development of problem-solving skills,

This paper discusses the implementation of a problem-based learning using problems that vary significantly in scope, from single-topic single-discipline problems to multidisciplinary problems that meet the needs of a multidisciplinary class.

Case-Based Learning - cases teach students about realistic decision-making situations involving one or more challenges: diagnosing technical problems and formulating solution strategies, making business management decisions taking into account technical, economic, and possibly social and psychological considerations, and confronting ethical dilemmas [1]. The cases should be real-life —situations based on professional practice coming out of magazines, newspapers or interviews from those involved in the case.

The idea of using real-world case studies, on technology innovations, in this course was based on Lundeberg, Levin and Harrington, [1] work stating that with real world case-studies students will be able to:

- analyze complex real-world cases,
- acquire theoretical and practical understanding of the subject
- become aware of the kinds of situations possibly facing as professionals in the future,
- develop critical reasoning skills,
- explore their existing preconceptions, beliefs, and patterns of thinking, and
- make necessary modifications in those prejudices, beliefs, and patterns to accommodate the realities of the cases.

C. Management of Innovation and Technology Course

MGT-370 is an undergraduate elective course under the management specialization. The main objectives of the course are

- Introduce of the important role of technology innovation in the Management strategy
- Understand the theoretical knowledge underlying the technological change and the ways firms come up with innovations
- Provide an overview of the strategies that firms use to benefit from innovation
- Understand the importance and role of formulating technology strategy**;**
- Design, develop and integrate a strategic management of innovation and technology

III. RESEARCH METHODOLOGY

To address the research objectives of the study a case study design was employed [7]. A case study based on Merriam;s [17] work that research focuses on discovery, insight and understanding from the perspectives of those being studied offers the greatest promise of making significant contributions to the knowledge base and practice of education.

With the qualitative case study research the researcher has approached the problem of a newly introduced technology innovation course to a multidisciplinary class, a problem of practice from a holistic perspective in order to gain an in-depth understanding of the situation and its meaning for higher education lecturers. The attention was focused in the teaching/learning processes rather than learning outcomes, in the general course context rather than some variable and in the process of discovery rather than in conformation.

The research method was designed to answer the question, how do students from different specializations in an inductive learning environment perform, collaborate, exchange ideas and acquire the subject.

The new course, MGT 370, management of Innovation and Technology was offered two times per week, sessions of 75 minutes each, to a multidisciplinary class of 10 undergraduate students. The curriculum was designed based on a student-centered approach including an inductive teaching and learning method.

To measure students' perceptions towards subject matter learning at the beginning of the course a pre-test has been completed to asses their conceptual knowledge of the principles of applying strategic management of innovation in a firm. Further based on the objectives of the course students worked, individually and in groups on question answering, situation exploration, realistic decision-making situations, contextualized problem sets and situations.

The classroom activities and Outcomes questionnaires provided data on student attitudes toward collaborative learning, problem-solving activities, and interaction with the lecturer and peers.

IV. DATA ANALYSIS

Based on the sample of the study the analysis of the results was made based on group work skills, communication and problem solving skills and content learning. The lecturer has moderated students work in class and has documented the pre-test results as well as their assessment results. see Table. 2

Inquiry Learning*:*

Students were given a question or problem based on real world technology evolutions as well as technology adoption sand diffusion or they have suggested a technological innovation of their preference so as to formulate good questions, search and gather suitable evidence, present results systematically, analyze and interpret results, formulate conclusions.

- *group work skills -* Science students reported that for such kind of assessments they prefer to work individually because they seem to have different preferences and knowledge towards technology innovations; they could formulate and structure in a different why their questions as well as search, gather, analyze and especially formulate conclusions.
- *communication -* Business and management students proved to be more communicative towards science

students and were suggesting real-life problems from businesses.

- *problem solving skills* – all students were thinking creatively and critically about ways to solve the given problem. Difference in backgrounds helped students to approach different related solutions fact that enabled them to analyze and interpret and present the results systematically.
- *content learning* – Content learning for all students was significantly satisfactory based on the discussion that derived at the end of the class.

Problem-based learning:

Contextualized, complex, open-ended, authentic problem sets on sources of Innovation and selection of innovation projects were presented to students individually and/or in groups for investigation. A class discussion followed as well as a group progress report on earlier/present learning issues and future plans.

- *group work skills* – students in some problems were asked to work individually and then join their peers into groups (coming from various disciplines) to exchange their findings, come up with a common solution and report it. It was interesting to note that the combination of independent investigation and group reporting led students to report solutions based on a combination of technical, business, management way of thinking and the reports were quite satisfactory having a professional view.
- *problem-solving skills* - based on the final group report, the observation was that students have reached a level of analytic comprehension through problem-based work.
- *communication* – During discussions for the development of the group reports students seemed to have shown resistance in sharing their investigation results. This basically derived from differences in the way they have approached the given problem and came up with solutions..
- *content learning* – the solution of problems based on the aims and objectives of the course required knowledge and skills. The complexity of the problems intrigued students, forcing them to go deeper into research to find and integrate material from various related sources so as to come up to a solution. This way students gained a better understanding of the courses content, developed problem-solving professional skills and have broadened their subject knowledge.

Case-based learning:

Real-world cases on technological innovations from the Harvard School of Business database were given to students targeting to expose them to the analysis of complex real-world cases, situations that they may possibly face as professionals in the future. Exploring, analyzing and discussing case real life situations students can better acquire theoretical and practical understanding of the subject and develop critical reasoning skills. Through initially individual work that was followed by group discussions and then group presentations, students will explore their existing ideas, beliefs, and thinking models so as to be flexible and make alternations their existing ideas, beliefs, and thinking models towards the realities of the cases

- *group work skills* –Students have analyzed the given case studies individually and then joined groups, again coming from different disciplines cases, so as to prepare for a group presentation. A noticeable exploration of beliefs, idea different way of thinking and analyzing the given situation led some students to disagreements. The lecturer who was working as a facilitator had to interfere and moderate the discussions clarifying some issues on the realities of the case targeting the modification of students' ideas, beliefs and thinking models so as to arrive to a common solution for presentation.
- *Problem solving skills* - Individual work on cases though has developed students' abilities in identifying relevant issues and improved their reasoning and problem-solving skills. Exploring, analyzing and discussing real life situations students have developed critical reasoning skills in finding creative solutions. It is interesting to note that if compare case studies to problem-based learning there were no major differences between the two methods related to performance or content learning.
- *Communication* - communication among students during the second stage of the case-based lesson plan was not satisfactory enough due to differences in educational background ideas, beliefs and thinking models. Some students have shown dissatisfaction in having to collaborate in their case analysis results with peers having different specializations.
- *content learning* – by exploring real-life cases, discussions of the results with peers and group presentations the performance of the students indicated gains in theoretical and practical understanding of the subject as well as case studies students' ability to recognize multiple perspectives was enhanced. Using cases developed students' ability to identify relevant to the content issues and exposed them to experiences and problem based situations.

V. CONCLUSION

Transformations from teacher-centered to student centered learning involves fundamental changes for both students and lecturers.

The inductive method used for this empirical study incorporated Inquiry learning - observations, problem-based learning – contextual complex problem solving, and case-based teaching – real-life case analysis.

Inquiry learning proved to be the approach that required a lot of effort from the lecturer in designing the context, based on questions and problems.

Problem-based learning incorporated complex, open-ended, authentic problems whose solution requires knowledge and skills specified in the courses aims and objectives. A variety of interpersonal problems had been raised during this method due to multidisciplinary educational background in group-work.. The lecturer must interfere as a facilitator to help student groups become effective teams targeting the development of students' professional skills such as problem-solving, and self-directed or lifelong learning.

The use of cases proved to be effective for the current elective undergraduate course with a multidisciplinary audience since learning aims and objectives incorporate decision-making in complex authentic situations. The selection of cases must address the learning aims and objectives with a wide variety of scenarios, had been raised such as identifying technical problems, developing solution strategies and making business management decisions.

The adoption of inductive methods can not reassure better learning and satisfaction for both lecturer and student. Any new teaching method should be very well planned, organized and implemented to meet the needs of the curriculum and students.

Students exposed to this methods that require more individual work full responsibility of their actions and minimum guidance must feel the lecturer as the facilitator who at the right time will offer them appropriate amount of guidance and support.

Lecturers deciding to implement inductive methods in their curriculum, they must search for cases, problems, complex situations that are based on real life scenarios that will offer students opportunities to exchange ideas, believes, knowledge, experiences and come up with professional solutions.

Abstract— **This paper present a model for the integration for the standardization integration inside the technical teaching in university context, taking into account the established requirements by the European Higher Education Area (EHEA). This methodology is based on the development of a new typology of document named as "standard supplement". The proposed methodology serves to identify the set of documents witch are necessaries in a specific subject, the knowledge, abilities and attitudes to identify with the academic competences, previously defined, and a guide for the development of the contents of each "standard supplement". The proposal structure of "standard supplement" is appropriate to different level of complexity and could be used as a link between enterprises and engineering education.**

Keywords: Standardization, EHEA, Engineering Education

I. Introduction

The EHEA shows an important change in the traditional methodology implemented at the universities. Nowadays, Master class is the most used pedagogical practice in the university. It consists of an expositive method where teacher explains a subject and student take a passive attitude. In this case, teacher has all the responsibility to prepare the subject.

Obviously, to make a change from this teaching method, which is based on the traditional expositive method, with low student participation, into a new teaching method with high level of student participation, is very difficult. This change is impossible to achieve if is based only on a methodological aspect. In order to allow an active implication of the students in their learning, their effectiveness depends on a high level in their personal work. For this reason, the didactical material plays an important roll if it is structured to influence in their attitude.

Actually, the use of standards and standardization field is lower that it could be desired in engineering education, perhaps its high interest in technical learning. For this reason, the main objective of this work is to develop and to introduce a methodology for the integration of standardization in technical education [1, 2].

Technical teaching can not be understood without a constant allusion to standards that, in most cases, establish conditions or restrictions related to a specific topic. The incorporation of additional viewpoints in the contents of standards could be considered as an important advance in the present proposal. This paper can offer a continued flow of updated knowledge, transforming the current pure normative feature in another in which coexists the normative one with the pedagogical one.

This methodology is based on the development of a new typology of document named as "standard supplement" [3]. The incorporation of standard supplement should be understood from the perspective of the educational innovation, to increase the presence of the standardization in technical teaching and documents, by means of the elaboration of documents with all the necessary requirements established for the conformation of an European Higher Education Area (EHEA) [4–7].

The election of the subject of Internal Combustion Engine (ICE), among lots of subjects in technical teaching (electricity, electronics, machine tools or automobile fields) is based on the high number of implicated knowledge fields.

II. Methodology

The methodology proposed can be divided into three phases. The first one will characterize the necessary standard supplements for the development of the specific matter; second phase identifies academic competences that should be included in standard supplements; at last, third phase shows a guide to develop the content of standard supplements.

A. Characterization

The characterization of standard set to the development of a specific matter is carried out by means of a classification of the different elements to standardize. This classification depends on every matter and should show the relationship among elements (material composition, position, functionality, manufacture) or other technical criteria, and it should help to give an hierarchical structure, being useful to relate the function that every element has in its set and establishing the interrelation among their different systems.

There are different ways to classify the elements of an ICE. The engine is an important part of a vehicle, being formed by great number of elements and auxiliary systems. This proposal is based on a functional and positional classification of elements, according to technical criteria.

Positional relationship establishes a distribution of elements according to physical position of every element in engine, establishing distinction between external and internal elements.

In one hand, basic external elements shape the structural base, being used profusely as a support for the fixation of auxiliary systems and other elements. Cylinder head and the engine block are significant examples of these elements. On the other hand, internal elements are usually hidden, for example, cog-saft and connecting rod.

Functional relationship is established according to the relative movement of connection among elements, classifying them in "active" elements, if there is a relative movement, and "passive" elements, when there is no relative movement between them.

Main active elements transform thermal power of the fuel in mechanical power. They are situated inside the engine, so they can not be identified to simple view; for example: piston, connecting rod and crankshaft.

They are several series of auxiliary systems in an ICE. Some systems are essential for engine operation, as cooling system, whereas other systems help to optimize their operation, as variable admission system. The most of the elements of auxiliary systems can be included in one of the precedent groups, establishing the positional or functional relationship between engine elements and auxiliary system elements.

The creation of the fourth group is necessary to include other elements not mentioned in precedent classification, as pulley check, cylinder head gasket or plain bushings.

Previous considerations lead us to the need of creation of the next four groups:

- Group I. Active elements

- Group II. External elements

- Group III. Auxiliary systems elements

- Group IV. Other elements

Fig. 1 show positional and functional relationship, that is, the interrelationships established among elements belonging to the same group and among different groups' elements. The identified classification is generated associating concentric way identities. The functional or positional relationship is reflected by means of the union segments among elements. For this way, active elements (group I) have been represented inside the internal circle (green color); external elements (group II) are inside the second circle (blue color); finally, auxiliary systems elements (group III) are outside circle (orange color).

It can be noticed the existing functional relationship among active elements, being evident the dependence among them, because all elements are related. Active elements are in the center of the classification because they are considered as essential elements in an ICE.

The situation in the diagram of group II, corresponding to external elements, is justified for the positional relationship among these elements, given that support elements of group I (active elements) and the most of auxiliary systems elements.

Group III is situated in the last level of the diagram. Every auxiliary system is formed by a series of external or internal elements, actives or passives, with a positional relationship with elements of group II.

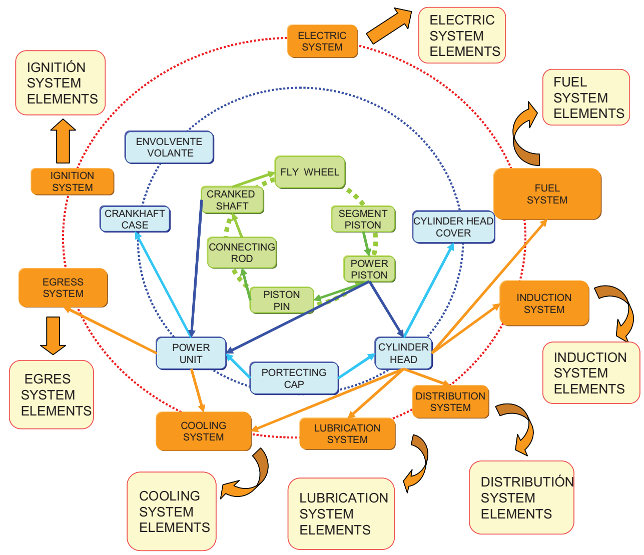

Figure 1. Positional and functional relation

B. *Contents*

Technical document presents, in most cases, references to standards that should be achieve, values that should be established, or allowed limits values. However the use of a standard is reduced, many times, to a simple reference. In the development of this proposed work, it is expected that the standard could be applied in other additional fields, with special attention to teaching context, because it is our point of reference, without underestimating of other possible ones.

The objective of this proposal is not to cancel or to modify the current standard contents, but adding an additional part in the standard supplement, where it is reflected, for each standardized element, the knowledge is considered necessary to be assimilated by an university technical education student, on the EHEA perspective. Due to they can find requirements in the technical educations in different levels, the development of the standard supplement may should have them in consideration, and to do so these requirements are included in this document.

This widening does not only consist of moving knowledge from a determined subject to the corresponding standard. Moreover, it is necessary to move requirements for the new teaching way. To achieve this, it adapts EHEA requirements in the standard content.

The development of aspect as:

- Methodological plurality

- Motivate components of a standard
- Attitudes and abilities acquisition
- Update of contents. University-company relationship
- Standard applicability. Work world relationship
- Relationship with other knowledge areas. Application of the Geometric Product Specification (GPS) philosophy [8]

will establish different bases to carrier out didactic material.

The content of the standardized supplement is developed in a different way if an individual element or set of elements are tried. Two actions are considered in the development of the didactic material so that students can adopts a more active role, which helps them to analyze, synthesize and think in an individual and collective way:

- Elements should be presented dimensionally justified, taking into account design and manufacturing requirements, according to their functional requirements. Functional requirements can be utilized as a guidance to develop a part of standard supplement used as a didactic material.
- Auxiliary systems should be presented to study their function inside the engine set. Therefore, the elaboration of maintenance guide to show possible cause of mistake, from the analysis of element's state, is proposed.

C. *Competences*

The adaptation of the standardization to technical educations takes into account academic competences that should be acquired. A protocol to show the adaptation process of the standard supplement is proposed in Fig. 2, where the relationship among academic competences and their professional activity is contemplated [9].

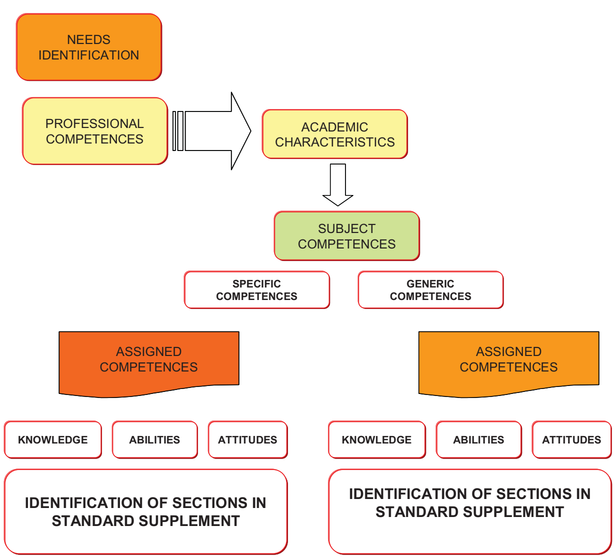

Figure 2. Competences protocol

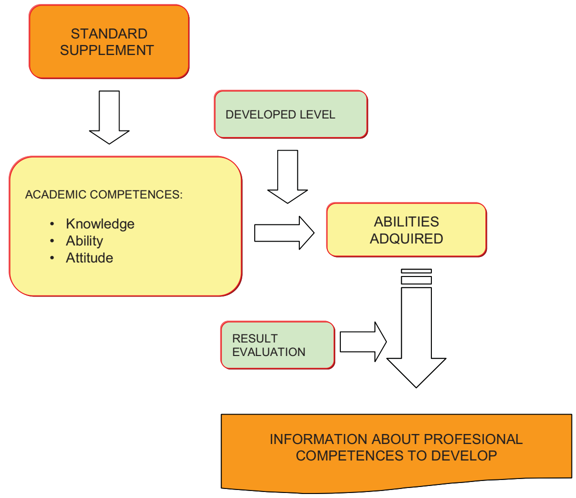

Figure 3. Standard supement generation

The protocol of competences and abilities is used to show a set of documents with a common guidance, which can be used as an aid material for the elaboration of a didactic material according to the capacities and professional necessities that should be acquired. The protocol, divided in two phases, includes:

- Phase I. Identification of society necessities
- Phase II. Development of competences that are implemented in standard supplement

As well, this work is only focused on the second phase.

Phase II contemplates the break down of knowledge, abilities and attitudes that standard supplements can give for established academic competences. These can be generic competences, common to the engineering, or specific competences, common to an engineering specialty.

The generated complexity level in the document should be taken into account, since the result of the acquired capacities should be according to the capacities established in professional competences (Fig. 3).

A matrix, for each of generic or specific competences, is elaborated to establish knowledge, abilities and attitudes [10, 11] that the document contributes and their level. This matrix is used to establish capacities that can be acquired and knowledge that are contributed for a certain competence. Structure of this information is shown in Table I.

TABLE I. STUCTURE OF MATRIX

SUBJECT:		**STANDARD SUPLEMENT:**		
Competence		***Action***	***Description***	***Level***
GENERIC				
SPECIFIC				

As an example, Fig. 4 shows a standard supplement proposed for an ICE connecting rod.

Some basic aspects of the model to be used in the development of standard supplements are considered:

- Clarification of objectives that should be reached. Academic competences are included in this document and they should be acquired.
- ˜Concepts representation. It is contrasted the importance that represents the incorporation of a high number of figures in the document.
- Document structure. The continuity of document has been considered as a disadvantage to structure it with different levels, having the possibility of a partial use (basic, middle and advanced levels).

Basic level includes the explanation of the elementary knowledge of the connecting rod-crank system, by means of the description of main parts of elements and their function. Finally, available applications for ICE are developed and justified.

Middle level presents the processes and materials used to carry out manufacture of the ICE connecting rod. A short description of employed systems is carried out, justifying their advantages and presenting main characteristics of used materials. A second part of this level develops functional requirements that have influence in the design and manufacture of element.

Finally, advanced level allows of determining the structural resistance of connecting rod, with a previous study of dynamic and kinematic system and forces.

The proposed objective is to establish and to put in order the content of standard supplement according to EHEA requirements and to give a pedagogical features, taking into account the document, which belongs to a standard.

The incorporation of EHEA requirements in each developed document depends on technical and functional characteristics of element. In this case, as it happens in other many ICE elements, functional requirements will be used to develop the knowledge that should be included.

The analysis of different functional requirements gives main and basic characteristics that the element must have. Once the element is characterized, a second analysis allows establishing operating conditions.

Dynamic and kinematic studies are used to determine efforts generated in connecting rod-crank system. Mechanical and structural calculations give the measured of necessary minimum sections.

The study of the element is closed by means of the selection of appropriate materials according to its functions, its solicitations and its manufacturing processes.

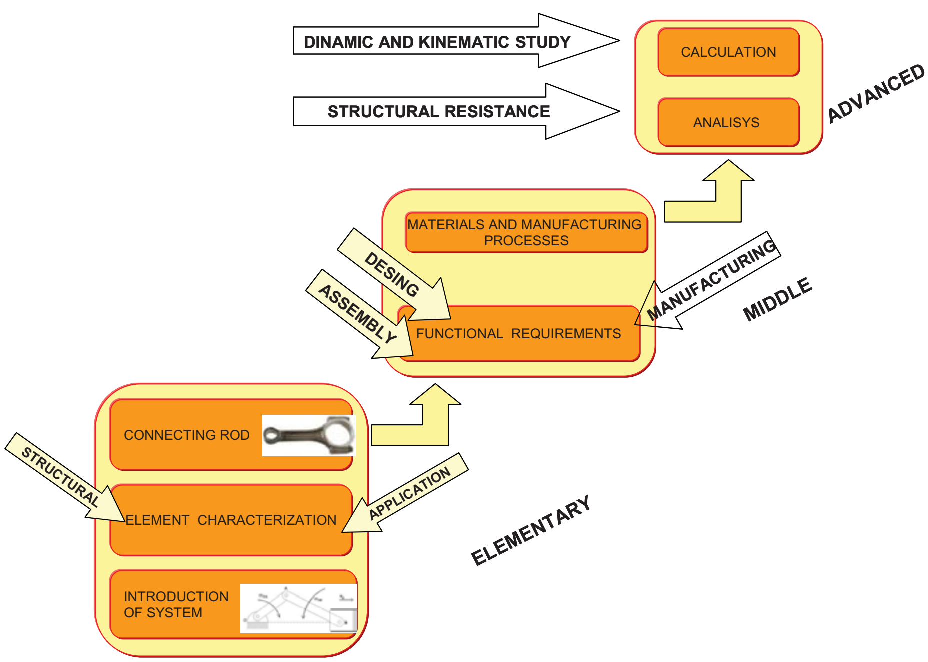

Figure 4. Application to a connecting rod

TABLE II. MATRIX OF COMPETENCES-ATTITUDES

SUBJECT:		**STANDARD SUPLEMENT:**		
Competence		***Action***	***Description***	***Level***
GENERIC	GC.01	Associate	Associating the system and his dynamic and kinematics variables to efforts that are produced in the element	Advanced
	GC.02	Associate	Associating efforts that are produced to the measured and structural calculation of the element	Advanced
	GC…	Compare Contrast	Comparing and to contrast the influence that dimensions of the system have on the set	Advanced
SPECIFIC	EC.01			
	EC.02			
	EC...			

The structure of standard supplement is corresponded with established complexity levels: basic, middle and advanced. However, these three levels do not reflected specifically, although if they are established, due to the continuity that the document should present.

III. CONCLUSIONS

Analysis carries out highlights the importance of standardization in the development of the professional activity, not considered widely in technical educations. Actually, the standard use and standardization field are low. It could be desired in engineering education a deep use, because of its high interest in technical learning. The incorporation of a standard supplement as didactic material can be used in the education so as to help and boost the use of standard documents.

It is necessary to develop a model to fill actual detected voids in some subjects. This development supposes the possibility to generate a non random model, equivalent to Geometric Product Specification philosophy, with a complete structured and coherent body for the ICE elements.

A protocol to evaluate the acquired academic competences has been elaborated. Its conversion to professional competences helps to determine the assimilation level of knowledge, abilities and attitudes. The elaborated protocol should include an evaluation performed by universities, oriented to the certification of academic responsibilities obtained, and an evaluation performed by employers, oriented for the certification of the professional responsibilities recognized.

The standardization can be used as a link between company and university technical educations. Responsible agents for the elaboration of a standard must stimulate existent communication channels, according to recommendation of EHEA.

The elaborated document show significant differences respect to conventional didactic material:

- Structure: standard supplement presents an additional value because of it is structured with different levels and allows to be applied to non university teachings, introducing advantages that standardization can give in other fields.
- Orientation to competences: the development of the oriented document to the acquirement of some academic competences, established in the moment of its elaboration, is useful to different agents on which the process has repercussions (students, graduates, academics and employers), being integrated their priorities in only one proposal.
- Integrative component: the integrative component that should present the elaboration of a standard can be taken into account so as to give the importance of involving the university and the industry as a base of its development.

ABSTRACT

This paper proposes the yPBL learning methodology, based on the well-known PBL method and adapted to software engineering process by using the "y" methodology. The yPBL methodology is defined as a mapping between the roles and phases considered in PBL methodologies to the roles, iterations and phases considered in the "y" methodology. Moreover, the yPBL method includes different situations of active and passive learning roles not only for the students involved in a course but also for the instructors. Indeed, software engineering instructors face the same challenge of any software engineer and needs to continuously update their knowledge in software technologies. The yPBL method has been designed using the Unified Modeling Language (UML) and the various interactions points between the various process actors as well as the information to be exchanged during the synchronous and asynchronous learning process have been specified using this language. Finally, interesting preliminary results of the experience of using this methodology in the INSA of Toulouse are included in this paper.

Keywords-software development process, problem based learning, unified modeling language, software engineering process

I. INTRODUCTION

Software engineering is a complex process demanding from development team members a high level of knowledge and experience in diverse areas going from project management skills to communication, design and implementation expertise. Moreover, the large diversity of software design and development approaches as well as the accelerated development of new software technologies requires a continuous learning process. This is not only the case for software engineers but also for academic instructors teaching software design and development courses.

Problem based learning (PBL) methods have been successfully used in different domains and its benefits have been largely demonstrated [1,2]. These methodologies ask for the active participation of the students within the learning process, playing not only the traditional passive learning role but also an active role where part of the knowledge needs to be discovered and applied by themselves. Moreover, the students may be asked to transmit the knowledge they have acquired to other students in order to reinforce the learning process as well as to demonstrate that the learning objectives have been achieved. Nevertheless, even if PBL methodologies have been designed to be easily adapted to any educational domain, the specificities of software engineering courses need to be carefully studied in order to improve the benefits of these learning methods while applying good practice approaches that are specific to this domain. As previously introduced, software engineering courses ask for multiple skills expertise acquisition and development. Indeed, students need to efficiently exert in the area of project planning, quality assurance, translation and traceability of customer requirements, analysis of the software context and constraints, mapping of functional and non-functional requirements to technical requirements, design of software solutions following good and well-known practices (e.g. design patterns or object oriented approaches), implementation of the designed solution, testing techniques, integration procedures and finally deployment and maintenance strategies of the software product and related documentation. The previous list is not exhaustive and shows the degree of complexity involved in designing PBL-based courses allowing students to play the required roles in order to achieve the software engineering learning objectives.

In the area of software engineering process, several methodologies have been proposed in order to efficiently support members of development teams to design and implement software products. Unified Process (UP) methodologies are very well known in the world of software engineering for providing an efficient process based on an incremental and iterative sequence of phases. Phases include analysis and specification of requirements, design and specification of the software solution and implementation, test, integration and deployment of the software product. These phases are planned and executed in incremental iterations where in each increment new customer requirements can be added within the process. Likewise, bugs detection and corrections as well as requirements change requests can be added in each iteration. As agreed in the software management plan, stable or experimental software products can be released at the end of the iterations.

UP methodologies have been specialized in the form of extended methodologies (i.e. Rational Unified Process, Enterprise Unified Process, Extreme Unified Process, Agile Unified Process, etc.). In recent years an interesting specialization known under the name of Two Tracks Unified Process (2TUP) has been proposed to face the reality of continuous changes of requirements and technologies that represents an invariant reality in software engineering. This methodology, also known as the "y" methodology due to its graphical representation, proposes a differentiation of 2 tracks for the Unified Process, the first (left) track represents the functional aspects of the software product and the second (right) track the technical aspects (e.g. technology, environment, platforms). This separation helps software engineers to concentrate on discovering and specifying the functional requirements that need to be satisfied (left track) while allowing them to explore and select the technologies that could be used to build the software solutions (right track). Once the functional and technical requirements have been identified and specified, both functional and technical tracks can be merged in order to produce the software design specification. From this point, the software product can be developed, tested, integrated and deployed. This sequence of parallel and serialized phases will be executed within the incremental and iterative process proposed by the UP method. Benefits of this interesting methodology have been demonstrated by its application in many industrial and research software projects.

This paper proposes a new learning methodology, based on the well-known PBL method and adapted to software engineering processes. This methodology called yPBL is aimed at being applied to develop software engineering courses within the context of real software projects. yPBL is defined as a mapping between the roles and phases considered in PBL methods into the roles, iterations and phases considered in the "y" process. The yPBL method defines a process where incremental and iterative phases and communication channels and deliverables are planned and defined to facilitate the interaction between external and internal actors involved in the real software project: "the client" and "the project team". Within the project team, students and instructors work together playing different roles in order to build the software solution required by the client. Guided by a real project, internal actors of the process are naturally involved in situations of passive and active learning. Indeed, similar to the students, software engineering instructors face the same challenge of any software engineer face to the accelerated software engineering evolution. For this reason, both instructors and students need to participate in a continuous learning process. The yPBL methodology also defines an internal process where the interactions between the internal actors are planned in incremental iterative asynchronous basis. In order to perform these interactions, internal actors need to work on learning activities including bibliographic research, course preparation and presentation and evaluation of peers based on real knowledge acquisition. Further in the software building process, internal actors need to apply their acquired knowledge in constructing the software solution. At the end of each planned iteration, interactions with the external actors (i.e. clients) are carried out in order to present and evaluate the product releases. During these interactions, the evaluation of the software product is done based on the client's satisfaction degree and the product qualities.

The yPBL method has been designed using the Unified Modeling Language (UML) and the various interactions points between the various process actors as well as the information to be exchanged during the learning, software construction and evaluation process have been specified using this language. The yPBL methodology has been successfully applied in several software engineering courses at the INSA of Toulouse.

The rest of this paper is organized as following. Section I presents a state of the art related to software engineering processes. Section II presents the yPBL methodology model. Section III describes a concrete study case illustrating the use of yPBL within a Software Oriented Architectures (SOA) course. Finally, several conclusions and perspectives of this work are presented.

II. State of the Art

In this chapter the state of the art aimed at providing the basis for the yPBL methodology is introduced. First section is aimed at presenting the main standards in software engineering processes. Second section briefly describes the 2TUP process that is the one promoted by the yPBL methodology. Finally, the main IEEE standards aimed at guiding and documenting software engineering process will also be presented.

A. Software engineering process

A software process defines the steps required to create a software product. One of the most mature and well-known software engineering processes is the Unified Software Development Process or USDP [3]. USDP was introduced as a standard process for creating software products based on the use of the *Unified Modeling Language* (UML).

USDP Introduces the concept of 4Ps: people, project, product and process. *People* working in a software development *project* collaborate within an adequate workflow based on the unified *process* using the common UML notation in order to build and represent the blueprint of the software *product*. The process includes all the activities needed to transform user's requirements into a software system. These activities include *project management, requirements specification, analysis, design, development and testing*.

USDP follows a *component-based approach*. This means that the software system being developed is based on software components interconnected via well-defined interfaces. Likewise, *object oriented design and development approaches* are followed within USDP.

There are three major characteristics differentiating USDP from other approaches:

- *Use-case driven*: the process is driven by the use cases or functionalities offered for each external actor (i.e. clients or any external entity interacting with the system). It means that the process does not consider functionalities that "might be good to have", but it is driven by the realistic usages of the system. In other words, use cases drive all the process phases: requirements, design, implementation and test.
- *Architecture centric*: during the process the software architecture is constantly refined including static and dynamic aspects of the system. It means that the form of the system is built progressively.
- *Iterative and incremental process*: the transformation of user's requirements into the software product is performed within an iterative and incremental process. During this process, the functions and the form of the system are represented by the use cases and the architecture respectively.

Various adaptations to the Unified Process (UP) have been proposed in the last years. These adaptations are based on the category of software system being developed, the organization involved, competence levels of development teams or the project size. Examples of these specializations are Rational Unified Process (RUP), Enterprise Unified Process (EUP), eXtreme Unified Process (XUP) or Agile Unified Process (AUP). However, most of the processes used today for designing and developing software systems are commonly based in the principles proposed by the USDP process. This is the case for the 2TUP process described in the next section.

B. *The "y" or 2TUP process*

As previously introduced, the Two Tracks Unified Process (2TUP) has been proposed to face the reality of the constant change of requirements and technologies of current software systems [4]. The "y" methodology proposes an iterative and incremental process composed by 2 parallels tracks aimed at capturing functional and technical requirements, followed by one centralized design track.

This tracks-oriented structure helps software engineers to concentrate on discovering and specifying the functional requirements that need to be satisfied (left track) while allowing them to explore and select the technologies that could be used to build the software solutions (right track). Once the functional and technical requirements have been identified and specified, both functional and technical tracks can be merged in order to produce the software design specification. From this point, the software product can be developed, tested, integrated and deployed. Further details of the "y" methodology will be presented in the next.

C. *Software engineering standards*

Several standards have been proposed in order to guide and document software engineering process. The most widely used in industry are the standards proposed by the IEEE:

- Software Project Management Plan (SPMP): specifies the structure of software project management plans that are applicable to any type or size of software project [5].
- Software Requirements Specification (SRS): specifies the structure and necessary qualities of software requirements specification documents [6].
- Software Design Description (SDD): proposes the necessary information content and recommendations for software design descriptions [7].
- Software Quality Assurance Plan (SQAP): specifies the format and content of software quality assurance plans [8].
- Software Configuration Management Plan (SCMP): describe the structure and content for a software configuration management applying to the entire life cycle of the software [9].
- Software Test Documentation (STD): this document defines the form of a set of documents for use in defined stages of software testing [10].
- Software Validation & Verification Plan (SVVP): specifies the structure of the validation and verification plan including analysis, evaluation, review, inspection, assessment, and testing of software products and processes [11].

These standards help to express and communicate in an unified way all the information related to the software process.

In the case of software engineering learning methodologies, the introduced software processes and related document standards, provide the basis to define a learning model where the learning objectives can be efficiently achieved while designing and developing a real software project. Next chapter introduces this software engineering learning model.

III. YPBL MODEL

The yPBL is a learning methodology, based on the PBL model and inspired in software engineering processes. As previously introduced, yPBL is aimed at being deployed in the context of software engineering courses based on the construction of a real software system. The yPBL model is defined as a mapping between the roles and phases considered in PBL methods into the roles, iterations and phases considered in the "y" process. As an intent to formally describe the yPBL methodology, the UML language has been used to build an yPBL model.

1) *yPBL use cases*

In order to follow the good practices for software engineering introduced in the previous chapter, the unified process has been used to model the yPBL methodology itself. As any unified process, the yPBL methodology is use-case driven as illustrated in Figure 1.

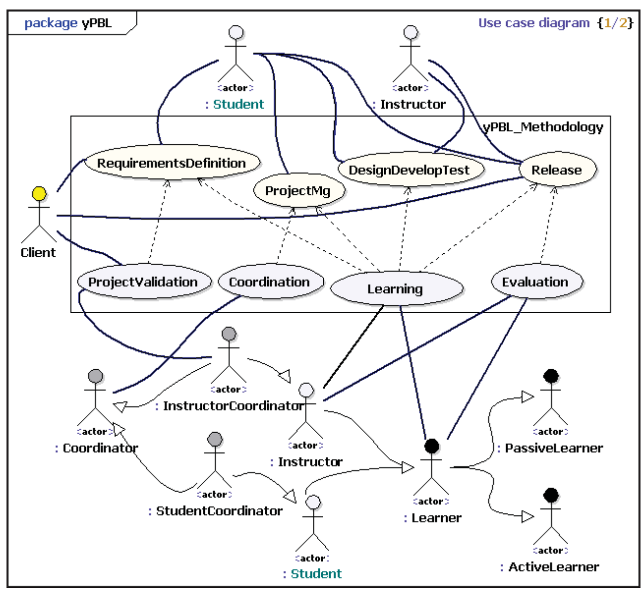

Figure 1. yPBL methodology use cases diagram

In this diagram the various actors interacting in order to achieve the learning objectives while constructing a software system are depicted: students, instructors and the external client.

Guided by the construction of the software project, two generalizations of actor roles are proposed in yPBL: coordinators and learners. The coordinator role is involved in the learning project management and the learner in the learning activities.

Specializations of the coordinator role are represented by instructor coordinator and student coordinator roles. These actors play a supporting role for activities such as planning, scheduling, hardware and software resources allocation. They monitor and control the project in order to early detect potential problems and work together to find efficient solutions. Specifically, the instructor coordinator actor is the one interacting with the external client in order to study and validate the project to be used to instantiate the methodology.

Generalizations of the learner role are defined by passive and active learners roles. Students and instructors play these learner roles. Actually, they are internal actors of the real process and as a consequence they are naturally involved in situations of passive and active learning face to the requirements for learning and applying software engineering technologies. Active and passive learning roles facilitate both instructors and students participating in the continuous learning process.

2) yPBL high level process

The yPBL method follows also the incremental and iterative process proposed by the Unified Process as illustrated in the activity diagram presented in Figure 2.

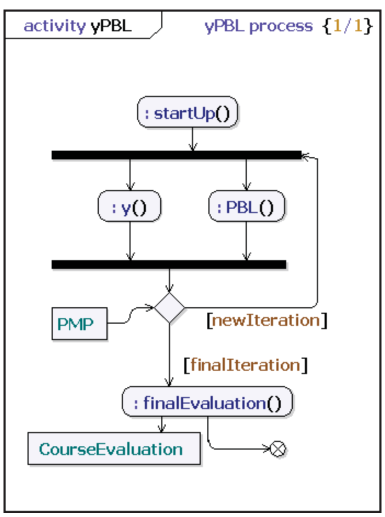

Figure 2. Process proposed by the yPBL

At the high-level yPBL process, an initial start up activity needs to be performed in order to prepare and validate the overall software-learning project. Once the start up activity is achieved, two parallel processes represented by the y and the PBL process are performed. The y process itself concentrates in software engineering activities. The PBL process targets the learning activities. During the overall yPBL process, specific adaptations to the standards presented in the previous section and proposed to guide a software project will be used to drive both y and PBL processes. The first standard is the Project Management Plan (PMP). This document is an adaptation of [5], [8] and [9] documents, and it is intended to control and manage the yPBL process. As illustrated in Figure 2, the PMP document is used for each iteration in order to control the project progress according the initial plan as well as to manage people, resources and deliverables involved in each phase for both software and learning project processes. Once the final iteration has been achieved, a final evaluation of the yPBL project will be performed. During this evaluation both learners participants as well as the learning process itself are evaluated. Results of these evaluations are reported in the "Course Evaluation" deliverable.

3) yPBL detailed level process

The various activities illustrated in the yPBL process presented in the previous section will be further detailed in this section. Specifications used to model internal yPBL activities are intended to describe the workflow process. In these specifications sequence of activates, interaction between the various process actors, as well as communication channels are specified.

Figure 3 illustrates the start up activity. This initial activity is performed as an interaction between the client and the instructor-coordinator.

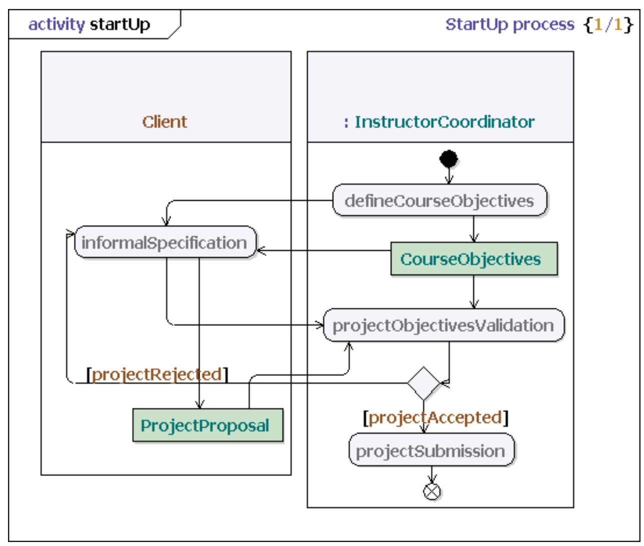

Figure 3. Starting up process

The start up activity starts when the instructor-coordinator defines the course objectives from the functional and technical point of view. Functional objectives are defined as abstract learning statements aimed at expressing the basic and fundamental knowledge goals to be acquired by the learners. Technological learning objectives are intended to express concrete statements based on current software technologies to be used by the learners in order to apply the basic knowledge goals defined by the functional objectives. The document called “Course Objectives” is used to collect these functional and technical objective specifications. This document is communicated to potential clients in order to allow them to propose an objective-compliant project. Clients are asked to propose an informal specification of the project in the form of a “Project Proposal” that will be validated or rejected by the instructor-coordinator. If the project is accepted it will be submitted to the rest of the yPBL process actors.

From this point and as illustrated by the high level yPBL process in Figure 2, two parallel processes guiding the software and learning project activities are started. Figure 4 illustrates the activity diagram modeling the software project process. Students and instructors perform collaborative or individual activities for every iteration of the y process. In order to stimulate autonomy skills, students are asked to work on the functional and technical analysis phase of the project based on the “Project Proposal” submitted by the client. During this phase, students need to interact with the client in order to clearly specify and validate the software requirements and produce the SRS document [6]. Likewise, students are asked to work on the PMP document in order to define the plan to be executed within the several process iterations. Furthermore, they are also asked to pay special attention in defining a realistic project plan based on the priorities of the requirements expressed by the client.

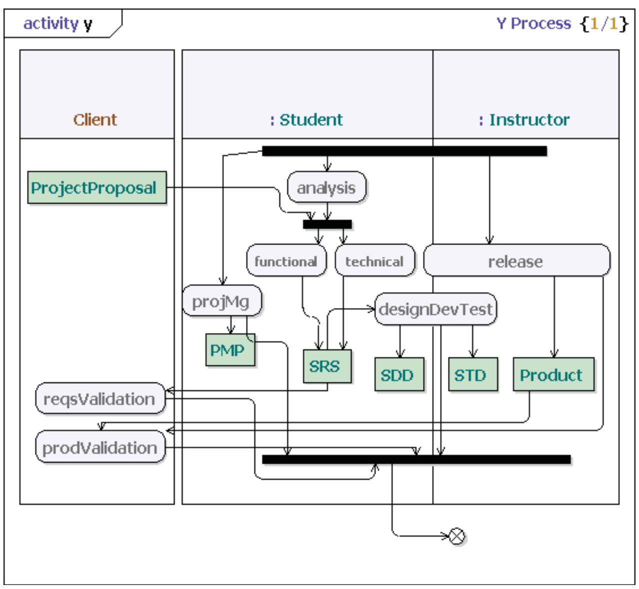

Figure 4. 2TUP or y process

During the design, development and testing activities, both students and instructors work together in order to produce the artifacts expected to be released in every iteration. In these activities the role of the instructor is clearly separated from the client role and this is one important benefit offered by the yPBL method. Indeed, the instructor plays a supporting role intended to help the students to achieve the software project objectives. During these activities, design and test oriented documents are produced following the SDD [7] and STD standards [10]. Following the PMP plan and before the end of the iteration, specific interactions need to be performed with the client in order to validate the “Product” release against the software requirements expressed in the SRS.

In parallel to the y process, learning activities guided by the “Course Objectives” are being carried out for every iteration. Figure 5 depicts the activities performed by the coordinators, instructors and learners during the PBL process.

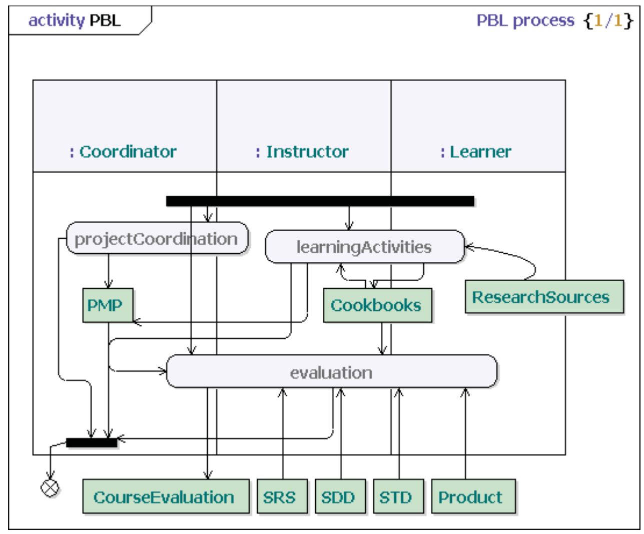

Figure 5. PBL process

Actors performing the role of coordinator (i.e. instructor-coordinators or student-coordinators) perform project coordination activities for every iteration. They work on the PMP document in order to facilitate the project progress and anticipate actions aimed at minimizing potential risks. Coordinators work together on the basis of periodic meetings or by email communication. During these interactions, coordinators exchange monitoring information collected during the process. This information can be used to encourage positive experiences and good practices as well as to work together in solutions to solve detected anomalies.

Likewise, instructors and learners work together in learning activities, which are naturally deduced from the plan, defined in the PMP. Indeed, as the project has been validated based on the learning objectives, the learning activities to be carried out in order to construct the software project can be directly deduced from the PMP. This is particularly important to guarantee the rationalization of the learning objectives and this is another important benefit offered by the yPBL methodology. Students and instructors work together to define and plan learning activities to be carried out in every iteration of the process. In order to efficiently carry out these learning activities accordingly with the plan, both actors need to participate in the research and preparation of the learning material. Instructors work together on the definition of a list of learning subjects. These subjects will be prepared and presented by both students and instructors. In order to facilitate the preparation of the learning material, bibliographic "Research Resources" need to be identified and proposed by both actors. In order to guarantee that the learning material to be produced is compliant with the plan, resources and project requirements, an approach based on the elaboration of "Cookbooks" can be followed. "Cookbooks" are aimed at proposing an efficient presentation of definitions and concepts (i.e. the ingredients), and how they can be applied to construct a particular software function or service (i.e. the recipes). Recommended resources and links are also proposed in the cookbook. Instructors and students carry out the preparation of the cookbooks and specific timeslots are reserved to allow them to present these learning materials. The cookbooks are also stored in a common repository in order to facilitate its access during the project process.

This is another benefit offered by the yPBL methodology. Indeed, internal actors play the roles of active and passive learners, working individually or within groups in learning activities including bibliographic research, course preparation and presentation. Moreover, the evaluation of these activities is carried out by the peers based on the real knowledge acquisition. Furthermore, during the software building process, internal actors need to apply their acquired knowledge in constructing the real software solution.

Finally, for every PBL iteration the evaluations is carried out based on the SRS, SDD and STD documents. From these documents the achievements can be objectively measured based on the requirements identification, solution design and implementation, and the test performed on the final product. Results of the evaluation in every iteration are stored in the "Course Evaluation" document.

The last activity considered in the yPBL process is the final evaluation. This final evaluation activity is carried out after the last process iteration. During this activity, all the process actors are asked to participate in a final project presentation including the final version of the project documents as well as the delivery of the final release of the project. During this activity, the functional and technical project requirements are finally measured, as well as the global satisfaction of the internal and external actors. The process itself is discussed and a list of suggestions and remarks are compiled and included in the "Course Evaluation" document. This information is very helpful to improve the process for future projects and also to measure and compare the final results.

IV. STUDY CASE

The yPBL methodology has been designed based on the experimental results obtained by applying PBL methodologies for software engineering projects in the INSA at Toulouse in France. During the last 2 years, the yPBL methodology has been experimentally used with students of 4th and 5th year of software engineering. These courses can be classified in two categories: introductory design and development courses and advanced technology oriented courses. For both categories of courses, the yPBL has been successfully followed.

In order to propose a friendly interface following the methodology, a template course has been defined using the Moodle learning management system [12]. This template is illustrated in the Figure 6.

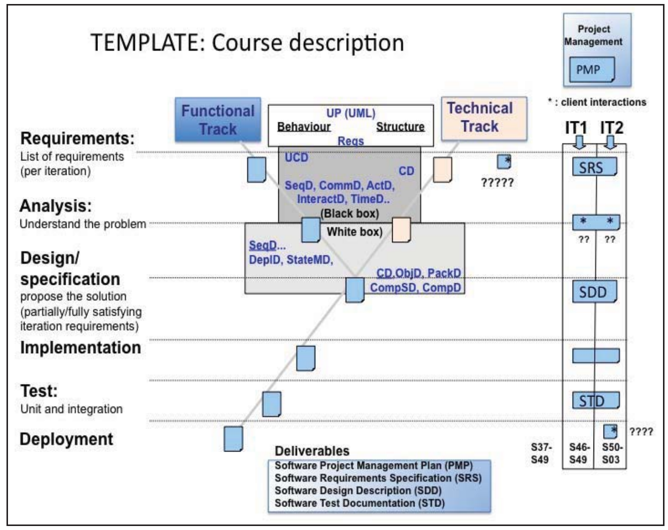

Figure 6. yBPL template for moodle interface

This template is used in order to facilitate the interaction between the various actors of the process. The interface illustrates the "y" software project methodology with the functional and technical tracks including the requirements and analysis phases as well as the merging central track aimed at designing, implementing, testing and deployments phases. For every track and iteration, explicit indications of document deliverables links are included (PMP, SRS, SDD and STD). Likewise, links to the documents produced during the learning process in the form of cookbooks are also included in the interface. This interface is configured during the start up process, and the "Course Objectives" and "Project Proposal" documents are also included. The interface is adapted to the various project and learning process actors in order to facilitate their collaboration during the whole process.

In order to illustrate a real instantiation of the methodology, a concrete study case based on a Software Oriented Architectures (SOA) systems course will be presented. Details of this study case are presented in the Table 1.

Actor	Description
Client	Direction of the DGEI-INSA department
Instructors	4 Software engineering instructors 6 Software oriented architectures instructors 3 English instructors
Students	60 students of the 5th year of IT and Networking engineering
Coordinators	1 instructor and 5 students
Learners (A/P)	5 instructors and 60 students

Table 1. Actors participating in the SOA course

The client proposing the project is represented by the GEI department of the INSA. The project proposed by the client asks for a system able to automate financial accounting activities. In the process a number important of users, interface and data needs to be considered to build the system.

The instructors participating in this course are divided in 3 groups: software engineering, SOA and English instructors. The first group of instructors targets the software engineering process and the second group targets the software technologies to be used to design and develop the software solution. English teachers participate actively in the project, working with the students in the elaboration of the documents in English versions. Moreover, English teachers supervise and guide the students in activities aimed at writing and presenting the various cookbooks developed during the learning activities and related to the project software requirements. The students participating in the project are divided in two categories: IT and Networking engineering students. Students work in groups of 12 students and each group can work in a different sub-system of the global project. The group of coordinators is composed of 1 instructor and 5 students, one student-coordinator for each groupe of 12 students. Finally, the learners groups are composed of all the students and 5 instructors mainly working in the area of software technologies.

The objective and subjective measurement results obtained from the application of the yPBL methodologies have been highly motivating. Indeed, instructors and students consider as very positive the gained experience from working in a real software project. Moreover, instructors remark the high motivation of the students, particularly when they perform learning and teaching activities. Furthermore, even if at the end of the project the full set of clients requirements have not been satisfied, students are able to explain the reasons for this partial result. They claim to have understood that living the process is the best way to know how to do things working and how to avoid in the future making the same mistakes.

Conclusions and Perspectives

This paper has presented an innovating learning methodology, based on the well-known PBL method and inspired and adapted to software engineering unified processes. The yPBL model describing the use cases driving the methodology as well as the various internal activities guiding the process has been presented. This model has specified the relationship between the roles and phases considered in PBL methods and the roles, iterations and phases considered in the Two Tracks Unified Process (2TUP) or "y" methodology. The yPBL methodology has been defined as a process where incremental and iterative phases are performed and specific communication channels are established by the way of standard documents in the framework of a real software project. A case study illustrating how this methodology has been instantiated at the INSA of Toulouse has also been presented. Motivating results have been obtained during the experimental application of the yPBL. At the moment of writing this paper, a new instantiation of the methodology has been started and a more important set of measurements will be performed in order to better analyze and evaluate the benefits offered by yPBL.

Acknowledgment

The yPBL methodology has been successfully designed, implemented and experimented thanks to the valuable and active participation and collaboration of the GEI and CSH departments at the INSA of Toulouse, including direction, administration staffs as well as the teachers and the students participating in this project.

Abstract— **We briefly review fundamental concepts related to systems theory and systems engineering. We also review and structure a list of important properties for an electronic system and paradigms and techniques applicable to analysis and design. Then we present two specific case studies, in which the systems theory approach to electronics engineering teaching and research has been very influential.**

Keywords: ***systems theory; systems engineering; electronics systems engineering; model-based systems engineering; requirements; requirement-driven engineering; validation; verification; systems engineering education; electronics engineering education***

I. INTRODUCTION

Systems theory is an interdisciplinary and holistic approach to the study of complex structures and behaviors [1]. This theory is the main foundation of systems engineering, which on the one hand, is evolving as a specialized professional and academic discipline and, on the other hand, permeates other disciplines as a process and methodology. We present here a perspective of electronics engineering education and research from the systems theory and systems engineering approach.

We can identify two extreme approaches to systems engineering. The top-down approach followed by the professional who acts in the role of a pure systems engineer, without attachment to any specialized branch of engineering or technology; and the bottom-up of the specialist moving to a more general and system-level perspective. Both have advantages and disadvantages. One can argue that pure systems engineering specialization lacks a knowledge of details and of real capabilities of technology and solutions, and that the devil is in the details. The danger of the second is not seeing the forest for the trees. Here we propose a zooming approach to electronics systems engineering, shifting from the micro to the macro view and vice versa, as appropriate, and pointing out relationships, general properties and how they depend on decisions taken at every level. In reality, this process is applied in science when dealing with complex analysis or design issues, such as in medicine, where it is common to combine the microanalysis with the physiological, anatomical and environmental view in studies and diagnoses.

After this introduction we first present a summary of the process typically applied in systems engineering, consisting of iteration between requirement analysis, functional design and synthesis, with verification between steps, iteration, top-down decomposition, and validation of results against the perceived need and objectives.

Then we deal with enumeration and classification of the properties to be taken into account in an electronics system, as a basis for requirement analysis, and the applicable design and verification methods. The identification and structuring of requirements and properties is one of the open problems in systems engineering and, although theory and methodologies have been proposed, it relies mostly on the open-mindedness and creativity of the analyst.

Then we continue with the presentation of two case studies in which the systems perspective has contributed to a differential approach to electronics engineering education and research. We end with conclusions and proposals for future work.

Electronics systems are now prevalent in every field of human activity. They are often complex, with many interfaces and relationships. Failure of one of those systems can result in economic damage and even loss of human life. We think, therefore, that it is relevant to propose an integral and system-level approach to electronics systems engineering. That approach should also be incorporated in research and education, conveying ideas, perspectives and techniques to future professionals.

II. SYSTEMS ENGINEERING

Systems engineering can be considered as a methodology or discipline in itself. Globe-spanning professional organizations such as INCOSE (National Council on Systems Engineering) and the IEEE Systems Council (a council formed by several IEEE societies) are promoting research, practice improvement and education in systems engineering.

A. Systems Engineering process

An objective and differential characteristic of systems engineering is the exploration of alternatives and early adoption of critical design decisions. Several process schemas for systems engineering have been proposed, such as the SIMILAR, by INCOSE [2]

We include here a simplified three-phase process (Fig. 1). This schema has to be run in iterative phases, verifying functionality against requirements, on the one hand, and design against functionality on the other. It is also applied in a hierarchical fashion following a top-down spatial decomposition of requirements, functionality and structure and applying the same cycle to every subsystem, module or component. This process has been assimilated to fractal geometry, with repetition of the process at different scales and not totally deterministic growth [3]. The results of the application are validated against perceived needs and objectives.

The main phases of the process can be summarized as follows:

- Identification, classification and contrast of requirements. A coherent, non-ambiguous and feasible set of requirements must be generated. Requirement definition is always a balance between capabilities and needs. This is a crucial step, as requirements provide the basis for performing all other key development activities such as system and component design, implementation, and testing.
- Functional design and behavior modeling. In this step it is important to think more about abstract functions that the system should perform, than about specific implementations. Functionality should be verified against requirements.
- Structural design, alternative selection, synthesis. Here, components, technologies and architectures are chosen to implement the functionality. The design has to be verified against functionality and behavior.

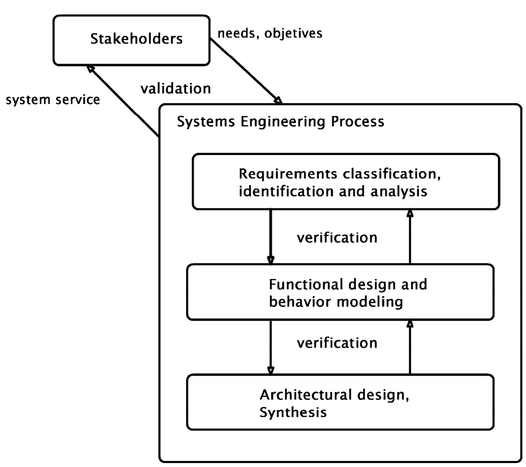

Figure 1. Systems engineering process

Model based systems engineering (MBSE) uses formal methods for modeling and analysis during the requirements, design, analysis and verification phases. A language oriented towards the modeling of complex systems and born as a subset of UML (Unified Modeling Language), with extensions, is SysML [5]. SysML includes diagrams for requirement, structure and behavior modeling, some of them common to UML.

B. Properties and requirements

A "well-formed" requirement is a constraint imposed on a property of the system. In order to establish requirements, it is necessary to first consider all relevant properties of the system. It is usual in electronics engineering to take into account properties close to the technology, such as time and frequency response, maximum ratings, etc. The systems engineering approach implies that more general properties or characteristics should be considered when analyzing requirements. We try to convey a structured list of those we have found important in electronics systems analysis and design:

- Involving system dependability, that is, the confidence that the system will provide the intended service [6]: availability, safety, integrity, maintainability, confidentiality, etc.
- Involving the ease with which the system can be used, reconfigured, tested or debugged: usability, manageability, adaptability, modularity [10][11], composability [7][8], testability, traceability, etc.
- Involving predictability in the execution of the intended functionality: input-output response (value and time), determinism, operating modes, graceful degradation, etc.
- Involving energy, power, and compatibility with the environment: power feeding, power efficiency, power and thermal management, power density, electromagnetic compatibility (EMC), etc.
- Economics: overall life cycle cost, cost of ownership, return on investment (ROI) , etc.
- …

In the design, which can include hardware, software, communications, sensors, actuators, and so on, the application of some paradigms and techniques can be considered, such as:

- Partitioning and distribution of functions, redundancy, replica determinism [9][42], etc.
- Distributed control and management, fault tolerance, real time scheduling, concurrency, etc.
- Computational models, hard-soft decomposition, programming paradigms, etc.
- …

Rigorous specification, verification and validation could demand the application of formal methods, modeling and simulation languages [4], RMA (reliability, maintainability, availability) analysis, etc.

Modeling and simulation is the preferred verification method before physical design. Electronics engineers have traditionally made use of simulation and modeling tools, based on hardware description languages (SPICE, VHDL, VHDL-AMS or Verilog) and even, more recently, hardware-software codesign-oriented languages (such as SystemC). Tools capable of multi-domain continuous, discrete and hybrid system simulation and modeling are very valuable for systems in which electronics is combined with other technologies. Modeling and simulation based on other computation models, such as the discrete event or finite state machines, are also often necessary.

III. Case study I. A Postgraduate course in modelling and control of inverters

Inverters or DC-AC power converters are widely used in uninterrupted power systems [19], renewable energy integration and distributed generation [41]. The expansion of renewable energy in the last few decades has heightened interest in inverter control techniques, both as autonomous generators (in a UPS, for example) and as a feeder connected to the electrical grid (in a PV solar farm, for example)

We try to describe here how the systems approach has influenced our research and teaching in this specific area. More specifically, what the impact has been on a recent proposal for a short postgraduate course in inverter modeling and control. It is not an objective to describe the proposal itself, but only to explain how systems theory, and systems engineering, has influenced its approach and development. Most of the decisions and orientations were adopted as a result of the requirements analysis phase.

Considerations related to high availability, a fundamental requirement for UPS, had an important influence. High availability means that redundancy has to be applied, which drove us to consider aspects related to modular decomposition. In fact, most modern UPS are modular, based on a set of easily replaceable modules working in parallel. A modular architecture brings additional advantages such as flexibility in expansion, adding power as needs evolve.

Paralleling modules implies that they must work in tight synchronization and share load. Parallel inverter control has been and continues to be a subject of constant research [12][13][14][15][16]. We are dealing with this problem as part of a study in the distributed, fault-tolerant, real-time control of modular electronics systems.

The combination of modular power converters can be approached from a more general point of view, with application of bond graph modeling techniques [18] (Fig. 2). This approach emphasizes analogies between different types of power converters, such as an inverter or a controlled motor. It is a typical example of the generalization process applied in systems theory.

When an inverter works as an autonomous generator, the analysis cannot disregard one of the most important requirements: disturbance rejection capability (Fig. 3) , or the ability to maintain wave quality under distorting or varying load. That is, low total harmonic distortion (THD). UPS applicable standards impose limits and establish test procedures [20]. This requirement had a decisive influence in the selection of the modeling and control techniques applied.

We propose a model for a controlled inverter that establishes a clear distinction between modulation and control (Fig. 4). This is a typical decomposition result of the application of a functional analysis phase. Pulse width modulation, or space vector modulation for a three-phase inverter, is studied independently of control [21]. The modulator only affects control through the actuation delay, which it can add to the loop, especially when regular modulation is applied [22].

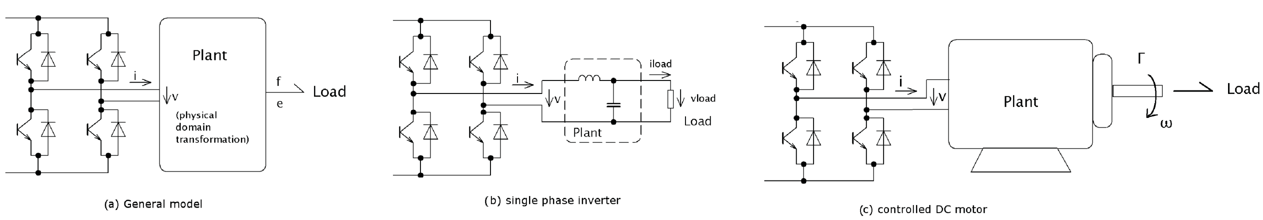

Figure 2. Bond graph models: generic, inverter and controlled motor

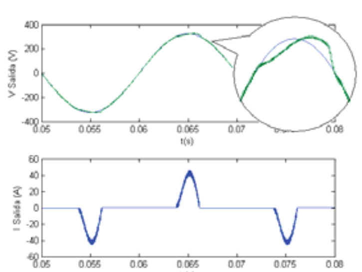

Figure 3. Inverter output under distorting load

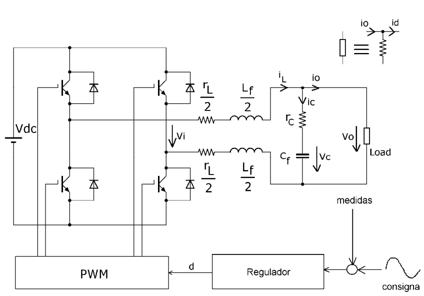

Figure 4. Single phase inverter model

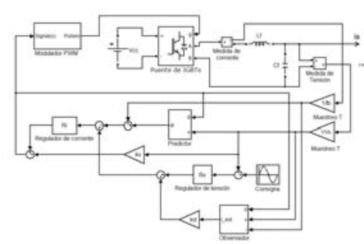

Figure 5. Digital controller model

The control technique applied determines set point following and disturbance rejection capacity, that is, output impedance [23][29]. We propose continuous and discretized state space models of the controlled inverter, which are then used as a basis for controller design [25][26]. Even the design of the controlled plant itself (the LC output filter [24]) is based on control requirements. We signal the importance of current control, in an internal loop, to yield quick dynamics and good disturbance rejection capability.

In a typical application of MBSE concepts, we decide to propose a reference controller, with the best possible performance: of continuous type, based on feed forward of output current, natural modulation etc. Against this reference controller others are contrasted and evaluated, such as digital controllers (Fig. 5) that can be implemented over microcontrollers or digital signal processors [17], and based on predictive current control and output current observer [27][28][29][30][31][32][33][34][35].

As a modeling, simulation and analysis tool we use the Matlab-Simulink suite, R2008b version, applying the Control System and Symbolic Math toolboxes, and the SimPowerSystems Blockset.

An exhaustive analysis of control requirements drove us towards the need of taking into account control related aspects such as reference sine wave generation. Synchronization of this reference with other modules or with the grid should be taken into account, and the applicable techniques studied [36][37]. The load sharing problem, with synchronization and without degradation of availability, motivated the research of classical techniques, such as the droop method, and other possibilities based on communication between modules and replica determinism.

A broad consideration of inverter applications includes the consideration of its integration in different kinds of electrical grids, in grid-feeding, grid-creation or grid-support mode [38][40] (Fig. 6). The modeling, simulation and control techniques are completely different from those applied for the inverter itself. We model the inverter as a voltage or current source and apply time-varying phasor modeling techniques [39].

The "zoom" view previously mentioned is applied in the lectures. The different control time scales, from the internal to that applied in grid integration, are contrasted. In the requirement, functionality and architecture analysis of the internal inverter, characteristics are associated with integration of inverters in modular systems on in electrical grids or microgrids.

IV. CASE STUDY II. TEACHING ELECRONICS IN A SECOND CYCLE CURRICULUM IN INDUSTRIAL ORGANIZATION.

In 2001 J.Q. started teaching Industrial Electronics as a subject in a second cycle curriculum in industrial organization, at the University of the Basque Country (UPV-EHU), Spain. The subject involves 30 lecture hours and an additional 15 laboratory hours. In a trimester, general, analog, digital and power electronics have to be taught to non-specialist graduate students, most of whom have no previous exposure to electronics. The course is geared toward graduate students with a technical engineering degree in chemistry, computer science or mechanics, for example. The most important concern was having a syllabus that was too scattered and blurred, difficult to understand and assimilate, in the short period allocated to the subject.

The syllabus was gradually refined over each of the several courses taught, and is now divided as follows:

- Introduction to industrial electronics: review of electrical circuits, basics of semiconductors, P-N junction, devices (BJT, MOSFET, Thyristor, IGBT). The different physical scales and ranges of application are reviewed, form micro-integration to power discrete devices (6 h. approx.).
- Analog electronics. A general and abstract approach is used to review the most relevant properties, characteristics and requirements: gain, feedback, linearity, frequency response, differential amplification and common mode rejection. At a more concrete level the operational amplifier and the most basic circuits are presented (4 h. approx.).
- Digital electronics. We review the basics of digital electronics, and then schematize combinational and sequential digital systems, paying special attention to fundamentals and examples of specific circuits. The objective is to give the students the foundation to understand the basics of microprocessors. Then we use a simple microcontroller model to convey the principles of programmable digital systems, including input-output and digital to analog and analog to digital conversion (8 h).
- Power electronics. A generic and abstract model of a power converter, including control, is presented. Specific models, such as diode rectifiers, thyristor controlled rectifiers, and switching DC-DC and DC-AC converters are briefly studied. We note differences and analogies in control and highlight basic concepts such as static and dynamic losses, efficiency etc. (8 h).

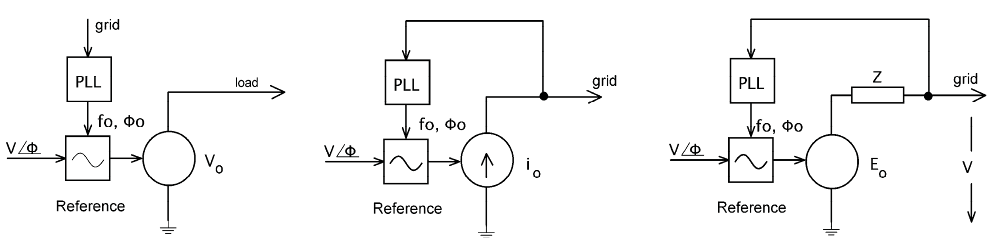

Figure 6. Grid forming, grid feeding and grid supporting inverters

Laboratory classes are partly devoted to practice with circuits and instrumentation, and partly to exercises and discussions. At the end of the trimester we study a relevant integral example. The few students with a previous background in electronics collaborate in the proposal and development of the example. The "zoom" technique is applied here to review characteristics, and the basics of the systems engineering approach are used to study requirements and associated functionality. Some examples of systems: a PV solar farm, a multiple lift system for an intelligent building, automotive electronics etc. (4 h)

We constantly strive to keep the system view in mind, using analogies to medicine and the human body: cells and tissues for devices, senses for analog electronics, the brain and nervous system for digital electronics and the locomotor system for power electronics. And we prioritize the requirement and functional analysis over implementation, although implementation limitations are taken into account to illustrate the need for a feasible requirement proposal for the systems.

Grading is fundamentally based on a final exam, based on questions and very short exercises. The overall experience has been very positive; more than 300 students have attended the course since 2001 with high average results and positive feedback in student opinion polls.

V. CONCLUSIONS AND FUTURE WORK

Modern electronics engineering has to deal with complex and critical projects and ample diversity of techniques and technologies [42]. Complex requirements have to be met, time to market reduced, and it is necessary to deal with limited budgets and design to cost constraints. Electronic systems must often be assembled from COTS (Commercial Off The Shelf) electronic subsystems and components, which may be manufactured half way around the world, and for which the most important task is to prescribe and verify characteristics against requirements. The systemic approach is a powerful tool to tackle with these demanding challenges. We think it should be included in academic curricula and applied in research and education.

Future research will focus on analyzing the possibility of using Case Study I as the basis for developing an educational example of MBSE, with application of the SysML language and perhaps other modelling tools, following a detailed systems engineering process.

Case study II can be the basis for the proposal to include a systems engineering subject in curricula [43]. INCOSE maintains a directory of systems engineering academic programs[44]. There are no Spanish programs included in the directory as of the writing of this paper.

ACKNOWLEDGMENT

J. Q. has maintained fruitful and interesting discussions in systems engineering related forums and wished to thank all of the professionals involved in those discussions.

Abstract— **Today's society is undergoing constant changes and this is reflected in the way the working world is structured. There is an increasing need of qualified professionals having to face changes and prove effective competencies dealing with the Information and Communication Technologies (ICTs).**
In this sense, the 21st Century university should offer students the suitable learning tools to become successful professionals. With this goal in mind the Tunning Project aims at implementing active methodologies by enhancing content learning and competencies acquisition.
In this paper, we include a comparative study of the efficiency of new learning methodologies across subjects, degrees and academic cycles and focus on the role of the ICTs in the learning process. Our objective is to assess the suitability of these new methodologies for technical subjects. Finally, we present a survey on professors' willingness to implement active methodologies.

Keywords-New learning methodologies implementation, continuous evaluation, students' satisfaction, competences and quality.

I. INTRODUCTION

Nowadays changes in society are being reflected in the working world. Likewise, the education area should be undergoing such dynamic pattern. Our globalized world demands really high qualified professionals able to face challenges and, at the same time, master key competencies and prove efficient skills in ICTs [1,2]. As a matter of fact, our 21 st Century University should train students to become autonomous learners and citizens able to cope with a constant changing working world.

Among other challenges, university students have to deal with a huge amount of knowledge just generated in the last few years [3], in this sense, their training should aim at enhancing self-learning ("learning to learn") besides from acquiring core contents, which will eventually become obsolete [4].

Therefore, universities should change their focus onto a more competencies-based view providing, then, future professionals with abilities [5, 6, 7] and habits that allow them to keep on learning throughout their professional careers. Definitely, ICTs can help achieving this lifelong learning goal as many recent studies have shown, among others, [1,2], within the Engineering field.

On the other hand, self-learning [4] is one of the most valued skills to succeed professionally.

In order to reach such an autonomous learning and master specific and inter disciplinary competencies (following the Tunning Project [8]) it is necessary to implement active methodologies in the subjects as through these new tools both professors and students can work on the subjects contents and competencies simultaneously. Not to mention, the key role ICTs play in this recent learning process model.

In this sense, the Polytechnic European University of Madrid and the Polytechnic University of Catalonia (EISEIAT) among others, are changing the scope of several University studies, such as Environmental Sciences or Telecom and Industrial Engineering to suit the European Higher Education Area (EHEA). As to the curricula, we have to mention that the learning is always student-oriented and based on the competencies this profile of students should have after graduating. With this goal in mind, we have incorporated new teaching methodologies and the use of ICTs in our classrooms and labs. Precisely, some of the methodologies used are related to the Cooperative Learning (CL) [9, 10, 11, 12] and Problem/Project Based Learning (PBL) [13, 14, 15, 16, 17, 18, 19]. These two methodological approaches to both teaching and learning allow students to become responsible for their own learning, decision making and knowledge developing starting from their professors' guidance, activities planning and new learning scenarios.

So as to apply such methodologies a professor must reflect on the specific learning objectives and the selection or design of problems and/or activities by firstly identify the learning needs of these students in particular. Besides, this professor should be aware of all the subjects taught in the same degree and, therefore, coordinate with the other professors involved. [20]. We would like to emphasize that during the whole process professors should design a follow-up plan of their students' work and, at the same time, an individual and team assessment. [17, 18].

The work presented in this paper is, therefore, a comparative study of the efficiency of active learning (AL) methodologies implementation in a wide range of subjects from different degrees and cycles at University. Not to mention, in this article we also focus on the use of the ICTs as a key tool in the learning process.

With this study, we aim at assessing and validating these new methodologies and tools in terms of suitability for technical subjects with such varied contents as the ones chosen for this research. Among others, we selected subjects from Environmental Sciences, Telecom and Industrial Engineering from the European University of Madrid (UEM) and the Polytechnic University of Catalonia (UPC). Besides, we have also focused on the possible differences in efficiency of those methodologies depending on the university cycle the particular subjects belong to. [1, 6, 7, 14].

Finally, we include a preliminary study on professors' knowledge on new methodologies and an example of AL methodologies implementation in a university subject with a small group of students from the UPC.

II. OBJECTIVES

Being aware of the multiple variables to account for in these typology of studies, we will precise the ones taken into account at each stage. In the first part of this paper we will describe our experimentation at the Superior Technical School (ESP) of the UEM.

First, we will assess the implementation of an AL methodology (Cooperative Learning and/or Problem/Project Based Learning) in three subjects of the first academic year in the Environmental Sciences, Telecom and Industrial Engineering degrees. Secondly, we will focus on the differences in acceptance of these methodologies across cycles and degrees within the same Technical School.

Aiming at the assessment of these new methodologies in terms of contributing to the learning quality and, more precisely, in the preliminary experimentation carried out in the selected subjects and cycles we have carefully taken into account the following points:

1. The evolution of the marks obtained by students: by comparing the percentage of grades resulting from the AL methodology implementation in the subject with the results from previous academic years when a more traditional learning approach was taken. In addition, the comparison of students' results between subjects where active learning techniques are applied and those where not both across degrees and cycles. We should emphasize here that only the subjects taught by the same professor during different academic years and using varied methodologies have been considered.

2. The results obtained from the student's satisfaction surveys dealing with the implemented methodology and the assessment of the competencies enhancement.

3. The results from the student's questionnaires on their satisfaction with the teaching staff.

Moreover, throughout the different sections of this paper we will comment on several studies carried out by other universities and whose results are very similar to ours, therefore, validating our work on the implementation of new learning methodologies in the hard sciences [6, 7, 14, 21].

Finally, we will include some professors' assessment on knowledge development and their application views on new methodologies of teaching and/or learning as well as a detailed description of the activities used during the implementation of such tools in our study.

III. DESCRIPTION OF THE ACTIVITIES USED

So as to design a wide range of activities to apply in each and every one of the subjects in this study we developed a common grid [22]. In it we have included examples of the key points to be considered when designing CL or PBL activities. In [22, 9, 16, 17, 18], a careful description of some of the activities carried out in the different subjects (scope of this study) is provided as well as other activities applied in similar studies taking place in other universities. Each activity aims at enhancing a particular competence, as it would be the case of team work (typically used in CL or PBL), oral communication or planning

Some of the activities that we can find in the above mentioned articles are the following:

1.- Project management and planning learning. A team work of maximum 10 students guided by a professor [20]. MS Project is used in here as a tool to plan and follow-up a project. Moreover, the professor will be handed in a weekly progress report on the specific project. Possible modifications from the original plan will be discussed and analyzed. On the other hand, the final project will be presented in video format (which should last no more than 10 minutes) and will be posted in Youtube (http://www.youtube.com/watch?v=NuIM_Ne5pvM) [23].

In addition, students will have to hand in written reports both from the initial project and the final one. These written exercises together with the video will be peer-assessed and defended in front of a jury formed by 3 professors from the Projects Department.

2.- Activity in English

2.1.- This 2h activity consists in explaining how to plan and conduct an oral presentation in English (theory) and practicing it later on. The professor spends between 30 minutes to an hour explaining how to present orally in this foreign language: organization of contents, use of sequencers and discourse markers, description of figures in pie charts, bar graphs, etc.) Not to mention, students are given all the vocabulary required to perform their presentation in English and, moreover, they also work on a divulging research paper from their studies specialization. After, students prepare their own presentation on the article during 30 minutes in the computer lab. Finally, their presentation is assessed by both their classmates and the two professors involved in the acti vity (an English teache r and a professor from their specialty).

2.2.-Development of Portfolios or Wikis in English from one to a group of subjects [24,25].

3.- Creating Jigsaws and/ or crosswords using the specific vocabulary used in each particular subject and online questionnaires (Using Moodle for example). They could be learning exercises or follow -up activities before an exam to revise core content. These and other activities carried out in our study can benefit from the use of a platform where students can participate in a discussion forum and/or an exchange materials and store different contents. In the UPC we mainly used the Basic Support for Collaborative Work BSCW [2, 17,18] from the Engineering projects Department server.

IV. RESULTS

A. *Comparing percentage marks of first year subjects.*

In this initial part of the study we compared three subjects of the first academic year in the three different degrees.

Therefore, in this section we present the percentage of marks obtained in the three subjects when AL methodologies were introduced and compare the results with the marks from previous academic years when such methodologies had not been implemented in the classroom. As we have mentioned before, we only considered those subjects taught by the same professor in different academ ic years and using different teaching/learning methodologies.

In Table 1 it is shown the percentage of marks obtained by students from academic years 2004 /2005 and 2005/2006, in which CL activities were introduced in a subject from the Environmental Sciences degree and comparing such percentages with the ones resulting from previous academic years when a more traditional methodology (based on the lecturing method) was used.

TABLE I. PERCENTAGE OF THE MARKS OBTAINED IN THE SUBJECT THROUGHOUT SEVERAL ACADEMIC YEARS.

n=nº students	Percentage of marks according to the total number of students (%)				
	AB	F	P	VG	EX
A. Year 01/02 (n=45)	4	40	41	13	2
A. Year 02/03 (n=29)	3	37	40	13	7
A. Year 03/04 (n=17)	19	33	33	15	0
A. Year 04/05 (n=16)	31	30	19	13	7
A. Year 05/06 (n=20)	10	21	25	23	21

This traditional methodology was based on professors' lectures and was complemented with practical exercises to reinforce the contents given in class. In those academic years the percentage of passing marks were of 56%, 60%, 48% respectively and it is during the academic year 2004/2005 when CL methodology is firstly introduced in this subject and activities are designed to cover approximately 30% of its syllabus. To this respect, we can observe that the total percentage of passing marks is 39%, which compared to the results from previous academic years is a considerable drop. We could explain this figure by taking into account that there seems to be an increase in Non Presented students AB (31%) as the percentage of passing marks compared to the total number of presented students is 67%. (From now on we will use the following abbreviations: AB as "Absent ", F as "Fail", P for "Pass", VG "Very good" and EX for "Excellent").

On the other hand, during the academic year 05/06 the amount of l ectures is reduced to 20 % of the syllabus and the rest of the core contents are worked through CL activities. We can see that this year the p ercentage of students increases significantly (69%) and the number of a bsenteeism is reduced when comparing with the percentages of the two previous academic years. At the same time, there also exists a significant increase in the percentage of VG and EX making the same comparison. Therefore, we could say that the more implementation there is of AL methodologies, the more familiar students become with them and this fact could explain the better results they obtain in academic years 04/05.

1) A. Comments:

The several changes made throughout the two academic years when AL methodologies were implemented together with the increasing experience of the professors involved in such challenge could imply that students may improve their results when most of the s yllabus is taught through an AL approach. We could also relate this success to the increasing number of subjects including AL methodologies during the second academic year within the Institution and, hence, to the greater familiarity of students with these new teaching and learning tools.

As a matter of facts students need to know about each institution's culture towards the use of new methodologies in the learning process. As we can see in the available literature on this topic such requirement also appear s in other pilot studies, as in [9][12][13][17] , which are examples mainly taking place at university level.

Another aspect to highlight from the results obtained in our study is the increase of VG and EX marks if compared with students' grades from prev ious academic years. It seems, then, that these active methodologies enhance and guarantee a greater learning of the students who join and involve themselves in the dynamics of the subject. Moreover, this sample of students (n) find AL activities more motivating than the traditional ones and this fact, in return, is reflected in their academic results. [17].

1st year subject in Telecom Engineering, specific branch of Sound and Vision. This is a practical subject which underwent the European Credit Transfer System (ECTS) adaptation during the academic year 05/06, which decreased the number of lecturing sessions to 20% and organized the rest of the tuition using CL activities.

According to our results it seems that the introduction of this methodology increases the percentage of AB and F students if compared to an academic year where traditional methodology was in use (15%). At first, we could think that some students may be reluctant to get involved into such new methodological approaches and so drop out the courses. However, as previously seen in the Environmental Sciences subject, results show an obvious increase in the total number of students obtaining the highest marks possible (VG and EX) in the academic year 2005/06 moving from 42% to 63%.

In previous studies [22], it has been shown that the implementation of these methodologies in practical subjects' results in raising the number of VG and EX but, at the same time, the amount of AB and F, therefore validating the results obtained in the present study.

At this point, we should reflect and consider the existence of other possible factors which could affect students' behavior. This would be the case of the degree of maturity of each individual, the familiarity of the student with AL approaches in other subjects or contrary to it, the lack of knowledge and/or practice of such learning tools or the low interest of students in them.

In the 1st year subject of the Industrial Engineering degree during the academic year 05/06 the number of tuition using the lecturing method is reduced to 40% and the remaining 60% is carried out by developing CL activities. And again, our results clearly repeat the trend identified in the preceding sections.

This fact shows that although some students do not get involved when using this active methodology, the ones who do increase their interest and motivation toward the subject in particular and they finally learn more and obtain higher marks.

B. Survey results on the satisfaction of students towards the implemented methodology.

The assessment on the introduction of the methodology has been carried out taking into account the students' view, obtained by filling an anonymous questionnaire on their satisfaction with the CL methodology at the end of the course. A complete sample of the survey is included in the following paper [22].

In this study, we have calculated the percentage of students who "agree" or "very much agree" with each question in the survey. A unique percentage is shown when no significant differences are found between the three subjects studied, in which case the percentage equals the total sample analysed.

One of the most relevant points is the section which deals with questions related to the learning process. In this part we can point out the following results:

91% of the students claim that they have learnt and understood the contents of the course.

63% of the Telecom and Industrial Engineering students think that the introduction of this new methodology has increased their interest in the subject while only 30% of the Environmental Sciences students agree with the methodology used.

As to competencies enhancement, 48% of the students agree with the claim that these activities have improved their oral skills and 40% consider them a key factor in the development of their written abilities. However, it is significant that although all the activities had been designed and planned to reinforce both competencies more than 50% of the students disagree. These results could be argued if we consider that a semester is insufficient time for students to perceive any progress in the development of their oral and written skills and, hence, they should keep working on such competencies in the following academic years.

70% of the students claim that this methodology helps developing their capacity to synthesize and understand information which, in fact, is one of the main targeted competencies in the EHEA.

85% of the Telecom and Industrial Engineering students think that this AL methodology has enhanced both team work and debate of information, as it is also observed in a similar study in this field [15].

In addition, 68% of the students in the sample consider this methodology as a key factor in increasing their ability in planning and time management. In fact, the activities were designed taking into account that such competencies are crucial for first year students and, therefore, should be emphasized and our results show that the implementation of AL methodologies in the hard sciences succeeded in this sense.

The following matter to be tackled was planning, and in here we would like to point out that 75% of the students in our survey found that their professor's objectives totally coincided with what was taught in the classroom.

However, we could observe varied opinions when students from different academic backgrounds assessed the preparation of the materials delivered by the professor in each subject. (See Telecom and Industrial Engineering 74% and Environmental Sciences 57% respectively).

Another relevant piece of information is drawn by the figures we obtained concerning team work sessions as 100% of Telecom Engineering students, 78% of Industrial Engineering and 43% of Environmental Sciences claim that those sessions were very useful and well-organized.

Besides from the data collected in the students' questionnaires, most of them think that the activities designed targeting AL methodologies implementation meant a greater workload and a consequent lack of time to carry them out. Thereby, professors should think about restructuring activities timing for the following academic years.

In the case of the subject taught in the Environmental Sciences degree, the professor has been incorporating this type of methodology steadily and confirms that teachers need a learning period to design the activities carefully and implement them properly in the class. This opinion is common to all the authors who consider that these kind of methodologies should be implemented in the subjects gradually with an improving period for the activities chosen of approximately 3 academic years [12, 26,27].

As to the results concerning assessment, 65% of the students in the 3 different degrees claim that team work evaluation has been fair and has helped improving the learning process throughout the whole year.

C. *Students' performance according to degree and cycle*

Once the study presented here was finished and we had carefully considered its results, another question came into our minds: whether these AL methodologies were equally considered across the different academic cycle or significant differences would appear. Through such results we would be able to verify and, after, validate behavior patterns within the same degree and also check for any repetition pattern occurring in each degree or cycle.

With this goal in mind we selected subjects from the first and second cycles in several degrees. The resulting figures were compared to subjects (within the same cycle) which did not incorporate any AL methodology in the classroom.

After introducing these new methodologies in the degree of Environmental Sciences we could observe a significant decrease of P (28 %) corroborating, then, the results initially obtained when only considering first year subjects and finding exactly the same patterns in the degree.

On the other hand, in the first cycle of the Telecom Engineering degree there seems to be a clear increase in the percentage of passing marks (P) when using AL methodologies. At this point, we would like to emphasize that the higher number of students' marks belong to the categories of (P) and (VG) and there is a decrease of students obtaining (F).

Finally, in Industrial Engineering first cycle we have also detected an increase in the percentages of (P) and (VG) with the implementation of such methodologies but the improvement in student's marks is even greater during the second cycle.

Hence, we could conclude that in Telecom and Industrial Engineering the introduction of LA methodologies generally improves the performance of students in the two different cycles.

D. *Professors' Global Evaluation*

So as to know the degree of influence of the introduction of AL methodologies in students' assessment of their professors' performance, we have analysed the results of university questionnaires on students' satisfaction taking into account and, thus, comparing the subjects following a Cooperative Learning (CL) approach and the ones with a more traditional learning approach in those surveys where students showed a lesser agreement with CL, that is to say, Environmental Sciences and Industrial Engineering.

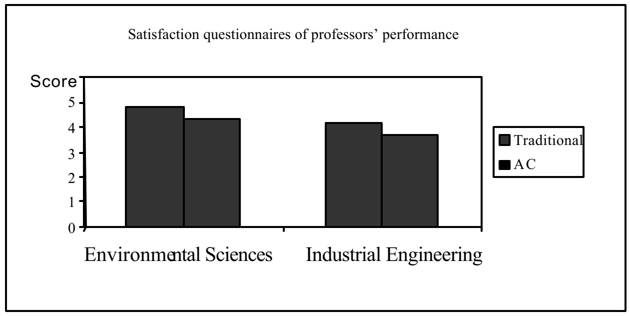

Figure 1. Student's results on satisfaction questionnaires of professors' performance.

According to the results shown in Figure 1 there are no significant differences in the global assessment given to professors regardless of the learning methodology used and the satisfaction of the students with it.

Focusing on each degree analysed, we could see that there is a slight change in Telecom Engineering results and there is a significant increase in the case of Industrial Engineering.

Among the several experiences carried out in the Polytechnic University of Catalonia (UPC), it is precisely in the Technical School of Castelldefels where a pilot plan for new learning methodologies in the classroom was implemented and where, in addition, specialized professors provided staff from the same university or others in Spain with the suitable teachers' training (later on). [28].

We could say that there is a set of key factors that could improve professor's assessment by students, among others, student's familiarity with the new methodologies used in the classroom and the proficiency and skill of professors in their application.

So as to assess the latter factor (professors self-assurance) a set of questions was developed after a School's Symposium in the EPSEVG Centre (UPC) [29][30]. Our aim was to find out which methodologies were familiar to the professors attending the event and which ones were applied or were to be implemented soon. Not to mention, grading their precise level of self-confidence during the process.

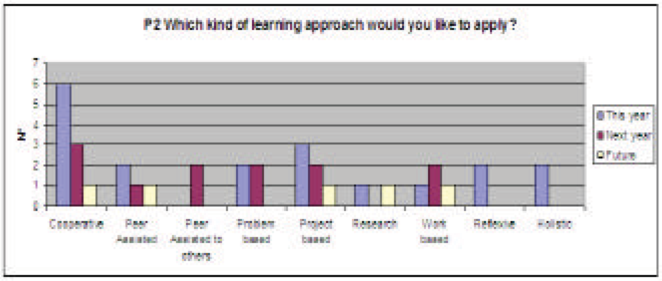

Figure 2. Professors' answers on their knowledge of methodologies, their application and future plans of implementation.

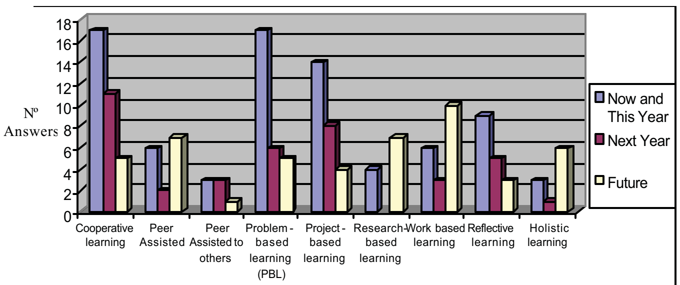

Figure 3. Professors' answers on their knowledge of methodologies, their application and future plans of implementation.

In 2008, we passed again the same test to several teachers from different Engineering Schools in Spain and France. Figures 2 and 3 show that the CL method was the most used during recent academic years but in Figure 3 we can see that two new methods have been used in the same proportion as CL: Problem Based learning and Project Based learning (this fact was shown by other studies). Moreover, we can also observe that some professors plan to use the Work Based Learning (WBL) methodology in the near future. In conclusion, our study can confirm that university teachers use new learning methods increasingly in order to be totally integrated in the EHEA in 2010.

V. CONCLUSION

The results presented in this paper show that the implementation of CL and PBL methodologies in first year subjects of three hard sciences degrees is positive. In addition, when comparing our results with the ones obtained by GREIDI (GRupo de Estudio en Innovación Docente en Ingeniería Universidad de Valladolid) group in academic years 2005 -2006 [2], we can see that the trends totally coincide, hence, validating our findings. In this sense, university students learn core concepts from each subject as well as enhance their oral skills, teamwork ability, planning competence and even leadership. Not to mention, their capacity of synthesizing and understanding the information given in each activity (especially designed by the professor for each subject in particular). We could say that all these elements will contribute to make students ready for the following subjects in their curriculum and to develop the competencies required in their professional career. [31, 2].

On the other hand, ICTs play a key role in the "newly" designed activities and constitute a solid platform or support for the subject's planning, material sharing and management by both students and professors. Therefore, our first conclusion would suggest that CL and PBL implementation is positive and suitable for the different technical subjects selected in this study, regardless of their contents.

Furthermore, this work shows that students are required a greater effort when using these AL methodologies but the more involved in them, the better results students obtain.

In the latter study concerning the comparison of results in terms of acceptance of AL methodologies implementation in different cycles and degrees, we can generally confirm students' higher performance but, at the same time, possibly because of their lack of awareness of their expected higher degree of involvement in such type of methodologies, there may exist some confusion among students and, hence, the is no acceptance patterns when considering academic cycles. Finally, we have observed professors greater self-assurance and experience in new methodologies implementation, which will, in turn, help students acquire more knowledge, training and confidence in its application in the classroom.

Attracting, Retaining, and Preparing *a* Diverse Academic Engineering Workforce:

The AGEP Model for Success

Jane Jacobi Clemson University South East Alliance for Graduate Education and the Professoriate Clemson, South Carolina
jacobij@clemson.edu

Abstract— The National Science Foundation (NSF) has recognized that the Nation's need for a technical workforce is in conflict with the changing demographics facing the nation. Our nation is rapidly becoming more diverse due to growth in groups that have traditionally been underrepresented in technical fields. Nowhere is this underrepresentation more evident than in academia. It was determined that one potential way to attract more underrepresented students to pursue engineering careers was to increase the diversity of the engineering faculty, proving powerful role models to potential technical students. Therefore, over 10 years ago, NSF began a program that sought to

diversify the Nation's faculty in engineering, science and mathematics fields, called the Alliances for Graduate Education and the Professoriate (AGEP). The AGEP Program is now a national network of multi-institution alliances. Nationally, the AGEP program has recorded significant gains in doctoral degrees awarded to underrepresented minorities in engineering. The Southeast Alliance for Graduate Education and the Professoriate (SEAGEP) Program includes the University of Florida, Clemson University, and the University of South Carolina. SEAGEP is the top producer of Hispanic PhDs in the country and is third in the production of African American PhDs in engineering. Best practices in recruiting, retention, and preparation for the professoriate are detailed.

Keywords̃ retention, professional development, engineering faculty, diversity

I. Introduction The United States is facing changing demographics that have potentially important implications for engineering education in the future. Today, the U.S. workforce includes 20.8% African Americans and Hispanics, according to W. Lance Haworth of the NSF Office of Integrative Activities [1]. Projections are that these two groups will grow to comprise 29.8% of the total workforce of 2020 [2]. Additionally, it is estimated that by 2050, a full

50% of the U.S. college-age population will be from underrepresented minority groups [2].

However, despite the increase in the workforce pool, these groups have not traditionally pursued engineering and science academic careers. In 2003, less than 17% of those earning science, technology, engineering and mathematics doctoral degrees planned to pursue an academic career [3]. Underrepresented minorities accounted for only 7.9% of all science and engineering doctorate-held academic positions in universities and four-year colleges in 2003 [3].

As Figure 1 shows, the number of underrepresented minorities receiving doctoral degrees in science and engineering has risen in the period from 1990 to 2006, but remains low, at only 10% of all doctoral degrees awarded in science and engineering to U.S. citizens [4].

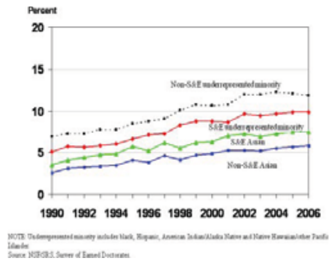

Fig. 1. Minority share of science and engineering and non-science and engineering doctoral degrees to U.S. citizens: 1990–2006.

Figure 2 illustrates the dramatic disparity between employment of majority and underrepresented minority faculty [4].

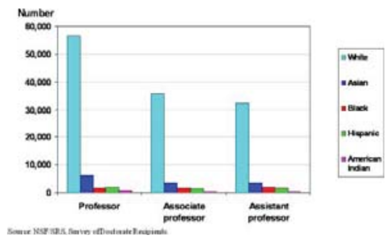

Fig. 2. U.S. citizen science and engineering doctorate faculty employed in universities and four-year colleges, by race/ethnicity and rank: 2006.

If no changes are made in science and engineering education that result in more representation from these groups, predictions are that the disparity will widen [5].

To address this issue, the National Science Foundation established a program in 1998 designed to diversify the student population pursuing doctoral degrees in science, engineering and mathematics. The Alliances for Graduate Education and the Professoriate (AGEP) program was designed to increase the number of domestic students receiving doctoral degrees in science, engineering and mathematics with special emphasis on those population groups underrepresented in these fields to prepare them for careers as faculty and research professionals.

The goals of all AGEPs include developing infrastructure that substantially changes the graduate school experience for underrepresented minority students and catalyzing institutional change. One of the major obstacles faced by underrepresented minorities that must be addressed if an institution wants to attract and retain a diverse student population is the lack of culturally appropriate student support systems. AGEP institutions address this obstacle directly. This national network of programs now includes 21 alliances that represent over 80 institutions [6].

NSF collaborates with the American Association for the Advancement of Science (AAAS) to evaluate the effectiveness of the AGEP program. A recent AAAS report provided an analysis of doctoral degree recipients from participating AGEP universities and revealed that in the first ten years of the program, the annual number of doctoral degrees awarded to underrepresented minorities in science and technical fields increased by 33.9%. The natural sciences and engineering fields reported an increase of 50%. In 2005-2006, the AGEP alliances produced 56% of all science, technology, engineering and mathematics doctoral degrees awarded to underrepresented minorities in the United States [5].

The University of Florida was awarded an AGEP in 1998, and five years later the project grew to include Clemson University and the University of South Carolina in the South East AGEP (SEAGEP). This group has implemented a variety of measures to develop a robust recruiting, retention and doctoral degree completion program impacting graduate programs in science, technology, engineering and mathematics. Additionally, professional preparation for academic careers is part of the program. The University of Florida has developed a mature program and is now the fourth-highest producer of Hispanic PhD graduates in engineering and the third highest producer of African American PhD graduates in engineering [7]. Both Clemson University and the University of South Carolina have been working to implement a similar infrastructure to enhance the diversity of their graduate programs in science, technology, engineering, and mathematics. The key elements in the SEAGEP program are described below.

II. Key Elements

The most essential component of a diversity program is support from top university administrators. Diversity at all levels should be a visible part of an institution's mission. However, beyond mere recognition of the need for inclusivity in institutional mission statements, some type of accountability structure should be in place. For example, at one of the SEAGEP institutions, the Graduate Dean has implemented a policy whereby graduate program reviews will include a diversity dimension; i.e., a department's record of awarding degrees to underrepresented minority students will, in part, determine allocation of resources from the Graduate School.

At Clemson University, oversight of the diversity mission of an institution rests with a Chief Diversity Officer. The Chief Diversity Officer reports directly to the President and provides leadership in implementing Clemson University's first Diversity Plan. The Chief Diversity Officer leads all efforts designed to foster a learning and workplace environment that is welcoming and supportive for all students, faculty, and staff. The Chief Diversity Officer supports existing diversity activities and develops and implements new initiatives and programs to provide focus and accountability for equity and inclusion across the university. Among the tasks of the Chief Diversity Officer is sponsoring of the annual National Conference on Best Practices in Black Student Achievement at Clemson University. Each year administrators, staff, and faculty who help universities recruit, retain and graduate African-American students at academic institutions across the country attend this conference, which provides a venue for dissemination of SEAGEP best practices.

At the University of Florida, Dr. Bernard Machen established the President’s Council on Diversity, which has been charged with the mission of gathering and analyzing diversity data at the college and departmental levels. The Council on Diversity has been formed to further the University’s commitment to equal opportunity. The President’s Council on Diversity is also charged with identifying ways to increase the diversity of the faculty, staff and students. The council is currently working to review the practices of each college and department within the University of Florida to determine whether improvements could be made to increase student, staff, and/or faculty diversity and to propose policies that serve to increase/retain underrepresented minority students, staff, and/or faculty.

The University of South Carolina has instituted a new set of Family Friendly policies, which is an initiative of the Office of the Provost. All science and engineering units have been encouraged to increase the number of female and underrepresented minority faculty. The new Assistant Dean for Women and Minorities in the University of South Carolina College of Engineering and Computing is tasked with assisting departments with identifying and recruiting underrepresented minority faculty.

The second component of a successful diversity program is comprehensive data collection capability. Defining an institution’s historical baseline as well as tracking current students requires a robust dataset that is not necessarily collected systematically by departments and graduate schools or readily obtainable from offices of institutional research.

AGEP institutions collect and report the following numbers annually: applications, admissions, new enrollees, total enrollees, admit to candidacy, and degrees awarded. These are disaggregated by field (engineering, chemistry, physics, mathematics, computer science, biological and agricultural, earth, atmospheric, and ocean science), race, ethnicity, and gender for a total picture of the graduate student population.

Pre-AGEP, this annual institutional snapshot was not collected at the University of Florida, Clemson University, or the University of South Carolina. The data not only can be used to identify trends, but also may indicate fields that are performing below national standards. Furthermore, the data may also indicate where interventions are needed. For example, if the data show that numbers of applications and admissions are increasing, but that this increase is not reflected by numbers of new enrollees, it would be appropriate to identify ways to increase the yield of admitted students.

Additionally, these data can serve whatever accountability systems are put in place, because they reveal departments that are performing below institutional standards. The data are shared with Deans to allow them to monitor their programs. This data collection and analysis effort also provides critical information for PIs seeking funding for diversity-related proposals.

Third, a highly visible office on campus should be established that includes space for students to meet. This legitimizes the program on campus and provides a physical presence that demonstrates the instruction’s commitment to students’ success. It also supports regularly scheduled professional development seminars and other student activities. A program budget to support program activities is critical. This should include funds to maintain the office as well as providing funds to support student travel and other student activities.

A Program Director who reports to upper administration is the final infrastructure requirement. This person has significant student advising responsibilities in addition to project management duties.

II. Program Activities: Recruiting

Recruiting for diversity is a critical first step, but one not always conducted or understood at the graduate student level. Unlike centralized undergraduate admission, graduate admission is a decentralized, often faculty-driven activity. At large institutions, some faculty do not actively recruit, but rely on students who contact them or who are already admitted into the department. These methods tend to exclude those outside of traditional engineering groups.

An active diversity recruiting program is needed, but to be successful it must be based on personal connections with those institutions and programs that support underrepresented minority undergraduates in the science, technology, engineering and mathematics disciplines. Including current underrepresented minority graduate students as recruiters is a powerful tool. SEAGEP has established a recruiting network that includes the National Science Foundation keystone program for underrepresented minorities, the Louis B. Stokes Alliances for Minority Participation in Science, Technology, Engineering, and Mathematics (AMP). SEAGEP participates in recruiting events at both the Florida-Georgia and South Carolina AMP programs, as well as at the University of the Virgin Islands.

In addition, a unique recruiting tool has been the establishment of a dual-degree program in engineering between the University of the Virgin Islands, the University of Florida, and soon the two South Carolina institutions. These programs allow the students from the University of the Virgin Islands to obtain an engineering degree that would otherwise not be available to them on their home campuses.

A major component of preparing undergraduate students for graduate school is undergraduate research. SEAGEP institutions therefore have supported a variety of undergraduate research efforts. These include academic year research at a student's home institution as well as summer residential research experiences. These experiences provide undergraduates with laboratory skills and graduate student mentors to increase their awareness of the graduate school experience. In addition, SEAGEP has sponsored several international undergraduate research experiences in Finland and Costa Rica.

III. Retention

Too often, it is assumed that once underrepresented minority students have been accepted, the process of diversifying the student population is over. Without a strong retention program, however, many of these recruits will be lost before they earn the doctoral degree. This component requires both human and financial resources. Underrepresented minority students often face unique challenges in science, technology, engineering and mathematics fields, including isolation and lack of awareness of the doctoral degree process, which require mentoring by program administrators. Having support outside of the department can be instrumental to a student's success. In addition, many of these students face greater financial obstacles than do majority students, and consequently seek outside employment that detracts from their academic responsibilities.

It proved critical to the retention of a significant number of SEAGEP students to provide short-term stopgap funding to bridge other funding opportunities. These retention awards were a key factor in maintaining an overall retention rate of over 80% to the Ph.D, a rate significantly better than the retention rate for non-SEAGEP students.

IV. Professional Development

In order to prepare students for academic careers, the AGEP program provides a portfolio of professional development activities. This includes both in-house and national preparation for the professoriate seminars and workshops. SEAGEP not only funds development, coordination, archiving, and online delivery of the professional development programs at the alliance institutions, but it also provides considerable travel funding to send students to professional society meetings. Participation in professional meetings is especially important for underrepresented minority graduate students as it gives them critical networking opportunities and provides entrée to an extended discipline-specific community.

SEAGEP funds are allocated to support development, archiving, and online delivery of the Clemson University Engineering and Science Education certificate and the associated seminar series. The graduate certificate program, one of only a handful in the United States, is designed for graduate students who seek experience in preparation for an academic career, who wish to further their understanding of the education process in engineering and science, or who are interested in engineering and science education research. The Engineering Science and Education seminar series is a one-credit course designed to bring contemporary issues in engineering and science education research into the classroom. Experts from academia, industry, and the corporate world are invited to make presentations on engineering and science education research issues including recruitment of minorities, retention issues, technology integration into engineering curricula, distance learning, engineering content into K-12 curriculum, learning theories, and education policy issues.

Global research experience is also a critical component for students' professional development. SEAGEP has been able to help support students with international research awards to conduct research in Bolivia, Columbia, Costa Rica, and Honduras.

To provide students with critical leadership skills, a SEAGEP Student Leadership Council has been developed. This group assumes the responsibility for planning student events such as the fall new student orientation and the annual student meeting, which features several days of professional development workshops and a scientific poster session.

V. Post Doctoral Project

To support the AGEP mission of diversifying the professoriate, SEAGEP provides funding for postdoctoral positions. Faculty partnered with SEAGEP to recruit underrepresented minority postdoctoral researchers in Zoology, Materials Science and Engineering, Chemistry Botany. Astronomy, and Microbiology and Cell Science at the University of Florida.

Feedback regarding this aspect of the program includes:

> *This post doc has been critical for his development. His writing and presentation skills have improved immensely and instead of giving up on a career in academics, he is now poised to land a nice professorship at a small college in the south.*

> *Having a longer postdoctoral study period really allowed her to develop her own unique research program. She was hired as a faculty member at Colgate College last Fall, and from what she has told me, she has hit the ground running with an active research program.*

Both the University of South Carolina and Clemson University participate in a Minority Postdoctoral Academic Career Training Program that is managed and funded by the State EPSCoR/IDEA program. In 2007, two of the five postdoctoral students supported were from the University of South Carolina, and one was from Clemson University. These students were provided a full year of support, and spent part of the year teaching at either a minority-serving institution or a primarily undergraduate institution.

VI. SEAGEP Alumni

To date, University of Florida SEAGEP has graduated 38 PhD students representing 28 departments in engineering and science. Of these, 8 are in academic positions, 14 are currently in postdoctoral positions, 8 are in government, and 8 are in industry. Of those not currently in academic positions, several have indicated an interest in joining academia at a later date. Interviews with this group indicated their belief that without the SEAGEP program they would not have successfully completed their degrees.

VII. Evaluation

The national data collection effort described earlier has shown an increase of 40% in PhD enrollments in the Biological & Agricultural Sciences in SEAGEP in the past 5 years and a 13% increase in PhD enrollments in Engineering. This was accompanied by a 27% increase in PhD degrees awarded in the Biological & Agricultural Sciences and a 20% in Engineering. In addition to this national data, the SEAGEP program has been extensively evaluated on several levels to determine what program components are most beneficial to the students, what the overall student experience is, and how this experience differs from other graduate students' experiences. Both quantitative and qualitative data has been collected. Mixed methods including focus groups, surveys, and interviews have been used. This methodological triangulation approach has produced a rich body of data that points to the success of the program at supporting and graduating increased numbers of underrepresented PhDs in science, engineering, and mathematics.

As mentioned earlier a significant obstacle to student success is the lack of appropriate support structures. SEAGEP students who were interviewed noted that the greatest benefit of the program came from the support they received as members of the SEAGEP community. Such support came through (a) monthly SEAGEP meetings, (b) dedicated SEAGEP administrators and staff, and (c) peer support, both academic and social.

The monthly meetings provide a forum for students to get to know each other, develop friendships, get advice from their peers, develop peer mentoring relationships. The meetings also provided them with a group of students that they encountered on campus at other functions. As one student explained:

So the only real support system I have from people from similar backgrounds is basically AGEP and some friends that I have, but mostly just AGEP. It's not that it's a problem having friends of different racial backgrounds, but I think you need to have that blend. Without this particular program I wouldn't have had that blend. It is not always easy or convenient to stop what you're doing and come over [to the monthly meetings], but it is definitely beneficial for me.

As for the importance of dedicated personnel, students commented that they are

people you can call on to say you are having a problem and get advice. And that is probably the most invaluable part of the program. A lot of programs offer money but they don't try to help to see your way through the program. You are pretty much left on your own. Here they try to cover all your bases.

With respect to the importance of helping students overcome isolation, comments included:

Since I am the only AGEP student in my department, I get to see other students in other majors and see what they are doing, see how their programs work and have the advantage of being able to know how other departments do their thing.

Some of the other programs, organizations, their meetings don't have that continuity, you don't have the family environment – you don't get that feeling, you don't know everyone in the same program. You can talk to someone on a given day and they will say, "Oh, I'm a member of that too."

As important participants, Deans, Department Chairs, and faculty advisors were also surveyed to determine the effect of the program on them. Sample comments included:

The program has greatly enhanced our ability to recruit and to nurture minority women for engineering education; in my case for the rapidly growing biomedical materials field where they will have the opportunity to become leaders in this field in R&D or education and become role models for a new and more diverse generation of women in biomedical engineering . . . The program has allowed us to focus on recruitment to strengthen diversity.

We also have added the outcome of placement of our PhD graduates into the professoriate as an important measure of success. Many of our departmental graduate staff members are using this opportunity to recruit students from these groups.

Indirectly, the Program has helped intensify our recruitment of students from traditionally underrepresented groups in ---. The Department now supports faculty visits to the national meetings organized by [National Societies for Underrepresented Groups].

To gain a richer picture of the graduate student experience in SEAGEP, a recent study was completed that included a survey of both SEAGEP students and a matching group of majority students to allow for comparison of the graduate school experience of the two groups. These results will be reported elsewhere, but preliminary analysis indicates that the difference between the graduate experience of SEAGEP students and the graduate experience on non-SEAGEP students is not statistically significant with regard to a wide range of issues concerning satisfaction with their program and quality of life issues. Those areas that do show a difference will be used to improve mentoring, advising and other areas as appropriate.

VIII. Summary

As the National Science Board notes,

Governments throughout the world recognize that a high-skill science and engineering workforce is essential for economic strength. Countries beyond the United States have been taking action to increase the capacity of their higher education systems, attract foreign students and workers, and raise the attractiveness to their own citizenry of staying of staying home or returning from abroad to serve growing national economies and research enterprises. [8]

While it is critical to the United States that the diversity of its research enterprise reflects the diversity of thought and opinion of all of its peoples, this is equally important across the globe. Reports from Australia, Canada, and Kenya indicate demographic changes in the student populations pursuing advanced degrees, and an awareness that these changes require a closer look at issues related to diversity.

Researchers in Canada have noted that increases in the non-White population are significant and that this makes it increasingly important to understand the factors of attrition and retention as they are related to racial origins and campus climate [9,10]. Researchers in Kenya have also studied ethnic diversity as it is affected by policy decisions in higher education [11]. In Australia, the growth from 8,563 doctoral students in 1988 to 39,531 in 2004 resulted in significant increases in the heterogeneity of students [12] and prompted studies of the impacts of policy on diversity. Diversity enriches the research and teaching enterprise, and it is clear that the increase in diversity of students pursuing advanced degrees is a global phenomenon. It is also clear that research into the issues faced by specific groups of students can result in programming and policy decisions that will enhance rather than hinder the success of these students who were previously not part of this enterprise. While diversification of the student population is a global experience, as conditions and obstacles vary from country to country, it will be up to education researchers in each to determine what the specific challenges faced by minority students are, and to make recommendations to ameliorate them. With respect to programming specifically designed to ensure retention and graduation of underrepresented students in science, engineering, and mathematics in the U.S., the AGEP program has demonstrated that achieving an increase in the diversity of students pursuing advanced science and engineering degrees requires dedicated personnel and a comprehensive approach that supports the students throughout the entire process. The model developed by the institutions in the Alliances for Graduate Education and the Professoriate is being used effectively in the production of doctoral degrees in engineering and science fields.

***Abstract*— This paper describes a teaching experience where Master 2 students have to solve a telecommunication problem without having specific theoretical required knowledge but using an experimental hands-on approach.**

Keywords-Telecom networks, Architecture and Protocol, Tests

I. INTRODUCTION

A. Problematic

Various issues can be considered during a lecture on wireless sensor networks [1], [2]: electronic design, risk for the human being, management of the energy, technologies of telecommunication, signaling and communication protocols… The education experiment described in this paper essentially aims at making future graduates to acquire the basic knowledge needed to choose between several software and hardware telecommunication architectures more or less adapted to a context, and to help them to evaluate the consequences of their choices on the software development associated to the each device. In that context, various telecommunication technologies used in personal networks (*PAN* for *Personal Area Network*) are nowadays potentially answering such needs such as remote monitoring of buildings, care of the elderly, structural health monitoring [3]…

B. Paper structure

The paper is structured in the following way. Section 2 presents the context and the objectives of a teaching experiment dealing with the implementation of a platform dedicated to test of several wireless sensor networks. Section 3 details the various technologies considered for telecommunication devices. Section 4 describes the methodology used by the teachers so that the students manage by themselves to find an answer to the question: "for a given configuration, what device is the most appropriate and what is the associated software development?" The concluding section gives the first conclusions on this teaching experiment as obtained from the student feedback.

II. IMPLEMENTATION

A. Context and objectives

In the AE (Automatic Control and Electronics) curriculum of the INSA Toulouse [4], considering issues related to the sensor networks, the students attend lectures about analog and digital electronics, communication networks (e.g. Internet) and telecommunication principles. There is no specific lecture on sensor networks. The objective of the experiment described in this paper is to get students acquiring software and hardware skills in heterogeneous wireless sensor networks. The goal is reached following an auto-training pedagogy such as the ones detailed in *Problem-Based Learning* [5], [6]. The students have to develop an experimental platform to test different telecommunication devices usually employed for personal area networks on one hand and to test different protocols involved in communication between wireless sensors and remote customers on the other hand.

B. Application description

The students have to develop an application of remote monitoring of several parameters of a room (luminosity, temperature) and of movements (intrusion in the room or displacement of one object inside the room). This application is based on terminal nodes made up of a sensor, a microcontroller and a telecommunication module. Several buildings can be inter-connected while the sensors inside each building must keep interacting, as illustrated in Fig. 1. Three families of nodes are used. These families have been chosen according to the data they have to transmit. Those data are different by their:

- Nature: some are binary (e.g. detection of a threshold), others are analogical ones;
- Criticality: processing data can be more or less critical;
- Periodicity: some data must be sent periodically, while other transmissions are event-triggered…

As far as their transfer is concerned, these data have different needs concerning the quality of service. These needs must be taken into account for the choice of a specific telecommunication technology and during the development of appropriate communication protocols.

The network is constituted of terminal nodes, gateways embedding various telecommunication devices and of a main station able to maintain communication with a remote user.

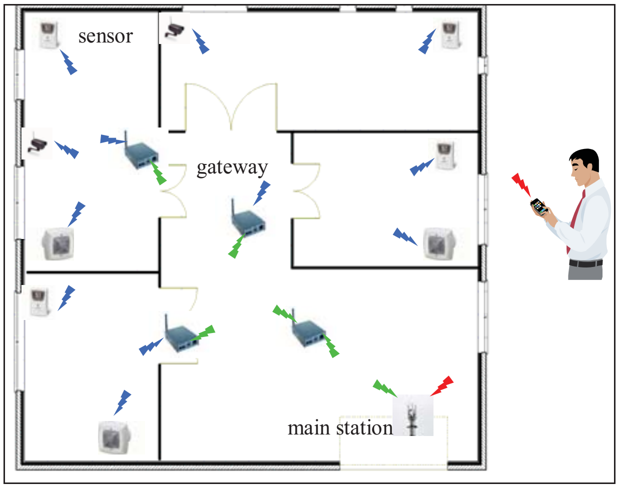

Figure 1. Example of a wireless sensor network

III. A SELECTION OF TECHNOLOGIES TO BE INVESTIGATED

This section presents the various telecommunication devices involved in the network as well as the various protocols which the students have to set up. Devices are connected via customized boards to the evaluation board of a microcontroller (MCBSTM32 [7] of *Keil*, processor ARM / ST). This configuration represents a "less embedded" solution than a dedicated electronic board which would have specifically been developed but it offers a high flexibility of use and of debug to the students by supplying a multi line LCD screen for display, free zones for oscilloscope test points, series connections to a terminal PC, diodes... The communication and signaling protocols are implemented on the microcontroller by means of the environment *μVision3* of *Keil* [8] which offers functions of simulation and transfer towards a microcontroller.

A. *Telecom devices*

Three technologies of devices are selected for this teaching lab work:

- A half-duplex transmitter using FSK modulation at 433MHz manufactured by Telital;
- An IEEE 802.15.4 transmitter manufactured by Microchip;
- A GSM / GPRS modem manufactured by Sagem.

The choice of these technologies is driven by the diversity of the services that they offer and by the diversity of their service access. The presentation of these services is the object of section B. The presentation of the service access is given below. Table 1 roughly summarizes the characteristics of these modules, the objective of the student lab work being to refine and to extend this table. The symbol "O" means an average performance, the symbol "+" a performance superior to average, and the symbol "-" a performance below average.

TABLE I. MAIN DEVICE CHARACTERISTICS

Device	Characteristics			
	Cost[a]	***Range***	***Access***	***Energy***
802.15.4	O	O	SPI	O
FM 433MHz	+	-	RS232	+
GSM/GPRS	-	+	RS232/AT	-

a. Initial and use cost

The column "Access" indicates the bus which must be used between the telecommunication device and the microcontroller to reach the communication services. Two buses are available: the RS232 bus which is implemented by a connection USART (*Universal Synchronous and Asynchronous Receiver Transmitter*) of the microcontroller, and the SPI (*Serial Peripheral Interface*) bus which is implemented by a connection MSSP (*Master Synchronous Serial Port*) of the microcontroller.

Three scenarios thus appear:

- The FM device is directly usable through RS232. That means that the device directly transmits the binary data flow on the medium;
- The IEEE 802.15.4 module using the SPI bus requires to set or to read registers to configure and use the service of telecommunication;
- The GSM / GPRS modem is used in the same way as any wired modem. The RS232 connection allows the use of the applications implemented on the device through "AT" commands like a classic PSTN modem.

B. *Signaling and communication protocols*

Each module studied in section A has specific communication and signaling services which can be extremely basic or may include complex embedded applications. The implementation of these services also differs a lot from one device to another. To develop the application of remote monitoring, students must initially understand the interest of these services, and then extend them if necessary. The following of this section details various aspects of the standard communication services offered by each module.

1) *Half-duplex FSK/FM 433MHZ device*

The FM 433MHz transmitter only offers a simple service to access the medium. It offers none of the classic services usually present on communication networks (based on the TCP/IP protocol stack for example) initially known by students during lectures about Internet basics: there is no addressing map, neither cyclic redundancy check, nor frame sequence number… The offered service is assimilated to a "simple" *broadcast* of data without other functionalities.

The student wishing to transmit information should follow the procedure below:

- Set the line TX of transmission;
- Write information on the microcontroller USART connection;
- Release the line TX of the device.

The instrumentation of this device is very easy; it is also possible to check a frame structure by capturing the RS232 frame with oscilloscope, both in sending and receiving modes.

This communication service is thus extremely simple to use (but also poor in functionality!); however students have to understand the need to release the line TX at the end of transmission if several transmitters alternately want to transmit (otherwise the receiver is unable to receive the data of transmitters emitting simultaneously).

This device is commonly and frequently used in the industry because of its low consumption and of its moderate cost. There are a lot of wireless sensor systems based on this technology; the most widespread examples are for home automation or for weather stations using wireless sensors. In spite of the simplicity of the services and the poor qualities of transmission offered by these devices, they offer a real interest in this lecture, essentially for two reasons. The first one is that the students have to ascertain that at a given moment, the risk of collision between two frames resulting from various sensors is unavoidable and even increases, obviously, with the quantity of simultaneous traffic. The second reason to study this device is related to the lack of reliability of this connection due to this risk of collision, but also to the loss of the signal quality when the receiver is far away from the transmitters or when it is not in direct vision.

Then, if it is required by the application, students have to consider additional mechanisms to make the connection reliable. Three solutions, that have different effects, can thus be envisaged:

- Set up a mechanism of detection and resumption of error;
- Make systematic redundancies of information, for example transmit the same frame several times to decrease the risk of collision and so decrease the risk of loosing a piece of information;
- Set up a mechanism of emission coupled with a mechanism of acknowledgement of the data that have been effectively received by the receiver.

The study of advantages and drawbacks of these solutions goes beyond the framework of this paper. However, the main consequence of the third solution is that the transmitter must also be able to receive data (to process acknowledgement)!

2) *IEEE 802.15.4 device*

The IEEE 802.15.4 device offers all the services defined in the 802.15.4 standard [9] via a *ZigBee* [10] stack. These services concern as well the communication and signaling protocols.

From the communication point of view, the device offers OSI/Transport level services, for example:

- The establishment of connection;
- The management of acknowledgments;
- The automatic retransmission mechanisms if data are lost…

There is also an advanced medium access control service which avoids the transmission of data through an already busy channel. The hardware offers various transmission channels; this allows a more accurate management of the bandwidth and reduces the risk of collision.

From the signaling point of view, *ZigBee* integrates many configurations of network topology: star, tree or mesh. For each of these topologies, it defines specific equipments, coordinator, and router in charge of the signaling mapping. To optimize the space memory on a microcontroller, *ZigBee* envisages a partial establishment of the signaling stack according to the targeted device. In this lecture, all the devices implement the totality of the *ZigBee* services.

From the student point of view, it is important to understand the interest of these services when the network topology becomes more and more complex. Indeed, *ZibBee* offers a management of the helpful services when the application targets aggregated traffics by data resulting from various sites. Services also offer a management of the communications (indifferently *unicast* or *multicast*) implying the crossing of several equipments: i.e. multi hop communications. The configuration of nodes, when an equipment fails or when the topology changes, is automatic if the appropriate services are activated. Fig.2 illustrates these various cases.

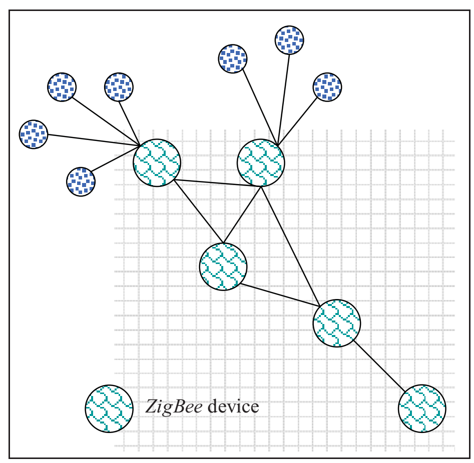

Figure 2. *ZigBee* suitable topology

3) *GSM/GPRS device*

The services offered by the GSM/GPRS device are different from those offered by the previous devices. They are more oriented towards embedded applications (voice, text, data, picture, video, music). From the user point of view, services like configuration of a topology, management of collision, etc. are hidden … If the appearance of these telecommunication devices may be seen out of the lecture scope, they are nevertheless very interesting. Indeed, the GSM remains a widely spread mean to transfer all kinds of information between an equipment with strong mobility and information server (typically “machines to machines”, *m2m*, applications) or a user. The parameter analysis on a vehicle fleet (position sensor, consumption measurement) is an industrial example. To keep a communication link between the sensor network and a mobile remote user, the students set up an application of SMS processing. This application allows to make the reporting of periodic events towards the user or to process a specific request of the user wishing to interact with the remote monitoring system (system deactivation, state of a sensor request…).

IV. STUDENT EVOLUTION

Students of Master 2 have to set up a prototype of a sensor network. They use this network to formulate generic principles on the wireless sensor networks: choice of a telecommunication device, communication and signaling protocols suited to a targeted application. This training includes 7 supervised sessions of practical works (3 hours each); free sessions are also scheduled so that the students can have access to the technical equipment.

The starting point is the application specifications. Various items are available: software development tools, sensors (this teaching is synchronized with another one which objective is the development by the students of all the electronic part of the sensors), microcontroller evaluation boards and devices, with a detailed technical documentation and datasheets. The interface boards between evaluation board and the three telecommunication modules are also given from the start.

Students have to discover and understand the manipulation of each device taken separately before starting to completely implement the platform.

The students have to follow the following evolution:

- Step 1: discovery of devices. For that purpose, they test every device by establishing a direct and basic communication (send of an *ASCII* characters) between a single transmitter and a receiver. This step is common to every device and requires no elaborated configuration nor to add services to those already offered by modules.
- Step 2: several transmitters on the network. By testing services offered by the first device (FM technology), students understand that it is necessary to add a field "address" in any emission of information. They also note a risk of collision and loss of frames which grows with the transmitter number if they do not use a device offering suitable services or if they do not extend those basic ones proposed by the device.
- Step 3: the network spreads out. The initial range of the first two modules (FM and *ZigBee*) is not sufficient to cover communication needs on more important distances. It is then essential to set up several modules with a suitable signaling service on intermediate devices.

Gradually, the students thus take into account a more and more complex topology until they consider the complete platform of test compatible with the application of remote monitoring. The objective for the students is to refine and to complete the information contained in the Table 1 by means of a platform whose technological solution is represented in Fig. 3. Indeed, this solution appears as the best compromise if all the parameters are taken into account. Effectively, if the criteria of cost and energy saving are ignored, the platform could consist only of sensors equipped with a GSM device allowing to cover all the needs of the application. On the other hand, as long as we only consider communications inside one site, a solution based on FM device could appear as sufficient. But this solution would require a very heavy development to guarantee the same flexibility of use and the same level of services offered by *ZigBee* device when the topology becomes complex.

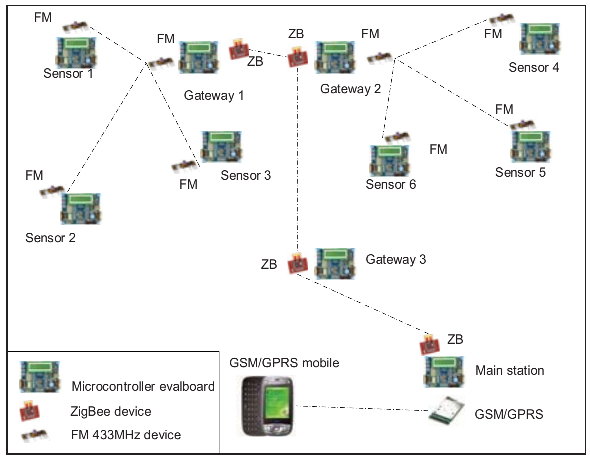

Figure 3. Platform solution

V. CONCLUSION

This paper describes a teaching experiment that addresses Master 2 students of INSA Toulouse. The scientific objective is the study of communication and signaling protocols involved in wireless sensor networks. In this course, students have to cope with a problem for which initially they don’t have any technological solution; they only possess the necessary general background. They must develop and experiment an appropriate study based on tests. To make these tests possible, the students set up a platform prototype based on various telecommunication devices. This platform answers a typical application of industrial site remote monitoring by the means of wireless sensor networks. The experience is conclusive, it demonstrates that even if Master 2 students have no specific knowledge in the field of the personal area networks, a scientific approach based on tests and analysis allows discovering generic principles.

I. INTRODUCTION

Manufacturing processes are an important element in industrial engineering education. In distance education, the learning of engineering subjects has a special difficulty, which can be reduced by means of the use of new technologies, and the practice of mixed models of learning [1]. One of these processes is the deep drawing due to its relevance in the industry [2]. This paper presents the development of a didactic computer tool created by the authors for the resolution of multi-stage deep drawing industrial processes. Thus, the tool has been realized for its use in the Master degree because it requires advanced knowledge in manufacturing processes. Although there are some software applications about the deep-drawing optimization, this one allows analyzing technological and economical constrains and it permits minimizing the total process time, from a global perspective. The model provides a comprehensive analysis occurring in multi-stage processes of axi-symmetric geometry work-pieces [3-5]. The scientific model is established from the Leu [6] and Sonis et al. [7] works that provides LDR (limiting drawing ratio) solutions based on normal anisotropy value, strain hardening exponent and others, applied to the drawing and redrawing stages. The authors extend this work to the ironing stages, and provide a global and integral science solution for the total process [8-9]. The model permits to modify and correct certain process variables in order to predict the impact of those that are not fully controllable. It is based on defining a set of boundary conditions of the process for determining a range within which it is stable. The simultaneous accomplishment of the boundary conditions involved in each process (deep drawing, redrawing and ironing) permits to limit a range of values that define each stage of the total process [10-11] (see Fig. 1).

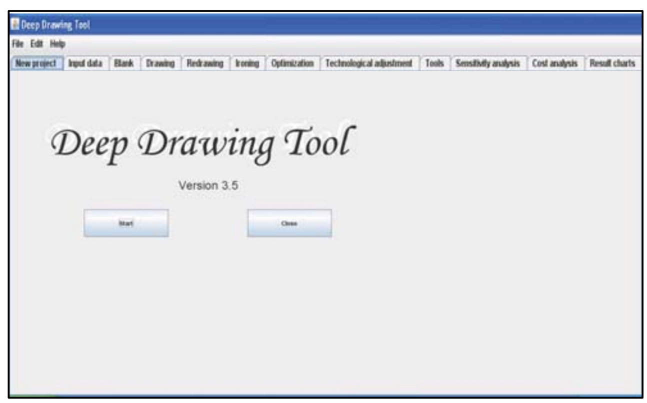

Figure 1. Main screen of the computer tool

Based on the technological model formulated, this paper presents a software tool created to implement the Aided System in a practical way. The computer tool was generated in a Java environment by creating a user-friendly interface and easy in its operation. The methodology has been the spiral model, software development model of evolution in which the software is realized in a series of incremental versions. This paper describes the tool constructed in their requirements, development methodology and structure. Finally, applies to the resolution of a case study, with the resolution screens that provides the Assisted System.

II. System Requirements

The system must comply several needs and characteristics of high-level of the developed system. The system must:

- Be independent of particular operating system. This should run on any system available in the market.
- Show the calculation results in a reduced time allowing easy interaction between user and system.
- Have a simple, clear and easy operation.

The interface design must meet the following general principles: a) Ease of learning: the user does not need much training time to use the interface; b) Consistency: all mechanisms of the interface are always used in the same way and thus produce the same result; and c) Flexibility: allow user interaction to drive the system through messages indicating everything that happens during the interaction.

The application consists of three parts:

- Calculation Module for data processing and generation of results.
- Materials: Module for the management of various materials that the system works.
- Interface Module intended for user interaction.

III. Methodology

The spiral model is a model of evolutionary software development where software is developed in a series of incremental versions. In the initial approach the incremental release might be a paper model or prototype as they are already performing approaches are achieved in more complete versions of the system. This model is suited to create products with different versions, improving with each approach, the current version and adding new functionality. Engineering can be developed through classical life cycle model or prototype construction. This methodology will, in each cycle, review the specifications of objects based on knowledge that is acquired with the operation of the aided system.

The spiral model is divided into regions of structural activities or tasks. There are generally three to six areas of work. These task areas are listed below:

- Customer communication: It includes the tasks necessary to obtain customer requirements. In this case a customer does not exist as such; the requirements are obtained from the project definition.
- Planning: Contains the tasks required to prepare the project, define resources and estimate the development time.
- Risk analysis: It includes the tasks required to assess technical risk and project-related tasks.
- Engineering: Contains the tasks required to set the system to be developed.
- Construction and adaptation: It contains the tasks required to build, test, install and provide user support.
- Customer Review: It includes the tasks required for the degree of customer satisfaction with the developed system.

When the evolutionary process starts, the software engineering team revolves around the spiral in clockwise direction, starting from the center. The first circuit of the spiral causes the development of a product specification; the following steps on the spiral could be used to develop a prototype and progressively more sophisticated versions of the software. Each step of the planning region produces adjustments in the project plan. Accordingly, the cost and the planning are adjusted by the reaction to the evolution of the client.

The spiral model can be adapted and applied throughout the life of the software. As the software evolves and the process progresses, the developer and the client understand and react to risks at each evolutionary level. This model allows the developers to apply the prototyping approach at any stage of product evolution. It will consider technical risks at all stages of development and reduce them before they compromise the project's development.

IV. Structure of the System

The purpose of this section is to describe the structure of the system, which has three packages that define it.

Each one of these packages corresponds to a module defined in the system.

- Calculation Package: Package that implements the functions of data processing and delivery of outcomes.
- Material Package: Package that implements the management functions of the several materials that the system works.
- GUI Package: Package that implements the user interface.

Each of these packages in turn contains classes that implement the functionality itself.

V. Development of the Computer Tool

The purpose of this section is to define the precise nature of the development system used.

Since the system must be compatible with different operating systems in the market, we have selected Java as development language. Java is a language of object-oriented programming developed by Sun Microsystems in the early 90s. The Java language was created with five main objectives:

- It should use the methodology of object-oriented programming.

- It should allow the execution of a program on multiple operating systems.
- It should include default support for networking.
- It should be designed to execute code on remote systems securely.
- It should be easy to use and take the best from other object oriented languages like C + +.

Note that Sun Microsystems released the bulk of their Java technologies under the GNU GPL, according to the specifications of the Java Community Process, so that virtually all of Sun Java is now free software. To facilitate the development and purifying, the system will use a modular development system.

Modular programming can be defined as one that addresses the solution of a problem by breaking it down into simpler sub-problems, each of which is solved using an algorithm or module more or less independent of the rest (hence the name "modular programming"). The advantages of modular programming are several: facilitates the understanding and resolution step; increases the clarity and readability of programs; allows multiple programmers working on the same problem at a time, since each one can work in one or more modules quite independently; reduce development time, reusing previously developed modules; improving the reliability of programs, it is easier to design and debug small modules than huge programs; and finally facilitates the software maintenance.

Moreover, we can safely say that it is virtually impossible to write a large program if we do not proceed to divide it into smaller chunks, covered by our poor human intellect. In general, the main problem is solved on an algorithm which we call algorithm or core module, while the simple sub problems are solved in sub-algorithms, also called modules. Sub-algorithms are subordinate to the main algorithm, so it is what decides in which order it should be implemented and how the sub-algorithms dataset. The main algorithm makes calls or invocations to sub-algorithms, while these return results to the former. Thus, the main algorithm is collecting all the results and it can generate the solution to the global problem.

VI. APPLICATION TO A CASE STUDY

This section shows the resolution of a case study developed by the Aided System. As input data following the dimensions of the piece that we want to obtain:

- External diameter $d_n = 150$ mm
- Length $l_n = 600$ mm
- Bottom thickness $s_n = 4$ mm
- Wall thickness $e_n = 1$ mm
- Material type UNS A95182.

A. New Project

Once implemented the program shows the startup screen. We will begin to work with the tool clicking on the START button (Fig. 1). If we click CLOSE the application will be closed. This screen also indicates the application title "Deep Drawing Tool" and the version we're using, in this case 3.5. From the home screen we can access at any stage after having run through the dialogs above, showing the titles of the corresponding phases.

B. Input Data

The input data are entered on screen "INPUT DATA" (Fig. 2), which indicates the size and type of piece we want to get. The dialog asks us about several data concerning the external diameter, length, bottom and wall thickness.

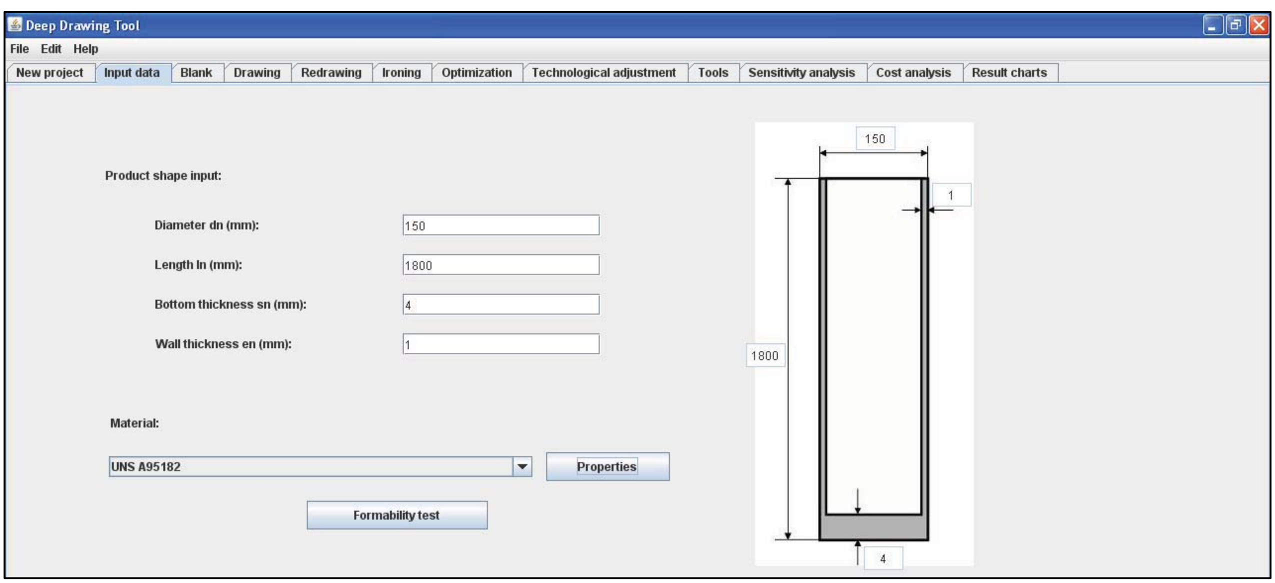

Figure 2. Input Data Screen

We must also choose the type of material in which we want to make the piece, with a choice between several options. In this version of the program we have selected three materials: UNS C26000 brass, UNS G10080 steel and UNS A95182 aluminum. For the present case we have selected UNS A95182 aluminum. Clicking on the PROPERTIES button it will be open a window informing us about the characteristics of the selected material (Fig. 3).

Figure 3. Material Properties Screen

By pressing the button "SOLVE" we can obtain the dimensions of the blank: diameter and thickness.

C. Blank Dimensions

The second step of the application is the study of the blank dimensions. The application displays the screen for determining the dimensions of the disc or BLANK (Fig. 4). For information purposes, this screen shows the data corresponding to the final dimensions the piece will have and the type of material chosen.

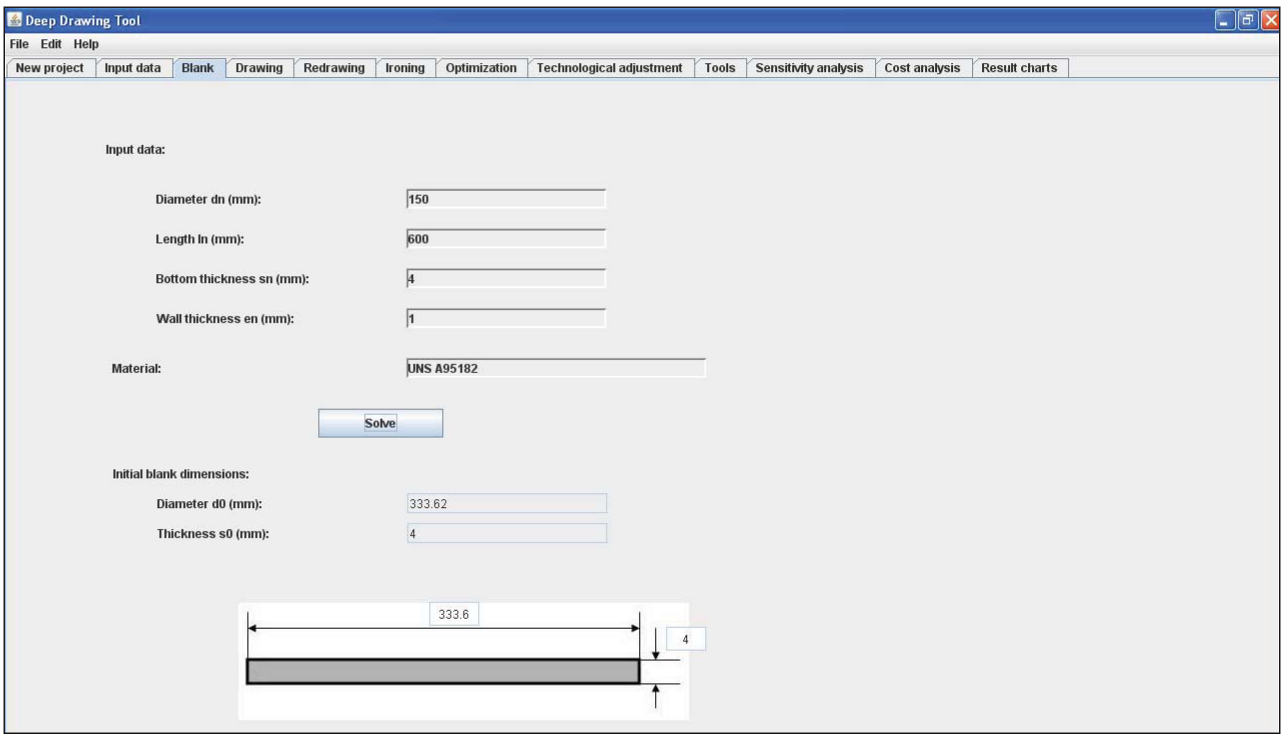

Figure 4. Blank Dimensions Screen

D. Drawing

The size of the disk obtained starting the program solves the first phase of the process of drawing or DEEP DRAWING, through the screen shown in Fig. 5.

The input data are those relating to blank diameter, thickness and diameter of the punch-stretching phase. It is important to show here the value of this diameter d_p because it will condition the design of this phase. It may be that the boundary conditions at this stage of drawing are to obtain a diameter smaller than the diameter of the punch inside the piece that we want to manufacture, an issue that limits the calculation at this stage [12].

The application requires the introduction of the value for efficiency coefficients in the two boundary conditions defined. The remaining input values are shown for information, since the application's taken directly from the database, depending on the type of material selected. SOLVE pressing the program calculates the drawing stage called Stage 1.1, providing the necessary data regarding the diameter of the stuffing, length, thickness, diameter of the punch, drawing ratios and thickness reduction, and maximum force applied during the process drawing.

Once it defines the drawing phase, the program performs the audit of the experimental conditions of drawing, for information.

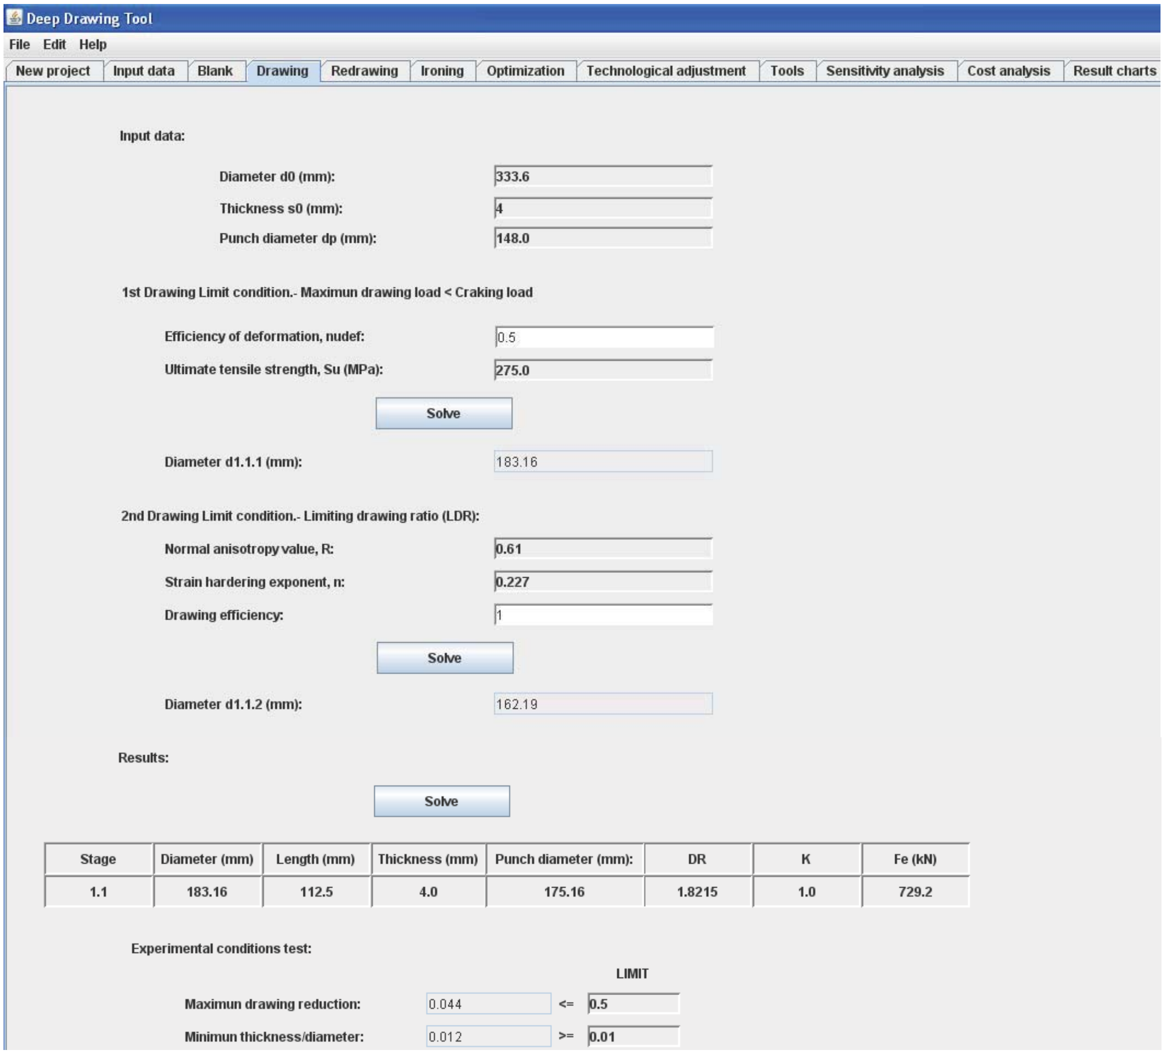

Figure 5. Drawing screen

E. *Redrawing*

The next phase of the process resolves redrawing or redrawing operations. From the dimensions obtained in the previous phase, embossing, which were provided as input, the program models at this stage on three boundary conditions (Fig. 6). In the first condition it is necessary to introduce limit values for the coefficient of friction, angle of the matrix and the radius die. The second boundary condition requires the application to provide the data for the efficiency factor and the value of the initial deformation [13]. The third condition is resolved based on the information that counts and that the application has already been introduced earlier. SOLVE proceed by pressing the calculation of phases for the process redrawing from 1.2 to Stage 1.n. It may be that it only requires a redrawing phase, as in the case presented, or even none.

In the event that, by the geometry of the piece to model, we evaluated in the case that it is not necessary redrawing stages, the program will provide a message that this case does not require redrawing phases.

The resolution redrawing process provides the results for the diameter of the stages, length, thickness, diameter of the punch, redrawing ratios, maximum force exerted at each stage and radio redrawing entry in the matrix for each phase.

The application also provides the results for Phase 1.m is that stage at which we could have come with redrawing process if the final dimensions of the piece had not limited the process. Redrawing, when the process is conducted in three stages over this "surplus ratio" in redrawing process is used to optimize the corresponding phases.

F. *Ironing*

The next phase of the model for the drawing process is solved by the application of three drawing boundary conditions (Fig. 7). The first boundary condition is solved in a straightforward way by applying the data for the material and geometry of the last stage of the process of redrawing. In the second boundary condition requires the application to provide the data for the efficiency factor and the value of the initial deformation. The third condition corresponding to the maximum ratio of wall thickness reduction is resolved based on the information that counts and that the application has already been introduced earlier. SOLVE proceed by pressing the calculation of phases for the drawing process, from Stage 2 to Stage n. It may be that it only requires a drawing phase, or even none will be necessary.

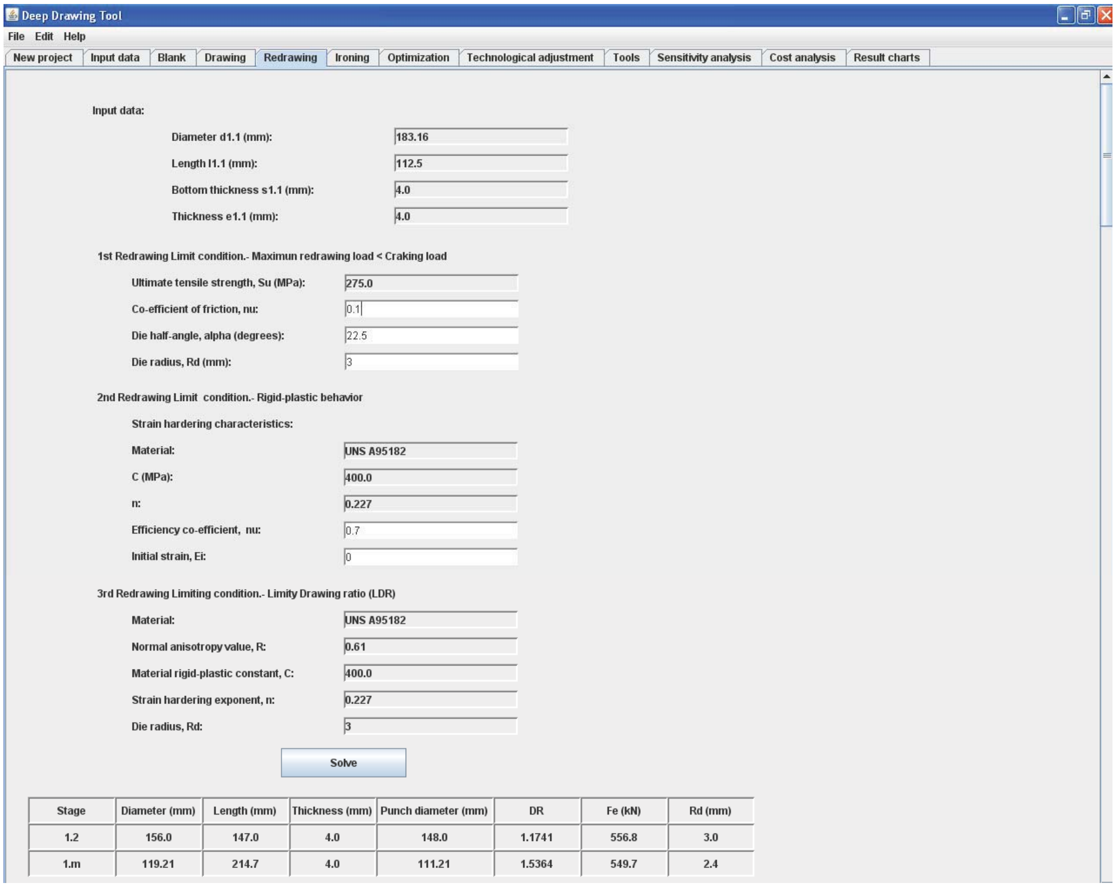

Figure 6. Redrawing screen

G. *Process Optimization*

Once provided the initial solution, the model is an optimization process in a comprehensive manner for redrawing and ironing operations (Fig. 8).

As input ratios appear stretched redrawing and surpluses in the last stage of each process. The model solves the optimization based on the definition of the number of times that it is necessary to split the surplus ratio (x_{re} for redrawing and x_e process for the drawing process), and operating parameters of the machinery involved in every stage of process [14-16].

Before proceeding to calculate the optimization process it is necessary to set the operating parameters of the machinery, for which the system will ask for entering the machinery used in each stage:

- Approach velocity
- Operation velocity
- Recovery velocity
- Tool total length

These data are entered via the dialog screen shown in Fig. 8. After entering the operating parameters of the machine, pressing SOLVE it proceed to the calculation of the optimization process, the following output shown in Fig. 9.

The results are the outcomes for each phase, optimized processes and redrawing stretched, diameter, length, thickness, drawing ratio, ratio of wall thickness reduction, drawing maximum power and operating time.

H. *Technological Adjustment*

The model allows adjustment technology by defining a clearance that increases the diameter of the hallmarks of the stages of drawing. Defined this clearance, the model automatically recalculates the entire process and provides a solution "adjusted" for the entire process: drawing, redrawing and ironing (Fig. 10).

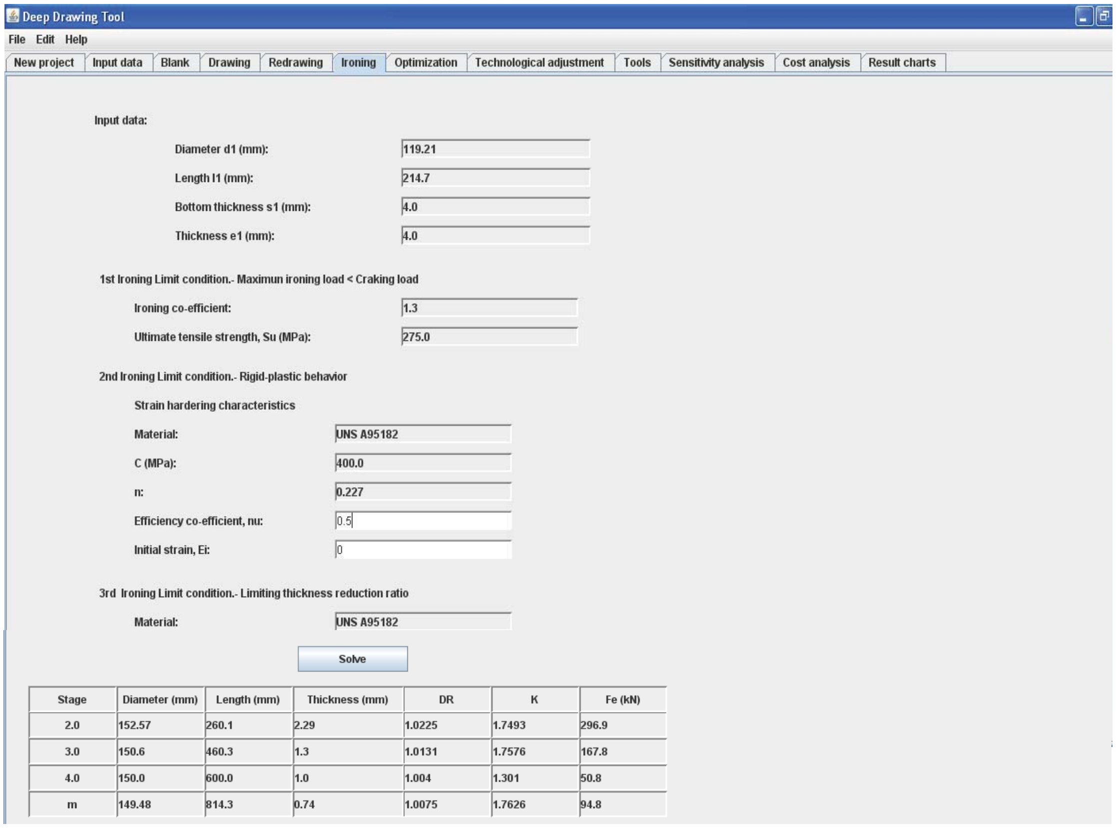

Figure 7. Ironing screen

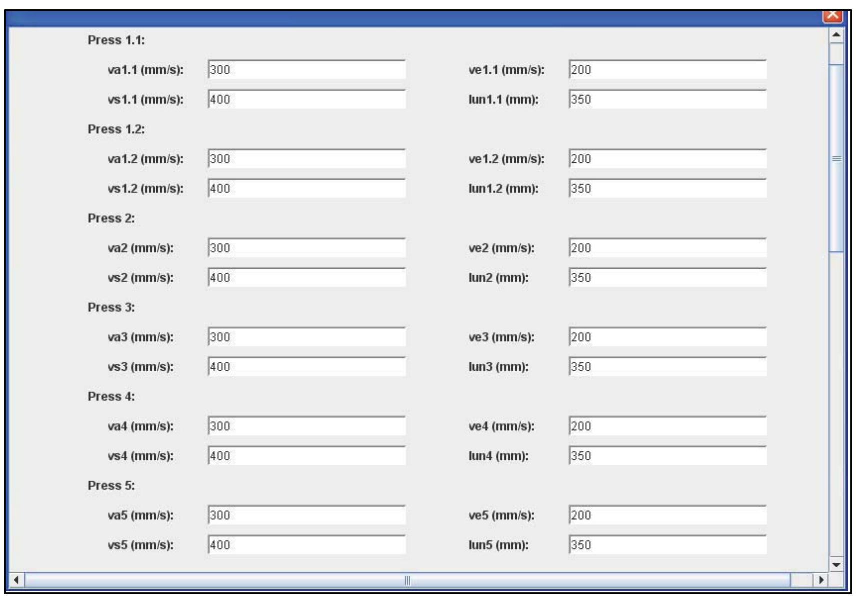

Figure 8. Machinery parameters

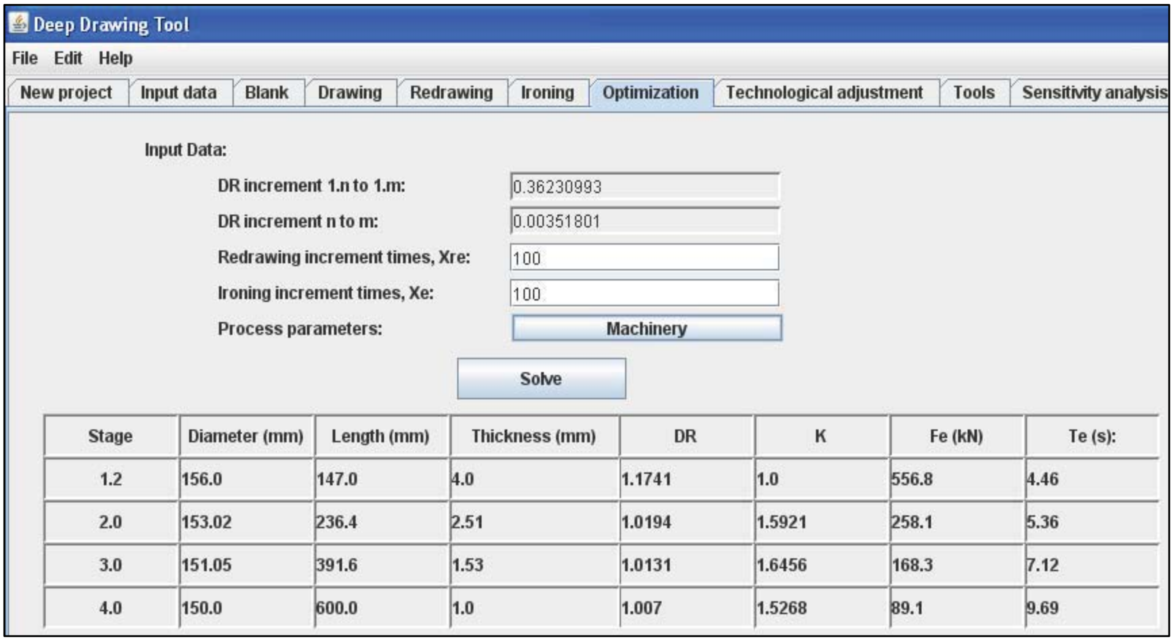
I. *Sensitivity Analysis*

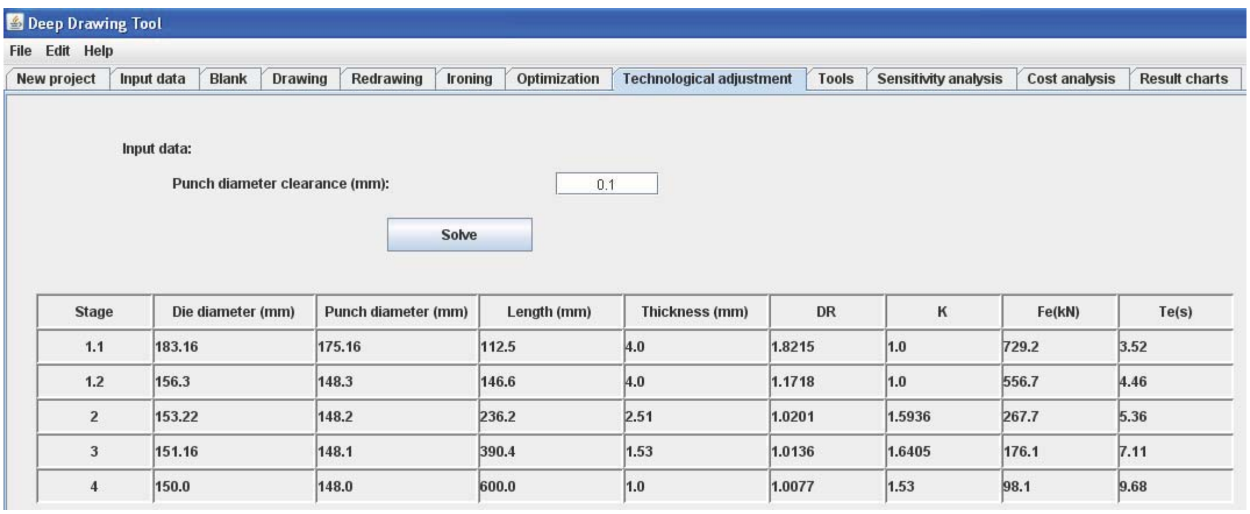
In the next phase, the process carries out a sensitivity analysis to the weathering of parent involvement in the process.

We define the diameter limit for each stage which can progress to the wear of the dies without endangering the stability of the process. Having established the limiting diameter setting a check is made as the diameter of the stage corresponds to the limit calculated (Fig. 11).



Stage	Diameter (mm)	Length (mm)	Thickness (mm)	DR	K	Fe (kN)	Te (s):
1.2	156.0	147.0	4.0	1.1741	1.0	556.8	4.46
2.0	153.02	236.4	2.51	1.0194	1.5921	258.1	5.36
3.0	151.05	391.6	1.53	1.0131	1.6456	168.3	7.12
4.0	150.0	600.0	1.0	1.007	1.5268	89.1	9.69

Figure 9. Optimization Process Screen



Stage	Die diameter (mm)	Punch diameter (mm)	Length (mm)	Thickness (mm)	DR	K	Fe(kN)	Te(s)
1.1	183.16	175.16	112.5	4.0	1.8215	1.0	729.2	3.52
1.2	156.3	148.3	146.6	4.0	1.1718	1.0	556.7	4.46
2	153.22	148.2	236.2	2.51	1.0201	1.5936	267.7	5.36
3	151.16	148.1	390.4	1.53	1.0136	1.6405	176.1	7.11
4	150.0	148.0	600.0	1.0	1.0077	1.53	98.1	9.68

Figure 10. Technological Adjustment Screen

J. Cost Analysis

In this phase of the system evaluated the costs involved in the whole process by introducing the input data for the total number of units to manufacture, raw material costs, hourly cost of labor and cost of electricity. The model provides the total costs for different solutions: initial, optimized and technological adjustment (Fig. 12).

K. Results

Finally, the model shows the graphs of results showing the evolution of certain variables over the entire process and showing a comparative for the solutions provided: initial, optimized and technological adjustment.

The graphics are as follows:

- Drawing Load vs Stage........................ Fig. 13
- Drawing Ratio vs Stage……………… Fig. 14
- K coefficient vs Stage……………… Fig. 15
- Length vs Stage……………………… Fig. 16
- Process total time…………………… Fig. 17

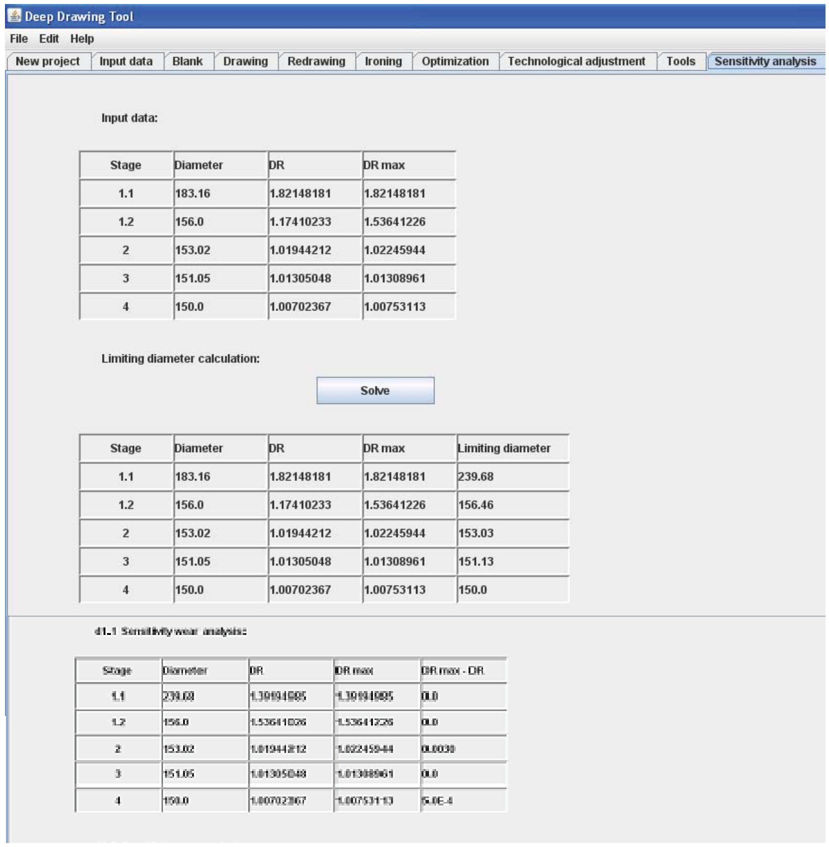


Figure 11. Sensitivity Analysis Screen

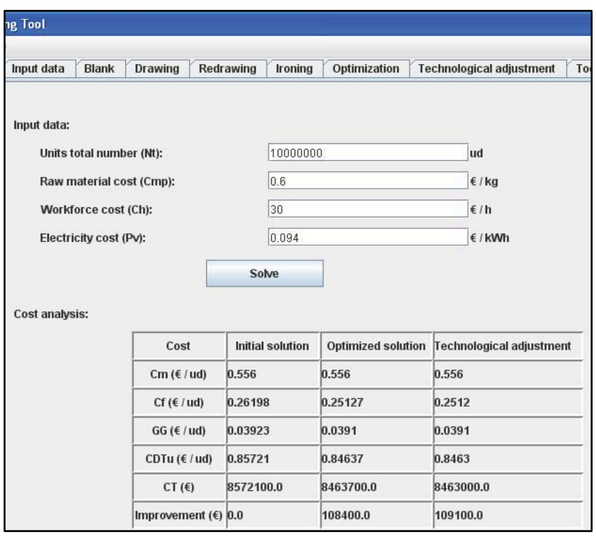

Figure 12. Costs Analysis Screen

CONCLUSIONS

This paper has summarized the functions of a deep drawing tool for engineering education. The tool allows selecting input data for getting the formability of material to deep drawing, selecting the process that provides the best solution from a technological perspective, optimizing the process for saving the material, knowing the influence of the punch in the results and considering the process cost.

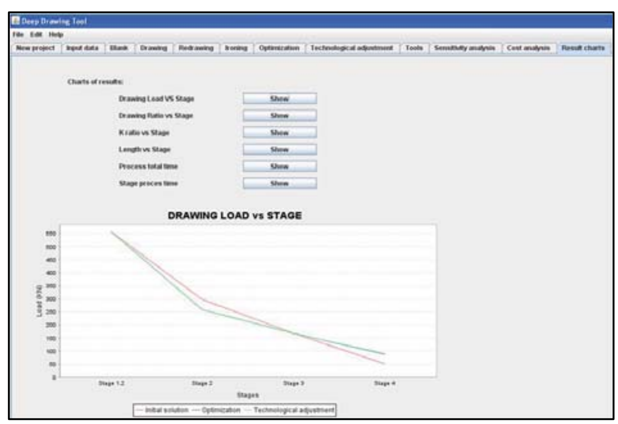

Figure 13. Graphic “Drawing Load vs Stage”

The structure of the system has three subsystems: Solve, module for data processing and the generation of results; Materials, module for management data of the system; and Interface, module for user interaction. The tool has been implemented in software tool programming, developed in Java. The paper describes each step of the tool, from the input data to final analysis and they are shown through the results given by the tool.

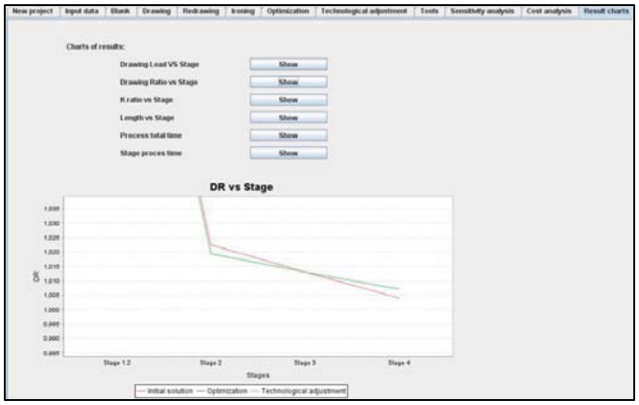

Figure 14. Graphic "DR vs Stage"

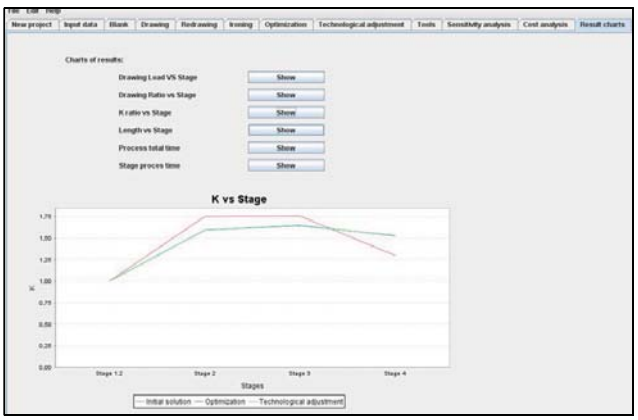

Figure 15. Graphic "K Coefficient vs Stage"

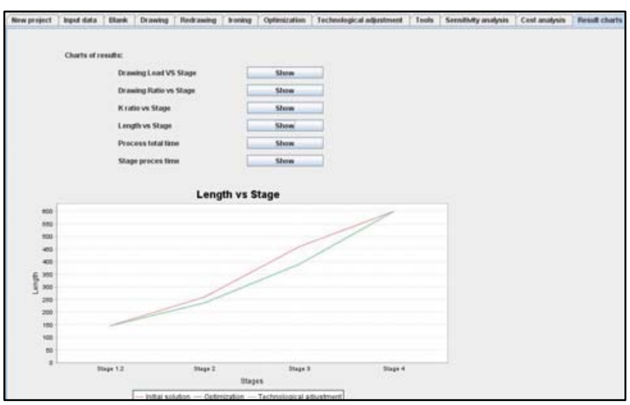

Figure 16. Graphic "Length vs Stage"

Future works, in this field, will go towards to implementation of the tool, and accordingly to the results, some improvements will be carried out.

Abstract— **In this paper, we review electronic design free software tools. We have searched open source programs that help with several tasks of the electronic design flow: analog and digital simulation, schematic capture, printed circuit board design and hardware description language compilation and simulation. Using some rapid criteria for verifying their availability, we have selected some of them which are worth working with. This work intends to perform a deeper analysis of free software tools and select some of them to use in education or in professional electronic design.**

Keywords- electronic design; free software;quality; evaluation.

I. INTRODUCTION

Free software is an increasing phenomenon that has attracted a lot of attention in academia, industry and among end-users. Following the definition of the Free Software Foundation (FSF) [1], free software concerns the users' freedom to run, copy, distribute, study, change and improve the software. Beyond its philosophical principles, the way many free software projects are developed, often against traditional software engineering practices, is also a research topic [2].

The interest in free software would not have increased without the success of many projects that are widely used and accepted [3]. GNULinux and the Apache web server are probably the most well known, but there are many others: user applications (e.g., GIMP, OpenOffice), programming languages (e.g., Perl, Python), internet resources (e.g., sendmail, bind), adaptations to embedded systems (e.g., OpenMoko, Nokia 770). However, not all free software programs have reached a high quality level and open source repositories [4] show many abandoned projects.

Regarding electronic design, the following question arises: Which is the state of free software tools for electronic design? Are they useful? The long term goal of the present work is to answer these questions, evaluating the situation of these tools and selecting some of them for education or professional use. In this paper, we present a first review of such tools and perform a preliminary selection. We also point out the main weakness detected.

II. OUTLINE

The steps we have followed are outlined in Fig. 1:

- Search for free software tools: we have searched free software tools that help in typical tasks of the electronic design flow.
- Rapid test and program selection: we have performed a rapid evaluation of the programs found. This has allowed us to select some of them for a further research and deeper evaluation.
- Analysis of rejections and summary of selected programs.

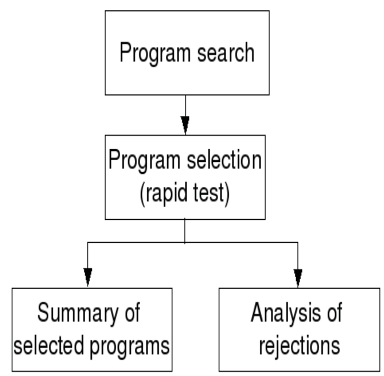

Figure 1. Main steps of the present work

III. SEARCH FOR FREE SOFTWARE TOOLS

A. Topics selected

We have searched for tools that are related to the following tasks:

- Analog simulation (AS): schematic capture with netlist generation, simulation engines and data visualization.
- Digital simulation (DS).
- Schematic capture (SC).
- Printed Circuit Board (PCB) Design.

- Hardware Description Language (HDL) design: compilation, simulation and waveform viewers.

B. Sources of information

We have searched in FSF [1], in classical repositories [4] and through the Internet using the Google Web search engine. Examples of keywords used are Electronic Design Automation (EDA), electrical, electronic, schematic capture, simulation, HDL, PCB, etc.

C. Programs found

In table I we have listed the number of programs found and the category they are included in. In some cases, they are divided into subcategories. In the analog simulation class, the sum of the programs in the subcategories does not equal the total in the category because there are integrated environments that belong to several subcategories at the same time.

TABLE I. NUMBER OF PROGRAMS FOUND AND THEIR CATEGORY

Category	**Number**	**Subcategory**	**Number**
Analog simulation (AS)	24	Simulation engine	9
		Schematic capture + netlist generation	10
		Data visualization	10
Digital simulation (DS)	13		
Schematic capture (SC)	22		
PCB design (PCB)	12		
HDL design (HDL)	28	Simulation and compilation	25
		Waveform viewer	3
Total	99		

IV. RAPID TEST OF PROGRAMS

Evaluation of software quality is still a controversial issue. There has been an evolution of this concept and the definition depends also on the perspective (architecture, source code, processes or community). ISO/IEC 9126 [5] offers a standard with six quality characteristic divided into several subcharacteristics. This quality model has to be adapted to every program. Other models focus on the free software world, analyzing their typical aspects: Open Business Readiness Ration, QSoS [6] and QualOSS [7]. However, applying those models to all the programs we have found is out of the scope of the present paper. We first have to pick up some of the software we have found. Thus, we have adopted a practical point of view and adopt the role of an electronic designer who wants to select a set of programs for further research. We have then specified five items in order to perform a rapid test.

- Is there a stable version?

A stable version would give confidence to software users. However, this question was not easy to answer. Traditionally release version 1.0 is the first one delivered to customers and considered stable. However, many free software projects follow the "release early, release often" rule [2], which means that the programs are available to the public well before they are considered stable. The Sourceforge repository includes information about the status of the software (alpha, beta or stable). But other downloadable programs have not this information. Therefore, this item was of limited use.

- Can it be easily installed?

If available, Windows versions usually pose no problem. For Linux users, probably the most interested in this kind of software, package management systems are the preferred way to install software because they solve all the dependencies. We have used the "aptitude" utility in the Kubuntu 8.01 distribution [8]. If no package is available, we have tried to compile the program from the source code and tried to solve the problems that appeared.

- Is the learnability good?

This is probably one of the most important points to attract new users. We have looked for user's manuals, "getting started" guides, wikis or web pages, examples etc. They should at least allow the user to start working with the tool.

- Can it work with a simple example?

We tried simple examples in order to check that the program is not only installed, but that can run simple simulations, draw simple schematics, etc. This is similar to the idea of the "hello world" program that can be found in many introductory tutorials of programming languages.

- Is it likely to be maintained in the future?

Any potential user should be interested in the project future and the probability that it will be debugged, improved, updated or extended. To answer this question, we paid attention to the frequency of new versions, the number of developers, the number of messages in mailing lists or the news that appeared in the corresponding sections.

The goal of this five item test is to determine whether or not it is worth evaluating the program in depth.

V. ANALYSIS OF REJECTIONS

In this section, we analyze the reasons that led us to reject many of the projects found. Table II summarizes the results. The terms used in the table together with further comments are explained in the next paragraphs.

TABLE II. MAIN REASONS TO REJECT PROGRAMS

Problem	**AS**	**DS**	**SC**	**PCB**	**HDL**	**Total**
Abandoned	8	4	13	6	8	39
Does not install	1	0	1	0	3	5
Poor learnability	3	3	2	0	1	9
Failure to work with simple examples	2	0	1	0	1	4
Other	3	3	1	3	7	17
Total	17	10	18	9	20	74

In the group of abandoned projects we have included projects that have had no activity (news, releases) for more than two years. In this group there are also projects that classify themselves as in ‘planning’ state. However, this state coincides with a lack of activity, at least in the cases we found. As can be deduced from the table, there is a high number of abandoned projects, a 53 % of the total of rejections. This is clearly a waste of effort. New developers should adhere one of the lesson of [2]: *“Good programmers know what to write. Great ones know what to rewrite (or reuse)”*.

With respect to the installation, many of the programs are available as Kubuntu packages, what makes the installation very easy. For the rest, source compilation is possible if the libraries it depends on are installed previously. We have been able to compile most programs successfully. A few of them showed compilation errors, such as undefined symbols, which prevented us from getting an executable.

There are not many programs that fail when dealing with simple examples like an RC circuit, HDL code with basic logic, etc. At least, the projects that are not abandoned and that can be installed are able to perform some operations.

Poor learnability is associated with a lack of documentation. Unfortunately, there are nine projects that are rejected mainly due to the poor documentation. In many cases they are hosted by attractive web pages, they are updated regularly and they can be installed without problems. But the section documentation is still under construction, or shows a similar message, so the newcomer hits the wall when trying to build up his own examples. From the user point of view, this is really disappointing. Electronic designers are not always programming experts and looking into the source code can be very hard.

The row entitled “Other” in table II accounts for other reasons to reject a program that are not in the previous categories. In some cases the programs are very basic, e.g. only a few gates in digital simulation, or they are oriented towards kinds of design not considered here, e.g. full custom design. There are also many examples of exotic approaches. For instance, programs that help to create modules for other tools, to debug or to write code. Integration of Spice-like simulation or hardware description with general purposes languages (Tcl, Ruby, Python) is a key point of several projects. Although they are remarkable efforts, we have stuck to the typical approaches to the electronic design topics considered in this paper.

We should mention that we have rejected two popular programs. Both of them are active and have been developed for many years. The first one is *Xcircuit* [9]. We could not make the examples work due to a segmentation fault. However this can be due to a packaging problem with Kubuntu and other Linux distributions should be tested. We could not compile the source code successfully either. The second one is *Alliance* [10], a set of CAD tools for VLSI design that includes a VHDL compiler and simulator. There is no package available in Kubuntu, and we also failed to compile the source code. This should be further researched.

VI. SELECTED PROGRAMS

The number of programs that we have selected is shown in table III .

TABLE III. SUMMARY OF NUMBER OF PROGRAMS SELECTED

Category	Programs selected	Total	%
Analog simulation	7	24	29
Digital simulation	3	13	23
Schematic capture	4	22	18
PCB design	3	12	25
HDL	8	28	29
Total	25	99	25

A. Analog simulation

We have found two motor simulations, *ngspice* [11] and *gnucap* [12]. They are both command line programs. *Ngspice* is based on the well-known Spice3 simulator originated at the University of California. Since 1999, its code has been bug-fixed, cleaned, ported to the GNU/Linux platform and improved with models and simulation options. *Gnucap* is the Gnu Circuit Analysis Package. It is not based on Spice and the engine is designed to do true mixed-mode simulation.

Gwave [13] and *Kjwaves* [14] are tools to view analog data from the output of simulations. *Gwave* is part of the gEDA toolkit. *Kjwaves* is written in Java and has a nice user interface.

Schematic programs that can output Spice netlists are also considered in this section. *Gschem* [13] is a graphical tool which is part of gEDA to facilitate the input of components. Once the schematic file and the required symbols are ready, they can be converted into netlists using the *gnetlist* [13] command. *Kicad* [15] is an open source program for the creation of electronic and schematic diagrams and printed circuit boards. It has an option for the creation of Spice netlists.

Finally, we have found an integrated environment which has its own flavour. It is called Quite Universal Circuit Simulator, *Qucs* [16]. It can simulate analog and digital circuits. It deviates from typical Spice-like simulators. The entry is graphical and the simulation itself can be seen as an embedded object in the main window, Fig. 2. The user documentation is very poor, but there are some specific tutorials that allow new users to run simple examples. Despite the documentation, we have kept this project as a valuable tool, due to its nice and intuitive graphical interface.

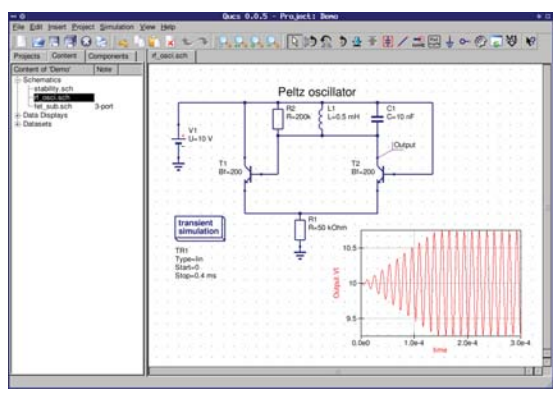

Figure 2. Screenshot of Qucs, taken from [16]

B. Digital simulation

Three projects gave us enough confidence in this section: *Tkgate* [17], *LogiSim* [18] and *Qucs*. *Tkgate* is an event driven digital circuit simulator with a tcl/tk-based graphical editor. It is a mature project that started at Carnegie Mellon University in 1987. *LogiSim* is written in Java and intends to be an educational tool for designing and simulating digital logic circuits. *Qucs* can not only perform analog simulation, as explained in the previous section, but also digital simulation. It is in fact based on the VHDL engine FreeHDL [19], but the user can simulate directly from a schematic entry without entering any VHDL code.

C. Schematic capture

Four programs have passed our rapid test. Three of them have already been reported in previous sections (*gschem, Kicad, Qucs*). The fourth one is *TinyCAD* [20]. It is a simple program that can print your diagrams or transform them into PNG images. It can be also used to output netlist for Spice or PCB programs. However, Spice output requires the introduction of many parameters by the user, which makes this process painful. In addition, only commercial PCB formats are possible as outputs, except for *FreePCB* (see next section).

D. PCB design

This is the category in which we have found fewer programs and as a consequence, fewer programs passed our rapid tests. This is probably due to the higher difficulty of the user interaction programming. The three programs are *PCB* [13], *FreePCB* [21] and *Kicad* [15]. *PCB* is now associated with the *gEDA* tool suite. Therefore, a schematic entry with *gschem* can be the first step of a printed circuit board design. The schematic file can be converted to a netlist compatible with *PCB* using the command *gnetlist*. *PCB* is a twenty year old application, which has been enhanced with Gerber generation, autorouter and GTK port. *FreePCB* was designed to be easy to use and ease to learn. It has only Windows version. In principle, netlist has to be entered semi-manually with a text editor. Since 2008, a utility written by a user allows converting *TinyCad* netlist into PADS-PCB netlists suitable for *FreePCB*. *Kicad* also allows the user to design a printed circuit board, starting from a schematic capture. All the steps of the design flow are integrated into a single graphical interface, much as the manner in which some commercial programs do.

E. HDL compilation, simulation and data visualization

We have found five compiler and simulator tools for HDLs. *Icarus* [13] is a command line verilog compiler, which is now associated with gEDA. In fact, there are two main commands: *iverilog*, which compiles the code, and *vvp*, which is the simulation run time engine. The ouptut of the simulation is a VCD file, but other waveform dumps are available. Typically, the user has to include a test bench within its program. *Ghdl* [22] acts in a similar manner, but with VHDL code. It is a command line compiler that can analyze or execute a design (test benches) depending on the flags used. In the latter case, VCD file format output is possible. *Veriwell* [23] is another command line verilog compiler which outputs VCD files. While last version is recent, documentation is worse than that of *ghdl* or *icarus*. *Signs* [24] can be used either as a command line or as an Eclipse plugin [25] for hardware design and simulation. At the moment, VHDL is the main language. Eclipse defines itself as an open development platform comprised of extensible frameworks, tools and runtimes for building, deploying and managing software across the lifecycle. It was hard to make it run the examples of the *Signs* tutorial, but this is probably due to our inexperience with the Eclipse environment. On the other hand, *Signs* has an integrated interface, Fig. 3, which is closer to commercial tools. The last compiler we have found is *freeHDL* [19]. Although the home web page has some characteristics of an abandoned project, such as empty pages and old documentation, it is the backend simulator used by *Qucs*, which is a quite active project. *Qucs* now accepts user written VHDL code in digital simulations. The results of a simulation are embedded as in Fig. 2.

Two waveform viewers are specific to digital simulation: *GTKwave* [26] and *Dinotrace* [27]. Both of them accept VCD and other file formats. *Dinotrace* comes with an interface to Emacs which allows source code and log files to be annotated with the values of signals.

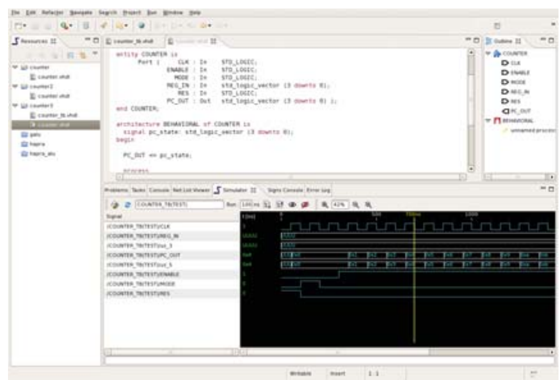

Figure 3. Screenshot of *Signs*, taken from [24]

VII. CONCLUSIONS AND FUTURE WORK

We have searched for free software tools that help in some tasks of the electronic design flow. Then, we have performed a rapid check and test of the programs in order to select which ones are worth continuing working with. We have found that about 39% of the projects are abandoned. On the positive side, we have found that there are several programs that cover each of the tasks considered in this study: analog simulation, digital simulation, schematic capture, PCB design and HDL design. Thus, we think that efforts should focus on improving existing projects, rather than on creating new ones, unless new projects include original approaches.

Generally speaking, documentation is a weak point. We have rejected about 9% of the projects for this reason. Even within the projects we have selected, we feel that user information should be improved. Sometimes we made the examples work with a mixture of documentation and intuition. New users should have a clear view of what software can do and where to obtain more information. However, we acknowledge that documentation is slowly improving in the projects we know for some years.

Another issue is the fact that people are not used to work with the GNU/Linux operating system and they are unwilling to change their operating system. One quick way to sort this out is by using virtualization. It is possible to use programs like *VirtualBox* [28] and *VMWare* [29] that allow users to work with different operating systems at the same time. This is a great way to try and use these free software programs that otherwise people would refuse because of the nuisance of installing and configuring GNU/Linux and the programs. It is also a great way to create an environment with the operating system and the installed programs that users can carry with them in portable media like USB memories.

In future, we plan to evaluate the selected programs in depth. For that purpose, we will use a quality model. We intend to apply a model based on the ISO/IEC 9126 standard [5] and a model specific to free software programs [7]. We want to derive from this study which is the suitability of the programs for real-world designs and where the efforts should be focused in order to improve them.

Design of an Educational Oscilloscope

A Hands-On Learning Tool

Abstract— **Paradoxically, most engineering students do not possess an in-depth knowledge on how an oscilloscope works. Automation is partly to be blamed for this problem. In fact, the existence of the "auto scale" button has eliminated the hassle of making adjustments, but at the price of dampening the students' curiosity and removing their need for deep understanding.**

We have found a powerful way of stimulating students' curiosity and of bestowing them with knowledge of the basic oscilloscope operation: While still using an oscilloscope-set, although merely as a display unit, we have by-passed its fundamental components (namely the vertical amplifier, the time base and the trigger circuit), with our own designed components, built outside of the oscilloscope-set. Our teaching strategy provides students with hands-on experimentation of the circuits that control vertical gain, the time scale and the trigger level. Our educational tool is *implemented in hardware*; it is not another simulation oscilloscope.

The effects of our didactic tool are highly positive, as demonstrated by student evaluation of circuit laboratories that took place before and after we incorporated the Educational Oscilloscope into the engineering curriculum. This paper provides the reader with the following educational facilities: the Educational Oscilloscope circuit schematics, as well as the explanation of its several components as provided to the engineering students at SUNY New Paltz.

Keywords-component; design; education; oscilloscope.

I. INTRODUCTION

Research has been conducted on the use of the oscilloscope as a tool for learning different topics. Examples of these topics include the engineering concepts of sampling and quantization [1], or even unsuspected topics, such as how to improve word-pronunciation by obtaining feedback from the speaker's voice signal displayed on the oscilloscope screen [2].

The focus of this paper is however on teaching the operation of the oscilloscope itself. Many books on the topic exist [3-5], but of course they provide knowledge that is theoretical rather than practical.

Several tutorials exist on the Internet where practical operation of the oscilloscope operation is taught via the use of oscilloscope simulation. In [6], the author discusses how to implement one such oscilloscope simulation with the objective of using it for on-line teaching.

Although the oscilloscope simulation approach has the advantage of showing what the different knobs and switches do, it has the disadvantage that it does not teach *why* they do it. Our educational objective is for engineering students to learn not only what the different control elements do, but mainly which circuits they control inside of the oscilloscope. We believe that students will have a better chance to achieve this objective by learning from a hardware circuit than from a simulated one. This belief created the concept of the Educational Oscilloscope.

The need for the Educational Oscilloscope was motivated by assessment of the SUNY New Paltz engineering course "EGE322 Electronics I Lab," performed by the paper's first author. As part of this assessment, there was a survey answered by the course students. One of the survey questions was: "Were you able to use the lab measuring instruments properly?" The common response of many students was that they were expected to use the instruments in the laboratory but had not received any training on how to do it. Such an obvious action had been overlooked! Using this student feedback, teaching of laboratory instrument operation was incorporated into the curriculum.

Although this action had a positive effect, student complaints about the use of the oscilloscope still remained, as evidenced by the following student's comment: "However, I still do not understand completely how to use the oscilloscope. Whenever I could not get a steady image, I would call the instructor, and he would touch the trigger control and make it work. He did not have time for explaining what he did in detail, as he was busy assisting other students."

To fix this problem, the Educational Oscilloscope was created. In order to implement the Educational Oscilloscope idea, a Senior Design Project was utilized. This Senior Design

Project was executed by this paper's second author and supervised by the first author.

II. THE EDUCATIONAL OSCILLOSCOPE

A. The Main Design Idea

The basic design idea is explained with the aid of Figure 1:

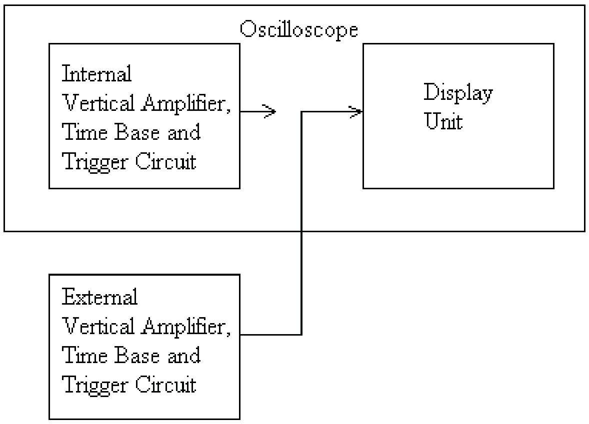

Figure1: The main idea in the Educational Oscilloscope

The oscilloscope internal components Vertical Amplifier, Time Base and Trigger Circuit are being by-passed by corresponding external components, which were designed in a Senior Design Project. The only unit retained from the oscilloscope is its display system (CRT electron beam and phosphorous screen).

With this action, the Vertical Amplifier, Time Base and Trigger Circuit have been "brought outside" of the oscilloscope unit, and therefore, students have now direct access to them. They have access to a circuit whose components they can see, touch and understand. They are able to relate operating on these components to the effects produced on the oscilloscope screen. This hand-on cause-effect interaction has a powerful didactic effect on the students' understanding of the oscilloscope operation.

It must be clarified that the external Vertical Amplifier, Time Base and Trigger Circuit are not as complex and elaborated as the corresponding components inside. As a matter of fact, for didactic reasons, our goal was to make them as simple as possible, as long as they are able to capture the essence of the internal components' functionality. As it turns out, this can be achieved by using simple Operational Amplifier, gate and flip-flop circuits, whose knowledge is acquired by SUNY New Paltz students in the Circuit Analysis and Digital Circuits courses.

B. General Block Diagram

The general block diagram is shown in Figure 2:

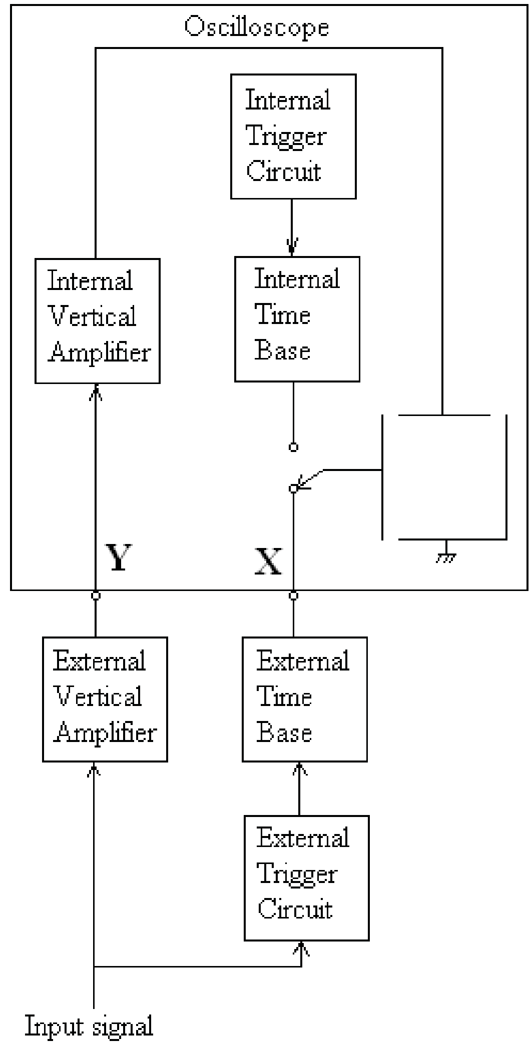

Figure 2: General block diagram of the Educational Oscilloscope

The signal to be displayed is input to the external Vertical Amplifier. This amplifier amplifies this signal with a gain that is controlled by the user. In other words, the user can control the "volts/division" by changing the amplifier's gain. The amplified signal is then output to the **Y** input of the oscilloscope. It must be noted that, although the signal experiences further amplification inside the oscilloscope, the gain of the vertical amplifier inside the oscilloscope is left fixed at a certain value, which gives the user total control of the signal amplification. (Accurately speaking, the Vertical Amplifier is the only of the three external units that does not by-pass the corresponding internal unit; it just adds to it. On the other hand, as will be seen next, the external Time Base and Trigger Circuit completely by-pass the internal ones.)

The external Time Base generates a saw-tooth waveform whose slope is controlled by the user. By changing the slope, the user controls the "Time/Division". The saw-tooth waveform is input to the "X" input of the oscilloscope and the oscilloscope is set in the **XY** mode. *This is the key idea of the design*! As illustrated in Figure 2, with this simple action, the external Time Base (controlled by the external Trigger Circuit) completely by-passes the internal Time Base (controlled by the internal Trigger Circuit). The oscilloscope's **X** input, which is normally used to produce Lissajous figures, is now used to connect the external Time Base.

By adjusting knobs on the external Trigger Circuit, the user can control the starting time of the saw-tooth waveform produced by the external Time Base. This in turn controls the instant of time at which the input signal starts being displayed. Details of the three external units are provided in the next section.

C. Individual Blocks of the Educational Oscilloscope

This section has two objectives: a) To explain to the reader the individual blocks of the Educational Oscilloscope and b) to outline the theoretical explanation on the Educational Oscilloscope that is provided to students. Accomplishing objective b) is the reason why the reader who is experienced in electrical engineering will find the following explanation simplistic. In addition, recall that the value of the paper is on education, not hardware design. The educational strategy is precisely to design very simple external circuits that are still able to capture the essential functionality of the internal ones.

External Vertical Amplifier:

The external Vertical Amplifier is shown in Figure 3:

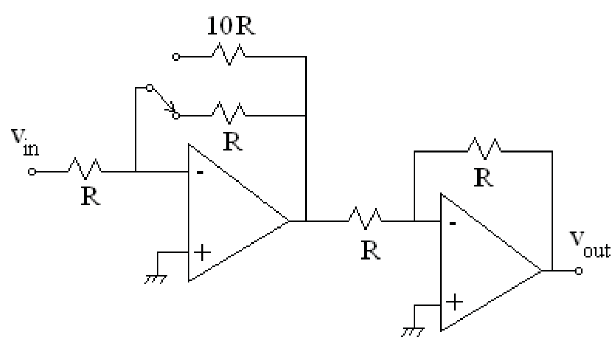

Figure 3: Schematic of external Vertical Amplifier

The equation of this circuit is:

$$v_{\text{out}}(t) = K_1 v_{\text{in}}(t), \quad (1)$$

where in the example, constant K_1 can take the values $K_1 = 1$ or $K_1 = 10$, depending on the position of the switch. The input signal to be displayed is connected to v_{in}, and v_{out} is connected to the **Y** oscilloscope terminal. Now, the vertical displacement $y(t)$ on the oscilloscope screen is proportional to the voltage applied to the **Y** terminal, that is:

$$y(t) = K_2 v_{\text{out}}(t), \quad (2)$$

where K_2 will keep the same value provided that the vertical gain control on the oscilloscope panel is not changed. Combining equations (1) and (2):

$$y(t) = K_1 K_2 v_{\text{in}}(t). \quad (3)$$

This means that the vertical displacement is proportional to the input signal through the proportionality constant $K_1 K_2$, and that thereby the "volts/division" can be adjusted externally by changing the value of K_1.

External Time Base:

The external Time Base is shown in Figure 4:

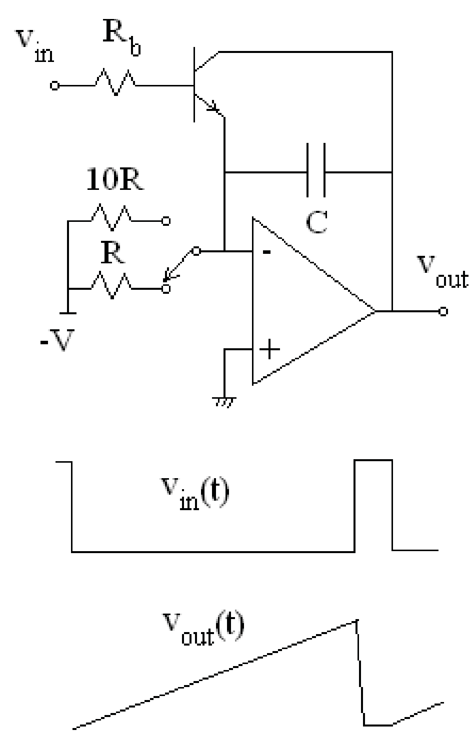

Figure 4: Schematic of external Time Base

The signal v_{in} is a digital signal. On one hand, when $v_{\text{in}} = \text{LOW}$, the transistor is off, which allows capacitor C to charge at a constant rate. This results in the output voltage being a ramp, whose equation is:

$$v_{\text{out}}(t) = K_3\, t \quad \text{for} \quad v_{\text{in}}(t) = \text{LOW}, \quad (4)$$

Where $K_3 = V/(RC)$ or $K_3 = V/(10RC)$, depending on the position of the switch. On the other hand, when the input voltage is high, the transistor saturates and shortens the capacitor, which produces:

$$v_{\text{out}}(t) = 0 \quad \text{for} \quad v_{\text{in}}(t) = \text{HIGH}. \quad (5)$$

The result is a saw-tooth waveform $v_{\text{out}}(t)$ (see Figure 4), which is connected to the **X** oscilloscope terminal. Now, the horizontal displacement $x(t)$ on the oscilloscope screen is proportional to the voltage applied to the **X** terminal, that is:

$$x(t) = K_3 K_4 t \quad (\text{for } v_{\text{in}} = \text{LOW}) \quad . \qquad (6)$$

This means that the horizontal displacement is proportional to "time" through the proportionality constant $K_3 K_4$, and that thereby the "seconds/division" can be adjusted by changing the value of K_3, which is the slope of the ramp (Equation 4). It also means that "time" starts at the instant where signal v_{in} becomes LOW and stops at the instant when signal v_{in} becomes HIGH. In order for the input signal image to be steady on the oscilloscope screen, the start and stop times have to be synchronized with the input signal. This is accomplished by the circuit described next.

The External Trigger Circuit:

The action of the external trigger circuit is explained with the help of Figure 5:

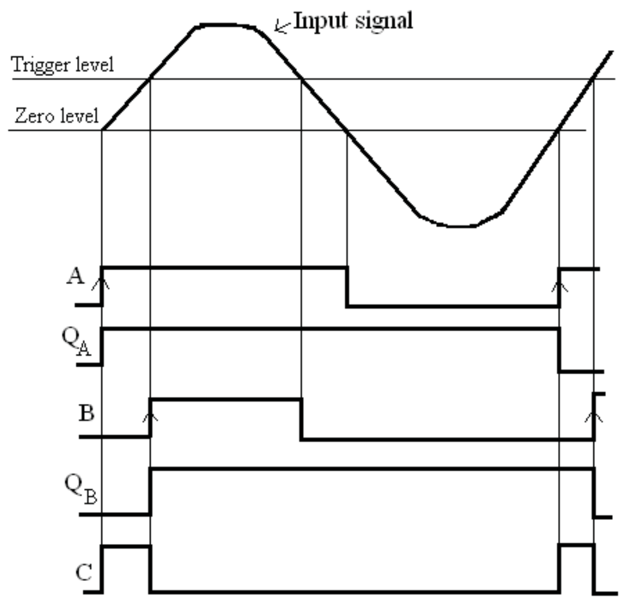

Figure 5: Waveforms in external Trigger Circuit

As illustrated by the waveforms in Figure 5, the external Trigger Circuit is very simple (remember the idea is just to capture the essence of the trigger functionality). The objective is to generate waveform C so that it can be applied to the input v_{in} of the external Time Base circuit (Figure 4). We achieve this objective in the following way: First we generate signal A, as the result of comparing the input signal with zero volts. The leading edge of signal A will be used to clock a "toggle" flip flop, thus producing signal Q_A. Then, we generate signal B, as the result of comparing the input signal to a triggering level selected by the user. The leading edge of signal B will be used to clock a "toggle" flip flop, thus producing signal Q_B. Finally, from Figure 5, note that signal C is an "exclusive or" (XOR) of signals Q_A and Q_B, that is:

$$C = Q_A \overline{Q}_B + \overline{Q}_A Q_B = Q_A \oplus Q_B \, . \qquad (7)$$

Using the precedent analysis, the circuit design of the external Trigger Circuit is straightforward, as shown in Figure 6:

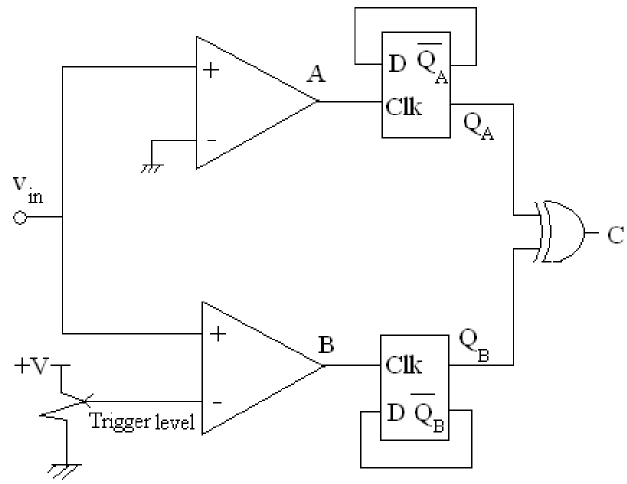

Figure 6: Schematic of external Trigger Circuit

The input signal to be displayed is connected to terminal v_{in} of Figure 6, and C is connected to terminal v_{in} of Figure 4. This means that C is the signal that controls the Time Base ramp waveform. In fact, C switching to the LOW state starts the ramp and C switching to HIGH stops the ramp. Therefore, by changing the trigger level (C switching to LOW), the user controls the start of the ramp, and thus the starting value of the displayed input signal.

In this very simplistic Trigger Circuit, the ramp is terminated when the signal crosses zero with a positive slope, and the saw-tooth waveform remains at zero value during the time interval when $C = \text{HIGH}$. Since our elementary external Trigger Circuit does not suppress the oscilloscope electron beam during this time interval, the displayed image will exhibit "retrace". Also note that this elementary trigger circuit lacks other features, such as the possibility of triggering the ramp with the negative slope of the input signal. Nevertheless, these inconveniences do not subtract from the didactic value of the circuit, which still manages to capture the essence of the trigger circuit operation.

Finally, Figure 7 is a snapshot of the input and output waveforms of the external Trigger Circuit. The sinusoid is the input waveform and the rectangular pulse is the output waveform (signal C in Figure 5).

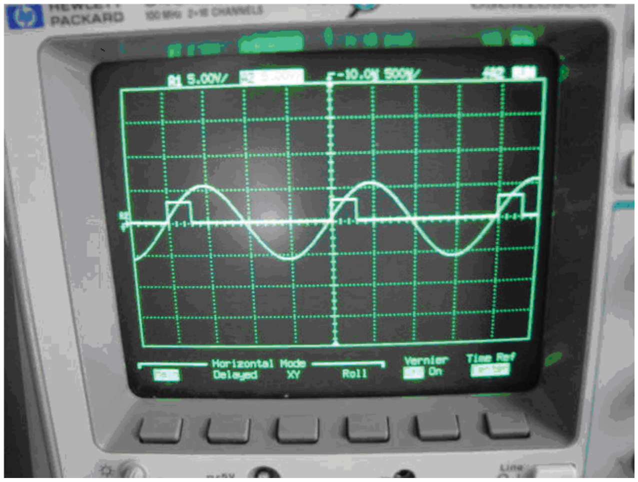

Figure 7: Waveforms of external Trigger Circuit

Figure 8 shows the previous sinusoid waveform plus the saw-tooth waveform produced by the external Time Base.

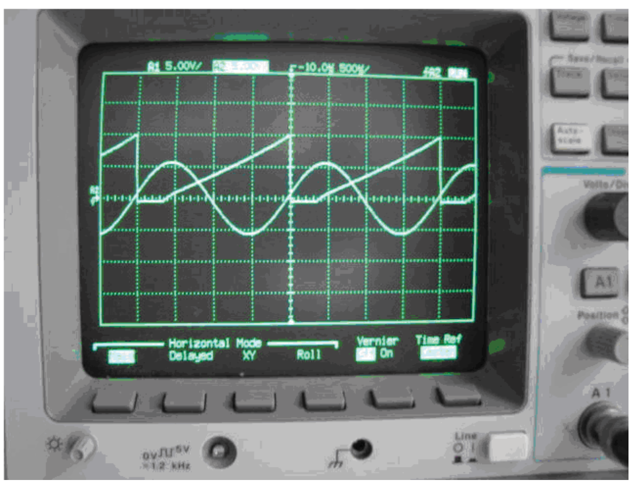

Figure 8: Saw-tooth waveforms of external Time Base

III. IMPLEMENTATION OF THE EDUCATIONAL OSCILLOSCOPE TOOL

The Educational Oscilloscope tool should not be implemented in an introductory level course such as Circuit Theory, because students have not yet acquired the theoretical knowledge needed to understand it. Therefore, students taking an introductory circuit laboratory should manage via the simplistic approach of hitting the “auto scale” button. Their time for learning the oscilloscope in more depth will come later.

At SUNY New Paltz this time is at the beginning of the course EGE322 Electronics 1 Lab. By the time that students take this lab, they already have acquired knowledge on the Operational Amplifier (as a block) and on gates and Flip Flop digital circuits, which is essential to understand the circuits used in the Educational Oscilloscope.

The Educational Oscilloscope is first introduced to the students as a lecture, which was basically outlined in Section II. After the lecture, and before students are allowed to put their hand on the Educational Oscilloscope, they are required to answer a set of questions. The objective of these questions is to force students to generate a theoretical expectation for what the consequences of their experimental actions will be. Without the students being able to produce this theoretical expectation, the didactic experience would have little value.

The questions were carefully devised to guide the learning process. There are three sets of questions: 1) Questions on the Vertical Amplifier, whose objective is for students to learn why and how the “volts/division” scale is changed; 2) Questions on the Time Base, aimed at teaching students why and how the “time/division” scale is changed; and 3) Questions on the Trigger Circuit whose objective is to teach students: a) why the time base generator has to be synchronized with the input signal and b) How to control the instant of time when the input signal starts being displayed.

Once students have answered this set of questions satisfactorily, they proceed to make measurements. By verifying their answers experimentally they gain powerful knowledge and understanding, as corroborated in the next section.

IV. ASSESSMENT OF THE EDUCATIONAL OSCILLOSCOPE

A specific assessment in the course EGE322 Electronics 1 Lab. was designed to test the efficiency of the Educational Oscilloscope tool. This assessment was conducted at the beginning of the fall 2008 semester, without the Educational Oscilloscope, and at the beginning of the fall semester of 2009, right after the Educational Oscilloscope was implemented for the first time.

The following rubrics were used in the assessment:

TABLE I: RUBRICS USED FOR ASSESSMENT

4	Deeply understands the oscilloscope operations. Consistently does all or almost all of the following: Is able to obtain the desired image on the oscilloscope screen by taking actions (operating on knobs and switches) based on his/her deep understanding. Does not need any help from the instructor.
3	Has an intuitive understanding of the oscilloscope operation. Does most or many of the following: After struggling for some time, is able to obtain the desired image on the oscilloscope screen. His/her actions (operating on knobs and switches) are based on intuition and on memorization of previous experiments. Needs minimal or no help from the instructor
2	Has a weak understanding of the oscilloscope operation. Does most or many of the following: After operating some knobs and switches, is able to get a non-stationary image on the oscilloscope screen. At this point, in order to get a steady image on the oscilloscope, he calls the instructor for help.
1	Has no understanding of the oscilloscope operation. Consistently does all or almost all of the following: After connecting wires, immediately calls the instructor for help. Usually uses the excuse: "I have connected everything like in the lab schematics, but it does not work".

Figure 9 shows the results of the assessment. The vertical bars represent the percent of students that fall in a particular rubric, as defined in Table 1. The white bars correspond to assessment performed in the fall of 2008, without the Educational Oscilloscope, and the black bars to assessment performed in the fall of 2009, with the Educational Oscilloscope.

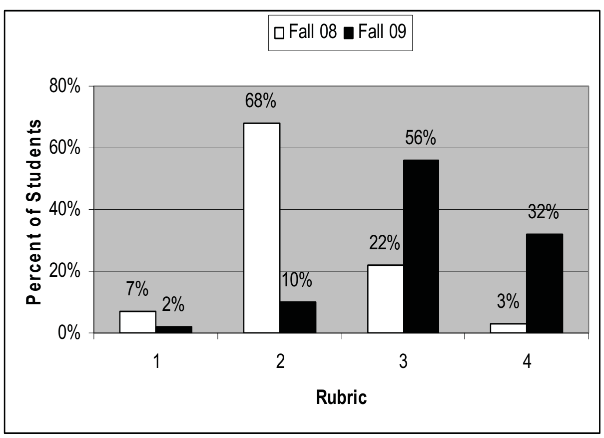

Figure 9: Assessment of Electronics 1 Lab without and with the Educational Oscilloscope

Incorporating the Educational Oscilloscope has the effect of shifting students from the lower to the higher rubrics. In fact, the student population migrates into the higher rubrics 3 and 4.

V. CONCLUSIONS

We have utilized a Senior Design Project to develop an Educational Oscilloscope, which is a powerful tool for teaching students how the oscilloscope works. The main idea is to by-pass the oscilloscope internal components by external ones that students can understand and manipulate.

The developed tool exhibits a very simple design, solely based on Operational Amplifiers, gates and Flip Flops. This is not a drawback, but rather an important didactic advantage. In fact, students who have taken basic engineering courses such as Circuit Theory and Digital Electronics are able to comprehend the design in its totality. Of course, such a simple design of the external components cannot duplicate all the functions performed by the oscilloscope internal components. This is quite acceptable because the main goal of the external components is to capture the functionality principle of the internal counterparts.

The proposed teaching approach is highly effective. This conclusion is supported by the graph of Figure 9, where we can compare the distribution of students in the different rubrics for the cases a) without the Educational Oscilloscope (white) and b) with the Educational Oscilloscope (black). We can see that the student population mainly migrates from the lower rubric 2 to the higher rubrics 3 and 4. According to the definition of rubrics in Table 1, this means that an increased number of students become better at completely understanding the oscilloscope operation, or at least they are able to understand it well enough that they do not need assistance from the instructor.

ACKNOWLEDGMENT

The second author would like to acknowledge Professor Damudaran Radhakrishna (Damu) from the Department of Electrical and Computer Engineering at SUNY New Paltz for his help in the design of the logic circuit in the external Trigger Circuit

***Abstract*— This paper is about how to improve the experience of students of the subject of database theory and practice, a subject many find somewhat daunting. It is by experiment that most scientists learn most about their discipline and in this paper the following ideas can be explored in simulations that in most cases use access to a database so that the exercises are personalised.**

The simulations are listed below.

- **Simple Entity-Relationship diagrams: Where simple Entity-Relationship diagrams can be composed from a set of components and their validity checked.**
- **Entity-Relationships and tables that describe the entities: Where the student has to decide from tables of two entities the degree of participation and the participation conditions. With prompting the correct solution can be found and as many attempts as necessary are possible.**
- **Structured Query Language (SQL): Given a database various SQL queries can input and the way that the queries are dealt with are shown in detail not just the final result.**
- **Functional dependency: Given a table from a database this can used to find out whether there is any functional dependency between any of the columns and also to show what the primary key/s might be.**
- **Normalisation: A topic that confuses may students. This allows table to be split into a number of sub-tables and the result can be tested as to whether the selected table can be joined together to form the original table.**

Each of these ideas has a simulation and these will be discussed in terms of how to run the simulation and explaining what the simulation is trying to teach. There are some third party software requirements and these will be explained together with the solution that is used for the demonstrations.

Keywords-Entity Relationship diagrams, participation conditions, multiplicity, Structured Query language, Tables, Normalisation, Functional dependency

I. INTRODUCTION

The tools are designed to be used with any database as they have a configuration files that are used to specify the ODBC-JDBC connection. There are also data files that can be used to store queries that have been used and have been shown to produce correct results. These data files are necessarily different for the various applications. For demonstration purposes a number of small databases files have been constructed that are typical database applications, one concerns a mythical Hospital and another, an online University.

To allow for connection a number of databases a configuration file is used that contains the details of the connection request required by the databases. The purpose of introducing a number of databases is to show that the software, written in java, is generic and can thus be customised by the user without any need to change the software. The configuration file format for the Open University course [7] which uses SyBase is shown below:

```
Hospital;jdbc:odbc:HospitalDSN;m359;m359
University;jdbc:odbc:UniversityDSN;m359;m359
```

Similar formats are used for the corresponding Excel and Access files.

```
University_Excel;jdbc:odbc:university;"";""
Hospital_Excel;jdbc:odbc:hospital;"";""

Hospital_Access;jdbc:Access:///C:/Netbeans_M359/Hospital.mdb;"";""
Univesity_Access;jdbc:Access:///C:/Netbeans_M359/University.mdb;"";""
```

The separator used in the Java simulation program is ";", the semi-colon and hence its use in constructing the entries in the configuration file

II. BACKGROUND

The idea of an Entity-Relationship model dates from 1976 at which time the paper by Peter Chen [1] proposed unifying the models that had been used prior to that, the network model, the relational model and entity set model to that of the Entity-Relationship model. Appendix 1 shows instances of each of these derived from Chen's paper. The idea of mandatory and optional participation does not appear to be supported at this time.

It seems that it took academia another six years before there was any publicised interest in applying these ideas to the teaching of database technology. Carol Chrisman [2] introduced the idea of using entity relationship models as a tool in the teaching of database design using the entity relationship approach. The notation used is that of Chen.

Then in 1987 another author Judith D. Wilson [3] takes up the baton and analyses some of the problems associated with how students use entity-relationship model and how to circumvent them.

An interesting contribution as regards using computers to help in learning SQL came in 2004 from tutors at the University of Queensland, Australia [4]. It was called SQLator and enabled students to check the correctness of a query before submitting it to a database. It was however limited to this one application and did not concern itself with entity relationships.

In 2007 Edward Sciore [5] introduced a system that dealt again with SQL but this was concerned with how an SQL query was processed in the computer that hosted the application.

In 2008 there was another SQL query simulation [6] that dealt with a range of queries that would be used in the construction and testing of a database design, but again notice limited to this one area. This paper was as much interested in how the system dealt with the query as to how structure the query

III. ENTITY-RELATIONSHIP DIAGRAMS

A. The Graphical User Interface (GUI)

This is the only tool that is based entirely on simulation. At this stage of learning in a database course it is only concepts that need to be learnt. The tool can be personalised using component names that are part of the course and also Chen's notation or Crows foot notation can be used As can be seen from Figure 1, the screen shot of the simulation, there are four text areas and a number of graphical symbols. The two entities are shown together with the relationship that exists between them. The purpose of the exercise is place two of the participation conditions at either end of the relationship and for information about the choice to be displayed in the text areas.

In some cases the choice is a combination where a simple relationship is not possible but has to be represented by a Relation for Relationship instead. The screen is slightly redrawn with another entity in the centre and relationships connecting all three entities. An explanation to this effect is given in the top text area, it is hoped that this is sufficiently detailed for the student to continue with what can be a difficult choice.

B. Information files

There are two sets of files relating to the text areas they have been called Explanations and Relations. For some users the explanations may need to be expanded and this is obviously possible as they are only text files. There are however some twelve files that would have to be changed for it to be complete

a. Explanations

These describe how the two entities are related in terms of participation conditions that have been chosen they appear in the top text area. An example where a RELATION FOR RELATIONSHIP has needed to be used

"Entities A and B have discretionary participation as is shown. But now the 'many' relationship of entity B to entity A is replaced by the 'many' relationship of the entity RELATIONSHIP with entity A. Both participation conditions for the entity RELATIONSHIP are of necessity mandatory"

b. Relations

These set out the entity descriptions in a table format as would be used when starting the potential design of a new database. The student then gets used to this type of presentation.

"Relation RELATIONSHIP
A1: A1s
B1: B1s
primary key A1, B1
foreign key B1 references A.
foreign key A1 references B."

An example of the text in the lower middle text area that is included when a RELATION FOR Relationship has needed to be used.

Foreign and primary keys are shown, as would be the case, in the other two lower text areas.

C. The exercise

The student is presented with the initial screen and has some instructions that explain the meaning of participation conditions and multiplicity and is encouraged to see how the entity table for each entity is set out in the text areas above each of the entities. Any combination of symbols is possible and the result for each should be noted. When those choices that give rise for the need of a Relation for Relationship are chosen, the student would be encouraged to note what these were but not pursue it but continue without completing that choice until all choices had been tested.

The pairs of symbols that do not require a Relation for Relationship are now known and these can be used to try and satisfy the situation where symbols have to be attached to all the three entities that are shown. The first text area gives some clue as to what might be an appropriate choice.

Figure 2 shows a completed exercise where the initial selection of participation conditions was optional and both ends had single occurrences. An explanation of why this representation is required is given in Appendix 2

D. The lessons learnt

The student should have now some understanding of how relations are expressed in the definition tables. How the domains are shown and how the primary and secondary keys are shown. There should also be some understanding of what is meant by a foreign key and hopefully why they are needed.

The relation for relationship idea will need further explanation but at least the idea will have been firmly entrenched.

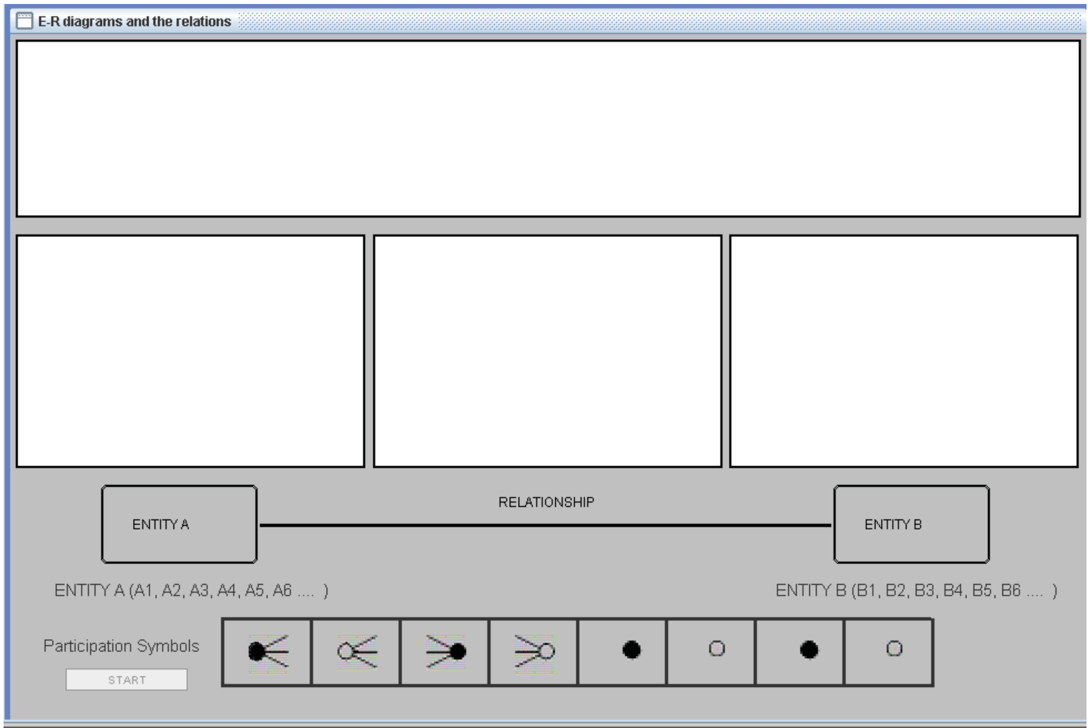

Figure 1. The initial screen for Entity Relationship diagrams.

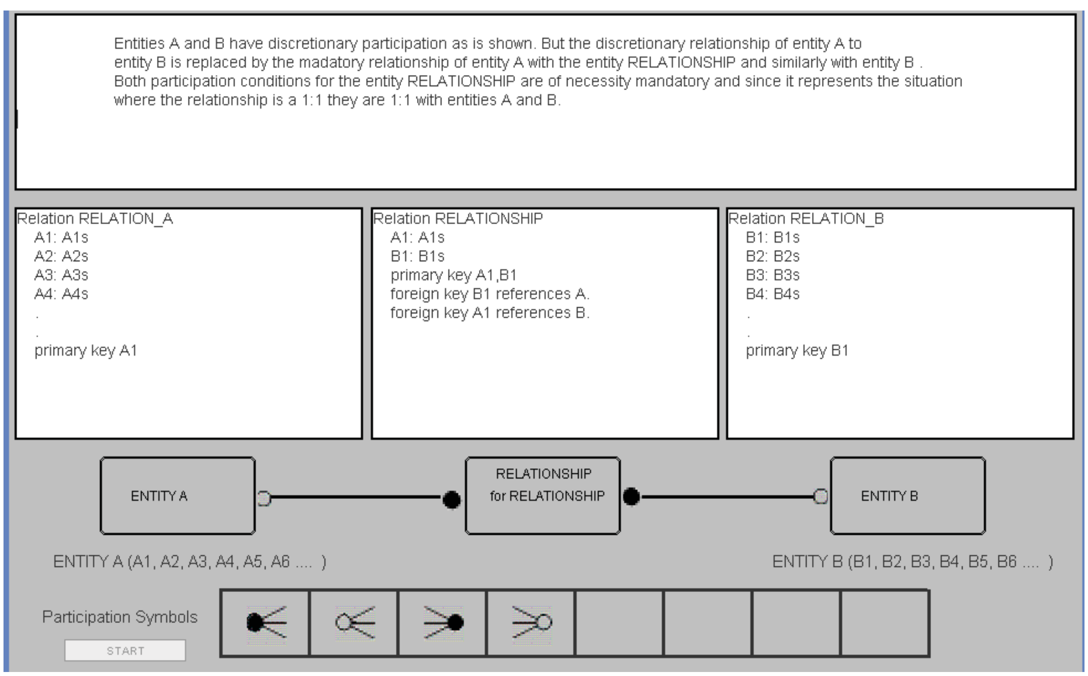

Figure 2Tables and ER diagrams that correspond to them

IV. ENTITY-RELATIONSHIPS AND TABLES

A. *The graphical user interface (GUI).*

There are three drop down menus, one to choose the database and two that choose individual tables from that database. The tables are displayed in their entirety once they have both been chosen. Two panes display the tables selected and the progress of the exercise.

For this tool it was decided to use a database for the data that was needed as this the simplest way of ensuring that the tool was general purpose and could be used on any database

Figure 3 shows the screen after a student has completed an exercise successfully. The same drawing and symbols are used as for the entity-relationship diagrams.

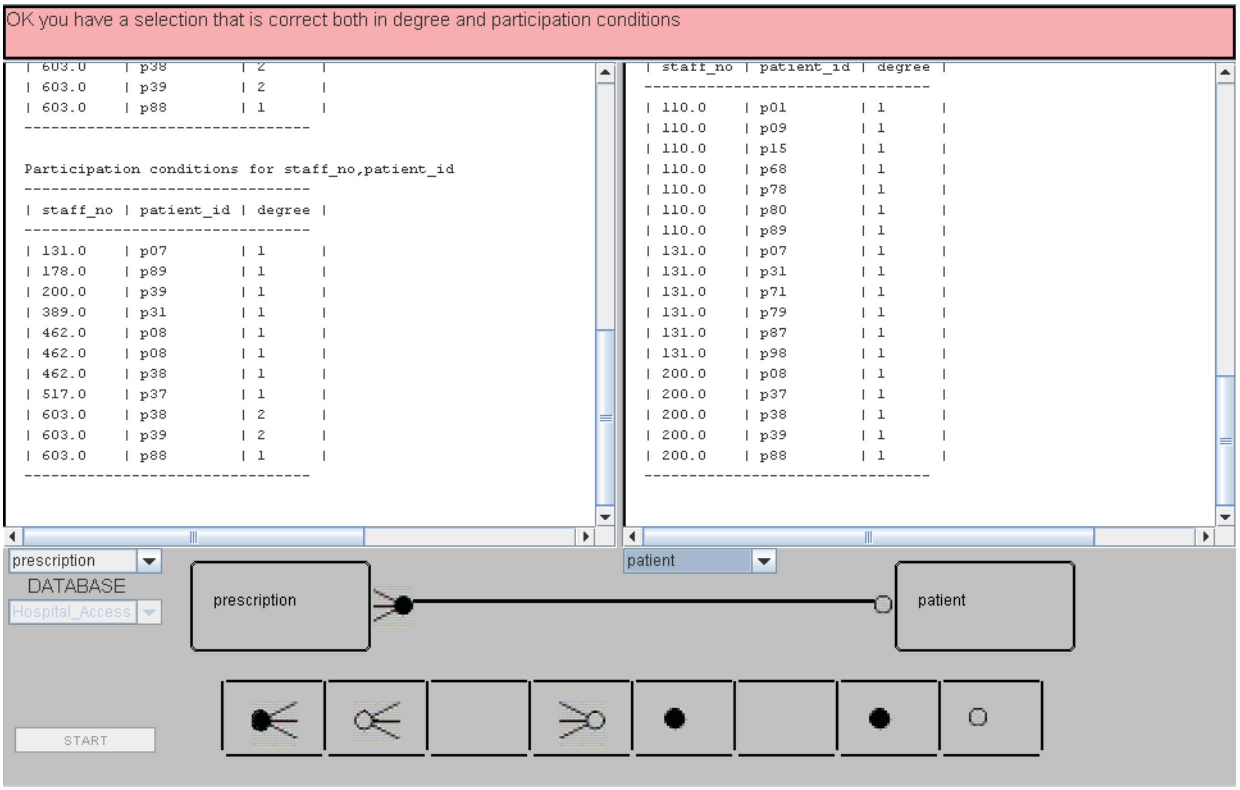

Figure 3Tables and ER diagrams that correspond to them

B. *The exercise*

Initially no database is selected and no tables. The top drop down menu on the left-hand side has a choice of database.

Some of the databases that are used relate to an Excel files some to Access files and some to Sybase files although in fact they contain the same data. When the database has been selected the other two drop down menus are available and tables form the chosen data base are listed. A choice has to be made for each menu and the table for each is displayed.

The student has to study the table and decide upon the participation conditions in degree and whether it is discretionary or mandatory. The symbols are chosen to reflect their decisions and placed on the ER-diagram. Whether this has been success or otherwise is shown in the upper text area with messages such as:

"OK you have a selection that is correct in degree but not participation conditions change the conditions" OR perhaps

"Wrong symbols chosen use the database output to make a better informed choice of symbols".

The progress of the exercise is thus apparent and only complete when the student gets the message *"OK you have a selection that is correct both in degree and participation conditions"*.

The first message means that the multiplicity of one or both the symbols needs correcting but that the participation conditions whether they should be shown as mandatory or discretionary has been achieved. The second message indicates that neither of the choices made is appropriate. In either case the table content is condensed so that for each entry in each table the degree of participation is shown and this makes the choices more apparent.

Notice that after the tables have been selected and the student has made an initial choice of symbols that screen is updated to show the participation conditions in degree for the common key between the two tables. This is helpful especially in the situation where the tables a long.

C. The lessons learnt

The strongest lesson here is the fact that trying to appreciate a mass of data can be a daunting exercise, even for the relatively small tables that are available, and that reducing the size of the problem by looking only at the primary key and the multiplicity of the key it is then possible to analyse the data visually more easily. Also it should be possible for the ideas mandatory and discretionary participation conditions to become clearer.

V. STRUCTERED QUERY LANGUAGE (SQL)

A. The graphical user Interface (GUI)

There are two text areas, one to show the output from the database for a query that has been input and a second one used to write a query. This text area is editable but can also have text inserted from a multiple choice drop text box. The database source can be chosen from the databases that are available and which have been written into the configuration file.

There is also an area on the screen where the meta-data corresponding to the chosen database can be displayed if the metadata exists, these are the table names and the column names within the database. This is useful when framing a query as these details are needed to write a correct query.

B. Query examples.

And typical entries for the University database, for SQL queries, are also as below:

SELECT * ; FROM staff;
SELECT name, staff_number ; FROM staff;
SELECT DISTINCT staff_number ; FROM tutors;
SELECT staff_number ; FROM staff ; WHERE name = 'Jennings';

C. The scope and format of the simulation of SQL queries.

The simulator is capable of dealing with queries that contain:

- SELECT clauses
- FROM clauses
- WHERE clauses
- GROUP BY clauses
- HAVING clauses and
- ORDER BY clauses
- And a single level of nesting

The simulator not only carries out the processing of the requested query but shows all of the steps in the logical processing model in the order that the database would carry out the necessary calculations. The tables are shown separately and titled to show their relevance to the various stages.

B. The exercise

Figure 4 shows the result of displaying the result of the query “SELECT AVG (height) AS average_height FROM patient”. The screen shows the complete SELECT clause and just the heading for the FROM clause. The order in which they are displayed is the order in which the database will process such a query.

The exercise proceeds by the student choosing the database from the upper drop down menu and then if a table of queries exists the query that they wish to run. Alternatively if the query that the student wishes to run is not available this can be typed into the upper right text area. Of course they have to get the syntax right for query to give any result.

The Sybase examples have metadata associated with them that allows the display of the columns of the relations. This is more of an aid to memory but it can be useful to have that information on the screen rather in a book that has to be searched through.

C. The lessons learnt

There are many lessons that the student will learn from experimenting with prepared queries and queries that they structure themselves.

The way that the various stages of the query are shown will help understand how the database deals with a query and also to construct their queries in a way that the database will understand.

They will also learn the need to be absolutely correct with the syntax of their own queries because otherwise the database will give an error message which usually is not that informative.

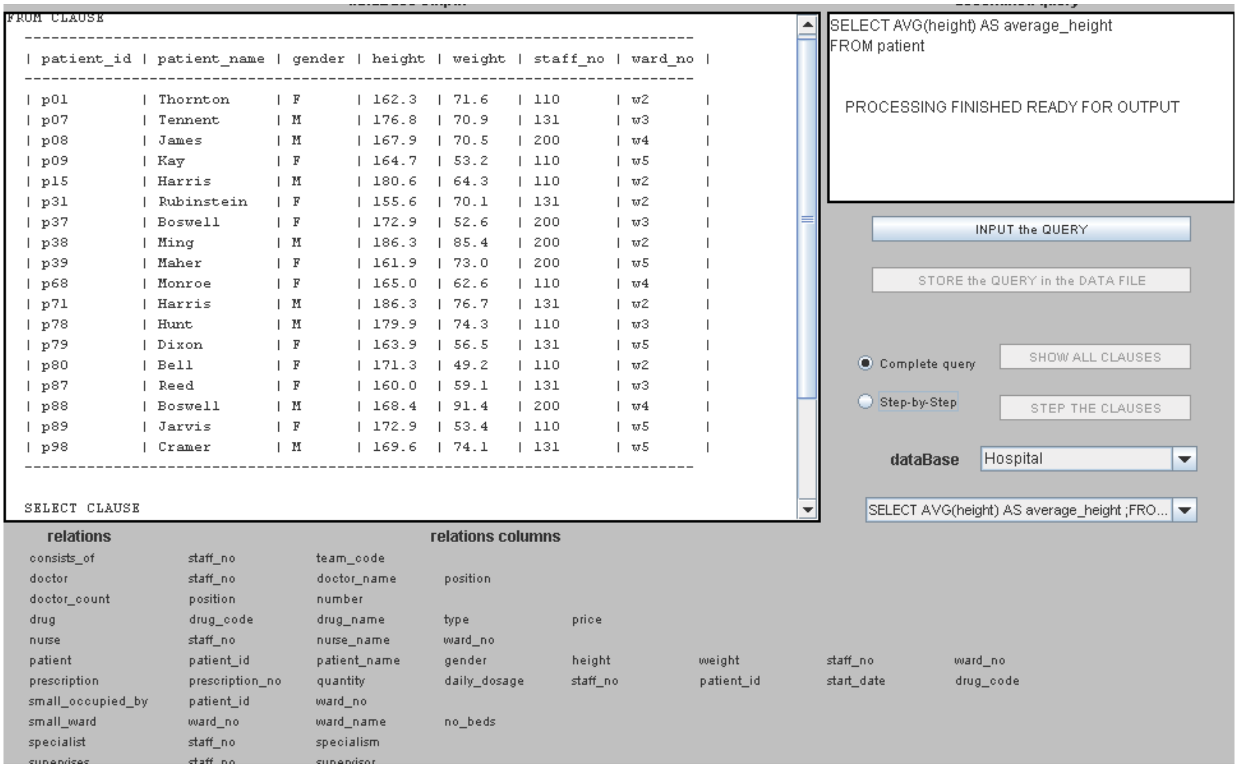

Figure 4 The screen showing the "FROM and SELECT" output

VI. FUNCTIONAL DEPENDENCY

A. The graphical user Interface (GUI)

As can be seen, from Figure 5, there are three areas shown on the right hand side of the screen, they have scroll bars that appear if necessary. The three areas are to display the results of single, double or triple determinant terms used for finding any functional dependencies within a table. There is screen area where the table is written out and three drop down menus and two buttons. The dropdown menus are used to choose a database and a table from that database or a data source being an individual page.

The far left hand button allows the exercise to be restarted at any time but preferably when one exercise has been completed. The reset selection button is used to begin a search through the table once a determinant has been chosen. The determinant is set via the check boxes above each column.

B. The exercise

As explained in the GUI description the START/RESTART button is pressed and that allows the choice of the database followed by the choice of the table.

The determinant to be tested is then chosen and the when satisfied the START SEARCH button is pressed. The student now has to work a little bit harder. The table has to be stepped through for each of the columns that are not part of the determinant. Once a column has been stepped through and a dependency is detected between the chosen determinant and the column then this is notified in one of the text areas at the bottom depending upon the length of determinant that has been selected.

This same procedure has to be carried out for all of the columns not within the determinant chosen. Clearly if all of the columns give rise to a notification of a dependency then a possible primary key has been found.

Various combinations can be tested but they should be combinations that the student thinks from observation would have some dependencies between the chosen determinant and the remaining set of columns.

C. The lessons learnt

A student with little idea of the meaning of functional dependency would eventually grasp the idea that it meant that for each particular determinant there could only be one instance of a parameter with a particular value in a column if that column was functionally dependent. If the column had two entries of the same value that there would be no functional dependency for that column. They would be able to understand the meaning of a primary and perhaps secondary key if there were one in the table The significance of the results should be seen when using the normalisation simulation as normalisation depends upon being able to identify any dependencies within the table

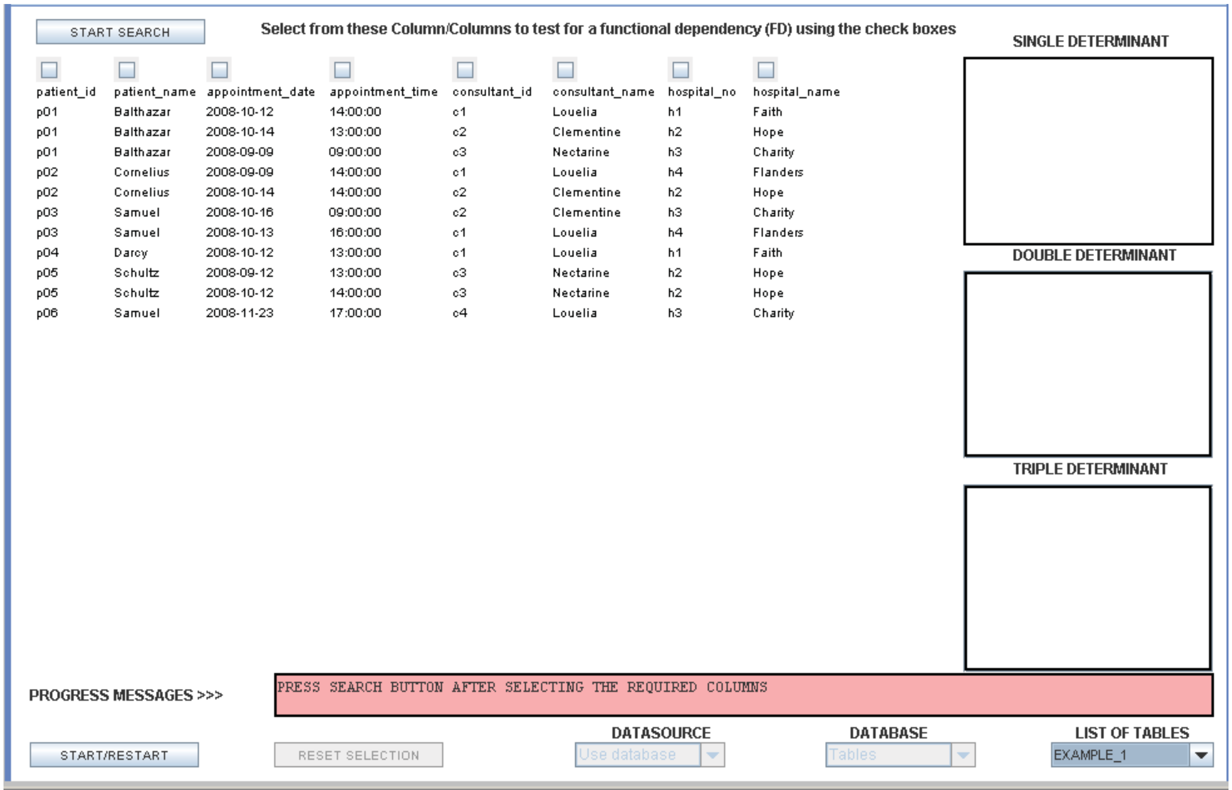

Figure5. The initial screen for functional dependency exercises where the database and table have been chosen

VII. NORMALISATION

A. The graphical user interface (GUI)

Figure 6 is a condensed view of this interface being in fact three pages to allow the display of the relatively large amounts of data that is possible using this particular tool. In Figure 6 the interface is shown part the way through an exercise. There are two prominent text areas; the top one is where the selected table is displayed and the lower one where de-selections of columns from this table are shown separately. The top text area also has a number of check boxes to allow the columns chosen in a selection to be indicated. There are drop down menus used to choose a database and a table within that database.

Initially the SHOW SELECTION button is enabled and when pressed will display the columns chose in the lower area. In order to make a fresh selection the RESET SELECTION button has to be pressed which resets the check boxes.

When the student is satisfied with all of their selections the RECOMBINE button is pressed and this joins the separate tables into one table. If the selection has been carried out correctly the original table will be drawn in the lower text area. If there has been a mistake and there is no dependency between the tables the table that results are dependant on which database is being used. For the Access databases the table that results is much longer and clearly wrong in this context. For the Sybase files the database indicates an error because the selections cannot be joined. The Excel databases cannot deal with joins and thus always give an error even if the table has been correctly partitioned.

B. The Exercise

This exercise should really be carried out after examining the chosen table for dependencies and the student should use the results to make an informed choice of selections. Selections are made and the recombination that results studied and explained even if there are errors. An example of a very small table is given in appendix 3 and it shows the effect of correct and incorrect normalisation.

C. Lessons learnt

Students find normalisation quite confusing and being able to experiment with different selections can help in lessoning the confusion. They learn how to split tables into a number of tables where the columns are sensibly grouped to include information that is relevant to individual tables. They learn to discriminate between what is needed in a table and what can usefully be put into a different table. They also learn that to be able to recreate the original table after division that there has to be information in both tables that is common to both tables and has some dependency. They should also appreciate the benefit that using the functional dependency simulation has given to them in running this simulation.

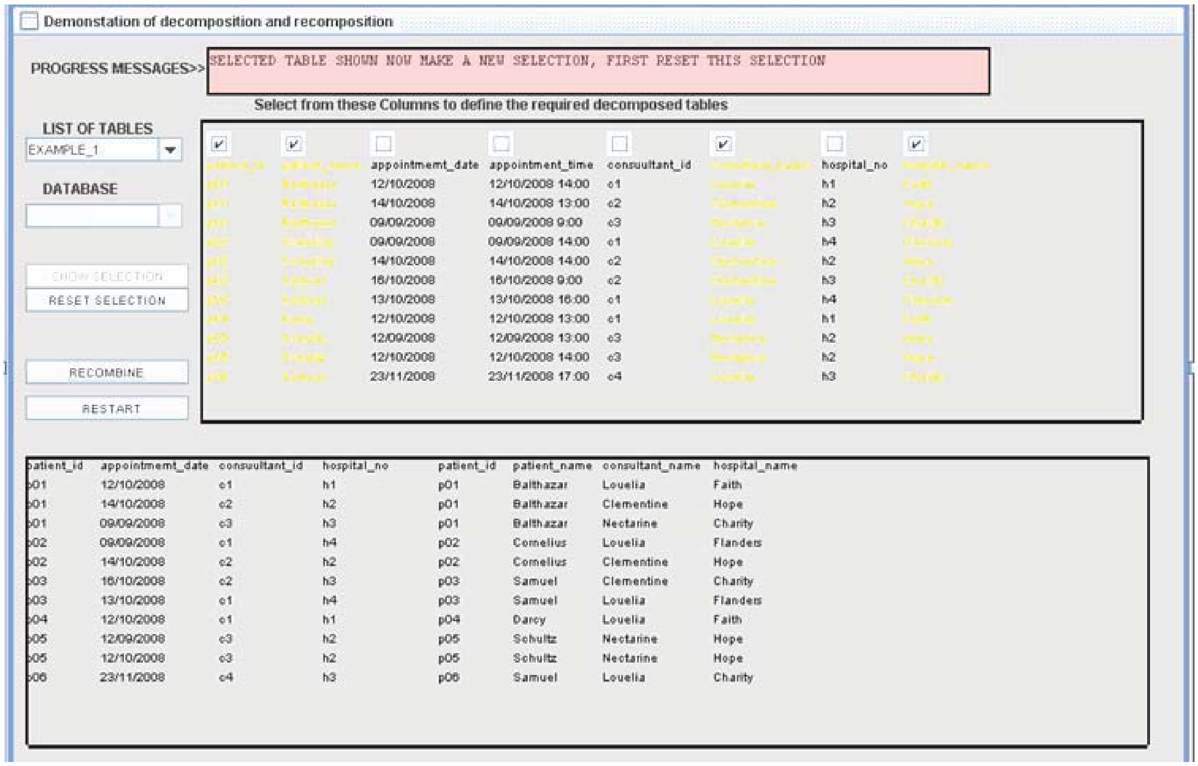

Figure 6. Selection of Tables prior to recombining them

VIII Third party software

To demonstrate that the simulations that involve access to a database a number of databases that are readily available, if not freely available have been used. MicroSoft Excel and MicroSoft Access are generally available to students as MicroSoft now offers fairly generous discounts to students so these were obvious choices. The Open University course ‘Relational databases: theory and practice’ uses SyBase for much of the SQL that the course uses and hence its use here.

Each of the databases used must have an ODBC data source registered with the Administrative tools of the host computer, such a registration is similar to the one in Figure 7. Figure 8 shows the need to specify the path to the database file in the case of an Excel file.

Excel has an ODBC-JDBC bridge as part of Excel so this would seem a great convenience to use Excel. It has its drawbacks as Excel lacks some of the facilities of a full database. Access does not have a bridge included and this did seem to be stumbling block at one point. However, a solution was found that had all of the capabilities required an ODBC-JDBC bridge from Hongxin Technology & Trade Ltd.

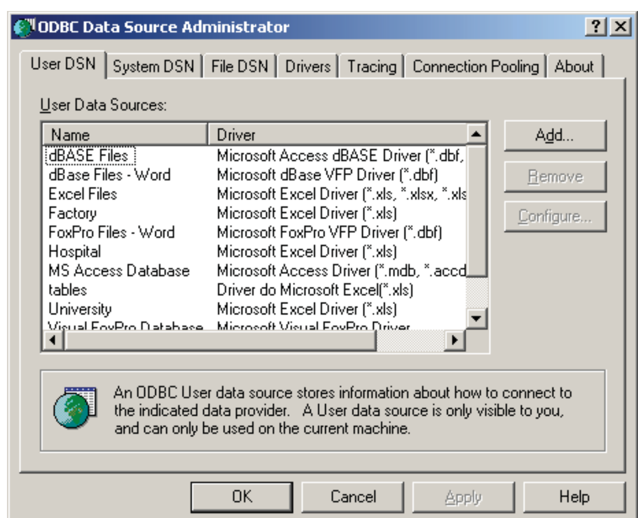

Figure 7 The user DSN examples.

The specification states “*HXTT Access packages include a Type 4 JDBC driver. Type 4 indicates that the driver is written in Pure Java, and communicates in the database system's own network protocol. It supports { UNION | INTERSECT | EXCEPT | MINUS } [ALL] query , INNER JOIN, FULL JOIN, LEFT JOIN, RIGHT JOIN, NATURAL JOIN, CROSS JOIN, and sub-query which includes single-row sub-query, multi-row sub-query, multiple-column sub-query, inline views, and correlated sub-query.”*

Sybase is a full database but does require a more complex setting procedure.

For students it might be a useful exercise for them to set up some Excel and Access files them selves. Full instructions can be found online from JavaWorld.

VIII ACKOWLEDGEMENT

I wish to thank Tony Valsamidis a senior lecturer at the University of Greenwich for his help in making it possible for some of these simulations to be tried out in the classroom in 2010.

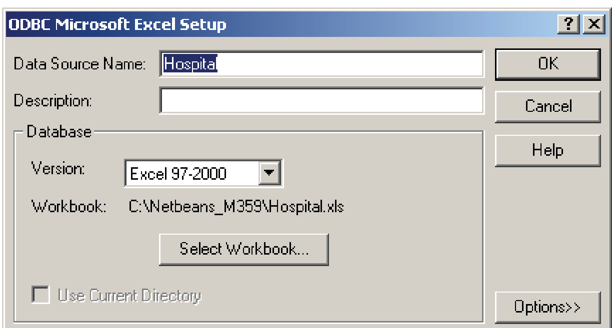

Figure 8 File setup as used

IX TESTING

Testing of the tools is to be carried out in 2010 and some results may be available later in 2010. The consensus of those that have seen the software is that it should help in students' understanding of relational database principles

XI Appendices

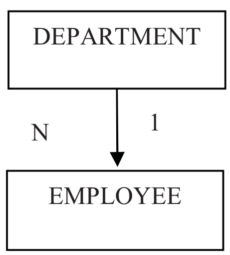
Appendix 1

A relational model of employee

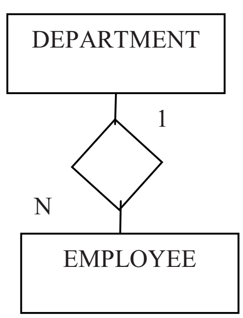
Role		Legal	Legal	Alternative	Alternative	
Domain	Employee-number	First-name	Last-Name	First-Name	Last-Name	No-Of-Years
Tuple	2566	Peter	Jones	Sam	Jones	25
	3378	Mary	Chen	Barb	Chen	23

Employee is the Relation and the components of the domain are the attributes.

A simple Network model



The equivalent entity-relationship diagram

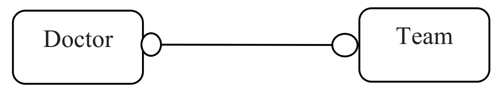


The above are all taken from Chen's paper.

Appendix 2

An example where the Relation for Relationship is needed

Consider a relationship had optional participation at both ends and use the example shown in figure 9.



Doctor (StaffNo, DoctorName, Position)
Team (TeamCode, TelephoneNumber)

Figure 9 an inadmissible Entity Relationship

Some teams are not headed by a doctor and some doctors do not head teams. That is none of the alternatives for the placement of the foreign key would not be possible, since the key indicates mandatory participation on the part of the owner of the key. Some doctors would not be associated with a team and some teams would not be associated with a doctor. In cases such as this, we have to introduce a new relation to represent the relationship.

Appendix 3

Sample table 'quota'

course_code	limit	date_reviewed
c2	3000	2007-10-01
c4	250	2007-10-01
c5	250	2008-04-23

The determinant course_code has a dependency between limit and between date-reviewed. Thus splitting the table into the two tables (course_code, limit) and (course_code, date_reviewed) would, when recombined give the initial table, but For the determinant 'limit' splitting the table into two tables of (limit, course_code) and (limit, date_reviewed) would produce the table

c2	3000	2007-10-01
c4	250	2007-10-01
c4	250	2008-04-23
c4	250	2007-10-01
c5	250	2007-10-01

Two rows that were not present in the original table have been introduced.

Abstract— **In principle, timetabling problems appear at every school and university. However, the degree of difficulty increases dramatically with an increasing number of students and courses for which the scheduling shall be carried out. From the mathematical point of view this is a "hard" problem, since the runtime on a computer cannot be estimated by a simple law (i.e. by a polynomial law) by the number of parameters. These kinds of problems are called "NP hard". There are three important versions of the timetabling problem at universities, known as the university timetabling problem, i.e. curriculum-based course timetabling, post-enrollment timetabling and examination timetabling.**

All specified problems are important for room management at universities, for the realization of courses that can be studied according to curricula, and for the satisfaction of students and teachers. These problems are related to the optimization of room management and personnel costs (e.g. by a uniform distribution of students). Thus, the solution to these problems is related to the optimization of "real" costs, a more and more important economic factor at (German) universities. Introduction of the two-tiered Bachelor and Master courses has raised awareness for these problems at German universities: due to the multitude of new courses the timetables which have been established and stood the test of time cannot be used any longer. Moreover classes tend to be more structured and have strong similarities to classical school situations; attendance is compulsory and dependencies between modules determine the feasibility of the curricula. This feasibility is also evaluated while accrediting new study courses. Since 2003, we have been using using an algorithm that has been realized by members of our team for the solution of the post-enrollment-based course timetabling problem at the Technische Universität Berlin. .

For classes with more than 2000 enrolled students, organization by itself is a challenge; problems may include splitting of those classes into several separate lectures, arranging the associated tutorials into small groups of students, allocating adequate rooms, and scheduling examinations. Moreover, homework and exams need to be administered, whereby, depending on the field of study, very different rules are to be obeyed. This especially pertains to the Department of Mathematics because it offers most of the compulsory classes in mathematics for all fields of study held at Technische Universität Berlin. These are the biggest classes at the university and are to be attended by the majority of students. Thus, the Moses (Mobile Services for Students)-Account has been being developed and used since 2004. This web-based software allows students to enroll in tutorials with a list of preferences for given dates. A special algorithm, providing a globally optimized (with respect to the students' wishes and resources available) solution, processes all registrations.

Keywords—university timetabling, academic administration, integer programming, NP-completeness

I. INTRODUCTION

One of the major challenges facing universities is the organization of the study supporting processes, especially for first year students. With about 28.000 students, TU Berlin is one of the German universities of technology with the largest student body. As a service for other schools, the Department of Mathematics is in charge of the mathematical education of most students, irrespective of their actual course of studies, making it the biggest „service provider" of the university. Since a major reorganization of the math-service seven years ago, every year, several thousand students from 18 different courses of studies are participating in one of the six „math-service" engineering modules (Analysis I-III, Differential Equations, Integral Transformations & Partial Differential Equations, Linear Algebra), altogether filling 9.000 to 10.000 spots in the above-mentioned modules. The largest class is the freshman course in Linear Algebra with a total count of more than 2.200 students per semester. The modules are organized as follows: In order to guarantee lecture class sizes of less than 350 attendees, one and the same lecture is being held numerous times throughout the week, sometimes even at the same time. The lecturers of the individual classes take care of presenting the same mathematical material to all attendees. In addition to lecture classes, all students have to solve the same exercises as homework and, in the case of passing the homework assignments are admitted to take the written examination at the end of the semester. Students also are eligible to attend small-sized recitation/exercise classes (so-called tutorials) in which the material of the lectures is manifested. The following list summarizes the administrational duties for performing these classes:

- Assigning all students to exercise classes
- Managing homework scores for admission to final examinations and course credits
- Managing registration of students for examinations
- Informing students about examination scores
- Collecting and submitting examination scores to the university's central examination office

Although all of the above tasks are typical administrational duties for student management at universities, the large course sizes make them very time-consuming and labor-intensive. This is especially true for the assignment into exercise groups for every module: All students have to be assigned to small (meaning total sizes of 15 to 30 students each) groups/tutorials in a way that assignments neither conflict with each other nor conflict with the individual schedules of the students while respecting certain capacity restrictions. However, the large course sizes not only present difficulties; they also imply a great opportunity of rationalization in the student administration. Against this background the development of MosesKonto (acronym for Mobile Services for Students and Konto as the German word for account) began in 2002 and was initially deployed in 2003 and has been used ever since — first for all math-service classes described above. Since the fall semester 2005/6, the assignment into exercise classes and management of exams has been extended to cover further courses, even across different schools. In 2002 we started with 5 math-services classes, in the fall semester 2009/10 54 classes offered by six of seven schools of TU Berlin are using the MosesKonto to create conflict-free timetables for their students.

II. TIMETABLING

Timetabling problems have always been an important administrative issue at universities. Due to the Bologna process [1] the construction of timetables has become more and more complicated, mainly caused by the diversity of the newly created courses of study. Consequently the need for IT-aided systems has grown. Unsurprisingly a huge amount of literature has been published over the last years ([2], [3], [4], [5], [6]). The university timetabling problems have been grouped into three parts: the university course timetabling [7], the post-enrollment timetabling [8] and the examination timetabling problem [9] . Focusing on these three problems within the scope of the PATAT 2008 [10], [11], [12], [13], an international timetabling competition (ITC2007 [14]) for solving standardized problem formulation was carried out.

A. Problem definition

The problem we focus on is related to the post-enrollment timetabling problem, which occurs for big lectures (typically with several hundreds of students) for which several small exercise/recitation classes are offered. These so-called tutorials are offered at different times and the students have to be distributed into these tutorials taking into account their individual constraints, e.g. students are enrolled in different lectures with accompanying tutorials. This means that many students with individual time constraints have to be matched conflict-free to one or more tutorials with different time slots. In general these constraints are known as "hard constraints", i.e., a timetable violating some of them is not suitable. A timetable satisfying all the hard constraints is called a feasible timetable. Furthermore the students are able to give a rating for the time slots (often called "wishes" or "soft constraints"). The goal of our solution approach is to find a feasible timetable which meets the student ratings as closely as possible. For us this seems to be an appropriate procedure for the post-enrollment course timetabling problem at a huge German university. Comparing our formulation to the one of ITC2007 we have to note that the hard constraints are both identical, but in the soft constraint definition the formulations differ a lot. In our opinion, solving our problem formulation (using our soft constraints) is easier than optimizing the problem formulation of the ITC2007. However, when comparing the problem sizes, we see that our problem with more than 5.000 participating students, more than 700 events and more than 17.000 tutorial-seats is much bigger than the problems of ITC2007 [15].

At the beginning of the project in 2002, we looked for a commercial software tackling our specific timetabling problem. To the best of our knowledge no suitable software tool satisfying our requirements was available at that time. By now several providers of timetabling specific software solutions exist, commercial ones as Scientia [16], CELCAT [17], Mimosa [18] or EMS [19], and non-commercial ones, as UniTime [20]. However, we believe that none of them can either cope with such huge problem instances like ours or do they have the same problem definition.

B. Solution method and comparison

The optimization step involves the computation of all assignments of students into tutorials, in a way that room and teaching staff capacities are respected and the computed solution is optimal in respect to the chosen priorities of dates. The problem admits a formulation as a constrained minimum-cost-flow network problem (Fig. 1, for details see [21]).

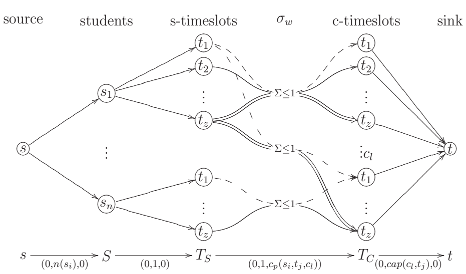

Figure 1. Network for several courses (boundaries and costs for all edges are denoted symbolically in the lower row)

To describe this in terms of a network flow problem let s Є S be a student. Nodes t_j Є T_S , representing distinct time slots, are linked to the student and each link of such a node to another t_j Є T_C represents a rating. Each t_j Є T_C represents one or more tutorial of the course C at this time slot, and *cap*(t_j,c_l) defines the capacity of this tutorial for this time slot as the upper bound of the arc linking the tutorials with the sink. The total demand for tutorials is defined as the flow at the source s. To safeguard that each student is assigned exactly to one seat in a tutorial for each course, some bundle cuts w are defined, forcing this property.

The resulting integer linear program finds a solution in acceptable time, i.e. within less than one minute for the largest instances seen so far on a recent machine. The data of the MosesKonto are accessed and preprocessed by the software TUTOP [22], which also formulates the integer program that is then to be solved by the commercial software CPLEX [23].

$$\min \sum_{s,c,ts} prio(s,ts) \cdot y_{s,c,ts} \quad (1)$$

$$\text{s.t.} \quad \sum_{ts \in T} x_{s,ts} = \ell(s) \qquad \forall s \in S \quad (2)$$

$$x_{s,ts} - \sum_{c \in C(s)} y_{s,c,ts} = 0 \qquad \forall (s,ts) \in S \times T \quad (3)$$

$$\sum_{s \in S(c)} y_{s,c,ts} \leq cap(c,ts) \qquad \forall (c,ts) \in C \times T \quad (4)$$

$$\sum_{ts \in T} y_{s,c,ts} \leq 1 \qquad \forall (s,c) \in S \times C \quad (5)$$

$$x_{s,ts}, y_{s,c,ts} \in \{0,1\} \quad (6)$$

Figure 2. Resulting integer linear program

The integer program (1)–(6) includes two kinds of binary variables – $x_{s,ts}$ and $y_{s,c,ts}$. In a solution a variable $x_{s,ts}$ equals one if and only if student s Є S has been assigned a tutorial at timeslot t_s otherwise $x_{s,ts}$ is zero. A variable $y_{s,c,ts}$ is set to one if student s Є S has been assigned a tutorial of the course c at timeslot t_s. Based on these variables we are able to formulate linear constraints specifying our version of the post-enrollment timetabling problem. In (1) the objective function is described, thereby *prio*(s,t_s) reflects the priority of the student s to have a tutorial at timeslot t_s. The goal of this linear integer program is to find a variable setting of the $x_{s,ts}$, $y_{s,c,ts}$ variables satisfying the constraints (2)–(6) and minimizing the objective function (1). The constraints (2) affirm that every student gets assigned to as many tutorials as he/she applied for. In (3) the two kinds of variables are linked. That means if the variable $x_{s,ts}$ equals one, or in other words, if the student s has been assigned some tutorial at timeslot t_s, there must be exactly one course c where student s participates in a tutorial at this timeslot t_s. To put it differently, if the student s has no tutorial at timeslot t_s (the variable $x_{s,ts}$ equals zero), he cannot be in any tutorial of other courses at this timeslot, and in consequence all the variables $y_{s,c,ts}$ must be zero. The constraints (4) safeguard that the capacity of the different courses are never exceeded. Finally in (5) the earlier mentioned bundled cuts are specified. The last constraints (6) postulate that all variables should have the values one or zero in a feasible solution.

Many problem-solution approaches of the post-enrollment timetabling problem use heuristic procedures ([6], [24], [20], [6], [25], [26]). Generally these techniques are able to provide good solutions but they are not capable to prove optimality, i.e. the user never knows if the current solution is the best one or if there exists a better one. On the contrary, approaches based on integer programming as ours are exact ([27], [28]). This means, if the problem is solved, the user can be sure that the found solution is a global optimum. This seems to be a very important feature for all users of the software. Several exact methods for solving different timetabling problems are known ([29], [30], [31], [32]), but to the best of our knowledge none of them is concerned with the post-enrollment timetabling problem.

C. *Statistics*

In table 1 some statistics concerning the development of the TUTOP specific key data are presented. We can easily see that the total number of participating users/courses has been increasing enormously for the last few years. This becomes even more apparent when we are considering the fall and spring semester separately. Another observation is that the number of tutorial spots has tripled since 2004, whereas the number of students has just doubled. This is due to the fact that for every student more courses of his current timetable are involved. In the fall semester 2004/05 every student applied for 1.65 tutorial spots on average and today is applying for 2.66 tutorial spots. Taking into account that we affirm the conflict-freeness for every student's timetable and caring for his personal preferences, this seems to be a surplus for every single student. The more courses are participating the more the students profit from their personalized automatic timetable creation resulting in a high satisfaction of the students and course offerers. The rate of approval for our work has significantly increased over the last years.

TABLE I. OVERVIEW OF TUTOP KEY DATA STATISTICS OF THE LAST FIVE YEARS

	courses	**students**	**tutorials**	**spots**	**Ø priority**	**tutorials/courses**
winter semester 2004/05	5	3270	163	5392	1.24	1.65
summer semester 2005	6	2681	149	4197	1.27	1.57
winter semester 2005/06	14	4051	326	8925	1.37	2.20
summer semester 2006	17	3569	350	8120	1.40	2.28
winter semester 2006/07	24	4507	418	11626	1.58	2.58
summer semester 2007	29	4248	461	11770	1.59	2.77
winter semester 2007/08	37	5173	540	14533	1.24	2.81

Summer semester 2008	38	4854	642	14015	1.24	2.89
winter semester 2008/09	46	5472	626	15139	1.23	2.77
summer semester 2009	46	5337	807	14032	1.29	2.63
winter semester 2009/10	54	6421	765	17073	1.26	2.66

III. IMPLEMENTATION

The MosesKonto software was implemented in Java, using a JSF [33] driven graphical user interface and using the latest web technologies within the Icefaces Java application framework [34]. The web application is running on a Java GlassFish Application Server [35] using a postgreSQL database [36].

The high adaptability and reliability of the web-based MosesKonto software induced not only a high number of users, but also an increased acceptance, especially among the course providers. This development manifested in a huge number of course providers willing to work on their administrational duties and responsibilities with the MosesKonto software. However, there is a difference between the spring and the fall semester since different courses are using the MosesKonto for creating timetables for their students. Some of the participating courses are using the MosesKonto only for the administration of written examinations. The combination of over 200 different courses (with “only” 54 of them using the software for timetabling in the fall semester of 2009/10) as well as over 22.000 individuals using the MosesKonto creates new administrational and organizational challenges for the MosesKonto. One of these challenges is the allocation of the different supported administrative tools and the private user data involved, which occasionally concerns sensible data like the results of written examinations. It was necessary to implement a user rights management system on the MosesKonto not only in order to protect the privacy of the data but also as a duty impelled by the proceeding process of decentralization When the MosesKonto was started in 2003, we created our own user management due to the lack of a centralized authorization system.

Since fall semester 2007/08 we have been using the central LDAP server (Lightweight Directory Access Protocol [37]) of TU Berlin. LDAP was originally invented to make frequently-used data available faster and more easily. It is also often used to authenticate users. Every member of the university has a central tubIT account (tubIT: IT service center of the TU Berlin), with which it is possible to use several independent services (e.g. email, WLAN), always using the same username and password.

Although single sign on frameworks such as Kerberos are used, one is not handed from one service to another service. Instead one needs to enter the username and password for each service separately. Therefore LDAP works much better than Kerberos and for a great number of applications standard LDAP modules exist. Nevertheless only one single central user administration is needed for different services.

In the near future, the MosesKonto will be integrated into the TU web portal to implement a real single sign on (with several other services offered by tubIT). Additionally, users have to be equipped with different detailed rights, depending on their role. Typically, the users of a system fall into one of the following groups requiring fundamentally differing access rights that can even vary between departments:

- Students, as a rule, are granted access to their own personal data and nothing else (exception: courses allowing team work). They are given write access for their own data and for registering for exams or exercise classes, otherwise read access only.
- The Administrator is given access to all information; he is provided with additional, special rights, such as the creation of new modules.
- Employees of the Service Center are usually responsible for all communication with the central office of examinations. The Service Center is the central contact for all students.
- Teaching Assistants are often responsible for entering the results of exams and similar tasks.
- Tutors will enter their input if the homework-related criteria are met and have access to the personal data of their students.

The growing interest of other schools in using the MosesKonto for the registration of their own exercise classes, examination and student administration outside the mathematical service modules required an expansion of the access right management to facilitate the independent administration of their students. These changes are responsible for different access right requirements for the above mentioned user groups. As a solution, we have implemented a hierarchical access rights management system mirroring that of UNIX [38]. All reading or writing rights for the different types of information and user interactions (e.g. access to the students’ personal data or to their examination results) are treated as a single, independent resource, whereas only the writing rights allow changing or submitting data. Passing these resources (reading or writing) is treated as a third type of resource. User groups (e.g. teaching assistants) can be created and are defined by their associated access rights. The owner of a group (either because he created it or it was associated with him by default) has the right to add or remove members of the group or grant access rights to group members within the limits of his own rights. Students are outside this access rights management, as their rights do not have to be defined on a per-module basis. The right to register for an exam, for example, can be managed through the use of a registration time period.

Facing the high number of courses using the MosesKonto for administrational tasks in students' management and therefore rising complexity and, more importantly, for the purpose of decentralizing the administrational duties it was necessary to develop a user-friendly and intuitive user interface for creating new resources and managing the already existing rights respectively. Therefore we created a JSF [33] driven graphical user interface using the latest web technologies within the Icefaces Java application framework [34].

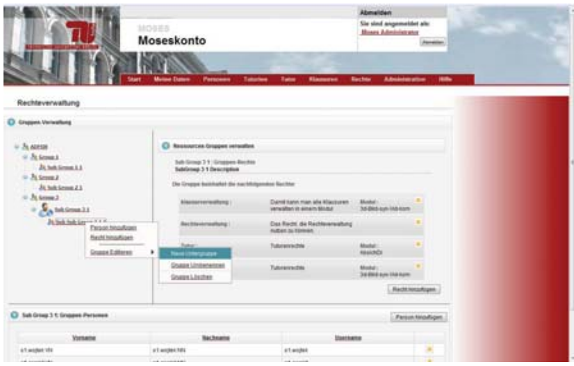

Figure 3. Tree structure of access right management

In order to be fully compatible with the webpages created in the earlier period of the MosesKonto and to keep the proven flexibility of right assignments, we stuck to the UNIX-based rights management and extended the existing three types of resources by adding a fourth type of resource, which gives the group associated to it the right of passing not only the reading or writing resource but also the right to pass this third type of resource, including the ability of passing itself. Finally, it is now possible to hand in every single task, assigned to a right, to a group of users, which again can assign it to another group or handle it themselves. Through this, the base for decentralizing the administrational tasks was created. As a next step we adopted the hierarchical structure of the rights management by arrangement of the groups in a tree structure.

If a member of an existing right group wants to create a new group now, he or she can only create it as a subgroup of the original group and pass the rights within the limits of his own rights. As a result, the tree structure develops on its own.

The new tree-structured user interface also simplifies the allocation of rights to a greater number of groups by associating all upper groups with rights associated to lower groups and vice versa. The upper groups are also able to delete or change the rights of the lower groups.

As a last step in improving the rights management system of the MosesKonto we combined the four types of resources mentioned before to a coherent group of resources.

This new created "resource-group" forms a layer of rights which, from the user's point of view, appears as an independent package of rights and can be assigned to different groups whereas the content, or more precisely the included resources, can only be controlled by the administrator.

However, one should bear in mind that these "resource-groups" are not used for verification of the given rights, but only the resources within the groups are relevant for the purpose of usage.

On the one hand this centralization of resources indeed decreases the flexibility of right allocation for the user, but on the other hand it increases the acceptance and usability of our right management system by letting the administrator combine sensible resources and give them meaningful and significant names and descriptions.

IV. OUTLOOK

The rapidly increasing number of courses using our tool motivated our group to develop more software solutions for different timetabling problems. We have recently finished the implementation of a tool which creates examination timetables for a huge number of written exams affirming that the students have enough time for preparation between two exams [39].

Abstract – **To benefit from data stored in growing numbers of database systems, the number of users capable of finding relevant information should also grow. They should be capable of posing requests, formulate relevant queries, and interpret the obtained results. The user interface should allow them to concentrate on the core of the problem without disturbances caused by details of the query language's syntax. We show the results of our study of the relationship between the interface offered by query languages and their users' ability to express their requests in a correct and comfortable manner. Our aim was to analyze the state-of-art in introductory database courses from this point of view, to design and to test an educational methodology appropriate for non-professionals. It should help them to achieve an advanced expertise in query design and development.**

All DBMS's contain SQL but many of them also have a version of Query-By-Example (QBE) language. Their developers likely believe that for non-professionals this sort of interface is more appropriate for creating queries than SQL. Our review of literature showed that the topic was hardly studied in depth. To do so, we designed and developed an educational methodology which addresses the frontier field between design of query languages, HCI, users' mental and conceptual models and performed an educational experiment that tested it.

Many of our presumed advantages of QBE have been proved correct. There are statistically significant differences in time, accuracy and users' satisfaction related to query creation. We also found out statistically significant differences in combinations of variables (time, accuracy, and satisfaction) and the level of task difficulty. The result may have a positive influence on non-professionals' exploitation of databases. It may lead to designing and developing a combined methodology that would benefit from positives of both: QBE and SQL.

Keywords- introductory database courses; comparison of QBE and SQL; query formation; mental models of query processing.

I. Problem Statement

The amount of data stored in database applications is constantly growing. To benefit from them, the number of users capable of finding and benefitting from them should also grow. Many of those search activities have been programmed, but new and new questions always arise. For that reason the database users should be capable of posing their requests. The users should be capable of recognizing whether they are solvable within the given database, formulate relevant queries, and interpret their obtained results. These issues are of a distinct importance for non-professionals in ICT as the query creation is for them just a tool for achieving their professional information. The user interface should allow them to concentrate on the core of their expert problem without disturbances caused by details of the query language's syntax. Thus, questions like the next ones can be posed: *Which query language satisfies the non-professionals' expectations the most? How to measure the effects of a query language to its users? What methodology to apply and how far to go in their training?*

In this paper, we show the results of our study that analyzed the differences between SQL and graphical Query-By-Example (QBE) in order to get relevant answers. We concentrate on distinctions that enhance learning processes of ICT non-professionals, and analyze the user's ability to express their requests in a correct and comfortable manner.

II. Purpose of Study

The choice of the background languages for our study was quite natural. SQL is a standard for database management systems (DBMS). Many of them also introduce their own semi-graphical version of the Query-By-Example language, often labeled as a QBE-like language (thereinafter QBE). Developers of DBMS likely believe that this sort of interface is more appropriate for casual and non-professional users. Nevertheless, our examination of literature showed that the topic was hardly studied in depth.

As similar considerations represent a frontier between design of query languages, computer-human interface, and users' mental and conceptual models, we designed an educational methodology which reflects all of these aspects and does not depend on a particular query language. Based on the methodology, we developed two parallel courses of query design and development. The first one follows the classical approach based on SQL. The second one also exploits the advantages of QBE. The methods were used in two parallel classes of the same *Introduction to Databases* course.

Three hypotheses were specified. They addressed speed, quality and comfort of query creation in the two languages. In all of them, we favored QBE i.e. we presumed that the users of

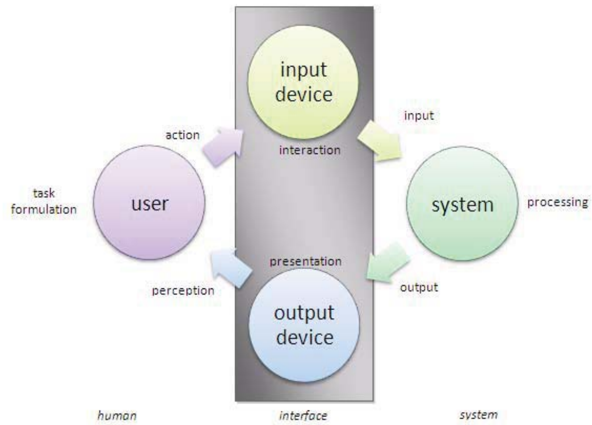

Figure 1. Basic cycle of interaction by Abowd [1].

QBE will be more successful in all three dimensions than users of SQL. Then, a pedagogical experiment was performed – the test group was using our new approach using QBE while the control group used the more traditional SQL.

III. Interaction Models

The human-computer interaction has been the key issue in designing our educational methodology. Here, "humans" mean database end-users, non-professionals in ICT. Our aim is to teach them query creation to the degree in which they can interact with their database applications and gain answers to their questions. Accordingly to Abowd [1], the interaction is executed in the way indicated in Fig. 1. Notice that the differences between QBE and SQL only address its "upper left corner". The rest is virtually identical for any query language because:

- The evaluation of the queries is hidden from the users;
- The presentation of the results does not depend on the used input language. In the same DBMS, it is identical for both of its query languages.

For that reason, the conceptual model of the interface, the user's mental model of this interface, and the query notation are the only factors playing key roles in the communication [2]. The conceptual and mental models are important for the design of human-computer interaction, as well as during users' learning. In a badly-designed conceptual model, confusing interaction can make the solution of the users' task more complicated. The learners with wrong mental models will meet with troubles during forming queries that should answer their requests. Oppositely, well designed interaction simplifies the problem solution on one side, and the creation of learners' mental models on the other one. The users' success rate and, consequently, the popularity of the query language will grow. Some sources [2], [3] indicate that these topics have been neglected by researchers. Nevertheless, we feel inevitability to explain the relevance of their research to our own one.

Prior to that, we introduce our terminology.

A. *Conceptual Model of the Interface*

For designers, the interface represents a communication channel between front and background activities. It transfers messages between the system and the user. The communication is based on so-called *conceptual model*, i.e., the general framework in which the data and information move between the front-side (visible, operated by the users) and back-side (invisible, executed by the DBMS).

The conceptual model represents the DBMS's functionality. It is preprogrammed. The experienced user's internal (mental) model of this functionality coincides with the conceptual model well. That's why the experienced users are capable of exploiting the features of their DBMS much better than non-experienced ones despite the fact that both categories communicate with the same conceptual model.

B. *Learner's Mental Model*

The main aim of education is to build proper mental models in the minds of learners. Their future mental models should become close equivalents of the conceptual model of the interface they are trained to use.

Every learner exploits his/her mental model to reason about the system, to anticipate its behavior and to comprehend why it reacts as it does [4]. During learning, each and every learner forms his/her individual model with his/her own internal objects and specific ways of understanding of how the computerized processing works. These models may not fully coincide with the conceptual model [5].

From the designer's point of view, the user and the system are "two partners of the same importance". From instructor's point of view, the conceptual model is "done" (i.e. static), whilst mental models are formed (i.e. dynamic) [5]. The educators are therefore supposed to familiarize their students with the conceptual model in a stepwise manner and verify to what degree their mental models match the reality.

In general, people are not very good at constructing and understanding our own mental models or using them for decision making. So, it is difficult to measure the "distance" between people's mental models and the conceptual model. On the other hand, for day-to-day purposes it is sufficient, if the learner's metaphors and analogies lead to their adequate control of the system. Due to that, the mental models we use are often extremely simple.

The mental models have some powerful advantages. They are flexible – they can be adapted to new situations and be modified as new information becomes available. But mental models have their drawbacks also. They are not easily understood by others; interpretations differ person to person. The assumptions they are based on are usually difficult to examine. As a result, ambiguities and contradictions within them can go undetected, unchallenged, and unresolved.

Also, learning never starts from scratch as each of us already owns many mental models. In truth, "*our decisions and actions are based not on the real world, but on our mental images of that world, of the relationships among its parts, and of the influence our actions have on it*" [5]. During the process of their learning, the computer users have to form their own models and to learn to work with them [6]. This also runs during learning of query creation. The role of teaching methodologies is to split the process into „edible chunks“. Each of them shows a small portion of the conceptual model and creates an additional piece of his/her mental model. These individual mosaics (as well as their previous experience with creating their mental images) are composed in the students' heads into their final mental models.

From the point of view of education, such an approach has one advantage. The educator can formulate "an optimal mental model" and build a methodology aimed to it. This so-called *target mental model* specifies the knowledge the students should get in the end of their learning processes. If there is a difference between the concrete mental model of a student and the instructor's target mental model, the instructor can (a) redesign their communication and/or (b) use other learning materials to enhance the transition from the student's current model to the target one [7]. Actually, this idea did motivate us to replace the traditional SQL-oriented courses to QBE-oriented ones as we felt that the former ones are not appropriate to achieve our target mental model (and consequently, the depth of knowledge) we would expect among non-professional users.

Learning is a back-loop process and its run can be illustrated as follows (Fig. 2):

- *Single-loop learning* is shown in the upper part of the picture. Every person has a stockpile of mental models for standard life situations. When we make a decision and then perform its relevant activity, feedback from the real world gives us information on whether our decision brought the desired effect or not. When the feedback is positive, it reinforces our mental model. In such cases, our aims may change, but our mental model remains the same. It is our dominating method of acting; it is simple and convenient. Once the mental model is fixed (and the responses from the real world coincide with our presumptions), our decisions are coming quickly.
- When the feedback from our environment is negative, *double-loop learning* is necessary. This process covers the entire figure. The negative feedback indicates the necessity to change our mental model. Unlike single-learning loops, this model includes a shift in understanding – from the simple and static one to a broader and more dynamic one. We start taking into account the changes in the surroundings that might cause our mental model's imperfection and try to include them as another piece of mosaic [8]. School education is built on continuing challenges to students' current mental models. Teaching methodologies represent recommended strategies guiding the educators and helping them to facilitate transitions from their current mental models to the targeted ones. Notice that there can be several methodologies describing parallel roads from the given mental model to the identical target.

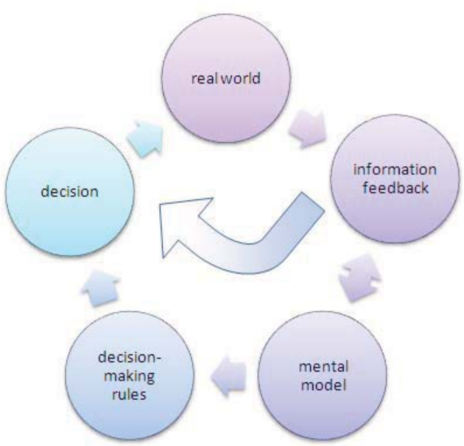

Figure 2. Double-loop learning [7].

C. *Query Creation Target Mental Model*

Our group of learners consists of future non-professionals in ICT. For that reason, the exploitation of databases is not their main aim; it appears as a part of a more general task. Consequently, the target mental model discussed in our paper is composed of the following pieces of knowledge:

1. *Formulation of a question* that can be answered by the means of a given database. As the question mostly appears as a part of a practical problem, it is formulated in a natural language.
2. *Feasibility of the solution* must be discussed. For example, the user must make certain that the addressed database contains all necessary data – otherwise the problem is not solvable and, consequently, there is no reason to open the query creation process.
3. *Transformation of the question* formulated in a natural language to a semantically-equivalent query written in a query language.
4. *Execution of the query* over the database.
5. *Interpretation* of the gained results.

The time allocated to databases in curricula is constant and limited; the proposed methodology must respect these boundaries. For example, the first and the fifth part might be "too specific" and strongly depending on an application field. As our group of learners has not a unified field of study, we overcome this problem by forming a wide range of application databases referring to popular fields like libraries, travel agencies, transportation, personal records, etc. Due to that, we can presume that all students have sufficient prerequisite knowledge and experience to formulate and solve relevant problems of "any" difficulty.

Our methodology is a reflection of Reisner's principal model [3]. Despite its age, the model is still relevant as the structure of databases and their interface has not changed substantially since. In her model, users' performance is determined by the time it takes to think about proper query design, to writ the query as the DBMS input, and to correct various types and numbers of errors. The thinking effort is what Reisner calls the *selection of an appropriate template*. From the point of view of time sequence, the process of query creation consists of two basic templates [9]:

(a) Understanding of the problem and its relation to the database structure;

(b) Formulating a correct syntactic construction that will produce the problem solution.

In detail, the problem consists of the following activities [9]:

- *Understand instructions*: The user must comprehend the instructions that describe the query task to solve the query correctly.
- *Construct deep structure*: The deep structure of a query task is a complete and thorough comprehension of which data must be retrieved from the database and how the result data must be structured. The deep structure of a query task is independent on the used query language.
- *Construct surface structure*: The surface structure of a query task is a query language expression that is a translation of the deep structure. If the user is satisfied with the query expression, he/she submits the query to the processor. When the user is not satisfied with the outcome, he/she makes correction efforts or tests.
- *Submit query*: The user submits the query language expression to the query processor.
- *Evaluate result*: The user reads and tries to interpret the information that he/she received from the query processor. This information may contain an error message or resulting record set (which itself can be correct or wrong).
- *Correction effort*: When the query was not processed or produced a wrong outcome, the user tries to understand the type of error and fix it.
- *Test expression*: The user supposes that the query is correct but makes its additional runs using modified data sets in order to verify its correctness in a more general manner.

The traditional target mental model includes SQL as a carrier for query creation. The reason is quite logical. SQL is a standard component of databases. Thus, the learned knowledge is widely applicable. On the other hand, SQL is a typical programming language with a very formal syntax. As such, it is strict and not well-legible. That's likely why designers of database management systems often introduce a parallel notation named Query-By-Example (QBE).

As SQL is a carrier, it is a substantial but not the decisive element of the target mental model. Moreover, a dependence of a methodology on a particular programming language is not a sign of its high quality. Thus, questions arise: *Can SQL be replaced by QBE? To what degree will the replacement be successful?*

We believed that SQL is too formal for casual and non-professional database users. For that reason we decided to reflect our considerations in the design of a new *Introduction to Databases* course. From one side, it would address the same target mental model as the traditional SQL-based courses do and, from the other side, it would exploit QBE as the query carrier.

To evaluate its effectiveness we designed a pedagogical experiment. The database course was prepared in two versions using the identical educational methodology. Fig. 3 shows its structure. Its third block was delivered in two versions – the traditional one using SQL and the newly developed one based on QBE. The pretest and posttest served for measuring the students' knowledge in the relevant classes (with QBE-class as the tested group and the SQL-class as the control group).

IV. RELATED WORKS

The relation between SQL and QBE was studied many times. Whilst SQL has its standard definition, there are many DBMS-specific versions of QBE. In our paper, we consider its form-based version in Microsoft Access as it was the tool used in our classrooms.

Former experiments comparing the two paradigms did not bring definite evidence on a statistically relevant difference between the effectiveness of their application [10]-[16]. Some of these unambiguous conclusions are presented in the comparative articles [3], [17]-[19]. In accordance to them, both languages require equal capability of abstract thinking and complete specification of the way from the input data table(s) to the output list of results. More recent papers targeting so-called visual query languages analyze different level of abstract thinking that the users of DBMS should have to accomplish their tasks [10], [16]. We have not found a study that would describe research on educational aspects of a graphic-form version of QBE and SQL that would represent an analogy to our study, except in [20].

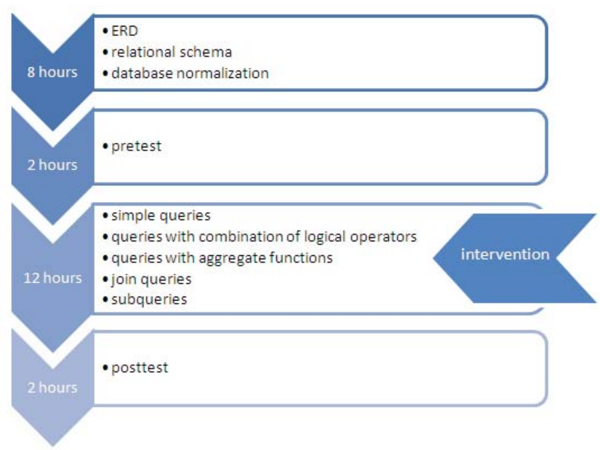

Figure 3. Timeline of the experiment.

V. Research Method

As Fig. 3 shows, the experiment was done during 24 hours of lecture in one semester. The figure also shows its stages. It has the form of a pedagogical experiment with pretest, posttest and two groups – experimental (tested) group and control group.

The design of our experiment followed the standard methodology and its outcomes were statistically evaluated. Its principal steps were as follows:

- Formulation of research hypotheses.
- Creation of experimental and control groups.
- Reliability/Item Analysis:
  - Estimation of reliability of the questionnaire and test.
  - Identification of items that might degrade its relevance and fixation of the problem.
- Execution of the experiment:
  - Simultaneous application and evaluation of the pretest in both groups.
  - Parallel run of courses in the groups.
  - Simultaneous application and evaluation of the posttest in both groups.
- Statistical analysis of the results.
- Interpretation of the results.

A. Target Group

The total number of students participating in the experiment was 116 divided into two groups:

- QBE – 59 students,
- SQL – 57 students.

The groups were formed from the students of the same year-class and were equivalent from the points of view of their age, gender and previous study results. The level of their knowledge was also verified during the pretest and confirmed our presumption on the group equity ($p = 0.330751$).

B. Dependent and Independent Variables

To formulate and verify hypotheses, one needs their variables. The independent variables are query tasks of five difficulty levels to be implemented using two query languages – SQL and the MS Access version of QBE. They represent independent variables in our experiment.

To study which of these tools is more appropriate for our target group the analyzed factors should express their appropriateness for their users. The studied factors were the users' performance and overall satisfaction with this activity.

1) Performance

Performance was measured using two parameters: correctness of the solution and the time for its accomplishing.

The correctness of query is its critical feature. It can be expressed as difference between the presumed (exact) solution and the one produced by the learner. In our evaluations we used the "Correct-Incorrect" scale where the queries semantically equivalent to the right answer (i.e. those always producing the same set of records) were characterized as the "Correct" ones.

Time for completion of the query was the second parameter. Time was measure for each query individually. The student could choose any test task to solve but he/she could not work on two or more tasks simultaneously. Thus, the gained values expressed the time periods each student spent on every of his/her solved tasks.

2) User's Satisfaction

Any software tool will succeed if and only if its users are happy with it. It can be expressed by user's opinions collected using a questionnaire. As personal opinions are rather subjective, 9-point Likert scale was applied in order to quantify their feelings on a numerical scale.

C. Reliability of Test and Questionnaire

In the case of didactical test, the value of reliability coefficient is to be 0.83 (83 %) and expresses the ratio between the sum of variability of individual task's score and the total variability of the test. The used estimations (*Cronbach alpha* = 0.83; *Standardized alpha* = 0.85) are satisfactorily close so one can presume the equal variability of the tasks i.e. no suspicious tasks were identified. All tasks were in correlation with the overall score and their removal did not affect the reliability coefficient. Thus, our selected tasks did not decrease the test reliability.

An identical approach was applied the questionnaire with similar results. In particular, the ratio between the sum of variability of values of individual questionnaire's item and the total variability of the questionnaire was 90%.

As the result, both instruments were claimed to be highly reliable.

D. Hypotheses

Three research hypotheses have been formulated:

- The members of the group using the graphic interface QBE will complete their solutions faster than the members of the group using SQL.
- The members of the group using the graphic interface QBE will produce more exact solutions than the members of the group using SQL.
- The members of the group using the graphic interface QBE will be more satisfied with their solutions and the way they were achieved than the members of the group using SQL.

The first two hypotheses were tested using a posttest consisting of the query creation and identical for the both groups. The third one was verified using the questionnaire.

E. Groups of Query Tasks in Experiment

The majority of analytical work comparing a query language towards SQL addressed selection queries i.e. the ones beginning with the keyword SELECT [11], [15], [16], [21]. For that reason we also concentrated on the same problem group.

In order to measure the users' cognitive efforts required for their task solutions, we split the tasks into five levels of difficulty. The criteria for the distribution were type of the query, complexity of the conditions the records have to fulfill, and the number of tables the query must include. Their order expressed their complexity starting with the simplest ones:

- *G*1: one table, a single condition and/or sorting of records,
- *G*2: several tables, a single condition,
- *G*3: combination of records from several tables,
- *G*4: aggregation of values stored in one table,
- *G*5: nested queries and subqueries.

The number of queries in the posttest was partially influenced by its presumed duration (90 minutes). For that reason, it consisted of 20 problems written in a natural language. The number coincides with the amounts of tasks mentioned in similar experiments [11], [13].

VI. Results

The results of the experiment were analyzed using linear models.

A. Verification of the Hypotheses

The hypotheses were analyzed using the one-way analysis of variance.

Our first hypothesis stated that the students applying QBE-based approach will need shorter time for query formation. The hypothesis has been proved ($p = 0.000383$).

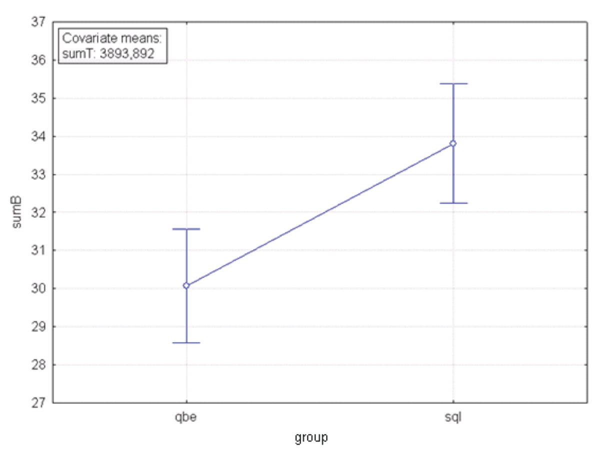

Figure 4. The means with error plot showing the correctness of the solution with respect to the mean time required for its creation.

The second hypothesis stated that the QBE students will create more accurate queries than those using SQL. This hypothesis was not confirmed. The quality of students' queries was almost identical in both groups ($p = 0.516098$).

The third hypothesis presumed that the QBE students will feel better comfort during their query creation and higher satisfaction with their results. This hypothesis has been confirmed ($p = 0.000515$).

B. More Detailed Results Related to Time Periods Required for Query Creation

The verification of the first hypothesis has proved that QBE queries have been made faster. To achieve a more detailed picture, we decided to include another factor – the time period necessary for the query completion. The analysis of covariance showed another statistically significant difference. It differed from our expectations. In accordance to it, if the time for the solutions would be identical, the SQL group responses would be more accurate. Fig. 4 shows the estimated means with the respect to the correctness of the query and time.

Based on data in Table 1, the zero hypothesis – the presumption that there is no statistically significant difference between the groups in the precision of the query formation – was rejected at the 99% confidence level. It shows that the relation between the covariate – the variable *sumT* (total time) – and dependent variable *sumB* (total score) – is statistically significant at the 0.01 level.

TABLE I. ANCOVA, UNIVARIATE TESTS OF SIGNIFICANCE FOR THE CORRECTNESS OF THE QUERY CREATION

	SS	*df*	*MS*	*F*	*p*
intercept	22703.16	1	22703.16	718.4995	0.000000
sumT	2217.19	1	2217.19	70.1685	**0.000000**
group	351.54	1	351.54	11.1253	**0.001168**
error	3412.59	108	31.60		

Meaning of the terms: SS = adjusted sum of squares, df = degrees of freedom, MS = adjusted mean square, F = mean square ratio, p = p-value (the probability of the observed data when the null hypothesis is true), intercept = the parameter in an equation, sumT = continuous independent variable (covariate), group = categorical independent variable, error = residual error.

TABLE II. ANCOVA, UNIVARIATE TESTS OF SIGNIFICANCE FOR THE OVERALL SATISFACTION OF THE USER.

	SS	*Df*	*MS*	*F*	*p*
intercept	778.8507	1	778.8507	595.6569	**0.000000**
sumT	24.9029	1	24.9029	19.0455	**0.000028**
group	6.4686	1	6.4686	4.9471	**0.028121**
error	147.7531	113	1.3075		

Meaning of the terms: SS = adjusted sum of squares, df = degrees of freedom, MS = adjusted mean square, F = mean square ratio, p = p-value (the probability of the observed data when the null hypothesis is true), intercept = the parameter in an equation, sumT = continuous independent variable (covariate), group = categorical independent variable, error = residual error

Similarly, the covariance analysis demonstrated a statistically significant difference between the groups even if the time is taken into account (Table 2). The zero hypothesis stating that there is no statistically significant difference between the groups when the time is taken into account could be rejected at the 95% confidence level.

It also shows that the relation between covariate *sumT* a dependent variable *vpS* (overall satisfaction) is statistically significant at the 0.01 level. In this case, the analysis of covariance ($p < 0.05$) confirms the results of the analysis of variance ($p < 0.01$).

C. Comparison of the Groups of Variables

The most interested results have been generated by ANOVA repeated measures. They helped us to show statistically significant differences between combinations of variables (time, accuracy, and satisfaction) and the level of task difficulty. Here, the division of problems into the categories *G*1-*G*5 played its role, too.

Tukey HSD test (Unequal *N*) allows us to analyze the relationship between the categories of tasks separately in the test and control groups. The detail results exceed the presumed size of our contribution. Therefore we prefer visualizing our outcomes in Tables 3-5 and Fig. 5-7.

1) Time Duration

The natural presumption that the more difficult tasks require more time to solve has been proved. Fig. 5 indicates the statistically significant differences between periods necessary for the query creation and selected combinations of time and category of the task. Each line corresponds to one of the groups.

The principle contribution of the next analysis consists in the identification of differences in query creation in the individual groups. In our particular case, the diagonal values are the most interested as they express the comparisons of the time periods. Naturally, we want to know the comparisons of time periods spent on the same tasks.

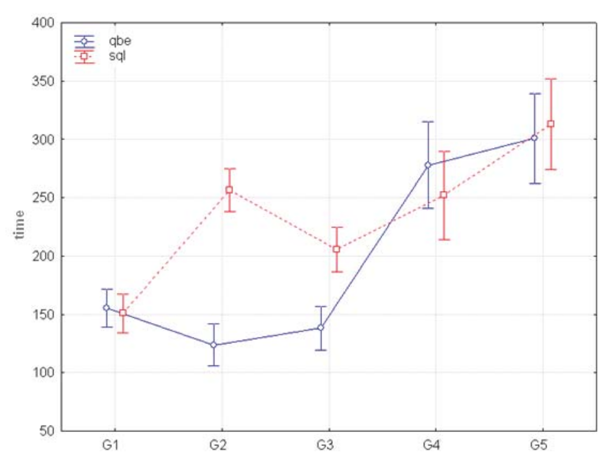

Figure 5. Categorized means with error plot for repeated measures of time periods.

There are larger differences between the groups *G*2 a *G*3 (Table 3): 0.005693 in the former case, 0.611760 in the latter. A statistically significant difference ($p<0.01$) has been proved in the case *G*2. It implies that the time for creating QBE queries with a single condition in multi-table databases is significantly shorter than that of similar queries in SQL. There was also an observable difference between the *G*3 tasks (aggregated queries) but it was not statistically significant (*G*3).

TABLE III. MULTIPLE COMPARISONS FOR TIME COMPLEXITY

Group (QT)	***SQL(G1)***	***SQL(G2)***	***SQL(G3)***	***SQL(G4)***	***SQL(G5)***
QBE(G1)	1.000000	**0.000032**	0.272150	**0.000073**	**0.000012**
QBE(G2)	0.940429	**0.005693**	**0.001846**	**0.000012**	**0.000012**
QBE(G3)	0.999810	**0.000013**	0.611760	**0.000013**	**0.000012**
QBE(G4)	**0.000012**	0.988066	**0.011454**	0.999009	0.763889
QBE(G5)	**0.000012**	0.445651	**0.000093**	0.303231	0.999998

Meaning of the terms: QT = query type

2) Precision of Solutions

There is a statistically significant difference between the precision of solutions in the student groups. The zero hypothesis stating that there is no significant difference was rejected. We would see the strong relationship between the precision of the solution and the task difficulty – see Fig. 6. The picture indicates a difference between some problem groups – in particular *G*1 and *G*3 – but they are not statistically significant (see Table 4).

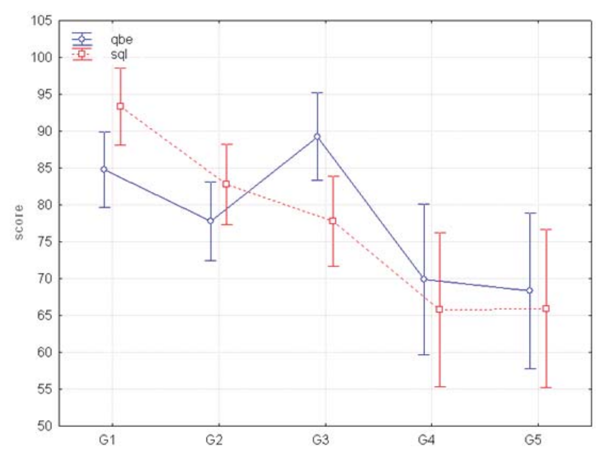

Figure 6. Categorized means with error plot for repeated measures of precision of solutions.

TABLE IV. MULTIPLE COMPARISONS FOR PRECISION OF SOLUTIONS

Group (QT)	***SQL (G1)***	***SQL (G2)***	***SQL (G3)***	***SQL (G4)***	***SQL (G5)***
QBE (G1)	0.992792	0.999999	0.968587	**0.029521**	**0.032071**
QBE (G2)	0.161187	0.999906	1.000000	0.519844	0.538235
QBE (G3)	0.999431	0.981135	0.948587	**0.001530**	**0.001701**
QBE (G4)	**0.001595**	0.411372	0.932978	0.999982	0.999524
QBE (G5)	**0.000509**	0.247468	0.820548	0.999988	1.000000

Meaning of the terms: QT = query type

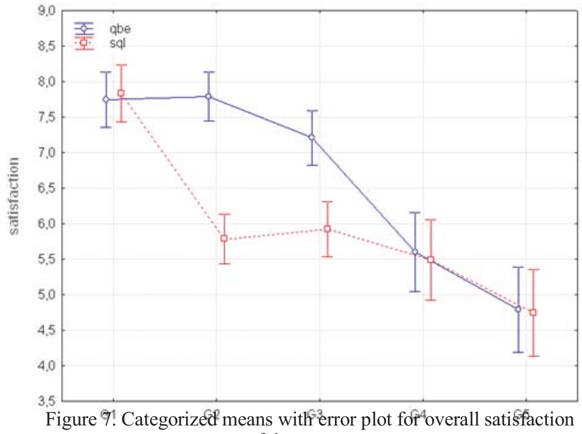

Figure 7. Categorized means with error plot for overall satisfaction of the user.

3) *Overall Satisfaction of Users*

Finally, we focused on the relationship between overall satisfaction of the users and the query type. Overall satisfaction of end-users is decreasing while query complexity is increasing.

One could anticipate this effect – its relevance to the subjective nature of this variable is obvious. If the end-user has to make greater effort to understand the merits of the task and used interface that does not offer sufficiently simple solution, his/her satisfaction would be on decline.

At the same time, the reader of the values on table diagonal comes to the findings that there is a statistically significant difference between overall end-user's satisfaction and different types of queries. There are apparent differences in overall satisfaction of the user in favor of QBE-like graphical user interface in tasks from the groups *G*2 and *G*3 (Fig. 7). A statistically significant difference ($p < 0.05$) has been proved in the case *G*2 (Table 5).

TABLE V. MULTIPLE COMPARISONS FOR OVERALL SATISFACTION OF USER

Group (QT)	*SQL(G1)*	*SQL(G2)*	*SQL(G3)*	*SQL(G4)*	*SQL(G5)*
QBE(G1)	1.000000	**0.000013**	**0.000015**	**0.000012**	**0.000012**
QBE(G2)	1.000000	**0.015005**	**0.000014**	**0.000012**	**0.000012**
QBE(G3)	0.697302	**0.001091**	0.380372	**0.000028**	**0.000012**

QBE(G5)	**0.000012**	0.095280	**0.028524**	0.547970	1.000000
			Meaning of the terms: QT = query type		

VII. DISCUSSION

We have prepared our paper as our contribution to the research of interaction between database end-users and relational database systems. In particular, we have been interested in comparing two interfaces designed for query formulation and to the problem of the future end-users training.

In order to identify the differences, we used one-way analysis of variance and analysis of covariance for solving of our research problem. One-way analysis of variance is simpler and it does not require the fulfillment of assumptions about regression in individual groups. On the other hand, if there are some differences in controlled variable between groups, its interpretation is less valid. Therefore it is recommended to realize both analyses and compare their results.

The results of experiment could have been affected by several factors. We must mention the process of participants' selection first of all. Our participants were students of the preliminary database courses. For sake of completeness of our statement, we have to add that the characteristics of students may differ in some details from typical end-user in non-academic environments. On the other hand, our approach is supported by several scientific papers from this research field [13], [15], 19], and [22] that applied a similar approximation of the term "end-user".

The second factor is the number of the participants in experimental and controlled group. Although it may seem sufficient, it is evident that we would become more general results if we could repeat experiment with greater number of participants and/or more than once time. We could not afford such numbers considering (a) the size of our institution (b) regular changes in the syllabus that exclude prolongation of the identical content over several consecutive years.

The different complexity of the tasks is another factor that might have effect on the experimental results. From the very beginning, we understood that tasks leading to subqueries may affect the overall reliability of some results of our test. They are much more complex than other four types of tasks. Their extreme complexity could therefore affect the overall end-user's satisfaction. As they are very frequent in day-to-day situations, we decided to include them to the test despite the above reservation.

We cannot forget in this discussion the limited duration of individual tasks as well as entire testing procedure. Although we took sufficient free float for each task, the clock displayed on the screen could have affected participant's activity and disturbed his/her overall satisfaction.

VIII. CONCLUSIONS AND FUTURE WORK

It has been experimentally confirmed that our methodology of query formulation brings several positive outcomes. These findings could act as an impulse for further considerations about database querying and the ways of their teaching and learning.

The main positive results is proving that the QBE graphic interface allows faster and more comfortable writing of low and medium difficulty tasks compared to the SQL text-based environment does. In these cases, the accuracy of produced queries remains comparable and the comfort of QBE users is higher. One can presume that the students will build their stronger attitude to the tool that allow them faster and more comfortable work i.e. they will tend to use it even in the cases when they would try to avoid SQL.

These results may have a positive influence on non-professionals' exploitation of databases:

a) Due to their quick progress in query creation, they might become higher motivated in further improvement of their knowledge and, consequently, in their more effective and efficient exploitation of their databases.

b) Design of some (very complex) queries via QBE is difficult, if not impossible. The non-professionals should be encouraged to recognize the limits of their expertise and ask ICT professional for their assistance.

Despite the fact that not all of our hypotheses have been confirmed, many of intuitively presumed advantages of QBE have been correct. This should motivate educators to design and develop a combined methodology that would benefit from the positives of both: QBE and SQL.

The research of database query languages and especially visual query languages for end-users has an interdisciplinary character that should teachers take into account in their training as well as pedagogical research. To inspire them, we identified some interesting open questions that might be included into future research:

- What are main trends in end-user database languages? In particular, what perspective do visual languages for query formation have? To what degree can end-users successfully tackle their tasks without being familiar with the internal structure of databases?
- To what degree the interfaces based on natural languages will change the situation? What will be their advantages and drawbacks compared to the form-oriented languages?
- Do contemporary languages oriented to the conceptual design of databases have a potential that would enhance end-user participation?
- Is it possible to integrate advanced features of distinct query languages into one interface that would benefit of each of them?
- Is it possible to create an intuitive interface that would allow mining of information from distributed heterogeneous databases? How to protect the users from getting lost in such environment?

Abstract—**This paper describes state-of-the-art simulation systems designed for information security and information assurance education, training and awareness. Being people the weakest link in the implementation of any security policy, it is of paramount importance to strengthen that link before it gets broken. The best way of improving the reactions of any person when security is attempted to be compromised is by providing him/her with better education, attractive practical training and raising the general awareness on information assurance.**

Keywords—information security; information assurance; network simulation; education; training; awareness.

I. Introduction

Information security has become one of the main priorities for governmental and private institutions. It has been shown in several occasions that a big amount of all security incidents is caused by human errors such as system misconfigurations, security policy breaches and careless systems administration. Since these actions were not done on purpose, most of them could have been avoided by improving the information security education of managers, the training of the system administrators and the general awareness of end users. Simulation systems are of great help for this task since they allow hands-on experience and user interaction. This sentence, attributed to Confucius, and also mentioned in [1], is self explanatory: "I see and I forget, I hear and I remember, I do and I understand".

This paper describes the results of a research on state-of-the-art simulation systems for information security and information assurance education, training and awareness. As first stage of the research, several of those systems have been identified and studied. The second stage makes an initial attempt to construct a taxonomy of the found simulators, following the one proposed by Saunders [1, 2] in which five distinct categories of simulation for information security are defined and described:

1. PacketWars
2. Sniffers + network design tools
3. Canned attack/defend scenarios
4. Management flight simulators
5. Role-playing

The found simulation tools have also been classified attending to their target audience, usability, learning curve required, level of detail, scalability, the possibility of being remotely used, etc.

The rest of the article is structured as follows. In section 2, brief descriptions on the research and on each of the found tools are provided. In section 3, the results of the proposed taxonomy are presented. Finally, the conclusion and possible future research are offered.

II. State-of-the-Art Simulation Systems

The current research has been performed by looking up different sources such as: IEEE magazines, IEEE Xplore Digital Library, ACM Digital Library, ISI Web of Knowledge, SpringerLINK Book Series, Google Scholar, Scientific Commons, Scirus, RefSeek or Scitopia, among others. Overall, more than one hundred references including journal and magazine articles, conference proceedings, technical reports, thesis reports, book sections, computer programs and web URLs have been obtained, classified and reviewed.

While other state-of-the-art reports on information security simulation focus on different aims of such simulations, the authors have special interest on information assurance and on the activities that allow transmitting the corresponding knowledge to the students. They have experience in both the education and private sectors in subjects directly related to information security. Within the University environment, the educational experience is directly related with grade and post grade subjects in Computer Science Engineering and Industrial Engineering at the Spanish University for Distance Education.

The education on information security subjects at University, when available, is most of the times mainly focused on theoretical issues. However, without an adequate practical teaching of information assurance matters, we are leaving the students with a weak knowledge that is not yet consolidated. The use of a security laboratory and/or a simulated network scenario is very beneficial as a mechanism for supporting active learning strategies such as: learning-by-doing, learning-by-example and learning-by-exploring.

While other forms of getting to the objective of simulating network security situations could also include adaptations, modifications or extensions to generic network simulators, in this article we have chosen to focus on the tools that are specifically designed having information security in mind. Nevertheless, some of these generic simulation tools and a description of their use for information security teaching can be found at: OPNET Modeler [3], OPNET IT Guru [4], OMNET++ [5] and ACME Studio [6].

Some of the analyzed tools are not specifically designed for an autonomous learning of information assurance aspects but are anyway included because they can be used to demonstrate certain concepts to the students even when the intervention of the trainer will be required in all cases.

Among all the simulation tools found during the research we are highlighting the following ones:

*A. **CyberProtect**, developed by US DoD's Defense Information Systems Agency (DISA) in conjunction with several entertainment software companies [7].*

CyberProtect is an old product. It has not been revised since July 1999. The product received several awards on its creation year: 1999 NewMedia Gold INVISION Award (Best Overall Design), 1999 NewMedia Gold INVISION Award (Technical Training) and 1999 International Cinema in Industry (CINDY) Competition Silver Award.

In spite of not being modified since 1999, the principles that guided its creation are still valid and the application is still fully functional. CyberProtect version 1.1 can still be obtained on CD from the Information Assurance Support Environment (IASE) of the US DoD's Defense Information Systems Agency (DISA) [7].

CyberProtect was developed as a training aid for novice network security professionals to familiarize them with information systems security terminology, concepts, and policy. It is an interactive computer network defensive exercise that provides the users with the opportunity of configuring network security features and running them against real world network security attacks. The users face a variety of security threats and must make practical decisions for allocating resources using the elements of risk analysis and risk management. CyberProtect simulates a complete fiscal year lifecycle of a simple computer network divided into four sessions. After each session, the user receives feedback on his/her performance. At the end of the last session, users are given a report detailing their cumulative scoring classifying the attacks by origin, type, and effectiveness.

*B. The Military Academy Attack/Defense Network (**MAADNET**) simulation designed by the Department of Electrical Engineering and Computer Science, United States Military Academy [8].*

The aim of this application is to simulate diverse aspects of building and managing an information system and combining them into an information assurance learning environment. MAADNET is built on a client-server architecture using the discrete events simulation (DES) paradigm. The user starts building a network on the client side in accordance with a given scenario that is then submitted to the server which will simulate different events. The user can build the network, enforce policies and employ more administrators. After that, several scenarios can be executed against the designed network in order to see how it behaves when attacked. After the simulation, the built network is evaluated in order to assess how well security was maintained.

The simulator was created for assisting in enhancing the quality of the Information Assurance courses offered to cadets of the US Military Academy. At a certain moment [9], MAADNET designers decided to take the option of collaborating and improve the work already completed by the creators of CyberProtect (see section A above). MAADNET was adopted by the US Defense Information Systems Agency (DISA) as an education tool for user, manager, and technician education.

The tool has been built using an Object Oriented Design with Java applets. It was also foreseen to be utilized as a web based application using Java Web Start technology. The server hosts the simulation engine, the attack scenarios and the evaluation mechanisms. On the other hand, the client hosts a scenario generator tool, a network builder and the simulation viewer. The simulation offered is a high-level one not providing all the details down to the network protocol level. The network is built using different components such as switches, routers, workstations, wireless access points, etc. Each of these components can have one or more traffic generators associated to it.

In order to generate realistic events, the Mean Time Between Failures (MTBF) is one of the parameters that could be configured for each of the entities. Also, the Mean Time To Repair (MTTR) is another parameter that can control the time that takes to put again the component into an operational status.

The defense strategy is static: once that the network has been built, it will not change during the simulation of the selected scenario. On the contrary, the attacks are dynamic in nature based on the specific scenario. The probability of an attack succeeding is a function of the type of attack and the skills of the attacker. Creating reliable and credible attack/defense models of an acceptable quality is the main challenge here. Attack trees and Petri nets have been used to model and represent the attacks within MAADNET. The modeled attacks can be from the Internet (outsiders), from an authenticated user (insiders) or from the wireless infrastructure (both outsiders and insiders).

*C. **CyberOps: NetWarrior**, developed from the above one by US DoD's Defense Information Systems Agency (DISA) [10].*

CyberOps: NetWarrior has been developed from the "Military Academy Attack/Defense Network (MAADNET)" simulation closing the evolution of the product line presented in the two previous sections. The main enhancements introduced are related to the improvement of the interactivity and a web based approach with better graphics.

The tool is an immersive 3D virtual environment, with realistic looking network equipment, similar to an interactive video-game, where the player (student) has to create a network within specific resource constraints. The student selects the security defensive tools and other options that are going to be used on his/her network and then sequences of computer generated attacks are launched in order to assess the strength or the selected solution.

The evaluation performed by the tool takes into account parameters such as the utilization of specific security hardware and software, the policies and procedures in place, and the impact due to the (un)availability of the specialized information assurance virtual personnel, as well as their training, certifications and experience. Money is limited so the student needs to perform a cost/benefit analysis in order to make right choices when building the network. The students receive feedback that helps them to understand their success or failure in protecting the network. This feedback is dynamic and it is only related to the specific configuration selected by the student.

CyberOps can be used as academic classroom, technical training and computer network defense exercise support tool through a series of security roles such as NetBuilder, NetDefenser, NetAssurer and NetWarrior. Multi-player game has been enabled and students can group in Blue (defenders), Red (attackers) and White (referees) teams in an interconnected exercise.

*D. The cyber DEfense Technology Experimental Research laboratory (**DETERlab**) of the Information Sciences Institute of the University of Southern California [11].*

The DETERlab testbed uses the Emulab cluster testbed software developed by the University of Utah. It is a public facility whose utilization for information security research purposes can be requested by any principal investigator to the Emulab Approval Committee. Using DETERlab, a pool of experimental nodes can be controlled and interconnected in nearly-arbitrary network topologies.

The DETER testbed facility, from its inception in 2004, has not been aimed to be used for teaching objectives for users without a solid background in information assurance but for researches made by a relatively small experimental community. It could be anyway used for educational purposes provided that the target audience has the necessary level of knowledge. The DETERlab testbed has been used as a laboratory by university-level cyber-security classes.

DETERlab possess a model for dynamic federation that enables separate testbed facilities to come together on demand in order to support large-scale, complex, heterogeneous, multi-party experiments. In order to support such complex experiments, a tool has been developed for provide the researchers with the possibility of easily creating, planning and iterating through a large range of experimental scenarios: SEER (Security Experimentation EnviRonment) [12]. SEER comprises several tools for the configuration and execution of experiments and provides a user-friendly interface for the investigators. Some of those tools included in SEER are traffic generation tools, attack tools, network configuration tools, and data collection and presentation tools.

The main DETER aim is to be able to provide support for security experiments that are repeatable. This enables the researcher to repeat the experimental conditions accurately and to modify them only in a controlled manner. Currently the testbed is composed of two linked clusters: one at USC ISI and the other one at UC Berkeley, with around 300 experimental nodes at the moment of writing this article.

*E. **CyberCIEGE** from the Center for Information Systems Security Studies and Research of the US Naval Postgraduate School [13].*

CyberCIEGE is a high-end, commercial-quality video game developed jointly by Rivermind and the Naval Postgraduate School's Center for Information Systems Security Studies and Research [14]. The tool shows a simulation in which the student has to be the decision maker of an IT organization. The aim of the game is to protect the system by using appropriate security measures involving procedures, physical and technical security, while keeping the virtual users productive and pleased.

The number of different scenarios that can be played is unlimited since CyberCIEGE has been designed to be completely extensible. Apart from the simulation engine itself, CyberCIEGE includes a scenario definition language (with the corresponding definition tool - SDT) and a scenario development tool that enable creating completely new situations, and a context-sensitive video encyclopedia that serves as instructional aide.

Some of those new scenarios have also been developed within the Center for Information Systems Security Studies and can be obtained from [15].

CyberCIEGE is available at no cost to agencies of the US Government and there are also educational licenses available at no cost to educational institutions. Finally, there is a free evaluation version that has limited capabilities.

A comparison between the features offered by CyberCIEGE and the ones by CyberOps NetWarrior (see section C above) can be found at [16]

*F. NIST IPSec and IKE Simulation Tool (**NIIST**) [17, 18].*

NIIST is an integrated Internet security simulation framework developed by the National Institute of Standards and Technology (NIST). The tool has been implemented in Java and integrated in the Scalable Simulation Framework (SSF), a discrete, event-driven, scalable modeling framework, and SSF Network Model (SSFNet) [19], a collection of Internet modeling tools for simulating Internet protocols and networks. SSF is mainly focused in scalability and high-performance for large networks simulation.

While the main goal of NIIST is not to serve for the security education or training, but to characterize and study IPSec/IKE performance and its influence on end-to-end protocols such as TCP, it still could be used to teach the fundamentals of the Virtual Private Networks (VPNs) and IPSec.

*G. The Real-time Immersive Network Simulation Environment (**RINSE**) for Network Security Exercises of the Information Trust Institute of the University of Illinois at Urbana-Champaign [20].*

RINSE is a highly extensible simulator designed for large-scale, real-time cyber-security training and exercises. The simulator consists of five components: the iSSFNet network simulator, the Simulator Database Manager, a database, the Database Server, and client-side Network Viewers. The iSSFNet network simulator, which was previously known as DaSSFNet, is the latest implementation of the C++ network simulator based on the Scalable Simulation Framework (SSF) [19] mentioned and referenced in the previous section.

Every simulation entity connects to the Simulator Database Manager, which provides the data from the simulator to the database and delivers control information from the database to the simulator. The Database Server communicates with client applications, such as the Java-based application “Network Viewer”, which allows the users to monitor and control the simulated network from the client side. From there, the user can issue several commands in order to influence the model behavior. These commands include five different types: attacks, defenses, diagnostics networking tools, device control, and simulator data.

As other simulators presented in the article, the type of educational target for this tool is aimed at large-scale network exercises. However, it still can be used for smaller security training scenarios in order to teach specific information assurance issues on a network.

RINSE has evolved into a more complex and generic network simulator: PRIME (Parallel Real-time Immersive network Modeling Environment) for large-scale real-time network simulation [21]. PRIME is a project of the Modeling and Networking Systems Research Group within the School of Computing and Information Science of the Florida International University that has also been used for information security studies such as attacks in routing environments [22].

*H. The Reconfigurable Cyber-Exercise Laboratory (**RCEL**) for Information Assurance Education at the Center for Information Systems Security Studies and Research of the US Naval Postgraduate School [23].*

RCEL is the result of a Master’s Thesis developed by R. J. Guild within the US Naval Postgraduate School in 2004. The thesis describes the laboratory as a “flexible collection of equipment that can be quickly interconnected and configured” [23] and illustrates six practical scenarios with different learning objectives. These scenarios provide the students with the opportunity of participating in all phases of the security lifecycle: analysis, design, construction and operation. The lab configuration can be quickly changed in order to be used for different activities. In this case, the author proposes the use of Symantec Ghost to create images of pre-configured stations that could then be rapidly deployed when required.

The lab is composed of several stations each of which are specialized in one network function, such as: authentication, domain controllers, DNS server, DHCP server, FTP server, PKI Certification and Registration Authorities, syslog server, e-mail server, web server, database server, disk images storage server, wireless access points, honeynet, vulnerability assessment (VA), switches, routers, firewall, Intrusion Detection System (IDS) and Virtual Private Network (VPN) devices. One lab can be interconnected to another remote one using a public network by means of a VPN. Whether interconnected to another remote lab or not, the main idea for each learning exercise is that part of the LAN (or a complete VLAN) is acting as attacker while other parts act as defenders.

Probably virtualization, while existing, was not so widely spread when this thesis was written. If we would like to build a similar laboratory today we would most likely use virtualization instead of having dedicated specialized stations for each of the network functions. The maturity of virtualization and the processing power of current hardware allow doing so with an acceptable performance as we can see in the system presented in the following section.

*I. **Tele-Lab “IT Security”** from the Hasso-Plattner-Institut für Softwaresystemtechnik GmbH at Postdam, Germany [24].*

Tele-Lab “IT Security” is a web-based tutoring system that introduces students to fundamental IT security concepts and provides an on-line virtual laboratory for them to be able to gain practical experience.

The system leverages virtual machine technology for using a single host system as many different machines at the same time and to assign a remote machine to a student providing him/her with administrator rights without jeopardizing the stability and security of the training system.

Tele-Lab is implemented by using User-Mode Linux. Users manage the virtual machines by means of a connection that uses the Virtual Network Computing (VNC) client application.

*J. The Network Security Simulator (**NeSSi2**) developed at the DAI Laboratory, part of the School of Electrical Engineering and Computer Science of the Berlin Institute of Technology, and sponsored by Deutsche Telekom Laboratories [25, 26, 27].*

NeSSi2 is an open source discrete event network simulator, published under the Apache 2.0 license, incorporating several security-related capabilities that makes it different from the general purpose simulators, such as profile-based automated attack generation, traffic analysis and interface support for the plug-in of detection algorithms. The plug-in concept allows the functionality extension without changing the simulation core itself. Theses extension mechanisms allow three different levels of abstraction: application, network and device level.

NeSSi2 is built on the JIAC framework [28], a service oriented architecture based on agents. Agents are used in NeSSi2 for modeling and implementing the network devices such as routers, clients, and servers. JIAC agent framework provides a rich and flexible basis for the implementation and testing of diverse security configurations and algorithms in NeSSi2 that allows combining the partial knowledge of the agents residing in the network, in a cooperative approach for identifying and eventually eliminating IP-based threats.

NeSSi2 consists of a simulation back-end, a front-end (Graphical User Interface – GUI) and a database management system hosting the results database. The back-end and the frontend are available for download, for Windows, Linux and Mac OS, at NeSSi2 website [26]. For the database management system, NeSSi2 developers recommend MySQL but SQLite is also supported. The simulator has been built using Java SE 6. The subnets, the network elements and their properties, have been modeled using the Eclipse Modeling Framework (EMF) [29] which also enables automated source code generation and, thus, the model can easily be extended.

K. ***S-vLab**, an experimental environment for teaching Java security developed at the University of Bologna, Italy [30, 31].*

S-vLab is a virtual laboratory for supporting teaching and learning in different domains. Among them, S-vLab can also be applied to the information security area, being one of its main goals helping students in understanding the Java Security Platform.

The tool provides a graphical editor and a set of building blocks that are suitable for designing a simplified version of a system or protocol. In order to test and assess the efficacy and the strength of the proposed solution, students are able to simulate attacks. When playing the attacker role, students improve their knowledge on how to analyze systems for weak points, how to choose designs that prevent these flaws, and how to deploy defenses.

*L. A Windows Attack intRusion Emulator (**AWARE**) from Fairmont State University [32].*

AWARE is an emulator built on Microsoft Windows XP and for Windows XP users. Its main aim is teaching those users to detect potential attacks using the XP included tools and to remediate the effects of those attacks. Some of the XP emulated tools include: the Process List inside the Task Manager, the Registry Editor (regedit), a visual version of netstat (in order to search for unusual port traffic) and a limited version of the Windows Firewall log.

The system also includes built-in tutorials that help the user in understanding the tools, how to use them, how they look like, etc. At the end of the simulation, the user is presented with an evaluation of the results obtained with an indication on how well he/she did.

The emulator tries to change users' passives attitudes and to provide them with the possibility of counteracting future attacks. Previous computer security knowledge is not required.

M. ***RADICL**: A Reconfigurable Attack-Defend Instructional Computing Laboratory from the Department of Computer Science of the University of Idaho [33].*

RADICL is a highly reconfigurable laboratory which main objective is to enable students to understand attack scripts and other malware and to use defensive strategies and tools. It has been designed and developed by senior and graduate students in Computer Science, Computer Engineering, and Mathematics.

The requirements include switching operating systems on each laboratory machine and reconfiguring the network topology in less than four minutes. In twelve minutes, starting from machines without partitions and without operating systems installed, RADICL can be completely configured and ready to run.

The laboratory comprises sixteen workstations with dual NICs and one Xeon server that hosts the OS images. Each of the workstations is partitioned into nineteen segments with the same size in order to provide multi-OS booting. The different networks are separated by using VLANs. Most RADICL activity does not require advanced networking. A KVM switch allows the control of any of the seventeen machines in the laboratory. The central image server consolidates all RADICL capabilities into a single web-based front end making unnecessary moving hardware or unplugging and plugging cables and devices.

Further development has been made in order to extend the capabilities of the original RADICL lab. For example, Team 54 of the Computer Science Department of the University of Idaho has extended the project and renamed it as Vrad LAB [34]. Among other improvements we can find the use of virtualization by means of VMware which enables the possibility of running up to 16 virtual machines concurrently, the central storage of operating system images on a server, the possibility of running multiple isolated experiments and the remote access to the lab.

Not all the analyzed tools are easily accessible; therefore not all of them could be tested, as it was the authors' intention. It appears that it would be a good idea to have more open source, freeware and/or inexpensive developments in this area and specifically individual tools that allow easily good performance training. Within the Electrical and Computer Department of the Industrial Engineering School of UNED (Spanish University for Distance Education) there are several efforts in order to provide such tools not only for the students but also for the general public.

One of those applications is the information security didactical system presented at [35] that comprises two different tools: a network attack simulator and an intrusion detection system, IDS. Both tools share a usable and really friendly interface, and are distributed as a kit that can be easily installed by the student in any computer, since the system is open-source and multi-platform. The system has been developed in Java using Eclipse IDE. The system allows two types of users: the student that wants to explore more in detail the way an IDS works, and the collaborator who would like to extend the system by adding new features, such as new attacks and new signature attacks for the IDS.

Another example is fragSim [36], an interactive simulator for studying the IP fragmentation process that is in the process of being extended to include extra functionality. fragSim is a completely web based network simulator developed for the Adobe Flash framework. This makes possible to have access to the simulator from almost any imaginable platform with the only pre-requisites of being connected to the Internet and having a web browser with the Adobe Flash plug-in installed. The simulator allows a degree of user interactivity where the user is able to define the desired network topology, the value for the Maximum Transmission Unit (MTU) on each of the links and the size for the telecommunications protocol stack upper layer messages that will be fragmented. The application has also been built to be graphically attractive in order to positively influence the user learning experience while capturing user attention. fragSim has been in use during the academic year 2008/2009 by the students of two subjects within the Industrial Engineering School of UNED (Spanish University for Distance Education): "Industrial Communications" at 5th course of the MSc in Industrial Engineering, and "Industrial Communications Networks" at 3rd course of the BSc in Industrial Engineering. Unfortunately, it is still soon to have enough student evaluations in order to assess their perception when using fragSim, but the tool will continue to be available to the same students on following academic years and it is planned to expand the usage to other computer network and communications courses. It is expected to receive valuable feedback that allows the implementation of improvements and new features.

III. TAXONOMY

Saunders [1, 2] produces a taxonomy by classifying the information security simulators in five distinct categories: PacketWars, Sniffers + network design tools (also named Flexible Network Design in other parts of his document), Canned attack/defend scenarios, Management flight simulators, and Role-playing.

PacketWars refers to a type of simulation that utilizes network attack and defense at a tactical level. Most of the simulators in this category are implemented in real networks with real equipment but not necessarily all of them due to the benefits of simulation and/or virtualization. The network infrastructure used to organize annual Cyber Defense Exercises (CDX) by governmental/military authorities, such as the ones organized by the US National Security Agency (NSA) [37] or the North Atlantic Treaty Organization (NATO) [38], will also fall into this category.

Sniffers + network design tools category comprises the tools that combine the use of Network Modeling and Simulation (NMS) packages with the use of network protocol analyzers (also known as sniffers). In this category, the tools mentioned in the introduction of section 2 [3-6], would be included. In this article, we have also included tools that work as a generic NMS but are specialized in information security modeling.

Canned attack/defend scenarios includes most of the tools analyzed in this article. According to Saunders, here we refer to simulators that are typically standalone and can be used as a game. As we have seen in the previous section, some of them have evolved incorporating the possibility of connecting to other remote "players" or being remotely managed. Therefore, not all of them are completely standalone applications.

Management flight simulators are, according to Saunders, applications built using a System Dynamics or a Discrete Event Simulation (DES) tool. However, in the research, we have not considered the requirement in this statement to be essential and, following [1, 2], the key feature considered for including one of the simulators in this category is the management of resources (money, personnel, devices, etc.) during the simulation, regardless of the tool used to develop the system or its use only by managers or directors.

Role-playing is a type of simulation that does not employ computer-based simulations but, as it can be easily inferred, actors playing different roles within a given scenario. In this area, the Cyber Defense Exercises mentioned before, in their part related to the strategic level decisions, would be included.

Taking into account these descriptions, the simulators analyzed in this article have been classified in Table I:

TABLE I. CLASSIFICATION UNDER SAUNDERS CATEGORIES

Simulator Name	Category
CyberProtect	Canned Attack/Defend Scenarios
MAADNET	PacketWars
CyberOps: NetWarrior	Canned Attack/Defend Scenarios
DETERlab	PacketWars
CyberCIEGE	Management Flight Simulators
NIIST	Not applicable
RINSE	PacketWars
RCEL	PacketWars
Tele-Lab "IT Security"	PacketWars
NeSSi2	Sniffers + Network Design Tools
S-vLab	PacketWars
AWARE	PacketWars
RADICL	PacketWars

As Table I shows, most of the tools analyzed in this article fall under PacketWars category. Saunders' classification was done with the aim of assisting in making a decision about the level of effort that would be needed to get started in the information security simulation world. However, the presented categories do not provide per se the intended knowledge to serve as assistance for making a decision; nevertheless, the required knowledge can be inferred from [1, 2], specially from the categories comparison table included there.

Therefore, in this article, the taxonomy has been broken down into several distinct tables. On the first two (tables II and III), the general technical features of the analyzed tools will be presented while, on the other two (tables IV and V) the focus will be put on the features related to the teaching and didactical capabilities of the tools.

TABLE II. TECHNICAL FEATURES

Simulator Name	Type	Remotely usable	Virtualization
CyberProtect	Simulator	No	No
MAADNET	Simulator	Client/Server Architecture	No
CyberOps: NetWarrior	Simulator	No	No
DETERlab	Laboratory	Yes (using a XMLRPC API)	Yes
CyberCIEGE	Simulator	No	No
NIIST	Simulator	No	No
RINSE	Simulator	It can be interconnected to real-world networks	No
RCEL	Laboratory	It can be connected to external organizations by means of a VPN	No
Tele-Lab "IT Security"	Laboratory	Yes	Yes
NeSSi2	Simulator	Yes (installing the frontend on a different machine)	No
S-vLab	Laboratory	Yes	Yes
AWARE	Emulator on Windows XP	No	No
RADICL	Laboratory	Web interface configuration	Yes

Type indicates the type of analyzed tool. Most of them are simulators, some of them are laboratories and we have an instance of an emulator.

The second column indicates if the tools can be remotely managed/operated.

The third column shows the virtualization capabilities of the tools.

Table II shows how analyzed tools have been classified into three types. Many of them are simulators: computer applications that reproduce the system behavior under certain specific conditions. One of them could be classified as an emulator: a computer application that models a system accurately, mimicking its actions and trying to exactly match the same behavior as the real system. The third type is for computer laboratories: sets of real devices typically separated from the production networks, and which main objective is to perform experiments in a controlled environment.

Regarding the capability of being remotely used, we have found tools that can be managed via web, by means of a custom made client/front-end, using an Application Programming Interface (API), and even connecting to real-world networks, or the ones that do not have any of these possibilities.

Finally, in table II we have classified the tools by indicating which ones use virtualization and which ones not. Virtualization is a technique that allows partitioning a single physical machine into several virtual machines that typically can run different instances of the operating system, not being necessary that those instances are identical or even of the same operating system.

TABLE III. TECHNICAL FEATURES (CONTINUED)

Simulator Name	Standalone	Scalability	License
CyberProtect	Yes	Limited by HW features	Unclassified application available at no cost
MAADNET	No	Limited by HW features	Not available outside USMA
CyberOps: NetWarrior	Yes	Good (by means of new scenarios)	Unclassified application available at no cost
DETERlab	No	Excellent (DETER Federation)	Public use. Projects under a principal investigator previously authorized by Emulab Approval Committee
CyberCIEGE	Yes	Good (by means of new scenarios)	Commercial. No cost for US Government or Education Institutions (also outside US). Free evaluation coy available
NIIST	Yes	Not applicable	Open Source
RINSE	No	Excellent	Open Source (PRIME SSF and PRIME SSFNet)
RCEL	No	Fair (by adding more machines or by interconnecting with other labs)	Not available outside NPS
Tele-Lab "IT Security"	No	Very good	Open Source
NeSSi2	Yes	Excellent	Open Source
S-vLab	No	Unclear	Open Source
AWARE	Yes	Not applicable	Unknown
RADICL	Yes (the network lab is not connected to other networks)	Fair (by adding more machines)	Available only at the University of Idaho

Standalone indicates whether the analyzed tool is/can be installed on a single machine.

The second column gives an indication of the growing capacity of the tool.

The third column expresses the type of license under which is distributed the tool.

In Table III, the tools have been classified as standalone or not. A standalone application is one that can run without a network connection on a single system. Please note that RADICL has been classified as standalone but taking into account that the whole laboratory itself is not connected to networks other than its internal one.

On the second column, a classification measuring the level of scalability of the solution has been presented. The scalability is the property that allows expressing the growing ability of the tool both in terms of handling increasing amounts of tasks and in terms of being readily enlarged. A scale with values: poor, fair, good, very good and excellent has been used.

The last column on this table indicates the type of license used for the tool distribution, if any. Note that some of the laboratories (MAADNET, RCEL and RADICL) can only be used on the premises where the lab is installed since they also do not have the possibility of being remotely managed.

There are not many tools that are ready to be used for standalone study. This is of paramount importance for the typical student of an Open University. Further development on such tools and/or simulators in-the-cloud would be desirable.

Also, while we found some tools that are open source, for public use or at no cost for educational institutions, it would be worthy to count on further efforts on this area.

Finally, it is necessary to remark that all of the tools found are in English, while it was expected finding some tools completely translated into other widely spread languages, such as Spanish. S-vLab web site and documentation is in Italian.

TABLE IV. DIDACTICAL CAPABILITIES

Simulator Name	Target Audience	Teaching Objectives	Learning Curve
CyberProtect	Novice network security professionals	Generic information security training	Fast
MAADNET	US Military Academy cadets	Generic information security training	Fast
CyberOps: NetWarrior	Information Assurance Students	Generic information security training	Fast
DETERlab	Academic and industrial cybersecurity researchers	Teaching is not the main target. It has been used as a laboratory by university-level cyber-security classes	Slow
CyberCIEGE	Information Assurance Students	Information assurance basics. Risk management. Resource management	Fast
NIIST	Researchers of new and existing intenet security technologies, protocols or protocol mechanisms	Research and evaluate the dynamic behavior of an interacting suite of security protocols in large scale VPNs	Slow
RINSE	Experienced network security professionals	Large-scale, real-time cyber-security training and exercises	Unclear
RCEL	Information Assurance Students with a profound technical background	Support of an information assurance education program	Moderate
Tele-Lab "IT Security"	Information Assurance Students with minimum previous knowledge	Many different subjects. Basic level	Moderate
NeSSi2	Computer Science students and professionals	Detailed examination and testing of security-related network algorithms, detection units and frameworks	Moderate
S-vLab	Students of 4º course in a 5 years degree	Java Security	Fast
AWARE	Windows XP users	Detect potential attacks and remediate the effects using Windows XP built-in tools	Fast
RADICL	Information Assurance and Computer Engineering Students	Understanding attack scripts and other malware	Moderate

The target audience column shows the expected main “customers” for the tool.

The second column provides a description of the main topics that the tool could be demonstrating to a potential student.

The third column depicts the speed of the learning process from the moment that the tool starts to be used.

In Table IV, as target audience we have mainly found information assurance students within computer science courses/degrees. However, the complexity of the tools makes some of them unreachable for people without a solid background in networking and information security. It is remarkable that there is one tool (AWARE) that is clearly targeted to users with only a basic knowledge on using their personal computers. The authors have tried to obtain the tool from the developers for further assessment without response so far.

The learning objectives cover a wide range of completely different possibilities. While some tools’ aims are deliberately high-level, specific ones, due to their focus on large-scale, complex experiments, many of the analyzed tools show different levels of generic information security training even appropriate to novice students. Those complex ones are not suitable for being used as starting point for teaching information security.

At learning curve column, an indication on the level of effort required for the student to be able to use the tool at an acceptable level of efficiency is shown. The use of the term “steep” has been intentionally avoided since sometimes has different interpretations. The used values are: slow, moderate and fast, being “slow” the one that shows more difficulties in reaching the target and “fast” the one with fewer difficulties.

TABLE V. DIDACTICAL CAPABILITIES (CONTINUED)

Simulator Name	Usability	Level of Detail
CyberProtect	Very good	Fair
MAADNET	Very good	Fair
CyberOps: NetWarrior	Excellent	Good
DETERlab	Good	Excellent
CyberCIEGE	Excellent	Good
NIIST	Fair	Very good
RINSE	Good	Good
RCEL	Good	Excellent
Tele-Lab "IT Security"	Good	Unclear
NeSSi2	Very good	Excellent
S-vLab	Good	Fair
AWARE	Very good	Fair
RADICL	Good	Very good

The usability denotes the ease with which the students can employ the analyzed tools in order to achieve the learning targets.

The second column shows how complex is the tool and how accurately represents the real system.

Finally Table V shows, for the usability, the values poor, fair, good, very good and excellent have been chosen, being “poor” the value that express a condition in which the student hardly can utilize the tool for achieving the objective without a considerable effort, and “excellent” the situation where the student start receiving benefits from the learning action from the very beginning.

The level of detail is related to the didactical capacity since it indicates the fidelity of the abstraction that the tool provides. It has to be noted that the closer to the real system, the higher the level of detail, but also the bigger the effort required. The values are exactly the same as the ones in the previous paragraph with a similar meaning.

As a final point, it can be added that it would be desirable to have more tools for students without previous experience in information assurance issues and covering diverse related aspects.

CONCLUSION

Not all the security simulators found and analyzed in this article are mainly developed having information security education, training and/or awareness in mind. However, most of them can be used in the purpose of illustrating different information assurance concepts and ideas. It would be desirable, anyway, that new tools were developed with a focus on enabling information assurance concepts teaching, not only for university students but also for anyone interested professionally in these subject matters. We think also that these tools must be extremely easy to use and also individualized, allowing a deep understanding of the concepts by doing “experiments” in the students’ own environment. In that sense, we are developing an effort to create an integrated toolset of information security training tools, in order to illustrate different aspects of the subject matter and we are also evaluating which of the analyzed tools in this paper could be part of this toolset.

When the tools research was started it was expected not to find many. Even when the number of identified efforts is non negligible, it can be stated that there is still a long way to be followed until finding an acceptable diversity in this kind of tools covering every information assurance aspect that needs to be taught. Therefore, further developments in this area are going to be, for sure, warmly welcomed by the education community.

ACKNOWLEDGMENT

The authors would like to acknowledge to the European Union Socrates the support in the IPLECS Project – Internet-based Performance-centered Learning Environment for Curricula Support Project ERASMUS 141944-LLP-2008-1-ES-ERASMUS-ECDSP as well as in the Project 142788-2008-BG-LEONARDO-LMP mPSS – mobile Performance Support for Vocational Education and Training Project.

mwyne@nu.edu

Recent decades have seen internationalization of the engineering practices thus making engineering education an international enterprise. Graduates from a certain engineering program may have to work not only in a different state (in case of USA) or a different country. The graduate may also be working in a multinational company. This situation further increases the interest among the institutes to get their program accredited. An accredited degree program is the one that has gone through a rigorous quality control system and has been approved by a national or international accrediting agency or organization. The importance of graduating from such programs is growing with the increasing demand of global engineers.

Engineering educators need to focus on several key areas, among which are development of curricula, graduate studies, research, development and promoting university-industry ties, and accreditation. Accreditation provides an educational institution or a program with a credential. The credential is most often a public statement that the academic unit satisfies a set of quality criteria established by the accrediting body. Through the accreditation process, the faculty, the facilities, the student body, budgets, recruiting practices, admissions procedures, course content, and other pertinent issues come under thorough review. The accreditation process may operate at a broad or narrow scope. A panel discussion is organized to discuss new directions in engineering accreditation. EDUCON-2010 panel session will provide a unique opportunity to educators, researchers and technologists who are willing to discuss how they are integrating digital technologies, instruction, and changes to university facilities in their programs seeking accreditation or how they think it should be done. It will also provide a forum for discussing and debating new directions and approaches relevant to accreditation with eager industrial and academic audiences. Following are some of the relevant questions that we would like to address during this panel session;

- Does accreditation help to maintain quality of education?
- What is the impact of accreditation on traditional learning environment?
- Are traditional approaches to accreditation meeting today's need?
- What are some of the problems with accreditation?
- How can accreditation be reformed?
- What are the new trends in accreditation?
- What are the important issues specific to engineering accreditation?
- What incentives do faculty members need in order to commit to accreditation activities?
- What are the alternates to accreditation, if any?

All these questions are the subject of ongoing attention and discussion by academicians, ABET and in various ways by other ABET member scociteies.

Course design approaches for the EHEA

Scaling up from pilots

Duran, Alfonso

Somacarrera, Maria Luisa
Univ. Europea de Madrid, Spain

Abstract— **After years of preparation and limited-scale pilot projects, full blown implementation of European Higher Education Area (EHEA) compliant degrees started in 2008 at the UC3M. This paper discusses the final stages of preparation, as well as the initial lessons from this go-live experience, focusing on a core (compulsory) second year subject of the computer engineering curriculum whose full-scale implementation started in 2009. Lessons drawn from the preparatory pilots are presented, implementation challenges are identified and analyzed, and both school-level and course-level required design approaches are discussed. Conclusions highlight that successful adoption of some critical elements of the EHEA methodology in the Spanish engineering education environment is far from certain.**

Keywords- Bologna, EHEA, course design, curriculum development

I. Introduction. EHEA adoption in Spain

The 1999 Bologna Declaration, currently endorsed by 46 countries, aims at the creation of a European Higher Education Area (EHEA) based on international cooperation and academic exchange [1]. It involves major reforms in the higher education systems (as well as an alignment processes with the European Research Area), including: Common adoption of a three-cycle structure (e.g. bachelor-master-doctorate); Quality assurance in accordance with the Standards and Guidelines for Quality Assurance in the European Higher Education Area (ESG); Fair recognition of foreign degrees and other higher education qualifications in accordance with the Council of Europe/UNESCO Recognition Convention.

In Spain, the first EHEA-compliant bachelor degrees started in September 2008, among substantial controversy. 33 Spanish public and private universities, out of the 75 existing ones, offered 163 programs. By Sept 2010, all bachelor degrees must be EHEA-compliant.

The Bologna Process Stocktaking Report 2009 [2] analyzes and compares, using various criteria, the current implementation status of participating countries, and Europe as a whole. More specifically, the Spanish National Report compiled by the Spanish Government in 2009 discusses in detail the current status of EHEA adoption in Spain [3].

The Spanish National Report analyzes the evolving regulatory framework within which EHEA implementation in Spain is taking place. This framework encompasses Royal Decree 56/2005 of 21st January, on official postgraduate studies. This Decree, later superseded, created a temporary legal base which led to the first EHEA-compliant postgraduate degrees, even though no EHEA-compliant undergraduate degrees (the natural source for candidates) could still be offered. The current regulatory framework is largely determined by Royal Decree 1393/2007 of 29th October, which regulates the organization of official university education and develops the new structure, encompassing:

- First cycle (Bachelor). According to EHEA agreements it could range between 180 and 240 ECTS; in Spain it has been standardized at 240 ECTS credits, equivalent to 4 years of full time study.
- Second cycle (Master's) studies, ranging from 60 to 120 ECTS credits.
- Third cycle (Doctoral) studies lasting between 3 and 4 years.

Royal Decree 1393/2007 defines 5 broad "branches" for undergraduate degrees: Arts and Humanities, Natural Sciences, Social Sciences and Law, Health Sciences, and Engineering/Architecture. Each undergraduate degree must be ascribed to one of these branches and must include at least 60 ECTS of "basic" courses. At least 36 ECTS of these "basic" courses should be on the topics listed for the degree's branch. For example, any Engineering/Architecture degree should include at least 36 ECTS credits from physics, mathematics, computer science, business administration, graphical expression (i.e. technical drawing), and chemistry [4]. No content guidelines were specified for master's level degrees in order to encourage universities to foster their unique specializations. Special degrees such as Medicine should be regulated separately from other degrees. Those degrees requiring certification for professional licenses such as engineering require additional content guidelines; however, these additional guidelines were not prescribed in R.D. 1393/2007; for engineering degrees, were only issued in February 2009, as discussed below.

Royal Decree 1393/2007 also replaced the previous government-approved closed catalogue of official engineering degrees by an open-ended evaluation and accreditation process whereby each university could propose whichever bachelor degrees it deemed appropriate. Therefore, these 163 new degrees were, for the first time, designed without a government-provided template.

II. CURRICULA DESIGN AND APPROVAL

The public university Carlos III of Madrid (UC3M) was the only one to embrace a big-bang conversion approach, proposing a simultaneous replacement of all its existing engineering degrees by the new ones. After completing the Quality Assurance review (ANECA), 80% of these proposals were approved by the education authorities, thus, in September 2008, 8 out of its 10 undergraduate engineering degrees were discontinued, and replaced by new offerings conforming to the new cycle structure, credit transfer system and pedagogical and assessment approach. The two remaining ones, which were particularly affected by unsettled elements of the regulatory environment (specifically, professional licenses granted at the master's level) will be transformed in September 2010.

This meant that all UC3M engineering degrees were simultaneously redesigned. Furthermore, as previously discussed, the curricula for these degrees were, for the first time, designed without a government-provided template, subject solely (since they all belonged to the Engineering/Architecture branch) to the stated prerequisites on the 60 ECTS of "basic" courses, encompassing 36 ECTS credits from "basic" subjects.

This created an opportunity to exploit synergies between degrees [5]. In some cases, such as the Univ. Europea de Madrid's Health School, the gradual (and, therefore, only partial) conversion to EHEA of related degrees has delayed the materialization of these synergies, while on the other hand it has provided the opportunity to gain from the experience of the first ones to undertake a full conversion (e.g., better understanding of the potential of IT support tools, such as anti-plagiarism tools). In the school of engineering of the Carlos III University, the first two years of degrees belonging to the same "family" (industrial, telecom, computer science...) will be identical, to allow for built-in flexibility for late career path changes as well as resource pooling in areas such bilingual groups. Furthermore, the February 09 decrees, that established additional content guidelines for regulated engineering professions requiring professional licenses, imposed "family modules" (i.e., "Módulos comunes a la rama industrial"), that all degrees of the same family must include in their curricula, in addition to the basic branch-linked subjects. Since these additional guidelines were issued when the corresponding bachelor degrees were already being offered at the UC3M, some "retro-fitting" has been performed on the curricula – and sent back to the education authorities for approval - to ensure they conform to the guidelines.

Implementing these changes while the degrees are already being taught complicates the process further. At UC3M, complying with the guidelines has often merely required minor content changes in various course descriptions, but in a few cases it has forced to introduce new courses (and delete others). Since the new degrees started in September 2008, and the new guidelines were published in February 2009, these changes are being located in the curriculum, whenever possible, not earlier than the second quarter of the second year, so that the first cohort of students had not taken these courses yet. As an example, the subject discussed in this paper, Foundations of Engineering Management (FEM), had to be moved, in three degrees, from 4^{th} year to 2^{nd} year. In some of these, it might have been preferable to locate it in the first term. However, since students would be attending the first term of the second year by the time the proposal would be approved, they were all assigned to the second term.

This issue is also complicated by the coexistence of professional licenses that require a bachelor degree and others that require a master degree. As an example, a bachelor in electrical engineering will be entitled to sign electrical projects. A bachelor in mechanical engineering will be entitled to sign mechanical projects. However, if either of them goes on to complete a masters program in industrial engineering, he/she will be entitled to sign both electrical and mechanical projects.

These changes also led to the creation of some subjects, corresponding to the list of the Engineering/ Architecture basic topics, which spanned all the engineering degrees. The subject analyzed in this paper, Foundations of Engineering Management, implements the "business administration" basic topic, and spans 7 different engineering degrees, from Telecommunications to Mechanical Engineering.

Regarding methodology, the Bologna process was supposed to involve a significant shift from instructor-centered "teaching" to student-centered "active learning". This necessitates methodological changes such as implementing continuous evaluation schemes, de-emphasizing theory-only lectures, developing assignments and class projects, and encouraging hands-on experiences. It should also allow the students to design their own curricula with a higher level of flexibility.

III. PREPARATORY PILOTS. LESSONS DRAWN

In preparation for the full-scale implementation, the UC3M and specifically its School of Engineering has been experimenting, learning and paving the way for these pedagogical changes while the legal framework was being finalized. Some groups were created for testing purposes and some degrees were chosen to extensively test out the new methodologies. The UC3M has funded a number of methodology adaptation projects and faculty training. New metrics for evaluating the faculty performance and a support infrastructure for the new pedagogical approaches have been developed. New computer tools, deemed more appropriate for the new environment, were sourced and tested (Moodle-based LMS, Turnitin© ...).

In anticipation of this full-scale implementation, the group involved in the project presented in this paper has gradually introduced, in the last few years, various elements of the methodology in lower-volume courses in existing degrees, and various approaches have been tried and evaluated in terms of their effectiveness and their scalability.

The EHEA-compliant Master in Engineering Management and Logistics, established under the provisions of Royal Decree 56/2005 and coordinated by one of the authors, has become an integrated testbed. Since its inception in 2006, all its subjects have been taught following the Bologna approach: approx. 50% of the grade is based on continuous evaluation, attendance is compulsory, emphasis has been shifted from lectures and theoretical examinations to individual and group assignments, number of lecture hours per ECTS has been reduced while workload has been concentrated in the student preparation, etc. This has provided valuable insights into the potential learning effectiveness of these approaches, but has also highlighted its difficulties and the risk of the instructor's workload exploding out of control, particularly in terms of grading assignments. Care must be exercised, however, while extrapolating these experiences to undergraduate courses, since Master students have a different, more mature profile and their number has been capped at 20.

To get some insights from student groups that are more similar to the undergraduate courses in which EHEA is initially being fully implemented, partial pilots have also been carried out in various student groups of the existing undergraduate degrees. Several English-based groups (where the institutional framework is more flexible, since students can always opt out into a Spanish group) have tried compulsory attendance, continuous evaluation and emphasis on homework assignments. In the last three years, four of these courses have been taught by foreign professors coming from institutions that routinely apply Bologna-like methodologies, and the results and the acceptance by the Spanish students has been closely monitored (with mixed results). Student reaction seemed to be heavily influenced by the specific profile and attitude of the professor involved, and his ability to positively engage the class. In all cases, however, there were complaints by students that could not attend the sessions and were therefore penalized. Three university sponsored pilots (one of them still running) have focused on improving teamwork and communication tools in a problem-based learning environment, making extensive use of interaction tools (such as electronic forums) and migrating to the web platform (Moodle based) on which the new degrees are supported.

These various pilots have confirmed the pedagogic potential of the "Bologna process" student-centric, outcomes-oriented methodologies. They have also, however, highlighted the significant hurdles must be overcome for their effective adoption in the Spanish engineering education environment, particularly when budget constraints are taken into account. Tackling these difficulties requires achieving the educational equivalent of the current manufacturing trend towards "mass-customization", in order to allow individually tailored learning paths with a level of resources similar to that required by standardized education.

These difficulties include:

- Resource requirements vs. availability. Pilots have highlighted the risk of the instructor's workload, particularly grading assignments, bursting out of control. On the other hand, and even more so considering the current economic climate and the sore status of the public finances, these reforms are generally being implemented under a "zero net additional resources" policy. That limits the approaches that can be implemented. "Craft-like" approaches that can be effective in the shift to a more active, participatory and student-centric methodology in smaller subjects can not be applied within existing resource constraints. Preliminary pilot results suggest that, unless course designs (and, particularly, evaluation procedures) incorporate elements specifically aimed at allowing scalability, these approaches can not be properly implemented with the current resources. Besides the need for additional resources, in some instances the need is for different resources, such as smaller, multi-functional classrooms, in which students can be rearranged in several working groups.
- Assessment process and motivation. This challenge relates to both instructors and students. Professors are evaluated and compensated according to their research output ("publish or perish"), with teaching being treated as a necessary evil. This complicates the implementation of pedagogical approaches that place heavy demands on their time and energy. As for the students, a substantial cultural and attitude shift towards assuming responsibility for their own development would be required, and it is not clear how to bring about this major change.
- Continuous evaluation. Conventional, individual written exams allow a reasonably accurate, fully individualized evaluation, which is hard to attain in a continuous evaluation environment, particularly if faculty resource constraints are taken into account.
- Consistency assurance. Guaranteeing a reasonable level of commonality in course contents and grading standards is harder to achieve in a proactive, student centered learning environment, where the learning is based to a substantial extent in a two-way interaction among the students and the instructor.

IV. GOING LIVE. COURSE DESIGN APPROACHES

To discuss the go-live experience, and therefore the implications of scaling up from the pilot experiences, this paper will focus primarily on the implementation project of a core (compulsory) second year subject of the computer engineering curriculum.

As discussed above, the potential synergies created by the simultaneous redesign of the various engineering curricula led to the creation of some subjects, corresponding to the list of the Engineering/ Architecture basic topics, which spanned all the engineering degrees. The subject analyzed in this paper, Foundations of Engineering Management (FEM), implements the "business administration" basic topic, and spans 7 different engineering degrees, from Telecommunications to Mechanical Engineering. This being a core (not elective) subject, this will result in a large number of parallel groups being taught in any given academic year. Since the implementation of these undergraduate degrees started in September 2008, and this subject is taught in the 2nd year, teaching started in September 2009 in 1 degree (Computer Engineering), and is scheduled to start in six more in the second quarter of this academic year (Feb. 2009). It may also be extended to the remaining existing degrees once they are converted, as well as to new degrees.

Designing the syllabus and teaching approach of new courses such as this requires taking coordinated design decisions at various levels. Decisions affecting the institutional and regulatory framework, as well as those involving shared physical infrastructures such as classrooms, must be taken at the University or School level.

A. Design decisions taken at the University or School level

Decisions taken at the UC3M or School of Engineering level include:

- Institutional framework for assessment procedures. University-wide guidelines governing continuous evaluation have been issued. A minimum of 40% of the grade has been allotted to continuous evaluation, with no minimum thresholds for either the continuous evaluation or the final exam. Attendance to laboratory sessions, however, can be made compulsory. Detailed provisions have been made for the case in which students do not attend the continuous evaluation; their final grade will be 60% of the final exam grade, even if for that particular course continuous evaluation accounts for more than 40%. Similar provisions apply to the "extraordinary", make-up evaluation that takes place in June-July for students that received a "fail" grade.
- Small groups for practical sessions. Each 6 ECTS subject involves, each of the 14 weeks that make up a semester, a 90 minutes large-group lecture for up to 120 students and a 90 minutes small-group session, in which each large group is broken up in 3 smaller groups. Evaluation takes place in the small groups. This is aimed at allowing a small group setting where interactive methodologies can be applied, while containing the overall cost impact.
- Multifunctional classrooms. The small-group sessions take place in smaller classrooms, specifically equipped to allow different seating layouts, including breaking up into small 6-member teams.

B. Design decisions taken at the course level

The lessons learnt from the previous pilots (discussed above), as well as the actual experience of those departments whose courses are located in the first year, and had therefore already faced these issues last year, was taken into account while designing the approach implemented in FEM this first quarter. This quarter's implementation experience, in turn, is being closely monitored in order to fine tune the approach for the second quarter and for subsequent years, as well as to serve as a basis for the design of subsequent courses by the same team. Furthermore, some of the approaches being piloted in this course will be presented to the management of the Engineering School, to analyze the potential of a wider implementation.

While incorporating all these elements into the actual design of the FEM, some detailed but nevertheless relevant additional issues arose. Several of them concerned the coordination of the small groups.

Splitting the large groups into several small groups requires that the course content is consequently divided in the components that can best be taught in a traditional lecture format and those that benefit from the interaction that smaller groups allow. The methodology for the small group sessions must also be defined. A sensible approach would be to use the weekly large group session to explain theoretical contents and use the other small group session to carry out practical exercises, case discussions and other activities that engage students in an active learning model. That was the rationale behind the two 90-minutes weekly sessions design decision.

That is, however, more easily said that done, since it creates a number of coordination hurdles:

- Large group-small group sequencing. Since practical sessions apply theory that must have been previously taught at the large groups, a precedence condition is created. Bank holidays affecting some sessions but not others alter this balance. Furthermore, actual experience during the first quarter highlights how otherwise minor alterations of the normal schedule become far more disruptive under this schema, e.g., time lost at some groups due to a student delegate election or to student satisfaction surveys.
- Weekly coordination among instructors in large and small groups.
- Since evaluation is carried out in the small groups, attendance and attitude in the large groups drop.

Another source of variability stems from the uneven attitude and profile of faculty members. Some faculty members can be reasonably expected to apply certain participative methodologies in a value-adding manner, while as others, if requested to apply them, may do so in a counterproductive way, leading to the dilemma of whether to allow heterogeneity in methodology.

Course-level design decisions that are being tested and monitored to tackle these challenges include:

- Stand-alone modules that can be taught in the small groups without precedence relationships. Some chunks of the syllabus are not excessively dependent on the rest of the components. They can be used to decouple the schedule of the various small groups; small groups that, due to the reasons mentioned above, find themselves "ahead" of the required theoretical contents simply devote a session or two to these semi-independent modules.

- Grading only some of the assignments. Grading only a fraction of the assignments or intermediate tests each student has submitted reduces grading workload, thus allowing more frequent and/or more complex assignments. A significant drawback is the generally negative attitude that students display towards sampling based grading. Various measures should be proactively taken to minimize this resistance, including clearly explaining upfront the whole grading procedure and its rationale and grading the same assignments for each student.

- Extensive utilization of educational IT tools. It encompasses fully exploiting the administration functionalities of Web based Learning Management Systems (such as Moodle©) to automate assignment collection, identify students that failed to turn in their assignments, etc. It also involves IT mediated grading, particularly through the utilization of test databases.

- Integrating antiplagiarism tools in the Learning Management System: The use of tools such as Turnitin© might help to deter plagiarism. However, using this tools, if not properly integrated with the LMS being used, increases the assignment administration workload. Use of widely utilized LMS's, such as open-source Moodle, increases the chances that antiplagiarism tools have been seamlessly integrated. This first quarter, an integration of Turnitin© into a Moodle-based LMS is being tested, with mixed results so far.

- Reutilization of existing educational material. Approaches such as using OpenCourseware can reduce the effort required by these participative methodologies.

- Integrating research projects into the pedagogic methodology. Actively engaging the students can be facilitated by involving selected students in actual research projects, as well as by including as a specific aim in the research projects the production of results that can enrich the educational process. In this specific case, a multi-year research project in which the whole Engineering Management group is involved provides both the setting for allowing particularly competent and motivated students to get an initial exposure to research, and a wealth of real-life problems, models and situations that are being used to develop the material for the practical sessions, thus leading to substantial synergies.

- Factoring attendance into the continuous evaluation. Initially, attendance was monitored in both the large and the small groups, with the idea of factoring it into the calculation of the continuous evaluation grade. It led, however, to classes in the large group being full of students that were there merely because they were forced to, who did not bother to listen and kept talking to each other, rendering the sessions quite hard to manage. The current approach is to make attendance to the large group sessions voluntary and to control attendance at the small group sessions.

V. Conclusions

The more tangible and formal EHEA elements, such as adoption of the three cycle structure, ECTS or Diploma supplements can be "imposed by decree" and will eventually be implemented. However, effective adoption of the supporting methodological and cultural elements, such as the shift towards an active learning, student centric, learning outcomes based approach is much less certain. On the other hand, implementing EHEA's formal aspects without adopting its methodological underpinnings could actually make things worse. The approaches and lessons discussed in this paper might be helpful in overcoming the stumbling blocks that hinder that implementation.

Abstract— **Visualizations are widely used in programming courses but the integration of these software tools into classrooms is not straightforward since there is a lack of information about the real benefits for learning and how to combine them with traditional lectures. We describe in this paper an experiment of using dual instructional support materials (textual and visual programs) in the lab classes in a Java-based CS1 course. The approach consists of two phases: students work the class concept in a traditional programming environment and the object concept in a visual environment as Greenfoot. The experiment shows positive results in terms of concepts understanding in students with no prior programming experience. Therefore we also suggest this as a possible way for integrating visualizations to the course.**

Keywords-component; Object-oriented programming, Visualization, Novice Programmers, Greenfoot

I. Introduction

Many studies have been carried out to know firsthand the main problems and difficulties in object-oriented introductory courses (CS1) both from the teaching and the learning point of view [1][2].

In a CS1 using an object-oriented language, it is crucial that students get a good understanding of key abstract concepts like object and class at an early stage [3]. Since in our degree on Computer Science we follow an approach that combines a strong start in basic constructs with early object-orientation [4], we are concerned with this issue.

Novice programmers do not have a concrete model in their everyday life to handle with these abstract concepts [5]. According to [6] between 75% and 83% of students are visual learners and, therefore, we could provide interactive visualizations for the students to concretize abstract concepts at the beginning of the course. Some of these visualization tools are devoted to help students “see” what an object actually is [7], as BlueJ [8], Greenfoot [9] or Alice [10].

Encouraged by this trend, we decided to use one of these tools in a first semester course in object-oriented programming with Java in order to engage students and improve their comprehension of the class and object concepts. However, the introduction of this software tools into the teaching practice is not straightforward since there is a lack of information about the real benefits for learning [7].

Consequently, using a visualization tool also implies to design a teaching strategy to make the use of such tools as efficient as possible from a pedagogical point of view. We have adopted an incremental approach separating and grouping concepts and stages. The class concept and the compilation stage are worked in a Java development environment. The object concept and its behavior are worked in a visualization tool for Java like Greenfoot, in which students’ programs can be run step-by-step or in continuous play mode without making changes in their source code. For that, we have developed several dual instructional support materials in order to work with the same examples in both environments.

In this paper, we describe the basis and motivation of our approach and present the experimentation developed to evaluate the impact of these dual material within our CS1 course.

II. MOTIVATION AND THE RELATED WORK

Research into novices’ understanding of object oriented has revealed several misconceptions and problems that concern the notions of class and object [3] and sequence of method calls and their effects on objects [5]. According to that and our experience, students have problems in the first stages of learning to understand the difference between classes and objects and between methods and their invocations.

Visual environments for teaching elementary object oriented programming have been developed in order to provide a concrete model to students and they might handle these abstract concepts [11], but there is little research into the effectiveness of such tools [12]. Moreover, it has been reported that the utilization of mere educational tools is not the best strategy. Students should also get acquainted with the professional programming environments they will use when working as professionals [13].

In [14] researchers attributed students' misconceptions about the execution of a sequence of instructions to the lack of distinction between the environment and the execution of a program, because both the class definition and the object creation were made in the same environment without a main program class.

Since we are aware of the very inconsistent results showed in different research studies, our perspective is that the program visualization should be used as a complementary resource but

CS1 students need also to face traditional programming environments.

In [15] researchers integrated the use of visualizations to students' preparation for exercise sessions as homework. Our study attempts to integrate visualizations during the lab classes in order to improve the aforementioned misconceptions.

III. THE TEACHING STRATEGY

In our classes, the learning resources are structured into didactic units about the fundamental concepts of programming and objected-oriented principles along with short exercises for further practice about the concepts. In lab sessions students develop these concepts by creating and writing programs using Java in the JGRASP[16] object workbench environment. One of the problems in traditional programming environments is that object behavior is not directly observable, but these environments allow students to get acquainted about general concepts relating to computation, such as source code, compilation, execution or declarations of fields and methods in the class. Complementarily, visual environments allow active interaction and experimentation with object instances and to explore behavior by dynamic access.

We argue that if students develop these concepts separately in two complementary environments (programming and visualizing), they will improve the understanding of them. Consequently we decided to develop dual instructional material that can be used both in a traditional programming environment and a visual environment. In the former environment, students will work the class concept and the compilation stage. In the second environment they will play their solutions in order to work object creation and invocation of a method on an object, and thus they will understand better the sequence, first object creation, after method call.

The overall objective is to provide students with additional support for the lab classes, allowing difficult abstract concepts to be illustrated and reinforcing more effectively, like the class and the object concepts.

Next, we will explain briefly the instructional support materials under study.

A. *Instructional Support Materials*

At the early stage of the course the class and the object concepts are worked through a typical early exercise where we model geometric figures. This domain is simple for students and it does not present an added difficulty in the domain knowledge.

In a first step, students are asked to represent the *Point* concept like a simple class whose attributes, *x* and *y*, are of Java's primitive types and getters and setters methods are defined. In a second step, two kinds of figures are introduced to show the collaboration between objects. The *Triangle* is a geometrical figure formed by three *points* and the *Circle* is formed by a centre point and the radius. Moreover, a UML representation of the classes is provided.

Students have to think about how to use the learned concepts to implement the solution. The development is done using jGRASP and the solution is seen in a visual environment.

IV. CREATING DUAL INSTRUCTIONAL SUPPORT MATERIALS

In order to create the visual instructional material, first we analyzed some of the most outstanding tools [11] and selected Alice [10], BlueJ [8] and Greenfoot [9]. All of them have its own website, books and papers that evidence that are well known and widely used. Moreover, these learning tools are recommended by Sun for users without programming experience [17].

During this analysis, we considered the following restrictions aimed at integrating the visual environment in the most efficient way in our CS1 course.

(i) Our students need to develop the basic java programming skills using proper syntax in order to accomplish assignments in this and other related courses. (ii) We cannot afford to spend a significant amount of class time teaching other environment, as well jGRASP, or event-driven concepts to support interactivity with GUIs. Indeed the main disadvantages of using visualization tools include the physical and cognitive overload required to use the tools both from students and teachers. It takes time to install and use the environment. (iii) The environment should allow us to represent visually the instances of classes described in our lab session material without changing the source code. Students have to experience how their code works to learn from their own mistakes. In the next paragraphs we describe the three tools we studied and how they fulfill or not our three requirements.

Alice (http://www.alice.org) is a 3D animation environment, developed at Carnegie Mellon University, in which objects and their behaviors are visualized. Its interface is based on drag-and drop manipulation of program components. Three-dimensionality provides a sense of reality for objects, but Alice hides the underlying language behind a "graphical" language, so it does not support teach text based programming.

BlueJ (www.bluej.org) is being developed and maintained at the University of Kent at Canterbury, UK, and La Trobe University, Melbourne. It provides a full Java environment in which the OO software project structure is presented graphically using UML-like diagrams. Users are able to create directly objects of any class by using icons, and then to interact with their methods. However, it does not display any visual clues about the object's state or behavior.

Greenfoot (http://www.greenfoot.org) was built by some of the same people who created BlueJ, so it is based on the Bluej platform. Greenfoot combines a Java IDE with a framework for producing Java programs that can be visualized in two-dimensional grid. This framework is based on a world environment with visual interactions between the world and the objects in it. Applications in Greenfoot are called scenarios.

TABLE I. VISUAL ENVIRONMENTS ANALYSED

	Alice	BlueJ	Greenfoot
Proper java syntax (i)	×Not text based programming	✓Full Java	✓Full Java
Java environment (ii)	×drag-and drop manipulation	✓Java IDE	✓Java IDE
Visual representation (iii)	✓3D	×icons	✓2D

Table I shows as the visual environments does cover (✓) or not (×) our restrictions to develop the visual instructional material. Greenfoot provides full java syntax, an integrated development environment, and 2D visual representation for our previous material.

Two Greenfoot scenarios were developed from the solution proposed for the exercises presented in the previous section (The point scenario and the geometric figures scenario). For each class, a visual class was created in the Greenfoot scenario. The aim was to minimize the student's contact with the way of programming in this environment, but providing concrete experiences with objects.

Fig. 1 shows a screen shot of the Geometric Figures scenario. The large grid area is called the "world" (1). In order to get a more real experience, a Cartesian coordinate system has been painted in which the geometric figures as objects will be created. The right side is the "class display" showing all Java classes involved in the scenario. From the bottom, the classes created by the students (2) are presented (Circle.java, Point.java and Triangle.java), and above them, the classes provided by the scenario (3) devoted to be a visual representation over the world (Circle_Greenfoot.java, Point_Greenfoot.java, and Triangle_Greenfoot.java). The way to interact with objects is through their methods showed in a context menu (4).

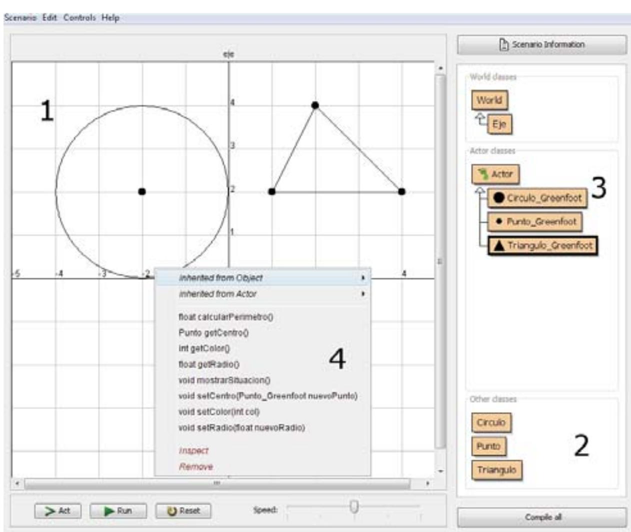

Figure 1. A screen shot of the Geometric Figures scenario

V. EVALUATION STUDY

We performed an evaluation study aimed at: (i) investigating the effect of using these dual instructional support materials in learning and (ii) examining whether these materials might contribute to better understand some basic object oriented concepts.

Two groups of students participated in the study. One group worked with the dual instructional material (GG, 15 students) and the other group just with the material for the jGRASP environment (CG, 18 students). All the students had roughly the same level of academic preparedness since those students with previous knowledge in Java were excluded from the study. Therefore, the concepts of object orientation in Java were new to all the participants.

Before the experimental sessions, the theoretical concepts were explained in common lectures. Two sessions were carried out to perform the scenarios described in the previous section. In both sessions the control group (CG) only used jGrasp whilst students in the other group (GG) were additionally asked to play their programs using Greenfoot. Sessions in this second group lasted a bit more since a briefing on the use of Greenfoot was required. Moreover, in their second session they were also asked to fill a questionnaire on the Greenfoot utility and usability as described below. Table II summarizes the experiment schedule.

TABLE II. EXPERIMENTAL PROCEDURE

Pre-experiment	Both	Lectures on theoretical concepts Class, methods, objects, instance, method call
Session 1	Both	Q1
	Both	Programming SC1 in jGRASP
	GG	Visualizing SC1 in Greenfoot
Session 2	Both	Programming SC2 in jGrasp
	GG	Visualizing SC2 in Greenfoot Q2
Session 3	Both	Q1

A. *Instruments for Data Collection*

We collected students' data and opinion using two types of anonymous questionnaires.

Table III shows the first type of questionnaire (Q1). It was aimed at identifying the level of understanding of concepts. It was filled for the first time at the beginning of the first session before performing the Point scenario (SC1). It consisted of a number of open questions where students described in her own words the concept of class, object, method, how an object is created and how methods are invoked. The students were not notified about the test in advance. This questionnaire was filled again at the end of the second session to measure students' progress in understanding concepts.

TABLE III. QUESTIONS FOR Q1

Evaluation Questionnaire - Q1
What is a class?
What is an object?
How is an object created?
What is a method?
How is a method called? Give an example if necessary.

The second questionnaire (Q2) was devoted to evaluate Greenfoot usability and its utility to improve the understanding of object oriented concepts, as demonstrated *in* Table IV. It was filled by students in the GG group at the end of the second session. This questionnaire had a number of closed questions in which a five-point Likert scale ranging from *none* (1) to *a lot* (5) was used to choose the response that best represented her opinion relative to features of the tool and scenarios. It also included a section with open questions where students were asked to express their opinions to enhance the dual instructional material and the experience.

TABLE IV. QUESTIONS FOR Q2

Evaluation Questionnaire – Q2
How easy is to use Greenfoot?
How easy is to visualize your exercise solution in Greenfoot?
How useful are the scenarios to understand the difference between class and object?
How useful are the scenarios to understand the creation of an object?
How useful are the scenarios to understand the state of an object?
How useful are the scenarios to understand the method call?
How useful are the scenarios to understand the collaboration between objects?
Would you like to visualize the rest of lab exercises in this environment?
How useful is the Point scenario to understand the object-oriented basic concepts?
How useful is the Geometric Figures scenario to understand the object-oriented basic concepts?
Do you think that the visualization is a good mechanism to understand better the object-oriented concepts or the jGRASP environment is enough?

B. Data Analysis and Results

For the sake of clarity we will structure the data analysis and results into two parts: the effects on learning outcomes and the students' perception about the usability and utility of the material.

Because we were interested in exploring whether there is a significant difference among groups before and after the experiment, we made an analysis based on the scoring of the students' answers for Q1 in a range from 0 to 10 points. Our hypothesis was that "if the groups could be considered equivalent in knowledge before the experiment, and after it they had significant differences, these differences could be attributed to the dual instructional material".

The data in Table V summarize the students' score for the questionnaire Q1, before and after the lab sessions. For each group we have identified the minimum and the maximum value for scores, the median and quartiles, and the standard deviation (SD) in order to have a first perception of the group equivalence.

TABLE V. MEASURES FROM Q1 SCORE

	GG (15 students)		**CG (18 students)**	
	Before	***After***	***Before***	***After***
Minimun	0	3	0	0
Maximun	6	10	7	9
Q1	1	6,5	1	4,25
Median	4	8	3	6,5
Q3	5	9	4	8
Mean	3,13	7,46	2,67	5,67
SD	2,13	2,16	2,25	2,68

Students from GG and CG found difficult to answer Q1 before the practical sessions, with a mean of 3.13 and 2.67 respectively. Since our groups are not formed by random assignment, an independent sample T-test was used to analyze the equivalence between GG and CG using the values of column before. This showed not statistically significant difference between GG and GC ($p= 0.5535$), so we can assume both groups were equivalent in knowledge before the experiment.

The column after shows Q1 score after finishing the second lab session. Students from GG increased their mean to 7.46 whereas CG only to 5.67. This shows a significant statistical difference between both groups ($p =0.0457$). Moreover, these results support the research made by [15] in which visualization was used to prepare the exercise sessions.

The Figure 2 shows in percentages the students' progress by ranges: a decrease in the grading (-10 to 0), an increase of three points (0 to 3) and an increase of more than four points (4 to 10). Most of students improved their grading after the practical work, but in GG even a 60% increased their grading in more than four points compared to a 44% percent in CG. Moreover, in GG no student decreased its grading whilst in CG a 6% got lower grades.

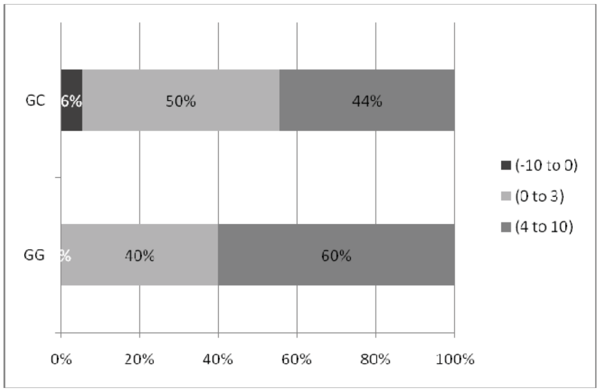

Figure 2. Percentages of the score improvement for Q1

Table VI presents the percentages of improvement for each concept asked in Q1. GG improves in almost all concepts, less in the concept of class. These data allow us to confirm the initial idea about the benefits of each environment. CG used just jGrasp in which the structure of class and the object creation are the necessary elements to run a program, whereas in Greenfoot scenarios students have to interact with objects through method calls. Results support our initial hypothesis that the dual material improves learning outcomes and suggests that practice in terms of exclusively programming might be not enough to understand abstract concepts. Comprehension of such abstractions might require special techniques like visualization.

TABLE VI. THE IMPROVEMENT PERCENTAGE FOR EACH QUESTION

	GG(Greenfoot)	CG
Class	46,67 %	66,67%
Object	60 %	44,44%
Instantiation	66,67 %	66,67%
Method	60 %	44,44%
Call a method	73,33 %	16,67%

With regard to the students' perception in the use of the dual instructional material, all students considered program visualization as a good mechanism to understand better the object-oriented concepts. About the usability of the Greenfoot scenarios, most of the half students perceived as easy to use Greenfoot (60% quite a lot to a lot) and easy to display the scenarios (60% quite a lot to a lot). Students (60% quite a lot to a lot) found the Greenfoot scenarios as more useful to understand the concepts of call methods and collaboration between objects.

Finally, although the scenarios seem to be useful learning resources from the obtained results that perception is not shared by students. Just 53 % considered the point scenario as useful and 40% for the geometric figure scenario. This is a typical problem in CS1 where examples do not solve any real problem so students do not perceive their utility [18]. However, complex scenarios are also difficult to visualize.

VI. CONCLUSIONS

The systematic utilization of educational tools for teaching programming is well documented in the literature. Visualization is considered as a mechanism to concretize teaching and provide students with visual feedback to reinforce their understanding.

We have studied if the use of dual instructional material (textual and visual representation of programs) could improve the understanding of the basic object oriented concepts. According to the results here shown, the use of the dual instructional material benefits learning: we found students using the visualization performed significantly better the questionnaires about object oriented concepts. Therefore, we recommend the use of this kind of materials for reinforcing.

In addition, other benefit of this kind of instructional materials is that students and teachers do not spend extra time learning a visual environment and how to program with it. Students keep learning syntax, resolving compilation errors and working with professional environments.

These results can be considered as preliminary since only one experiment was performed. However the statistical significance of the result encourages us to continue exploring this approach. In fact we are currently working on developing more scenarios and improving the visualization process in order to tolerate better the errors in the students' programs and to unify the visual and the textual environments.

ACKNOWLEDGMENT

The authors give special thanks to Sara Tena and Rosa Romero who have developed the Greenfoot scenarios.

Abstract— **In this paper, we are providing a study on the issue of interoperating Learning Management Systems (LMS) and Remote Laboratories, in a seamless integration. This study emphasizes the need to make Remote Laboratories seen as a pedagogical material within the LMS. We are presenting a novel and original approach to make these two types of platforms communicate (LMS and Remote Laboratory) under a loose coupling relationship. The main purpose of this work is to bring a better follow-up of students to the tutor and the students themselves, and therefore to lead to an enhanced learning experience. (Abstract)**

Keywords- Remote Laboratories, Distance Learning, Learning Management System, Interoperability, Learning experience, Hands-on Approaches, Personalized Learning, IMS-LD, SCORM.

I. INTRODUCTION

Remote training services exploded with the growth of the Internet. Information Technologies and Telecommunications appeared therefore as a keystone for the leverage of Remote Laboratories (RLabs) in Distance Learning curriculum. Before the last few years, ongoing research in Distance Learning primarily focused on conceptual teaching or case studies, in the form of remote courses, works directed remotely or remote projects, but without possibility of real practical activities.

Hands-on approaches however are mandatory in scientific and technical education, especially in engineering curriculum [1]. Mainly, this study emphasizes that hands-on approaches help the students in making the link between theory and real problems, in supporting motivation and curiosity, in contributing to their personal development, in building socials networks. Because heavy and expensive industrial et laboratories facilities can neither be moved nor easily duplicated, a lot of efforts were made for the development of platforms, which now allow remote interactions between geographically distributed users and a pedagogical materials hosted in the school [2,3,4,5], laboratory [6] or company walls [7]. In these publications, all researchers accord to observe that it is not enough to create an interactive Web Site: it is compulsory that the conditions of experiments are realistic, productive and protected. In Distance Learning, one could add that interoperability is another mandatory characteristic, as Learning Management Systems (LMS) are the containers of remote learning activities and student's follow-up, and they are not yet able to include remote hands-on activities, while they already host lectures, tests, etc. Remote practical works are therefore ignored, because excluded since of their low interoperability, from the LMS. This paper addresses the problem.

In this paper, we are primarily interested in the interoperability between any Learning Management System and any Remote Laboratory. We identify the LMS as the element in the Information System that endorses the role of exposing the teaching contents on line while ensuring the follow-up of the user learning throughout his course of study. The purpose of this article is therefore to propose new models of interactions between these two types of platforms (LMS and Remote Laboratory) for a better follow-up of students, and therefore an enhanced learning experience.

The paper is organized as follows. Section 2 introduces a presentation of LMS in the light of relevant elements for integration with Remote Laboratories. Section 3 presents some elements of today's architecture for most common Remote Laboratories. Section 4 presents our approaches to make the two previously exposed architectures interoperate. Section 5 concludes.

II. Learning Management System (LMS)

In order to face problems in Education and life-long learning, such as the fast evolution of pedagogical materials and contents, many institutions and companies have turned towards e-learning, which makes it possible to learners, to acquire knowledge and competences without having to move of their place where they live or work. This calls the citation from Jesus del Alamo: “"If you can't come to the lab, the lab will come to you” [8]. In order to facilitate the organization and the success of these new ways of learning, software solutions appeared, known as “Learning Management Systems” (LMS). LMS are platforms created for managing remote curriculum and teaching through the Internet, while also proposing an electronic follow-up of the students throughout their learning experience.

The LMS are Web applications, which provide to their users (designer, tutor, learner, coordinator, and system administrator or super user), a set of tools ([9], [10], [11], [12]), or services allowing especially for:

- The designer:
    - To build and maintain his/her pedagogical materials by integrating resources and activities of any type according to a hierarchical structure carried out according to the standards, mainly at the SCORM (Sharable Content Object Reference Model [13] or IMS-LD (Instructional Management Systems-Learning Design [14]).
- The tutor:
    - To organize the groups of training and to determine the parameters and the processes of the training sessions.
    - To carry out the follow-up of the students.
- The learner:
    - To reach and follow courses according to their own rhythm, auto-evaluation using tests constructed and carried out according to IMS-QTI specifications.
- Both the tutor and learners:
    - To communicate in a synchronous way (chat) or asynchronous (mails, forum, shared documents).

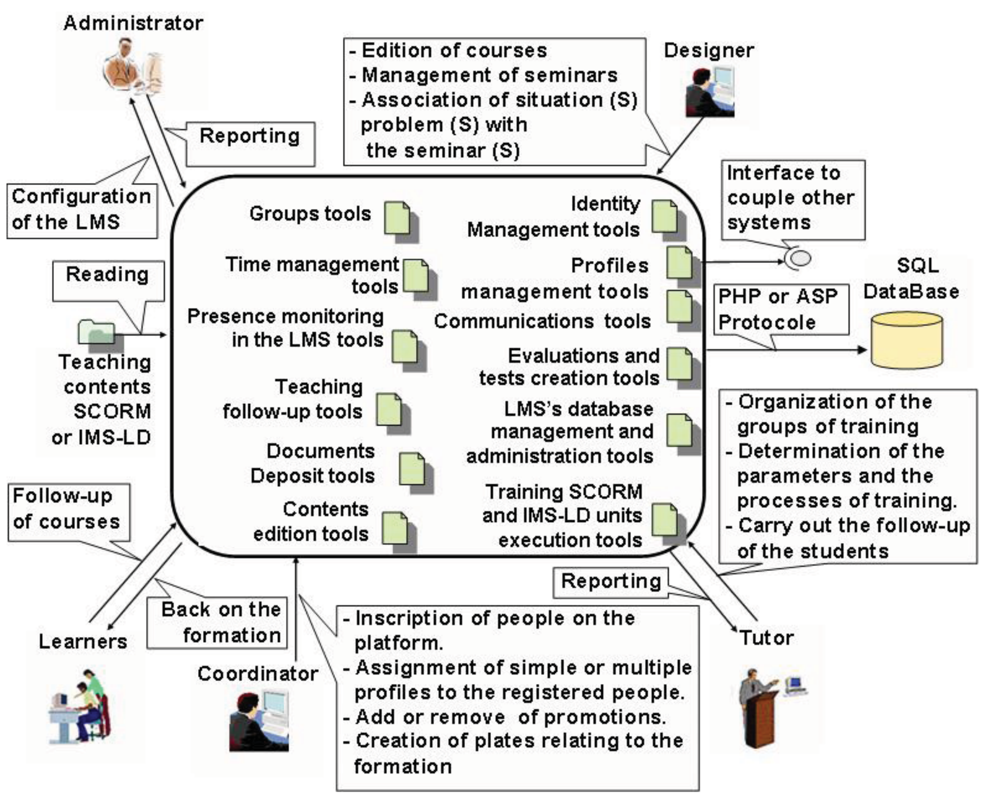

Figure 1. Figure 1 : LMS's components and Functioning principle

- The coordinator:
    - To register people on the platform.
    - To assign simple or multiple profiles with the registered people.
    - To add or remove of promotions.
    - To create areas relating to a module of training.
- The administrator:
    - To configure the platform according to the desired organization.

The Figure 1 shows the common most frequent components, which can be met, in a given LMS, as well as the functioning principle of this last one.

III. REMOTE LABORATORIES

The remote laboratories are referring to practical works carried out remotely on real devices under the assumption of a learning experience. Learners, tutors as well as devices to be handled are not in the same place. A typical architecture for the remote laboratories is given on figure 2.

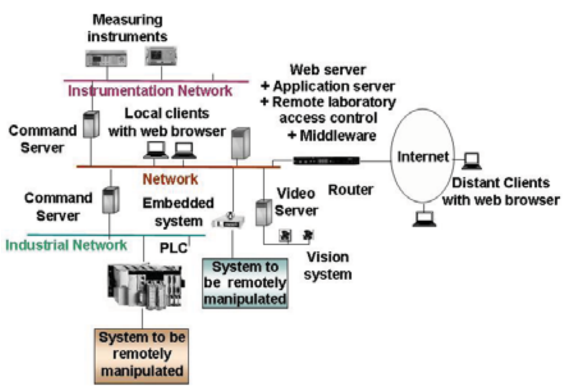

Figure 2. Figure 2: Typical Remote laboratory structure

The common software architecture is composed as follows (figure 3): the device itself, a local computer connected to the device, which plays the role of a gateway between the device and the remote computer of the user, and the associated middleware, through which information is exchanged between the local and the remote computers. There is, of course, a reason why this architecture is so widespread. In fact, most of devices must be locally handled by a computer in order to be remotely controlled over the Internet. There is no denying that some device directly embed an Internet connection, but this is only because they embed a modern operating system inside the device, which therefore does not require a dedicated local computer; yet it does not make much difference in the presented architecture: local computer (would it be embedded in the device itself or as a separate computer linked to the device, middleware, and remote Graphic User Interface (GUI)).

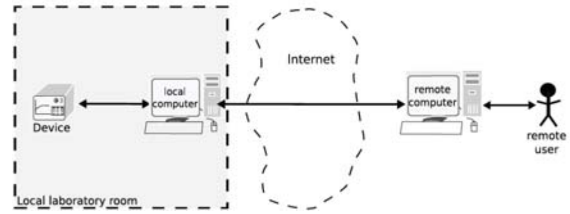

Figure 3. Figure 3: The widespread software chain of remote laboratories.

but to build a middleware allowing remote clients to connect to the local computer that handle the device. That is the reason why the first remote laboratories were using software solutions such a VNC1, as it provided them the remote control over the local computer connected to the corresponding device. Nonetheless, those solutions were given up as they lack security and they require a lot of bandwidth, in favor to software development following the Distributed Architectures paradigms, such as Service-Oriented Architecture.

This evolution was mandatory to open the Remote Laboratory middleware to the other services in the Information Systems, and especially to Learning Management Systems, as we will study it under the following section. The connection between LMS middleware and RLabs middleware is at the core of our approach.

IV. A NEW APPROACH TO COUPLE A LMS AND A RLABS.

As already evoked in section 2, many institutes have already included remote formations in their curriculums. However, these platforms, largely used today, are not designed to integrate remote practical works, whereas remote practical works propose to put the theoretical teaching into practice, they are found excluded from the LMS, for lack of sufficient software technologies. The fact that the RLabs session is unlinkable to a Learning Object in the LMS at the moment comes with strong drawbacks:

- all the situations of training are hardly proposed online, and especially,
- no follow-up of students can be proposed during remote hands-on approaches,
- no authoring tool for setting-up the associated learning scenario,
- no possibility for the student to easily confront experimental results towards his/her theoretical exercises conducted in his/her LMS session.

It has to be noticed that especially the latter one (decreasing the learning enhancement by putting technological barriers between theoretical and practical learning experiences) strongly violate the first principle of laboratories in general,

[1] Virtual Network Computing

which are designed to let the students making theory and practice meet during the same learning session.

We therefore think that part of ongoing research in RLabs should focus on making RLabs and LMS converge. The gap [13] between platform of remote practical works and the LMS is due to the fact that remote practical works require specific developments. They are thus stored in platforms' owners, while no standard exist for RLabs. As for LMS standards, such as SCORM [14] or IMS-LD [15], nothing is designed for RLabs, because so far those standards did not excepted the pedagogical content to be hosted outside the L(C)MS2. Moreover, it is difficult to imagine to host all the remote practical works in a LMS, in the same way that lectures or directed works, which requires much less interactivity between learners and educational contents.

This said, a pragmatic solution to integrate RLabs within an LMS, would be to carry out a loose coupling, between these two platforms through an interface in the forms of modules or "plug-ins", allowing to connect any RLab to any LMS, as long as the shared vocabulary and data exchange protocol (the module of the LMS, and its correspondent for the RLabs) is available on both parties.

Our research tasks thus initially concentrated to make a research on the platforms of LMS having a plug-in system. After a long bibliographical search we discovered that there do not exist academic documents covering this kind of subject. In practice existing LMS (e.g: Moodle, Claroline, etc.) allow the use of third-parties libraries through a plug-in system.

One can afterwards recover information on the set of "widgets" W = {w1, w2, …, wn} used in the remote GUI of a RLab (whatever the technology of the RLabs). It is therefore possible to store the set of widgets of each RLab in a repository, which could be queried afterwards, so that the remote GUI could be instance on the fly, after the set of widgets delivery. If this set of widgets is hosted in the LMS and seen as usable resource in learning scenario in LMS, the connection between LMS and RLabs become effective. Indeed, the LMS have the knowledge and comprehension of the widgets, and the RLabs is built upon instantiation from the widgets retrieved within the LMS. The widgets are therefore the keystone for interoperability between LMS and RLabs.

In this study, the aim was not to reinvent the wheel as for a widget repository for RLabs. [16], [17], and [18] proposed an architecture which make it possible to display a set of "widgets" by making an entry from a Unit Of Learning (UOL) in the IMS-LD standard. Thus while proceeding to small improvements of this architecture, we think that it is possible realizing the development of some modules and "plug-ins" of extensions, to use it as bridge or interface to couple in loose manner, an LMS and a remote "Widgets Laboratories".

[2] Usually the difference is made between the LMS, which expose pedagogical content to the students and tutors, and the LCMS, meaning Learning *Content* Management Systems, which is held responsible for providing authoring tools and scenarii engines. In this paper, we are using the stretch of language where LMS denotes both the LMS and the LCMS.

Thus, this is the approach, which we try in this research project, to realize by proposing a new architecture allowing to remotely controlling a system via its deported GUI, made up by a set of "widgets".

A study of the functioning of "Wookie" [18], showed us that it is possible to make this coupling while making:

- An entry from a UOL (Unit Of Learning) IMS-LD according to the architecture of figure 4.
- A simple entry (i.e. not from an IMS-LD scenario) from the LMS according to the architecture of figure 5.

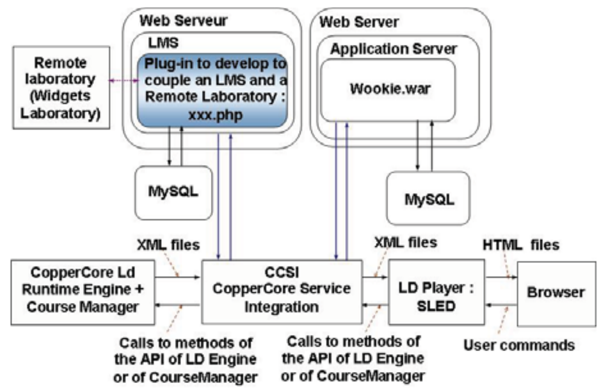

Figure 4. Figure 4 : LMS Remote Laboratory Coupling with an entry from an UOL IMS-LD

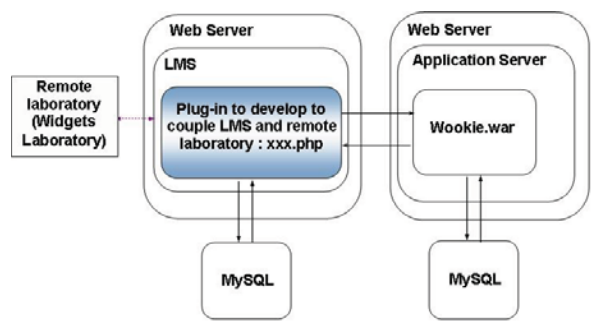

Figure 5. Figure 5 : LMS Remote Laboratory Coupling with a simple entry from the LMS

The Plug-In, in these two architectures carries out the two following principal operations:

- Request "Wookie" to have an instance of the "Widgets" to deploy in the LMS to command the instrument or the system,
- Parse the response sent by "Wookie" to create a GUI of the command of the instrument or system in the LMS.

We chose in a first step to work within second architecture assumption, by leaving an entry from a IMS-LD scenario in second step, as it lead us to use all the chain composed by : SLED, CopperCore, and CCSI ([19], [20], [21]).

Wookie responds to request (GET request for a widget/set of widgets instance) by sending a response in XML form, about information relating to the “widget” or the whole of the “widgets” for which it was requested.

Typical responses from the Wookie server is as follows:

- For one widget:

```
<?xml version="1.0" encoding="UTF-8"?>

```

As for authoring of the RLabs possibly connected to a LMS, the process is to describe a set of widgets in the Wookie fashion, setting a package for “Wookie” [23], and then to used it as a UOL in the learning scenario hosted by a LMS compliant with IMS-LD. This also means that the RLabs is reusable through different LMS, as long as it supports IMS-LD standard (loose coupling).

However, while processing in this way, there is not enough loose coupling, in our opinion. The main issue is that Wookie repository of widgets is populated from its config file describing the widgets (a set of widgets according to the W3C standard with its file config.xml, containing the URI of the start page as well as metadata, and loaded in “Wookie” via the its admin pages of this last one [22]). This is however compulsory if we want to connect an existing RLab to Wookie without having to reengineer its widgets. In order to solve this problem, we think that it is possible to modify the source code of “Wookie”, so that it could import these informations from the RLabs itself. A first simple solution consists in introducing these informations directly into the database of “Wookie”. Another solution is under study as we are conducting research in this matter, and especially using the Web 3.0 (ontologies) to represent the GUI of a RLabs in our RLabs framework (called OCELOT [23]). Such ontologies could be aligned with the concepts and relationships proposed by Wookie so that the widgets issued by such a framework could automatically be populated in the associated wookie meta-widget representing the RLabs, and allowing the connection with the LMS thanks to IMS-LD.

V. CONCLUSION

In this paper, we tried to a new approach which tries to close the gap between LMS and RLabs. The main issue is to find a solution to use the Rlabs in the UOL (Unit Of Learning), conform to standard IMS-LD, so that the walkthrough of the student during RLabs session could participate to the LMS follow-up of the student.

The main result is a loosely-coupled approach based on existing software which allows the follow-up of students during RLabs sessions through their use of predefined widgets expressed in a Wookie server, which are themselves usable in a UOL in IMS-LD standard. The biggest open issue is the provisioning of the Wookie server. Several means are under study, from standard insertion in database, to automatic provisioning through ongoing research in ontologies alignment, but each of these should still be tested in a real experiment in a broader audience in order to gather data on their scalability. Future works will consist in studying different granularity of expression for the widgets, in order to refine the follow-up of students during RLabs session in their learning walkthrough, so as to as better learning experience could be delivered to both the students and the tutors.

Abstract—**This work emphasizes the importance of the formulation and application of didactic videos mainly in subjects where the classes are exclusively theoretical, as in the case of the subject ET016 – Electrotechnics, taught at the School of Electrical and Computer Engineering – UNICAMP. It is mandatory and it is offered to the students of the following Colleges: Food Engineering, Agricultural Engineering, Control and Automation Engineering, Mechanical Engineering and Chemical Engineering. In this subject, basic concepts of electricity are taught: single-phase and three-phase circuits; electrical energy production, transmission and application; physical principles and main application of transformers; electrical machinery of induction, asynchronous and direct current; and basic concepts of electric installations and protection devices. Upon elaborating and making these videos available, we aim at arousing a larger interest on the students, causing them to complement and reinforce the content taught at the attended theoretical classes.**

Keywords - Alternating Current Circuits, Electrotechnics, Engineering Education, Didactic Videos.

I. INTRODUCTION

Historically, in the period from 1970 to 1980, there was a subject named ET515 - Electrotechnics at the School of Electrical and Computer Engineering (SECE) - UNICAMP - Brazil, lasting six hours weekly, with four hours in the classroom and two hours in the laboratory. From 1981 on, the subject ET616 – Electrotechnics started being taught using two hours in the classroom and two hours in the laboratory and from 2004 on, we also took the responsibility to teach the subject ET016 – Electrotechnics, with just two hours weekly in the classroom. Detail: all these subjects have the same summary imposed by the respective receiving courses.

Currently, ET616 and ET016 are offered to students from the following Colleges: Food Engineering, Agricultural Engineering, Control and Automation Engineering, Mechanical Engineering and Chemical Engineering. In these subjects basic concepts of electricity are taught: single-phase and three-phase circuits; electrical energy production, transmission and application; physical principles and main application of transformers; electrical machinery of induction, asynchronous and direct current; and basic concepts of electric installations and protection devices. ET616 e ET016 do not have the same level of complexity as similar subjects offered to the students at the SECE.

Before the inescapable quality loss in transmission and the resulting assimilation of the content mentioned above, allied to our taking priority in the activities of the graduation teaching, and being aware about the students need in having a fundamental knowledge of good quality on alternating current circuits, the means we found to reduce such loss was the production and broadcasting of videos with exhibition of experiments, which are not accomplished by the students who currently attend ET016.

Among the achieved objectives with the formulation and application of the videos up to now, elaborated by us, we stand out:

- Greater interest aroused in the students in complementing and reinforcing the taught content at the attended theoretical classes.
- Flexibility in accessing for the videos and the didactic material are available via Internet.
- The production of didactic videos may be useful in several teaching, researching and extension areas, concerning the information broadcasting in a dynamic way, enabling that real laboratory experiments, which not always may be reproduced

wherever one wishes, to be accessed by anyone interested in them.

Other important comments and analyses about the importance of the use of didactic videos, and how the recording must be done with details and precision in its captures, so that it becomes clear, having no illumination and image framing problems may be found at all references [1 – 8].

II. ELECTROTECHNICS DIDACTIC VIDEOS

From elaborated scripts in experimental rehearsals, we produced didactic videos for the following presented topics, making a brief comment on the presented script.

1. Voltage-Current Characteristic: an experimental procedure to obtain the relationship between the applied voltage and the resulting current (characteristic curve) in a two-terminal device (6’58”).
2. Root Mean Square (RMS) Concept: a visual approach about this concept and experimental confirmation of the rms value of a sinusoidal voltage (3’53”).
3. RC Series Circuit: sinusoidal steady-state behavior of a RC (resistor-capacitor) series circuit connected to a sinusoidal waveform generator (4’02”).
4. RL Series Circuit: sinusoidal steady-state behavior of a RL (resistor-inductor) series circuit connected to a sinusoidal waveform generator (4’28”).
5. RLC Series Circuit: sinusoidal steady-state behavior of a RLC (resistor-inductor-capacitor) series circuit connected to a sinusoidal waveform generator with variable frequency (4’27”).
6. Unbalanced Three-Phase WYE-connected Load: the importance of the fourth wire in an unbalanced three-phase wye-connected load (3’00”).
7. Three-Phase Voltages: experimental observation of the relation between line and phase voltages on a three-phase system (3’02”).
8. Power Factor Correction: the importance of the power factor correction of a single-phase induction motor through the connection of capacitors in parallel (4’48”).
9. Rotating Magnetic Field: an elementary experiment shows the operating principle of a three-phase induction motor (5’01”).
10. Simple Type Switch: a switch is one of the most basic yet important devices in an electrical installation. This movie teaches how to install a single pole switch to turn on and off one or more lamps from a single location (2’43”).

Fig.1 - Examples of Screen from the Videos

11. Three-way Switch: it is specially designed to work in pairs and this movie call attention how to install this kind of switch to turn on and off one or more lamps from two places (3’17”).

12. Four-way Switch: it is designed to work with the three-way switch. This movie teaches how to install two three-way and one four-way switches to turn on and off one or more lamps from three locations (4'05").
13. Residential Connections in the Electrical Network: some concepts about the connection of the residential power grid (3'00").
14. DC Motor Starter: this movie shows how to start a DC motor without large starting current and how to protect against excessive speed when the field current is low (5'20").
15. Starting of Induction Motor: how to use a star-delta device to prevent a large starting current in a three-phase induction motor (5'05").

Note : the information in brackets, as in (5'01") for the Electric Motors movie, means the length of the film in minutes and seconds.

For a higher easiness in accessing, these videos have been available at the Youtube Website, with audio in Portuguese. The screens example of the elaborated videos may be seen in Fig. 1.

III. METHODOLOGY

The movies have been created with the following technical characteristics to make the access over the dial-up connection internet easier:

- Average run up to 5 minutes per video
- 15 frames/s: 320 x 240 pixels.
- Video for broadband connection: 150 Kbps.

The first equipment used was a Digital Nikon Coolpix 7600 - 7MP (Digital Camera) and now we have a camcorder JVC – GZ – HD3U.

The final video image editing has been accomplished through "Windows Movie Make" which is available for Windows XP and Windows VISTA users, Fig. 2.

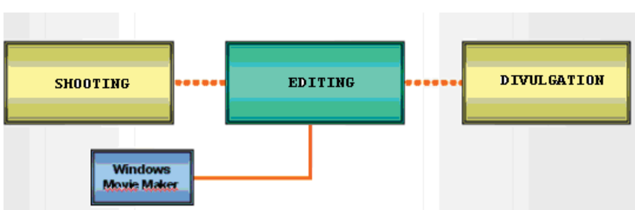

Fig.2 - Editing Scheme of the Didactic Videos

The main subjects addressed on the videos have been complemented with Circuit Illustrations, Electrical Diagrams and Formulas, placed in before and/or after the exhibition of the experiment shooting, aiming at determining the theme addressed on the video.

IV. RESULTS

As mentioned above, the videos about basic experiments on alternating current have been available at the most popular video website of internet, the Youtube (www.youtube.com) and they can be found through the terminologies ET016 and ET616 (subject acronyms). The receptivity of these movies is presented on Table 1.

The students may watch and comment the content of the movies on the Website. Remarks about the movies, video contents and their didactic means of exhibition have been constant on the received messages. As an example, we present some of the comments:

- "I am an electronic technician and I find these subjects very interesting. Congratulations on the teacher's explanation!"
- "Very good. This is the kind of video that I enjoy watching. I suggest that you improve the sound of the next videos and also insert subtitles in Spanish. Congratulations."
- "Very Good!!!!"
- "It helped me a lot, and solved many of my doubts. I admire the work of Professor Barreto very much. I have read his thesis on the manufacturing of an electric vehicle, and I admit that it was one of the best materials I have ever found.The details and technics presented are fantastic."

We know that these videos are being adopted as didactic material at other Universities and Technical Schools.

The importance of this subject in the professional life of engineers has been evidenced through the messages we have received from former students, as well as requesting access to didactic material available over the internet through the TELEDUC environment:

- "The material will be very useful to review the concepts learned from the subject that you teach".
- "I would like to ask you if I could access the material of the course since it is indispensable for my activities at work".
- "I am thankful for the attention given, and I take the opportunity to congratulate you on the excellent organization of the classes".

The TELEDUC environment is a platform to the implementation of courses (subjects) over the Internet, aiming at the distance education, which has helped us on the connection with the students and on the disclosure and application of the didactic material, besides the attended classes. A master's degree work, which analyzes the students feelings concerning this tool as a didactic support on the teaching of Electrotechnics may be seen at Castilho, (2005)[2].

take experiments in easy way to communities with very low technology availability.

TABLE I

Number of visualizations (September/2009)

Didactic Videos	Number of visualizations
1. Voltage-Current Characteristic	951
2. Root Mean Square (RMS) Concept	2915
3. RC Series Circuit	27152
4. RL Series Circuit	4787
5. RLC Series Circuit	12081
6. Unbalanced Three-Phase WYE-connected Load	5232
7. Three-Phase Voltages	3237
8. Power Factor Correction	3736
9. Rotating Magnetic Field	5983
10. Simple Type Switch	1880
11. Three-way Switch	4058
12. Four-way Switch	2570
13. Residential Connections in the Electrical Network	878
14. DC Motor Starter	936
15. Starting of Induction Motor	817

V. THE SCHEMATIC DIAGRAM

A didactic video as well as a Virtual Laboratory project can attend several important requirements as cost reduction, easy handling, simulations and destructions in several learning sessions. From theoretical environment up to physical implementation, it is possible to specify some layers in a strategy to divide the design in levels and assure the laboratory usability, Fig 3.

All necessary parts to create a test environment with monitoring resources and a learning system can be seen in a core system layer. There are Input and Output devices to adjust appropriate income signals and to show the effects in alarms, displays or even a simple point to be measured.

In order to meet the speed, flexibility, portability and high quality demands, it is possible to use popular computer software and an efficient picture format as “FLASH” and vector images, respectively.

The path to the physical environment can be done through the local network or even using the Internet. Nevertheless the great contribution made by a didactic video is the possibility to

Fig.3 - Design and implementation layers

Other advantage is the possibility to transmit, reproduce several turns, stop and go in different moments and situations, not excluding the interaction with virtual laboratory and a physical implementation e validation, Fig 4.

Fig.4 – Virtual laboratory

VI. THE PARADIGM OF 3E

A despite of all educators efforts to improve the learning environment with news resources, creativity and new methodologies; they can face a new reality, Fig 5. The nowadays students, as the current workers, are not the same of few years ago. Besides the basic knowledge, the new student has to develop, in a school time frame, the “paradigm of 3E”, Fig 6. The academics have been discovering that there are much more behind the E from E-Learning expression besides Electronic.

The first “E” is about “Entrepreneur” skill, where his carrier and his personal investments depend on his proactive actions to collect its results in a short term. Not so long there was a time where a good school was enough to launch good students to prominent carriers, making to emerge amazing executives, lapidated by capitalism, in order to support the demand for human capital, one of its fundamentals.

Fig.5 - Basic knowledge compression

Increasingly its complementary training session has been moved to academic seasons, pushing students and educators to follow an additional agenda. It has created an even more robust curriculum, where good students become potential investors, handling a new theory that consider business and natural resources, as well as ROI (Return of Investments) and stocks, besides other commodities, financial indicators and management programs. This new procedures will transform potential undergraduate “baby juniors” in pre-warmed tires able to jump faster in a start line racing, reducing the time to market and accelerating the productivity. The main issue is the possible high social cost involved in this warm up procedure. The professional learning curve, when moved to academic season, can compromise the education and abbreviate the productive period for each professional life, against the original plan. Since there are confident suppliers for qualified human capital, the restructuring process has been anticipated and even more frequent in work world.

Fig.6 - The paradigm of 3E

The second “E”, from the “paradigm of 3E”, means “Entertainment”. There is no chance to handle stress, rush, the huge schedule and a competitive usual work environment without good humor and health. One alternative to develop this support comes from Entertainment. In academic season it means much more than a good life support, it means preparation for a social life, where the citizen building and the relationship skill will be mandatory for a well succeeded carrier. With direct impact in self-conscious and self-confident, the entertainment activities can improve the world vision, the general culture and the ability to handle different situations in personal and professional life. This is not a new concept but the issue comes from a new constraint created by a huge academic schedule responsible to accommodate new and complex procedures. The premature professionalization has pushed several new activities to academic season compromising the social life construction, extremely important for all moments of the citizen, the students and professional lives. As part of relationship program several university's programs include various classroom-specific programs where students in education courses receive diversity training as part of their teacher training, while students in the business school focus on understanding global cultural differences. There is no doubt about importance of diversity and social integration, in fact companies want to hire graduates who are prepared for the real world. Recruiters were once glad to discover that students understood the impact of diversity in the workplace, for instance.

The third “E” means “Expertise”. It is easy to understand and believe in the usual statement:

“Your value is in your unusual skills”

It can explain a well succeed soccer player makes more money than several competent PhDs. This point of view has generated a rally, one student competition to develop new skills as fluency in several languages, specialization, extra scientific tasks and foreign academic programs besides others activities.

Language training programs seems to be a wise idea, but how long do you take to learn Mandarin? Again, there is a time constraint to accommodate the language training with graduate season, for instance. To work in France, you need to learn French, and to work in other countries, such as the Netherlands, Singapore or China, you can get by on English for an extended amount of time. In Japan, your lack of cultural familiarity may prove even more challenging than not being able to read the road signs. There are skills that are more valuable in a global marketplace, like a language. Beyond language training, future workers who plan to tackle foreign assignments or whose work will require them to collaborate with customers, coworkers or suppliers in foreign place have to enroll in extra executive education courses.

From the point of view of curriculum analyses it certainly represents a positive wave, but there are at least two issues in the horizon:

- In a long term will not be differences between students, it will promote an academic qualification upgrade offering best professionals to companies, but for the same salary. Even if it means an achievement, there is a great chance to create damages in other fundamentals as basic knowledge or even school programs stimuli and retention ;

- There is no time to accommodate so many new tasks without compromise the basic knowledge for professional and personal lives.

VII. CONCLUSIONS

We have noted through this work that we can use amateur shooting equipments and software that is easy to handle, as it is in "Windows Movie Make" to produce great results, when dealing with didactic video production, and thus contributing to the improvement of the teaching and the knowledge propagation.

The videos answer a claim from the students to make easier the understanding of the electrotechnical theory, for it deals with the practical aspects, and this subject does not include laboratory classes.

The contribution to the teaching and learning process through the videos may be observed through an improvement on the students' performance at the evaluations, as in tests as in exercises available at the TELEDUC environment.

The knowledge disclosed this way is being useful to our students and to students from other teaching institutions, who may watch countless times, a specific concept on fundamental electricity. The videos and the way they are disclosed, bring up conditions so that the learning process happens in a more efficient and faster way, being available for a larger number of people, besides the students having the benefit of being able to watch the experiments when they have time, and be able to review the subject.

The formulation of didactic videos by teachers and/or students to disclose knowledge and to motivate learning is something that must be stimulated and encouraged.

A despite of well succeed initiatives to promote an even better E-Learning quality, there are so many changes to do in order to accommodate so many new tasks in students lives. It seems to be necessary to discuss a new curriculum, new assessments, new values and targets involving the academic institutions, the government, the corporations and society.

ACKNOWLEDGMENT

We thank:

- The School of Electrical and Computer Engineering - UNICAMP, which has always supported us on the development of didactic activities of graduation;
- The UNICAMP superior entities for the concession of a work scholarship for the student Rafael Alexandre Sousa Martins, to support us on elaborating the didactic videos.

Abstract—**This paper describes the importance of developing learning tools, such as virtual laboratories in different areas of science with emphasis in chemistry, through the development of a virtual laboratory that allows students to access to an environment of experiential learning. It has two main stages which are: a virtual world (software) where the student is guided by an integrated environment with the features necessary in order to perform the practices and at the same time, has a capture stage (hardware) that is responsible for making the process of experimentation as real as possible, offering the instrument's sensation or machine's sensation during the experiments. Throughout the document the steps for the completion of the virtual laboratory are seen with the results so far.**

Keywords-chemistry, distillation; virtual laboratory; virtual reality.

I. INTRODUCTION

Today the implementation of educational tools in interactive environments has allowed the acquisition of knowledge, it presents an innovative and efficient way to learn and teach giving the opportunity for students to access experimentation in an almost real manner, allowing their full learning which is not dependent on specific artifacts and materials but on accessing to the virtual laboratory.

Nowadays, there is an increasing popularity in virtual laboratory environment for its prominent advantages of intuition and interactivity between teaching and studying [1]. Interactive tools accompanied by modern educational theories configure a tool that currently has a very important impact in students of all areas of science and technology and has a main role in the current educational process.

The objective of the virtual laboratory proposed in this paper is to create a laboratory environment which motivates students to discover connections between theory, simulation, and physical systems through independent experimentation with up-to-date professional tools. [2]

The implementation of information and communication technologies has developed different types of virtual laboratories, in this case is being developed a virtual laboratory which has a virtual world that allows the immersion in an environment conducive to practical implementation of distillation in chemistry field, along with an electronic device specifically a virtual reality glove that has the function to capture the movements and position of the student's hands, and thus making the practice very close to reality and generating a theoretical and practical learning.

Although theoretical concepts are essential and need to be taught, it is very important to also show students how to apply the theory they have learnt in very different and important practical situations. [3] In some areas of knowledge the apprenticeship is not complete until you have developed different practical activities, so an example of this case is the chemistry field. Many subjects are based on it (practicing and experimenting), especially subjects which have more practicalness, such as: programming, physics, chemistry, and other engineering subjects. [4]

Besides the development of such interactive tools is necessary to promote a new culture in the learning process, since there must be a motivation with students who are interested in using tools and devices built for intellectual growth, is necessary to discard traditional pedagogy that leaves very little scope to the student and instead propose a constructivist pedagogy which guides the student to identify and define the problem, the proposal procedures, collection and interpretation of results and making decisions. [5]

Besides, virtual laboratory can also benefit distance education and learning-on-the-job students, who maybe asynchronous in time or in space, even more, for the cost and time needed for traveling to a local lab would often prevent them from using such real laboratories. Moreover, the virtual laboratory resources can be shared by many institutions and students worldwide, which can save much money. [6] There are many applications and advantages of virtual laboratories as their implementation in distance education or the acquisition and management of expensive tools and machinery that is not easily acquired.

Therefore, the main research question to be solved is: How to develop a virtual laboratory of basic distillation that can be handled from an electronic device (virtual reality's glove), to support the teaching process of distillation? From the previous question and development experience of the research group in this type of tool, the following questions arise also be solved with the investigation: How to design and develop a motion capture device that allows sense signals generated by a hand movement? And how to design and develop a three-dimensional interface that allows displaying the manipulation of objects in a basic distillation laboratory from a remote hand and support the teaching process distillation?

II. Virtual Laboratories

A. History Background

Due to the need for student support systems to make their laboratory practices, with the aim of optimizing time and resources required in a controlled environment to provide security, the advancement of new technologies of information and communication and adoption of recent educational and pedagogical practices, emerged virtual labs as a support for the process of student learning.

The approach now in education, where new spaces are built and troubleshooting, virtual laboratories, have gone deep into the pedagogical practices, for over 25 years or so, when its use began. The first approach to virtual laboratories appears in 1984, where the concept of virtual instrument and its characteristics were determined according to the fundamentals of programming. [7]

In 1992, virtual laboratories described the object-oriented programming in the development of a laboratory simulation. In 1994 was presented a study by Vanderbilt University in the U.S. which develops a simulation-based virtual laboratory to support traditional practices, which concluded with the need for this tool to learn basic skills and equipment management, which optimizes both the time of pupils as the laboratory staff, in 1994 was written an article [8] in which is explicitly defined a virtual laboratory as a simulation program.

Already in the IMTC conference (IEEE Instrumentation and Measurement Technology Conference) held in June 1996, started to present different aspects of what is a virtual laboratory.

B. Concept

A Virtual Laboratory is an interactive virtual space that incorporates all the technological, pedagogic and human resources in order to perform practical activities, adapted to the student's and teacher's needs in a virtual learning environment [9].

The virtual laboratory is composed by a virtual world which is based on the required pedagogy by the area of science where it is implemented and the development of the virtual environment to make it comfortable and real to the student. Along with a hardware tool which is an essential resource for learning as it provides comprehensive real sense of the object that is being manipulated within the virtual laboratory.

In addition the laboratory should have the following Characterisitcs says Vikram Padman and Nasir Memon [3] Accessibility, Observability, Ability to simulate realistic scenarios, Realistic, Separability of virtual network, Remote Configurability, Ability to share resources efficiently. With accessibility it is understood that a student can easily access the virtual laboratory and its elements, the Observability characteristic is about the possibility of students to observe the effects of their actions within the virtual laboratory, as it would be in reality.

The ability to simulate realistic scenarios, where realistic, mean that the virtual laboratory should have an environment that gives a real sensation of the practice. The separability of virtual network, Remote configurability and Ability to share resources efficiently are Referred to the capability of the virtual laboratory to allow interacting with it by many students at the same time, without generating problems in the virtual environment also the virtual laboratory should permits to be modified at any time by the laboratory's administrator.

C. Importance

Despite distance education acquires some results in theory teaching, the expansion of the experiment manipulation teach has become the main factor which restricts the further development of distance education. [4]

The importance of virtual laboratories can be seen in distance education as these allow students to access information from different places, it is not necessary for them to be at the same school or even in the same location.

Engineering students need to practice and perform experiments in laboratories in order to complement their learning process. However, instructors and equipment are not always available. Additionally, there may be risk and trouble using some equipment that may hurt students or damage the equipment. [10]

In these cases the use of virtual labs is the best option for engineering students where is needed to use equipment that do not have or it use is dangerous for the student. Thus, it appears that some of the main reasons for using these tool: the decrease in investment in expensive machines, the expansion in the restricted access to expensive laboratory equipment and, the limited availability of free time in laboratories for new practices to enhance knowledge on a specific issue and reducing the cost of consumable items.

III. Chemistry Virtual Laboratory

The virtual laboratory was designed and is under development to support the teaching of chemistry distillation consists of three basic components: an interaction device (suits, gloves, helmet or other component that allows movement user), a motion capture device (electronic device that receives signals (movement) of the user and transmits to the computer) and a software interface (virtual world) that contains a three-dimensional scene with real-world elements simulated, which is operated with the signals received from the motion capture device. Additionally, the software interface (virtual world) incorporates in its operation a teaching model and didactic to facilitate the learning process.

The interaction device consists of a virtual reality glove which senses movements of the student's hand capturing the different activities that can do in the distillation process in the virtual laboratory implementing low-cost sensors that make the glove more accessible to all users. The motion capture device is responsible for capturing the different signals from the virtual reality glove to identify and order it with reference to the voltage found on the analog inputs of a microcontroller and then feedback a response to the virtual world of the computer where it generates a real-time response to the action performed by the student.

The software interface (virtual world), includes the basic elements of a laboratory distillation within a scenario of three dimensions, which are handled according to data supplied by the motion capture device. The interface is being developed with software for virtual worlds building in third dimension (such as VRML, X3D and Blender), signal capture programs, programs with special procedures and intelligent agents (developed in Java programming language), enabling to provide an interactive environment for users. Additionally, the interface has a constructivist approach and a learning component based on the resolution of problems, some examples are showed in table 1.

TABLE I. EXAMPLES OF SOME VIRTUAL LABORATORIES

Virtual Laboratory's name	Authors
Vital (virtual Information assurance laboratory)	Vikram Padman and Nasir Memon [3]
Virtual laboratory for signals And systems	Virginia L. Stonick [2]
Simulated lathe virtual laboratory (LaSiTo)	Julieta Noguez, Gilberto Huesca [10]
UVL (universal virtual laboratory)	Michael Duarte, Brian P. Butz , Susan M. Miller, and Annapoorna Mahalingam [19]
The Robotics and Computer Vision Virtual Laboratory	Lucian Rodrigues de Queiroz, Marcel Bergerman, Rubens Campos Machado, Samuel Siqueira Bueno, Albert Elfes [20]
VnLab (virtual networking laboratory)	Josep Prieto-Blázquez, Joan Arnedo-Moreno, and Jordi Herrera-Joancomartí [9]

IV. METHODOLOGY

The development of the project involves a combination of several methodologies: one for the development of the research process Table 2, one for an interaction device (virtual reality glove) Table 3, another to do the motion capture device Table 4, one for the design and development of a software interface that reflects a virtual world of a basic distillation laboratory supported in the teaching model of problem solving Table 5.

Initially defined and explained in Table 2, the research process that will be followed from the research process models proposed by Morgan silver [11], Lerma [12], Tamayo [13] and Cerda [14].

TABLE II. RESEARCH METHODOLOGY

Stages	Description
Defining the topic	During this stage, it was clearly defined and precisely the work area or field of research problem.
Indentifying the problem	During this stage, it was specified in detail and precisely the problem. Defining the limits of the research.
Defining Objectives	During this stage, the objectives were defined taking into account the actual results, scope and results.
Definition of Justification	During this stage, it was defined the motivations that led to the development of the project.
Development framework	During this stage, we took into account the previously constructed knowledge, which is part of the existing theoretical structure and experiences in the world.
Definition of the methodology	The investigation was developed in three phases, the first consist of the construction of interaction device (Virtual Reality glove). In the second phase, was built the motion capture device. In the third phase, there was the software interface that contains the virtual world of basic laboratory distillation.

The development of interaction device (Virtual Reality glove) was done following the steps described in Table 3.

TABLE III. INTERACTION DEVICE METHODOLOGY

Stages	Description
Planning and organization	At this stage is defined what will be done, the list of activities, team work, artefacts that constitute the device and the required tools.
Requirements	At this stage is setting out the different characteristics that the device must have
Analysis	At this stage, is analyzed the requirements set at the previous stage and build a model to define which are the components of the device and how they operate, determining the physical structure and technology used.
Devices design	At this stage, are made the sketches, proposals for structural design and performance, overall design of the glove, transducers design
Development and construction	At this stage, is made the glove implementation, the sensors, signal conditioning and signal transmission
Tests	At this stage, individual tests are performed and capture device.

The motion capture device is done following the steps defined in Table 4.

TABLE IV. CAPTURE DEVICE METHODOLOGY

Stages	Description
Requirements	At this stage is defined the requirements of motion capture device taking seeing the requirements and system software in general.
Analysis	Taking into account the requirements, the devices are designed as well as their characteristics
Design	Design and simulation of the capture system.
Implementation	Performing the installation of the device.
Tests	Adaptation and testing of signal acquisition

The methodology for the design and development of the software interface that contains the virtual world of a basic distillation laboratory will follow the RUP methodology from the models Jacobson, I., Booch, G. and Rumbaugh [15], Weitzenfeld [16] Scharch [17] and [18].

TABLE V. VIRTUAL WORLD METHODOLOGY

Stages	Description
Business Modeling	At this stage is identified the main processes that will be performed in the laboratory, will make the process diagrams, domain model and a glossary of terms.
Requirements	At this stage is defined the virtual laboratory requirements for which were made the initial list of use cases, the clearance of these, their model and documentation of each use case.
Analysis	At this stage is defined the conceptual view of the virtual laboratory, for which it was done, sequence diagrams, collaboration and activity for each use case, the state diagram and model analysis.
Design	At this stage is defined the programming vision of the virtual laboratory for which shall be carried out CRC tables to establish the responsibilities of the objects, the interface model, the logical model, physical model and data dictionary.
Implementation	At this stage the schedule is made of the various systems that comprise the virtual laboratory, which will be made for the deployment diagrams, packages and components and the code of each of the subsystems.
Tests	At this stage the tests are conducted and system integration of each of the systems comprising the virtual laboratory

V. RESULTS

The developments achieved in the project, offer opportunities to acquire knowledge for the deployment of new virtual labs, creating virtual worlds, design and development of motion capture devices based on wireless sensors and cameras, as well deploying applications as telepresence, which can be used generically to build solutions in education, health, entertainment, industrial, etc.

The project helped to identify mechanisms to incorporate the teaching model of problem solving within the operation of the virtual world, which has facilitated the use by students of the device.

The construction of the laboratory includes the formation of a task force comprised of people from different professions (system engineers, electrical engineers, designers, educators, teachers and students of the subject of chemistry), who have worked in an organized and have allowed the approach new projects, seen from different perspectives.

VI. DISCUSSION

The design and development of virtual laboratories oriented to education should consider incorporating educational and teaching models, because it facilitates the use and student motivation to perform the various practices in the laboratory.

The practices that students will perform in the virtual laboratory, must be integrated with the programming being done by the class teacher, as this allows better results in the transfer of the different concepts.

The development team of a virtual laboratory oriented to education must have professionals from different areas such as systems engineers, electrical engineers, designers, educators and experts in the field that allows the construction of the laboratory from different perspectives.

Abstract— **This paper presents a Processes Management Model for Higher Education (PMMHE) characterization. With the PMMHE is possible to produce a comparative measurement system (benchmarking) of organizational, tactical, logistical and operational processes for formation, training and coaching programs in higher education institutions. The current PMMHE's release has impact on engineering programs and emerges as a strategy of the Colombian Government in its effort to articulate the university and industry, particularly the software industry and education of software engineering and their related areas at technical, technological and professional levels. The model is defined as knowledge management tool, which provides a scenario of variables and requirements classified by process categories and areas, practices, resources and products of processes, in which the institutions can to develop assessment practices to exchange resources, knowledge assets and best practices. This scenario is seeking to promote the establishment of a process improvement environment in higher education programs of engineering. It is very important to emphasize that the model's strategy is the transition from the subjective to the objective, for obtaining impact and spread and internalization knowledge, beyond the mission statement of institutions. This derivation from hypotheses to the thesis supported in facts, leads the formal use of statistical process control for knowledge management which includes the measurement systems analysis and collect measures about teaching - learning collective and individual processes under constantly balancing between the theory and the practice about the scientific and professional aspect. Also, this paper presents the lessons learned and the assessment for applying the model to 58 companies and 5 institutions of higher education related with the software industry in Colombia.**

Keywords- Process Maturity Model in Higher Education; Measure Systems for Higher Education, Knowledge Management in Higher Education.

I. Introduction

In the last 10 years, one of our lines of research work has been the development of quality management systems applied in higher education. The focus of our research is the several adaptations of software engineering's innovation frameworks [3], particularly, CMMI, ITIL, PMI, SWBOK, SPICE and ISO (12207-20000-15504...).

Due that academic community at university-level in Colombia are using information and communications technologies (ICT's) in their certification processes for their higher education programs, in great part achieved with our work, currently our actions are pursuing in way of get that the higher education institutions are developing strategies to formalize processes for management, authoring, instruction and assessment of the university programs offered in Colombia.

The document is divided into seven sections. In the first part, we establish introduction and organization of this paper.

In the second part, we provide an overview of the process and competences paradigms that allow defining the different kinds of educational processes. This way, the educative programs appears with organizational, primary, support and adaptive processes. Additionally, we present an overview of the three different studies that support the model proposed: Academic and Administrative Management of Educative Institutions, Quality Assurance System for Higher Education and Software Quality Colombian Network. Finally we establish the research problem we are trying to solve the model and the applications discussed in this paper.

In the third part, we propose that, if the educational programs are in crisis, a paradigmatic change as a discipline is required and we propose the management by processes support in competences for that change. In addition, based on maturity models arguments, we assume that all paradigmatic change can only be possible adopting a critical attitude and then promoting a new paradigm. This part ends with describing the specifications and architecture of the Academicals Programs Framework: Knowledge assets management; Authoring, Development and Maintenance; and, Instruction, Certification and Professional practice.

In the fourth part, we exemplified by a studies case of on how it is adapting the PMMHE framework in training non-formal programs in state institutions and undergraduate and graduate programs in various universities in Colombia. In addition, we reflect briefly on the scope and utility of this framework as benchmarking tool. The application of PMMHE demonstrates that the software paradigms are adaptable in different environments

In the fifth part, we explore the future trends we consider promising for research in the short term: Higher Education Accreditation and Assessment, Personal competences certification and Peers School.

Finally, in the sixth and seventh parts, we present the Conclusions, Acknowledgments and References of the paper.

II. BACKGROUND

A. Relationship beetween Process and Competences Models.

Processes are generally defined as "a set of interdependent tasks transforming input elements into products" [1]. A process generally comprises the following elements [2]: a purpose; the responsibilities of the participants in the process and their duties; the entrance criteria for the elements or conditions needed to begin the process; the inputs (artifacts, information or material) needed to perform the process; the activities, tasks or actions which make up the process; the outputs (artifacts or assets) that result from produced or modified by the process; the exit criteria (elements or conditions) needed for process completion; the process measures that support the process performances or future performances; tools, techniques and knowledge used in enactment the process; the adaptation patterns for tailoring the process in several contexts; the interfaces with others processes; and, records of information to future use.

We have [4] renamed (Fig. 1) the inputs and outputs as input resources, process and product. The input resources may be of use, consumption or transformation. The output resources include products and information. Use resources are used as service functions to the process. The consumer resources are materials that will be consumed during the process. The service functions are performed by roles and each role has competence units (CU) and each CU is associated with the activities of the process. A process can be atomic or compound. The atomic process consists of tasks of direction (leading and management), support, primary and adaptation (instantiation through planning and performance). A composite process consists of sub-processes that can also turn are direction, support, primary and adaptation processes. The politics of the processes includes the objectives and the business rules for each resource category. The scope, knowledge and quality of the process and its products, is seen around all types of resources and is established through the functional and nonfunctional requirement [5] that define them.

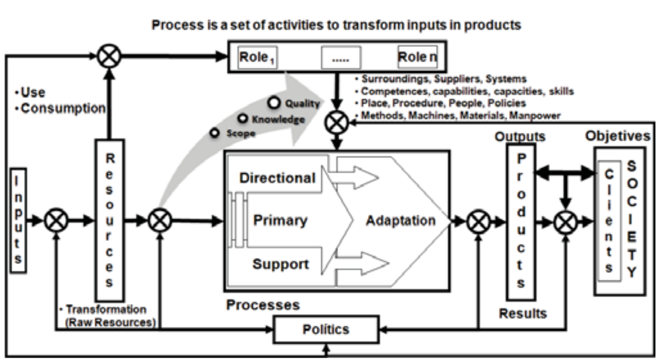

Figure 1. Process Model [4]

A special role belongs to human resources when they are assigned and are responsible for the implementation of relevant activities of the processes. In our work, the role is associated with the units of competence, which are closely linked to the people performance in the processes. This fact raises the competences assigned to the roles of individuals are vital and interdependent with the processes.

B. Academic and Administrative Management of Educative Institutions

In order to establish a collaborative (all for one) and cooperative (one for all) network was conceived the GAYA Project [6] (Fig. 2) as Colombian educative sector unit. This unit was appreciated as a system supported in new telecommunication technologies and different educative agents (entities, government and communities). This unit was developed to model, share, deploy, monitor and make consensus in the different knowledge associated with the educational processes, mainly in aspects as to make and to establish the insurance and model politicians of quality processes about configuration and requirements of inputs, resources and products and/or services.

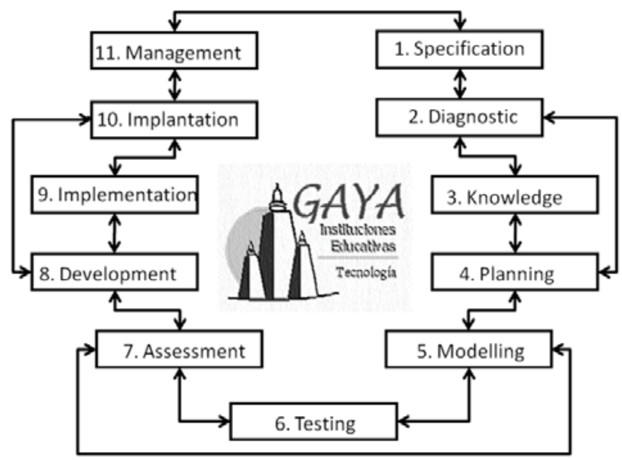

Figure 2. GAYA Model [5]

GAYA is a process to develop an educational institution in five levels:

1. Recognized State: An educational program is in a recognized state when indirect communications features or inadequate, quality management and process implementation limited and inconsistent relationship with users and providers. Processes are ad hoc and even chaotic. Few processes are defined and success depends on individual effort.

2. Normal State: An educational program is in a normal state if it has basic processes to track costs, plans, programs, agendas and functionality. The discipline in this state repeats early successes processes in similar applications.

3. Formal State: An educational program is in a formal state of formalization, whether the activities and administration are documented and integrated as standard processes in the school. Thus, institutional

activities, is developed and maintained, usually using approved procedures.

4. Managed State: An educational program is in a managed state when there are standard measurements about features about resources. Thus, the processes are quantitatively and qualitatively understood and controlled.
5. Optimized state: An educational program is in a sate optimized, when it makes continuous improvement through quantitative feedback, valued in the process.

The processes carried out to climb each of the levels are summarized in the Table I and fig. 2.

TABLE I. PROCESS TO GO THROUGH THE GAYA´S LEVELS

Process	Description
1. Implantation	Identification of needs for determination processes of development
2. Diagnostic	Establishing criteria for selecting organizational entities to model and training needs assessment and knowledge of human resources in the process.
3. Knowledge	Determining organizational entities candidates, for selecting the organizational entity and human resource development will intervene in the process that will be modelled.
4.Planning	Planning scope, policies, objectives, activities and resources required to implement the process on the selected organizational entity in Phase 3.
5. Modellling	Development of an organizational entity modeling pilot using the software.
6. Testing	Simulation or execution of pilot.
7. Assessment	Evaluation of pilot test, which decides whether to continue with step 8 and repeat the steps 5, 6 and 7.
8. Development	Scheduling and resource allocation for mounting the organizational entity modeled, tested and validated in stages 5, 6 and 7.
9. Implementation	Implementation of the organizational entity according to the programming stage 8.
10. Implantation	Training and Installation of the organizational entity produced in step 9.
11. Management	Administration and Organizational use of the entity-mounted stage 10.

Through the GAYA project was possible to establish the need to define and establish a quality management system for the higher education institutions. This need was referred to the National Education Ministry of Colombia when we presented the results of the pilot project about five Colombian universities. The event was the beginning of a new project: Quality Assurance System of Higher Education (In Spanish "Sistema de Aseguramiento de Calidad para la Educación Superior" – SACES -. SACES is described in the next section.

C. Quality Assurance System for Higher Education (SACES)

This project created the SACES System for Colombian Higher Education Institutions (HEI) [7] automatically perform the steps associated with the registration and qualified institutional type processes as: Legal personality recognition, Approval of feasibility study for public higher education institutions, Institutional character change, Recognition as a university, Redefinition for offering preparatory courses and Authorization for creation of institutions. With this process-driven system the presidents of educational institutions can apply the qualified and track record in each of the stages and requirements: Filing, Assignment of pairs, pairs Visit, Evaluation, and Resolution Rules.

The SACES (Fig. 3) is the first process management system that has the Colombian National Education Ministry that manages roles and responsibilities within the process. Specifically, the system has the following processes which are pre-defined roles (Table II) and on which it is possible to establish performance statistics and process and product quality.

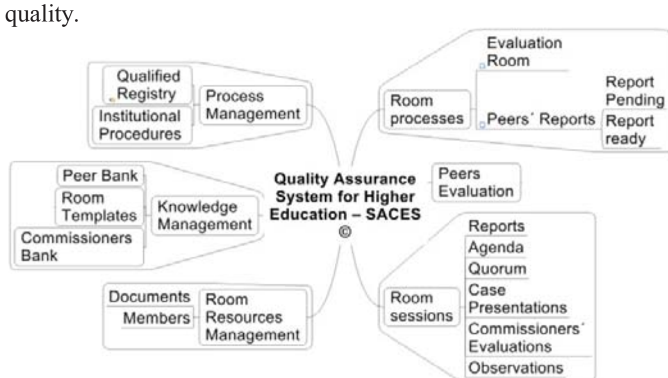

Figure 3. SACES [7]

TABLE II. PROCESSES AND ROLES IN THE SACES

Process	Roles
Process Management • Qualify Registry • Institutional Procedures	Presidents of Institutions System Manager Leader Manager Legal Operator Verifier Operator
Knowledge Management • Peer Bank • Room Templates • Commissioner Bank	Room Secretaries System Manager Leader Manager Verifier Operator Academic Peers Academic Commissioners
Room resources Management • Documents • Members	Presidents of Institutions Room Secretaries System Manager Leader Manager Legal Operator Verifier Operator Academic Peers Commissioners
Room Sesions • Evalution Reports • Commissioner Reports • Peers Reports • Validatios	Room Secretaries Academic Commissioners

Although SACES processes are ISO9000 certified and who use the system do it like a social network, the owners and users have identified the need to formalize the competences to enhance and certify the performance of those using the system. One of the actions to undertake in the short term is the creation of the peer's school to improve verification visits to the institutions.

SACES operates within the legal framework that is supported and verified by academics peer institutions to meet the quality legal requirements. Such conditions are classified as program and institutional Terms.

The program quality terms are: Correspondence between the name of the program, curriculum content and achievement of goals; adequate reason for existence of the academic program; a curriculum; Activities that strengthen academic knowledge; Adequate training in research; The proper relationship with the external sector; Number and quality of teaching personnel; Educational media for teaching; Physical infrastructure in classrooms, libraries, auditoriums, laboratories and spaces for recreation and culture.

The Institutional terms are: Selection and evaluation of students and teachers; Existence of a formal administrative and flexible structure; Self-assessment culture; Graduate program; Institutional Welfare in health, culture, living, recreation and economic and labor conditions; Adequate resources to ensure compliance with quality goals, welfare and ability to project into the future, according to the needs of the region and country.

SACES system as a whole that detects weaknesses around the terms of quality though failing to analyze the processes and resources (including the skills of those involved), thus, the institutions do not yet demonstrate the quality of its processes and one notes the need to go down to the process performance and quality of results to truly determine the quality requirements at all levels.

D. Software Quality Colombian Network

The Colombian Network of software quality (RCCS) [8] (fig, 4) is a knowledge management tool based on an engineering model, which seeks to strengthen the national software industry and related services supported in software quality standards and international specifications.

The RCCS has been designed in response to the call of SENA and COLCIENCIAS to Support the Strengthening of National Capabilities in Software Quality, as an area model to facilitate the collective construction of knowledge part of the various agents involved, with the initial purpose of facilitating the process of implementing CMMI [9], adapted to the culture and national context.

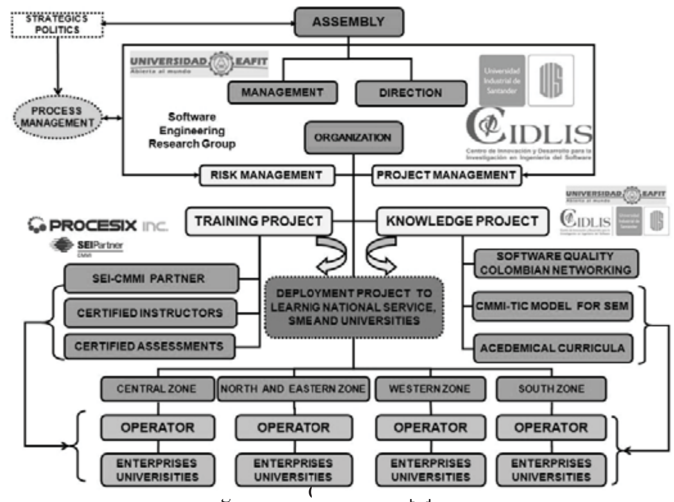
The country has been divided into four geographical areas: North-East Zone, South-West Zone, Center Zone and Coffee Zone.

RCCS network has as main objectives:

- Define and manage programs to support the implementation of software quality models for Small and Medium Enterprises (SMEs) in the sector nationally.
- Develop research projects and methodologies applied in quality models for industry and others who meet the purpose of strengthening the domestic software industry.

RCCS is developing seven sub-projects to achieve its objectives:

1. Creation and implementation of RCCS
2. Training and Certification of CMMI leader appraisals.
3. Training and Certification of CMMI instructors.
4. Implementation the CMMI model in software SMEs
5. CMMI initial assessment of software SMEs
6. Development of a model of Software quality for SMEs
7. Educational programs improvement in software quality



The training and education activities related to this paper are defined in sub-projects 4, 6 and 7. In the sub-project 4 met the needs of education and training demanded by SMEs. In the sub-project 6 was determined the process model. And, in the sub-project 7 will be defined improvements to educational processes in software quality.

The processes established to improve educational programs are (Fig. 11): Process management (improvement, definition and training), Project Management (planning, monitoring and control), support (decision making, asset management, measurement and quality assurance).

The development of sub-project 7 has served as a benchmark to create an approach to integrate the results of GAYA y SACES projects, provided a way to integrate the academic and management processes of academic institutions regarding the management, the authoring and the instruction related to the competences model and academic degrees.

E. Issues, Controversies, Problems

Considering the problem as the difference between a desired state and current state, now we summarized the problems set out from the issues, controversies, scenarios and results achieved in the projects described in the preceding paragraphs.

Some of findings encountered in our observations are as follows:

1. The various stages (fig. 10) involved in the process of teaching - learning of basic education, professional basic education and applied engineering professional Education in engineering education programs are not fully formulated and are delivered as if they were

independent and this fact causes weaknesses when graduates seek to integrate the workforce.
2. Most Universities do not develop training activities for the integration of graduates from academic programs to the productive sector, thus, there are delays in their incorporation into the workforce.
3. In the case of information technology and communications, the universities do not distinguish between educational programs in science and engineering; for example, do not differentiate between academic programs in computer science and software engineering.
4. Many Universities are more concerned about the financial benefits that the results of the professional performance of graduates.
5. Higher educational institutions do not manage the knowledge and the competences of the processes associated with the educational program management.
6. There is not benchmarking models of processes in the higher educational institutions without which it is difficult to define policies for the processes improvement because without such studies cannot establish the best practices of learning and educational management in Colombia.
7. The curriculums are made without contextualizing with the reality because they are not integrated into the current social processes.
8. The Colombian educational objectives are process-oriented to integral formation but this is not aligned with these objectives because to do so would require competences-based curricula because the competences are directly relationship with the processes.
9. Although some international approaches to develop and adapt competency-based curricula have been transferred to our environment such approaches are not fully understood and properly adapted because there are no techniques to define maturity levels of learning - teaching proven strategies in order to adapt our environment and there is no effective, clear and practical methodology to develop and manage competences-based curricula.
10. The community is not prepared to appropriate formation, leading, coaching and teaching with competency-based curricula.

III. HIGHER EDUCATION PROCESSES MODEL

From the background now we will try our framework for our Processes Management Model for Higher Education (PMMHE). PMMHE is the product of the software educative programs improvement sub-project (Objective 7 of RCCS project). PMMHE has as principles, the top management structures developed with the GAYA [6] and SACES [7] projects to establish the basis for designing the teaching-learning processes to treat the primary process of formation.

The Education in this project has the perspective of the process approach, also called project-based learning or problem-based learning (PBL), which induces competences-based learning.

A. Competences-Based Learninig (CBL).

Now explain briefly CBL, defining its parts and some examples (Table III) and Figures 5 and 6.

TABLE III. CBL COMPONENTS

Parts	Description
Role or degree	An academic program which is composed of several competence units. For example (Fig. 7): Patron, Waiter, Cook and Cahier Roles
Competence Units	Each of the areas of process that plays a role. For example, support, planning, development of the work of cooking, cooking management processes for the example in Fig. 7
Competence Unit Assessment	Overall rating being made to all units of competence about perfomance and product and process quality.
Competence Elements	Each of the practices that a place within a competence unit.
Perfomance Criteria	Each of the sub-practices that a place within a competence element.
Evidence required	Each of the Work Product produced in a sub-practice
Essential Knowledges	All knowledhges units to run a sub-practice.
Knowledge units(Fig. 6)	Each is composed of the doing core, and the assesment unit and the the body of knowledge. For example; Fry potatoes. Demands to know about potatoes, how they are fried, and how it does the quality test of process and product.
Assessment units	Overall rating being made to the doing core using the Analyssis Unit and Synthesis Unit.
Analysis Units	Lets break down all parts in order to do performance and quality assessment.
Synthesis Units	Allows synthesis concepts in order to do performance and quality assessment.
Doing Core	Each is composed of the being core, the knowledge core and the assesment core.
Being Core	Each is composed of the phisical core and mental core charactristics of the person.
Knowledge Core	It is the basic knowledge of the a person.
Phisical Core Characteristics	Appearance of a human body.
Mental Core Characteristics	Psychological aspect of a human.
Analysis Core Characteristics	Key analytical aspect of a human.
Synthesis Core Characteristics	Key synthetical aspect of a human.

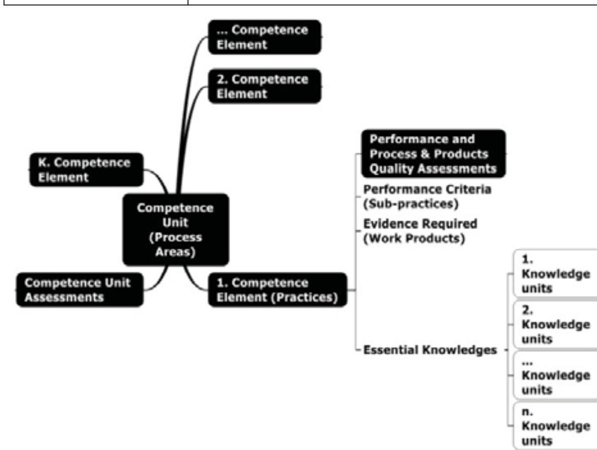


Figure 5. Competence Unit

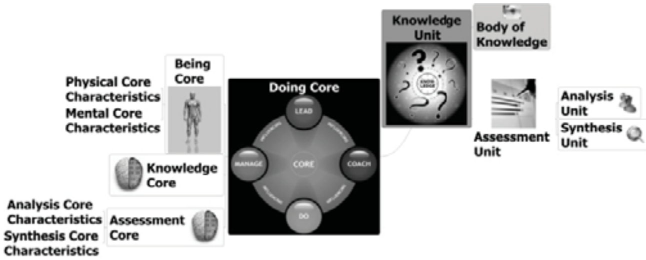

Figure 6. Knowledge Unit

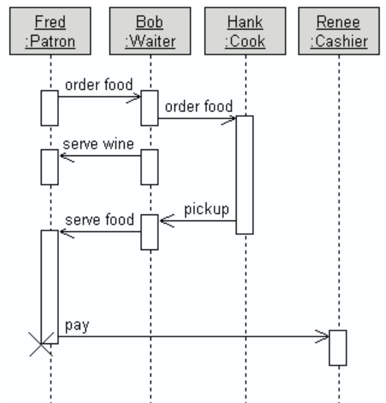

Figure 7. Restaurant Service Process [16]

The process of competency-based education is structured around a process as is the case for example (Fig. 7) where the process is the restaurant service, and each of the roles would trivially, to develop educational qualifications. This teaching-learning process requires teamwork, mentors, special educational materials, instructors, resources, managers for the teaching process, records of evidence, assessments, among others.

B. Description of PMMHE.

Such components are shown in the abstraction that represents "MANAGEMENT AND DIRECTION" in the upper block of the architecture model (fig. 8). The components that emerge in this structure correspond to three processes: Academicals Programs Assets Management (Knowledge assets management); Authoring Process (Authoring, Development and Maintenance); and, Instruction Process (Instruction, Certification and Professional practice).

1) The Knowledge Asset Management Process (KAMP).

The KAMP follows the guidelines established for project GAYA to improve academicals programs and manage baselines during the development or use of the academicals programs.

2) Authoring Process (AP)

The AP is designed to make the processes of academic program development under the vision of processes competency-based formation using project management as a support tool to develop an engineering process with:

- Specifications to support an academic program with units of competence, elements of competence, performance criteria (activities of a process), knowledge, applications and the establishment of evidence required to certify the skills acquired.
- Design to produce teaching-learning develop knowledge assets (learning objects) that are seen as technological applications which consist of reusable software components supported by software and hardware system and human resources
- Verification, Validation and Integration of components.
- Develop a comprehensive improvement process for resources, content, practices and the same authoring.

AP also includes development and maintenance processes to manage, maintain and update knowledge of authoring, to make them consistent, permanent and relevant to the learning process.

3) Instruction Process (IP)

The instruction process [11] is established following learning sequences through teamwork activities to solve problems through projects. The projects are supported by a tutor, a coach and several assistants, who are charged with overseeing all activities of the students. Tutors, coaches and assistants must be certified in the training process before offering academic education programs.

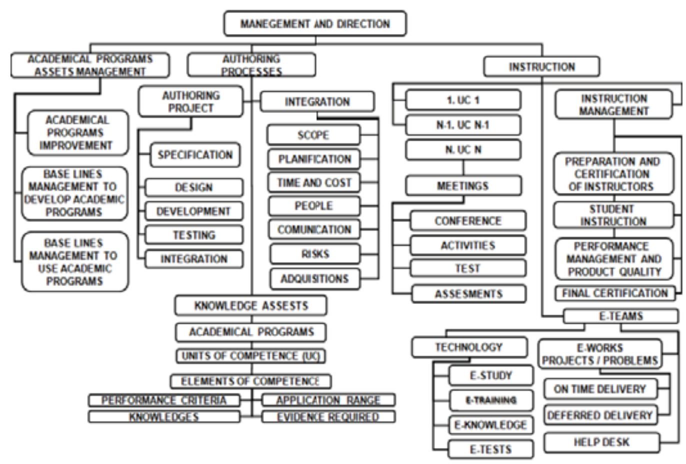

Figure 8. PMMHE [8]

IP may include certification procedures and, eventually, be linked to occupation; a fact that makes feasible the continuous monitoring practices of certified human resources and allows continuous improvement process directly into jobs.

C. Curriculum development methodology for competency-based educational programs

The methodology PMMHE combines the steps of GAYA methodology [6] with the steps of the Educational Software Engineering methodology [17] and has 11 stages (Fig. 9). The structure of the methodology combines project management with an adaptation of the software development life cycle. The structure includes the possibility of having the bodies of knowledge (for example, the Software Body of Knowledge) or the construction of bodies of Knowledge from processes in situ or from experimental prototyping construction processes. The bodies of knowledge should be associated with functional decomposition as specified in UML sequence diagrams [18] in which every lifeline represents a role type with its performance criteria (practices that can be executed).

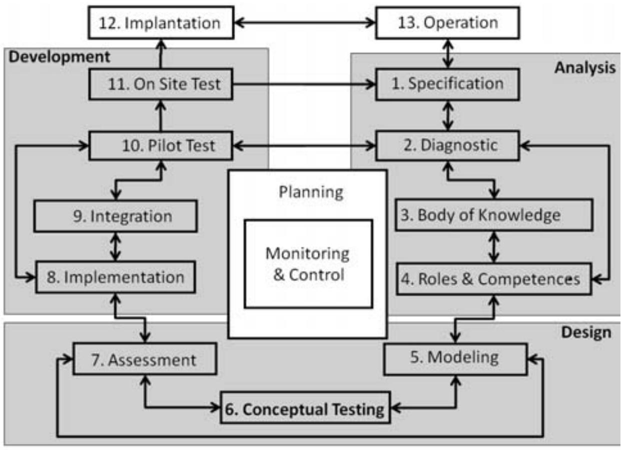

Figure 9. PMMHE [6]

It is absolutely indispensable that the programs have information and communication technologies for development of all activities.

The model is an adaptation of the CMMI models [9] [10] [11] [12] [13] [14] for development, acquisitions and services. The relationship is shown in Table IV where authorship associated with development, management and acquisitions services. It should be noted that the acronyms mean: The Asset management of academics program process (KAMP), Authoring Process (AP) and Instruction Process (IP).

D. Benchmarking from PMMHE

One consequence of the adaptation and comparison of PMMHE with the CMMI constellations is that the CMMI tools can be adapt to develop benchmarks for comparative measurements around the Process areas and roles. From this perspective, also, we can infer that it possible adapt the CMMI assessment methods [14] to solve the second problem that emerged in paragraph II.E. The assessment process can be done at individual or organizational unit using the measuring process of RCCS [8].

IV. PMMHE Prototype

Currently, we are verifying and validating PMMHE through curriculum development environment for software engineering. To determine which curriculum to mediate, we established the followings criteria:

1. Find the more difficult process of assimilation by the companies participating in the project RCCS.
2. Developing a competency-based academic program that would not affect the autonomy of educational institutions and instead enhance its programs.
3. Establish affinity groups to the perspective of the issues set out in the paragraph II.E.

The chosen program associated with project management and included aspects of process management, engineering and support (Fig, 10). The validation project was called " Improvement of Educational Programs in Software Quality”, in Spanish: "Mejora de Programas Educativos en Calidad de Software -MPECS"

TABLE IV. Processes CMMI and Competences in PMMHE

Constellation	Categories	Process Areas	R[1]
Common for all Constellations	**Process Management**	**Organizational Innovation & Deployment**	**All**
		Organizational Process Performance	**All**
		Organizational Training	**All**
		Organizational Process Focus	**All**
		Organizational Process Definition	**All**
	Project Management	**Project Planning**	**All**
		Project Monitoring and Control	**All**
		Risk Management	**All**
		Quality Project Management	**All**
		Integrated Project Management	**All**
		Requirement Management	**All**
	Support	**Process & Product Quality Assurance**	**All**
		Configuration Management	**All**
		Measurement & Analysis	**All**
		Decision Analysis & Resolution	**All**
		Causal Analysis & Resolution	**All**
Adquisitions	Adquisitions and Delivery	Agreement Management	KAMP
		Adquisition Requirement Development	KAMP
		Solicitation & Supplier Agreement Development	KAMP
		Adquisition Validation	KAMP
		Adquisition Verification	KAMP
		Adquisition Technical Management	KAMP
Development	Engineering	Requirement Definition	AP
		Requirement Management	AP
		Technical Solution	AP
		Product Integration	AP
		Verification	AP
		Validation	AP
Services	Process Management	Organizational Services Management	IP
	Project Management	Service Continuity	IP
		Supplier Agreement Management	IP
		Capability & Availability Management	IP
	Service Establishiment and Delivery	Service Delivery	IP
		Service System Development	IP
		Service Transition	IP
		Insident & request management	IP
	Support	Problem Management	IP

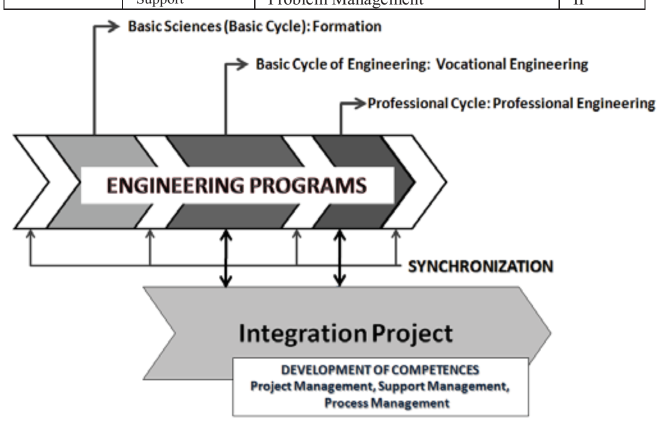

Figure 10. MPECS Project

[1] Relationships between CMMI process areas and MPECS.

The Work in the project covers 5 universities in all regions of the country's strategic and the National Apprenticeship Service (SENA). The roles covered in the project include administrative, faculty and students. Each role is associated with some areas of the CMMI process adapted by the competences-based model for educational sector as shown in fig. 11, establishing the relationships between the curricula development guides for educational programs of the SENA, the Competency Lifecycle Framework (CLF)[2] [10] and the CMMI model as described in Tables V and VI.

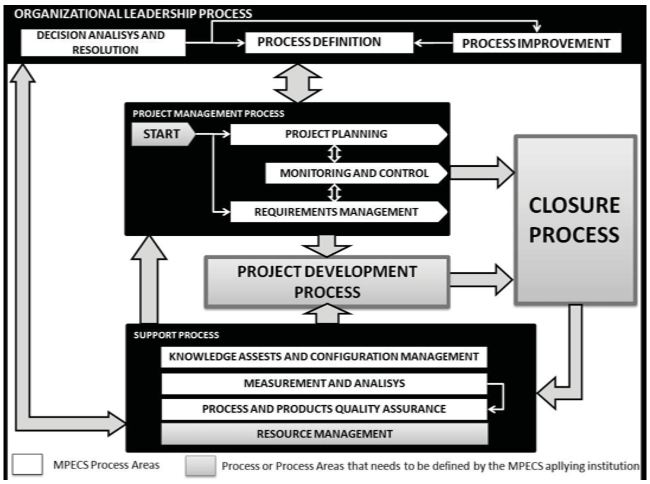

Figure 11. MPECS Prototype Model [8]

Each institution is using MPECS, adapting it to the regional and institutional needs according to MPCES Meeting[3] Strategies [20] shown in Figure No. 12. The Methodology of Meetings covering the project life cycle MPECS: Initiating, Planning, Implementation, Monitoring, Control and Closing. MPCES prototyping has been used for process improvement in Management of business practices, research project management, and degree project management, among others.

The MPCES program roles have been established are: asset managers (learning objects managers), tutors, instructors and assistants. Students play roles of project leader, planners, knowledge managers, coordinators of development and developers.

Upon completion of the prototype implementation MPECS hope to have completed:

1. The benchmarking of the participating entities with respect to the process management, project management and support and their process areas.
2. Proof of certification of competence for all roles we have defined.
3. The benchmarking of the roles, not people, which will allow us to define levels of maturity of such roles.
4. Have established improvements for the problems referred to in paragraph II.E.

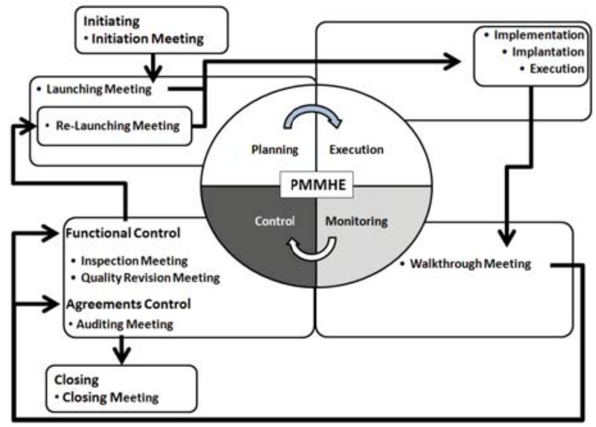

Figure 12. Strategy for development of MPECS prototypes

TABLE V. PROCESSES AND ROLES IN MPECS

Process	Roles
Project Management	Team Leader Planning Manager Leader Manager
Product Development	Design Manager Test Manager Team Member Inspector Manager
Process Management	Process Manager Quality Manager
Support	Support Manager

TABLE VI. RELATIONSHIP BETWEEN MPECS COMPETENCES MODEL AND CMMI MODEL

MPECS Competences Model		CMMI Model
Unit of Competence		Process Area
Competency Cluster [10]	Element of Competence	Practices
	Perfomance Criteria	Sub-Practices
	Evidence required	Work Product
	Essential Knowledges	-
	Other Applications	Amplifications

V. FUTURE TRENDS

With the work we are expected to proceed with completing the following perspectives:

1. Create a benchmarking model for programs of higher education in order to establish objective improvement processes [15].
2. Create a benchmarking model for graduated students.

[2] The CLF is a matrix that identifies the specific competencies required for a particular CMMI-based professional role in the lifecycle phases for each unit of competences. The competency clusters for MPECS are: Achieving and managing agreements; Decision making and problem solving; Project planning and managing; Interpersonal communications and facilitation; Integration, articulation and expression of information; Understanding and adapting to organizational contexts; Model interpretation of the unit of competence; Product or service tailoring, adaptation and application; and, Professionalism.

[3] A meeting is any activity as assemblies, meetings, conferences, inspections or other gatherings that requires careful planning and detailed to achieve the results on each of the processes to develop in each institution to ensure the success of prototype curricular improvement MPCES.

3. Create benchmarking model for assessments leaders, teachers, attendees and educative managers at educational institutions.
4. Develop a software system for integral managing of academic programs based on competencies considering the management, authoring and instruction processes.
5. Adapt and integrate the competency model to be compatible with frameworks of human capital management [19]

VI. Conclusions and Acknowledgments

We have presented in this paper work related to the improvement process in engineering education processes of the institutions of higher education. The paper has shown the ongoing work that has evolved from the research to the implementation of educational quality assurance systems. The document shows how a project from emerging in the software production sector, impacts academic programs, to consider opportunities for improving performance of the graduates as they develop their professional activities. The study discusses the process of learning - formal learning as a competences certification model that impacts all administrators, educators, students and alumni of the educational institutions relationship with engineering.

We express our gratitude to:

- SENA, PROEXPORT and COLCIENCIAS for his contribution to the RCCS project funding.
- The institutions involved in the project RCCS-MPECS: Procesix Inc.; System School of EAFIT University; Electrical, Electronic and Telecommunication School of the Industrial University of Santander; and ParqueSoft.
- The Members of the RCCS Workgroup, special mention to: Pablo Henríquez, Vice-president of Procesix Inc; Liliana Gomez, Owner, GreenSQA S.A; and Raquel Anaya de Páez, Professor and Researcher of EAFIT University.
- The research groups of Industrial University of Santander, San Buenaventura University, Medellin University and Autonomous University of Manizales.
- The members of the Members of the CIDLIS group, special mention to: Heidi Patricia Camacho Grass (Quality Assurance Chief), Maria Rocio Duran Serrano (Administrative Coordinator), and the MPECS support team: Lilia Yarley Estrada (MPECS Planner), Claudia Liliana Rodriguez (Communications Support) and Martha de Flórez (Administrative Support).
- The educational community and the National Education Ministry of Colombia for their contributions and experiences.
- The following Electronics Engineering students of the Industrial University of Santander who have collaborated significantly on developing educational mediations and remains working with us in the MPECS implementation: Lina Paola Aparicio Pico, David Fernando Prada Barrera, Sergio Andrés Castellanos Gómez, Carlos Augusto Reyes Morales, Francy Yolima Cáceres Vargas, Sergio Andrés Tarazona and Fernando Fragozo Vásquez.
- Johanna Marquez Otálora, who helps us considerably in the definition and review of competences structure and stages for MPECS implementation inside the higher education programs at several Colombian Universities between June and October 2009.
