The goal of the TAIST program in ICTES is to prepare students with comprehensive understanding of the hardware and software technologies in ICTES, with in-depth knowledge of embedded systems in VLSI designs and embedded software development, as well as broad knowledge of their applications in communications, networking, signal processing, human interface, artificial intelligence, etc. Students also experience actual development of embedded systems using the state-of-the-art Computer Aided Design (CAD) tools for both hardware VLSI (Very Large Scale Integration) and software in "Embedded Systems Design Exercise Class". Here, students work in teams to also learn about project management, product planning and marketing aspects of the embedded systems development. Master of Engineering. program in ICTES welcomes full-time students as well as part-time students from the industry, both of which will greatly benefit from the unique learning environment which this program is designed to provide. Furthermore, the graduates of this program can further pursue a doctoral study at Thai universities or at Tokyo Tech. ICT (Information and Communication Technology) is the fastest growing sector in the economy with a 70% increase in growth rate projected between 2002 and 2012. However, there is an enormous shortage of ICTES engineers, especially in the area of embedded systems, and this trend will continue to grow with the coming of the "ubiquitous society" in a global scale. The Master of Engineering program in Information and Communication Technology, therefore, has been established to offer an outstanding and state-of-the-art education in both theoretical and practical areas in ICTES with a strong focus on embedded systems. It is expected that all Thai graduates of the Master of Engineering Program in ICTES acquire the necessary skills to be the leaders in Thailand's electronics industry, and also to be highly competitive in the fast-growing global embedded systems market.

TAIST ICTES program has the courses shown in Tables 1 and 2.

TABLE I. REQUIRED COURSES

Computational Mathematics Set theory; Relations; Formal proof methods; Finite automata; Regular expressions; Context-free grammar; Pushdown automata; First order logic; Theories related to counting, graphs and networks; Interplay between continuous models and their solution via discrete processes; Vector spaces, basis, dimension, eigenvalue problems, diagonalization, inner products, unitary matrices; Introduction to applied statistics and its application to intelligent systems; Introduction to supervised statistical learning including discrimination methods
Software for Embedded Systems Software programming; Embedded operating systems and middle-wares; Verification and testing for Embedded Systems; Software issues in the design of embedded systems; Microcontroller architectures and peripherals; Compilers and debuggers; Timer and interrupt systems; Interfacing of devices; Software issues in communications and networking.
Hardware for Embedded Systems Basic digital system design; Processor architecture design; Very Large Scale Integration (VLSI) design methodologies; Hardware concepts on microcontroller architectures and peripherals; Device interface; Hardware for communications and networking
Software Design Exercise for Embedded Systems Hardware and software development tools; software project management techniques and tools; Embedded operating systems; Software development project: requirement analysis, software detailed and test case design, software coding and testing, software documentation; Project planning; System specification design; Software coding; Software implementation and verification on Field-Programmable Gate Array (FPGA) prototype board.
Hardware Design Exercise for Embedded Systems Hardware development tools; Hardware Description Language (HDL); Field-Programmable Gate Array (FPGA) design flow: input and output pin assignment, synchronous and asynchronous logic design, logic simulation and optimization, verification of design constraints; Custom hardware development project; Software and Hardware implementation and verification on FPGA prototype board; Practical issues on microcontroller and FPGA.
Research Methods in Information and Communication Technology for Embedded Systems Research principles and methods in information and Communication Technology for embedded systems problem analysis for research topic identification, data collecting for research planning, identification of samples and techniques, research analysis, result explanation and discussion, report writing, presentation and preparation for journal publication.
Seminar in Information and Communication Technology for Embedded Systems Presentation and discussion on current interesting topics in information and Communication Technology for embedded systems at the master degree level.

TABLE II. ELECTIVE COURSES

Communication Information theory; Signal processing; Communication systems; Data and digital communication concepts; Theory and techniques in data communications: transmission, encoding, decoding, error detection, error correction, link control, networking, and standards; Communication hardware and software; Synchronization subsystems; Time-division multiple-access systems; Code-division multiple-access systems.
Signal Processing Digital signal processing theory; Video and audio processing; Discrete-time signals and systems; Linear time-invariant systems; Sampling of continuous-time signals and convolution; Infinite Impulse Response (IIR) and Finite Impulse Response (FIR) filter designs; Discrete Fourier transform; Fast Fourier transform algorithms; Relations between Fourier Transform (FT), Discrete-frequency Fourier Transform (DFFT), Fourier series Discrete-time Fourier Transform (DTFT), and Discrete Fourier Transform (DFT); Speech analysis; Speech recognition; Speech sysnthesis; Vector quantization (VQ) techniques; Hidden Markov model (HMM); Speech and audio coding; Noise reduction; Morphological analysis; Formal language; Parsing; Spoken language human interface; Image transformation and filtering, image segmentation, image object detection, High-efficiency video coding fundamentals, video coding standards, processing requirements, architecture for the DCT, hardware for motion compensation, nonstandard coding techniques, perspective on the "ke-tai"(mobile phone) service, network human interface
Intelligence Processing Human interface; Human information processing; Artificial intelligence; Concept and design of human-machine interface; Trends of human interface design; Graphic user interface, interactive software design; Hardware technology for human interface; Foundations of human visual and auditory systems; Information processing of the perceptual systems; Color vision, Space perception; Auditory and visual scene analysis; Current research and application of artificial intelligence; Artificial intelligence languages; Search techniques; Knowledge representation, reasoning and inference; Machine learning; Expert systems.
Environment and Control Systems Control system theory; Laplace transform; Control system description and block diagrams; Dynamics of typical controlled systems; Development and simplification of transfer functions; Analytic tools for predicting system response and performance; Geographic Information Systems(GIS) for environment control; spatio-temporal database, fusion of embedded systems and distributed intelligent systems, remote-sensing techniques for environment control; Disaster Control Systems; Spatio-temporal GIS for disaster prevention, map-embedded information processing systems for local government,

mitigation of earthquake disaster, tsunami disaster, Car navigation systems; data structure for car-navigation, map-data utilities; Environment control systems, Power management systems and methods
Selected Topics in Information and Communication Technology for Embedded Systems Selected topics in information and Communication Technology for embedded systems at the master degree level. Topics are subject to change each semester.

In addition to taking courses, all the students are required to perform research and write their master theses.

Thesis

- Each student is assigned to a laboratory in NASDA in the second semester.
- In the thesis project (2nd year) the students perform research under the supervision of Thai University staff (*advisors*), NSTDA staff (*co- advisors*) and Tokyo Tech staff (*co- advisors*). Advisors and co-advisors compose a thesis committee.
- The students receive credits for the thesis project.
- The project is conducted at NSTDA laboratories.
- In order to prepare for the thesis project and get an overview of ongoing research, students attend the master seminar and a course on selected topics in embedded systems. After choosing a topic for a thesis project, but before actually starting the research, a student writes a thesis proposal containing a problem statement for the proposed research, positioning of the research with respect to other research, an overview of the literature in the field, and a planning for the project. The proposal should be accepted by the thesis committee before the project can start.

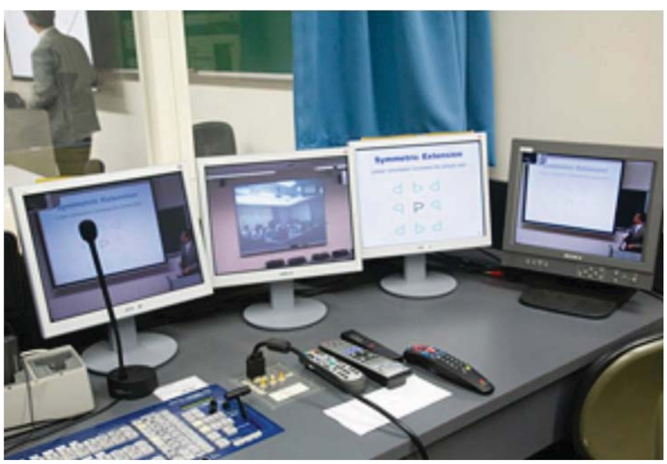

Figure 2. Distance Education Control Room

- The students perform the research according to the plan in the thesis proposal and write theses about the result.
- The project is finished with a defense of the thesis in front of the thesis committee.

V. DISTANCE EDUCATION FOR TAIST ICTES PROGRAM

TAIST ICTES lecture courses are taught by a team of Tokyo Tech professor as a main lecturer and a Thai faculty member as a co-lecturer. Co-lecturers supplement the course taught by main lecturers and undertake exercises. In 2008 among 18 courses 7 were 1-week intensive face-to-face lectures given by Tokyo Tech professors who traveled to Bangkok, 7 courses were completely delivered from Ookayama campus in Tokyo or Suzukakedai campus in Yokohama of Tokyo Tech, and the rest were combination of face-to-face and distance education.

We use H.323 video conference system with about 500kbps. Fig. 2 shows a control room attached to a distance education classroom. There are 4 video cameras and 2 video projectors in this classroom. A lecturer can give a lecture by showing a computer screen or by writing on a blackboard. He can see students in the remote site behind local students (if any) sitting in front of him.

Since most of Tokyo Tech professors are not accustomed in conducting distance education, CRADLE distributed a one-page instruction entitled “Notes on Distance Education”, which had been used in conducting distance education. In addition, we had a training session entitled “How to Conduct TAIST ICTES Distance Education”, which includes operation of communication equipment, usage of tools, and educational methods. A Teaching Assistant (TA) is assigned to each lecture course, and he/ she helps the lecturer by assisting the preparation of lecture materials, connection with the remote site, and controlling the cameras. Lecture materials and other information for students are put on a special TAIST ICTES site named ELITE (E-Learning for Information Technology Education) operated using a hosting service of Tokyo Tech TSUBAME super computer.

Figure 3. Lecture Transmitted from Tokyo

Figure 4. TAIST ICTES Classroom

For some TAIST ICTES courses, lectures are recorded and the videos are put on the ELITE site together with the lecture materials as shown in Fig. 5, so that students can review the courses afterward.

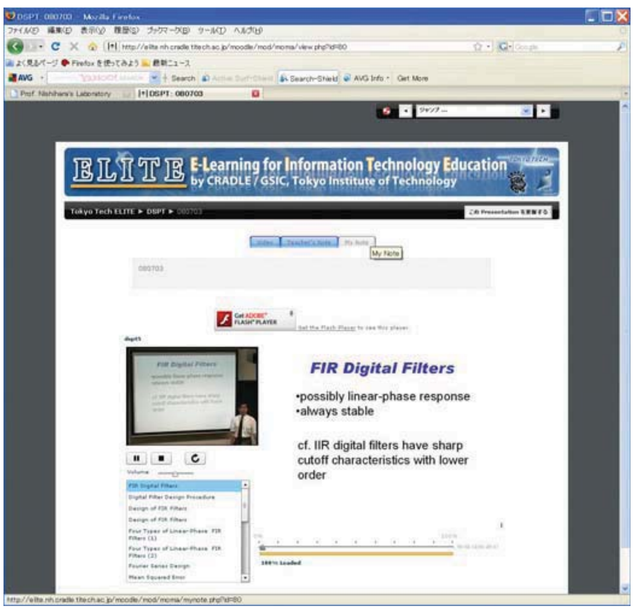

Figure 5. ELITE Site

In the thesis projects, second year students have to make presentations for thesis proposal, progress report, and final defense. We use video conference systems for such occasions.

After finishing the first academic year, we compared the grades of the 26 first-batch students. Except for some students who did not take some elective courses, we compared grades of 7 distance education and 7 face-to-face courses for each of 21 students, and we found no significant differences. This is probably because the number of courses in each style and the total number of courses per student are too small. So we compared the grades of all the students in the lump. The results are shown in Fig. 6, where face-to-face courses have higher grades with 99% significance. As seen in the figure, the course "4.1 Digital Signal Processing Theory" has the lowest score among all the courses, and the course "5.2 Human Information Processing" has the second lowest score. The courses 4.1 and 5.2 are difficult subjects from the lecturer point of view, and the lecturer of 4.1 is probably too strict in grading. If we exclude the course 4.1, there is no significant difference between distance education and face-to-face courses.

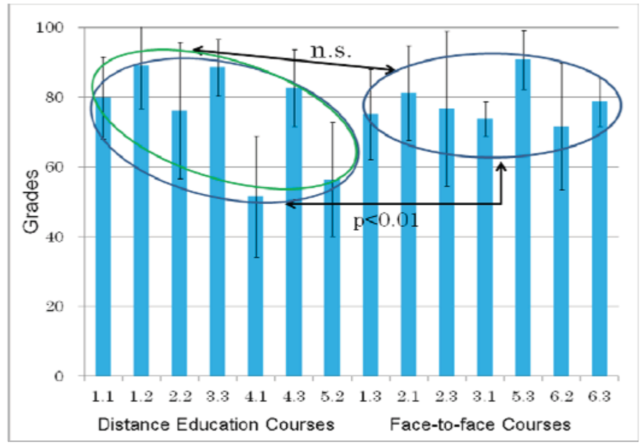

Figure 6. Comparison of Grades

The grades have 99% significant correlations between the following 4 pairs;

- "1.1 Algorithm and Software Design" and "2.2 Processor Architecture Design",
- "1.1 Algorithm and Software Design" and "2.3 VLSI Design Methodology",
- "1.2 Embedded Software Design Techniques" and "2.1 Basic Digital System Design", and
- "1.2 Embedded Software Design Techniques" and "2.3 VLSI Design Methodology".

Those courses cover fundamentals of hardware and software, and so it is considered to be natural that there are correlations among those courses. Other pairs of courses that have correlations with marginal significance are as follows;

- "1.1 Algorithm and Software Design" and "5.2 Human Information Processing",
- "1.1 Algorithm and Software Design" and "2.1 Basic Digital System Design",
- "1.2 Embedded Software Design Techniques" and "2.2 Processor Architecture Design",
- "2.2 Processor Architecture Design" and "1.3 Real Time System Design",
- "2.2 Processor Architecture Design" and "2.1 Basic Digital System Design",
- "2.1 Basic Digital System Design" and "2.3 VLSI Design Methodology", and
- "2.3 VLSI Design Methodology" and "6.2 Environment Control System".

The following one pair;

· “2.2 Processor Architecture Design” (distance education) and “3.1 Information and Coding Theory” (face-to-face education)

has negative correlation coefficient of -0.965 with 95% significance. They are, of course, rather different, but there may be other reasons. Investigation will be continued for the following years.

ELITE site is also used as a student evaluation system using 4 Lickert scale questionnaires. Some of the results are shown in Fig.7. Sense of achievement for distance education is higher than that of face-to-face education with marginal significance. This is probably because students felt more sense of achievement after overcoming the unusual situations of distance education. Other items of questionnaires have no significant differences between distance and face-to-face education. We believe that those facts justify the use of distance education. It is to be noted, however, that those result from much effort of lecturers and co-lecturers.

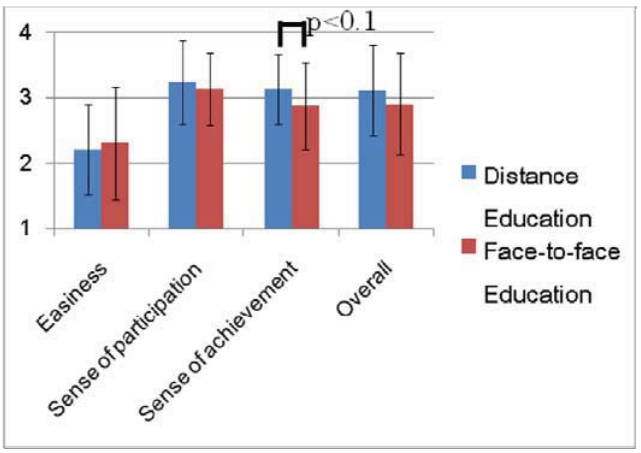

Figure 7. Comparison of Questionnaire Results

For the course “4.1 Digital Signal Processing Theory”, questionnaire results are summarized in Table 3. The results are generally favorable, but improvement is necessary for picture quality, sense of participation, and sense of achievement. The score is not so good for the question to compare the course with face-to-face lecture. It is 2.5, just a median of 1 and 4. So we believe we are doing well.

To improve the picture quality, we are seeking for the use of high-definition video in which lecturer’s facial expressions are easily seen [5], and lecturer can much more clearly see the students. The key for that is whether we can secure enough bandwidth, which is still a big problem because internet is usually a best-effort network.

TABLE III. QUESTIONNAIRE RESULTS

Question	1	Average	4
Interest	uninteresting	3.5	interesting
Easiness	difficult	1.9	easy
Lecturer’s face	Unseen	3.5	seen
Moving picture	Bad	2.9	good
Lecturer’s voice	unclear	3.7	clear
TA’s help	useless	3.8	useful
Exercise format	Bad	3.5	good
Sense of participation	not felt	3.2	felt
Sense of achievement	not felt	3.2	felt
Compared to f2f	Bad	2.5	good
Overall Bad		3.0	Good

VI. CONCLUSIONS

New joint graduate program operated by Tokyo Tech, NSTDA, and Thai universities is introduced, where distance education is well utilized. The roles of co-lecturers are very important to have good educational effects, if not comparable to face-to-face courses. The program has just started, and continuous improvement is necessary in educational systems, technical supports, and collaboration framework. Joint degree system will be much more attractive for many students, and we are studying its feasibility.

ACKNOWLEDGMENT

The author is indebted to members of TAIST Committee at Tokyo Tech, NSTDA, and Thai universities, i.e. SIIT, KU, KMITL, and KMUTT for the fruitful collaboration. He also thanks members of CRADLE and GSIC (Global Scientific Information and Computing Center), Tokyo Tech, for their kind cooperation and supports to TAIST project. Thanks go as well to CRADLE students who helped in collecting and analyzing data.

Abstract— **A special session is proposed to present a view of the current status of Engineering Higher Education in LatinAmerica with respect to areas in which UNIVERSIA is promoting.**

Keywords: Engineering, Higher Education

I. Introduction

UNIVERSIA, launched in Spain on 9 July 2000 with a clear vocation of serving the university community in Latin America, is the largest Latin American network of university collaboration. It includes 1,100 universities and colleges in 15 countries. Universia partner universities represent 76 percent of the university group of countries where it operates, with 10.9 million students and 885,000 teachers.

UNIVERSIA tries to act as a promoter of change and innovation to help universities to develop shared projects. Also it creates new opportunities for the university community in order to meet the demand of the business environment and institutional sustainability criteria. Its vision in this way is to be the largest network of Spanish and Portuguese that promotes academic and the university-industry cooperation.

II. Focus Areas

This session will include papers concerning the action lines promoted by UNIVERSIA:

1. Information to support learning and training.
   - Detecting the necessities for corporate training and disseminating the academic knowledge with training resources throughout universities.
   - Disseminating business experience to the university environment.
2. Employment. Practice and career development.
   - Helping universities to increase the employment opportunities of graduates in collaboration with university employment services.
   - Helping companies in the selection process for graduates and internships.
   - Opening to teachers and researchers channels of communication with companies and institutions for business development of research results.
3. Observatory. Center for the future of science and higher education.
   - Building physical and virtual spaces for debate and discussion on trends in higher education involving all stakeholders (companies, institutions, universities, government, etc).
   - Helping the academic community in the process of transition to the new educational scenario.
4. Social Networks.
   - Creating platforms for leisure participation on issues of interest to academics (virtual environments, social environments, chats, blogs, contests, etc.).
   - Organizing events that promote responsible and participative entertainment (music, sports, debates, etc.).

Innovative Practices for Learning Human-Computer Interaction by Engineering Learners

Jaime Sánchez, Mauricio Sáenz
Department of Computer Science
Center for Advanced Research in Education
University of Chile
Santiago, Chile
{jsanchez, msaenz}@dcc.uchile.cl

Abstract—**This paper presents an innovative experience with teaching and learning Human-Computer Interaction in the field of Computer Engineering in the Faculty of Physical Sciences and Mathematics at the Universidad de Chile. This is a pioneering course in Latin America, and has been offered every year for the past 20 years without interruption. The content of the course is constantly renewed and updated. As a result, students have been able to learn of a wide range of aspects regarding Human-Computer Interaction that must be taken into consideration when designing any kind of software or device for human use. At the same time, students recognize that the issues and methodologies taught in the course are not only useful for their training as engineers, but are also helpful for everyday decision making.**

Keywords- HCI Learning, HCI in engineering, constructivist learning, usability

I. Introduction

Throughout the years, learning has been explained as the analysis of several theories proposing various learning models. One of the aspects these models focus on is distinguishing between different degrees of activity/passivity in the role of the student [16].

Traditional or frontal teaching puts the students in front of an instructor who provides them with theories, concepts and a variety of content [8].

In this scenario, the students are mere passive receptors of information that a transmitting instructor presents and explains, be it with the help of old technology (blackboard or whiteboard) or digital technology (projector, computer, etc.) [1]. This way of teaching and learning that responds to a behaviorist-positivist model, has prevailed in education for decades, and is slowly experiencing changes and innovations that point towards a model in which the learner is the main actor and is active in his/her learning, constructing knowledge through change in the meaning of the experience, interaction with others and the organization and reorganization of his/her mental schemes [19].

In this new scenario, the role of the instructor is that of a facilitator of meaningful student experiences and a mediator or coach for the learners' construction of knowledge through practice, discussion, analysis, comprehension and active commitment [2], [16].

It is precisely in this context in which the teaching and learning of Human-Computer Interaction (HCI) in the field of Computer Engineering within the Faculty of Physical Sciences and Mathematics at the Universidad de Chile takes place. This HCI course has been a pioneer in Chile and Latin America. It has been given every year for the past 20 years, being constantly renewed and updated in synch with the newest prevailing technology. As a result, students have been able to learn of a wide range of general situations involved in Human-Computer Interaction that must be considered when designing any kind of software or device for human use. This implies development of a capacity for analyzing problems on a technical, cognitive and functional basis from a design perspective, and critically analyzing interactive Interface design methods and techniques.

The main reason why people do not use fully many specific systems is that their interfaces are not conceived and designed for end-users to interact with them, providing false cues for their use and mechanisms that lead to errors [4], [12]. The objective of HCI is to generate usable, understandable, safe, functional, intelligible and useful products. These are products with interfaces that are easy to interpret and understand, that provide visible cues for their operability, and that consider human error in their design [4], [18].

HCI makes it so that end-users are the center of any development and design [10]. This is to say that the design of the application is born of the needs and interests of the user, occurs with the user's constant participation and culminates in a high degree of usability [21]. For this reason, human-computer interaction favors systems with interfaces that are designed based on the user's needs, coming to know and understand the user, and even making the user part of the design team [7], [13]. In this way it is assured that the application is usable and understandable, and as a consequence, can be used by the end-user [4]. At the same time, these systems must be modeled and implemented by considering all the technical and functional specifications, and by following software engineering methodologies in such a way that a robust, functional and reliable system is obtained [5], [17]. The idea is to generate applications with interfaces that help, improve and widen the sphere of the user's experience, together with providing more reliable solutions, saving costs, improving the efficiency of processes, and most

This study was partially funded by the Project CIE-05 Program Center Education PBCT-Conicyt, Chile.

importantly improving people's productivity, efficiency and ways of life.

In addition to being associated to software engineering, human-computer interaction is heavily influenced by other disciplines of knowledge, such as the cognitive, biological, psychological, sociological, and anthropological sciences, as well as graphic and industrial design and ergonomics [15]. All these disciplines contribute to and inform the design of human-computer interaction by responding to questions such as: How does the human being behave in social and cultural contexts in time and space? How do his/her social relations and interactions occur? How do users perceive? How do they memorize? How do they process information? How do they know and learn? How do they solve problems? How do the brain and the sensory organs participate in their interaction with the software and with digital devices? How are the concepts, theories, elements and components of graphical and industrial design incorporated into the design of user interfaces?

II. THEORY AND PRACTICE

For Myers [11] it is important that students of computer engineering know and learn of the issues underlying user interfaces. This author points out that interfaces are the added value of computer systems, and generate competitive differences in that the hardware and software become commodities. His reasoning is based on the fact that if students do not know about human-computer interaction, their competences will not be useful with regards to the needs of the industry. Reality coincides with these arguments. The heavy commercial competition of modern technology products is based on the novelty, interactivity, usability and usefulness of interfaces. For example, the current commercial competition in the field of touch-screen interfaces and its various designs points to interface designs that are increasingly natural, usable and understandable for users.

One of the keys of our HCI course has been the learning methodology and its constant renewal, innovation and updating. This learning methodology consists of applying the theories, concepts and models studied in class to practical, applied, real and pertinent case study projects. On the basis of a global issue dealt with during the course, the students resolve and develop a series of HCI application case studies and a final human-computer interaction project that integrates and unifies the results of the previously developed cases, with increasing degrees of requirements, depth and complexity.

Just as today the tendency is for interfaces to revolve around multi-touch devices, technological changes are so fast and diverse that new and varied interfaces are constantly emerging. The field of human-computer interaction is especially sensible to the constant technological changes and innovations in the world of technology. In this way, learning of human-computer interaction implies that, in addition to attending classes, building up knowledge and managing information, students must be constantly reading papers published in the latest HCI journals and conferences in order to know of current HCI tendencies and issues.

The classes for the HCI course are given with a variety of nuances and orientations. Some sessions consist of presenting, analyzing and discussing theories, models and content, while others involve collaborative teamwork, planning, developing and evaluating progress on the design of the application case studies. Periodically the students revise and analyze their progress together with the instructor and teaching assistants, who support, mediate and facilitate the conceptual and functional decisions that students must make.

A. Application case studies

As has already been mentioned, the course presents the students with some application cases studies of a design or the redesign of human-computer interaction that the students must resolve. The students' work evolves from the design of human-machine interfaces to the design of human-computer interfaces. These case studies are organized into a central global issue, such as transportation, education and navigation that are finally linked in order to achieve a more complete HCI design, and produce it for the final project.

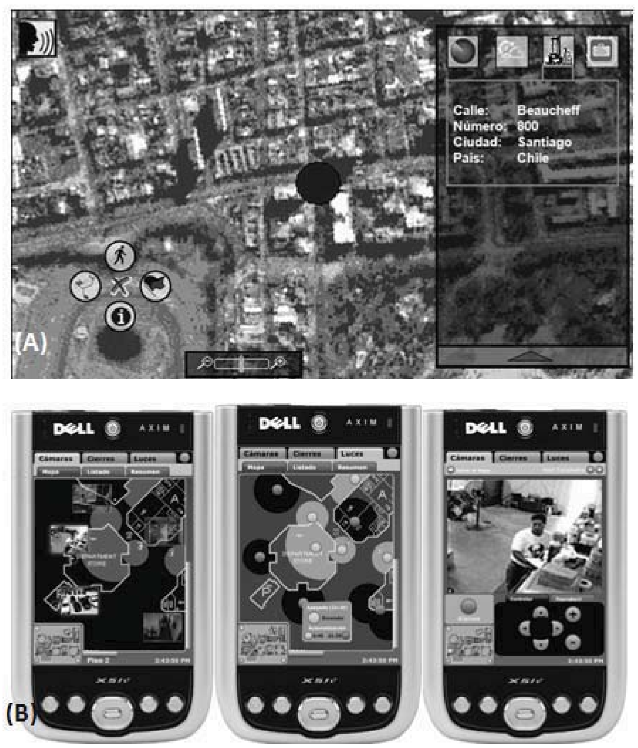

Figure 1. (A) Interface proposal for GPS devices developed by students of the course in 2006 (B) Proposed assisted control system for jails

All of the proposals for the resolution of the application cases from each team of students are presented, analyzed and discussed during the course. This implies that, in addition to learning about concepts and their application, students learn and reinforce their skills for designing and making presentations before an audience. As the course evolves and the application cases become more complex, the demands on the quality of the presentations increase, which obligates students to present, apply and use the course content studied impeccably and in great detail.

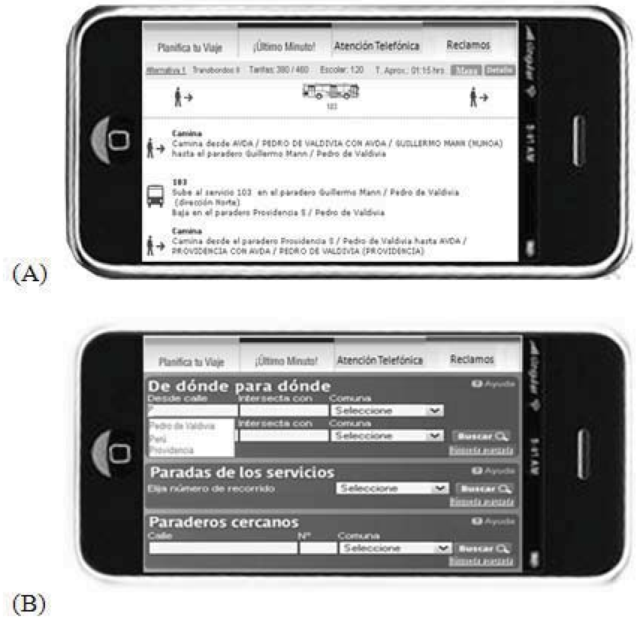

Figure 2. (A) Design of a mobile application in support of public transport (B) Proposal of a mobile design for the Transantiago website

The issues involved in the application case studies are varied. Students have designed and redesigned several web sites and portals, audio and information devices for vehicles, remote controls, multifunctional office equipment, remote home control systems, assisted control systems for jails, zoos and shopping malls, GPS navigation devices (see Figure 1), information systems for public transportation and systems related to education, among others. One of the key points of these case studies is that the designs must be user-centered, which implies working with and for end-users. The end-users evaluate the prototype designs providing their particular visions, problems, concerns, interests and needs.

The HCI case studies are not only varied, but are also related to real situations in real contexts. For example, in the year 2001 an analysis was made of the interfaces used in the new automatic charging devices installed in the newly replaced public bus system of Santiago. In 2007 the design of an application that would allow the user to locate the best route to/from work and home, as well as the best means of transportation, was studied.

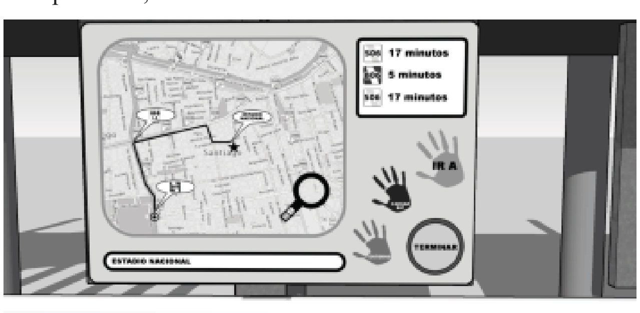

Figure 3. System interfaces designed by the students for the system-solution of a Transantiago bus stop

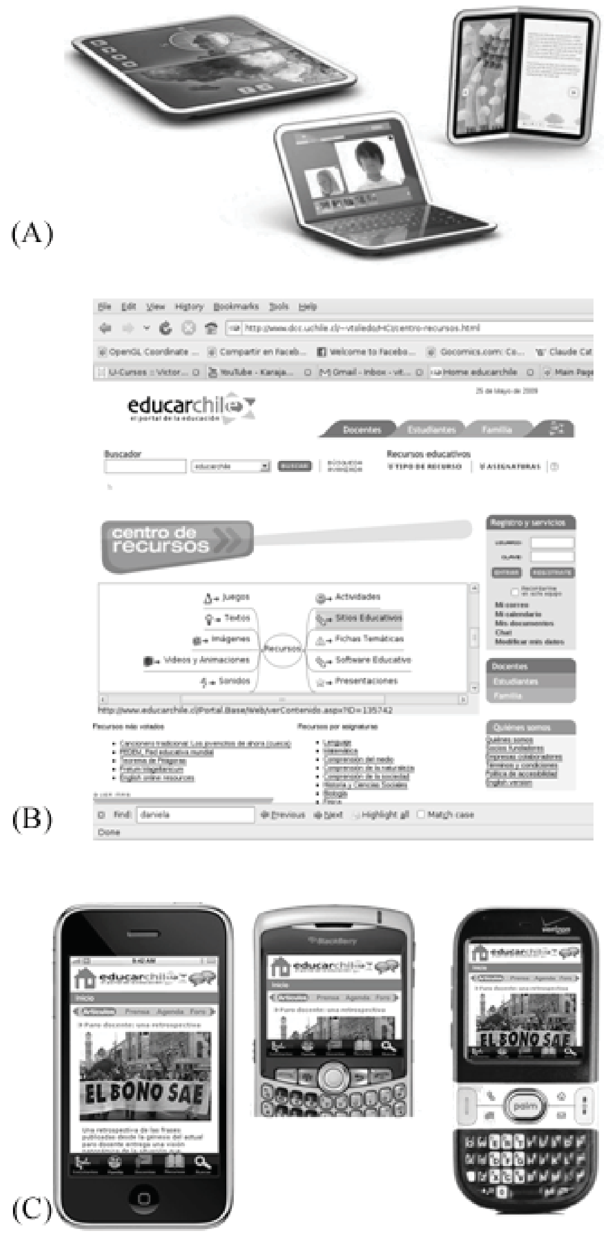

Figure 4. (A) Digital book interfaces designed by a team of students from the course. The students were not only concerned with designing the interface or the hardware device, but considered the context in which the technology designed would be used as well. (B) Redesign of the interface for the EducarChile web site. (C) Proposal of a mobile interface for the EducarChile web site

At the beginning of 2007, a new urban public transport system, called Transantiago, was implemented in Santiago de Chile [20]. This system emerged as a response to the almost unmanageable and chaotic situation with the buses that operated in Santiago up until the end of 2006 [6]. Thus, in 2008 the issue for the course was Transantiago (Figure 2A). Students evaluated and redesigned the Transantiago web site (www.transantiago.cl) (Figure 2B). The final project systematized, collected and linked all of the previously resolved application case studies during the course, resulting in a higher degree of complexity, as the design of a system-solution for transport focused mainly on providing information in order to help with decision making by taking passenger comfort, context and surroundings into account. To do this, students had to consider that the proposed interface must be implanted at bus stops and subway stations, in addition to other places that students deemed convenient (Figure 3).

Last year, in 2009, the central global issue of the course was education. Under this issue, the students designed an innovative interface for a device that would serve as digital text for high-school students. To do this, students had to find a technological solution that could be used as a book, a workstation, or an information search engine. This had to be done according to the user's needs, in order to be presented as a reusable resource with low maintenance costs, and the contents of which could be updated. To this practical problem, an important technological variable was added; the printed book upon which the device was to be based had still not been replaced by any existing digital technology, for which reason the device had to integrate a correct functionality based on a creative and innovative design. As a result, the students generated interesting and innovative interface proposals, in some cases using existing hardware devices, and in others they generated proposals for the development of new hardware (Figure 4).

Figure 5. Presentation of the redesign of the EducarChile.cl web site to the manager and professionals of the site from Fundacion Chile and the Enlaces network of the Chilean Ministry of Education

The second application case study this year consisted of students evaluating the interfaces involved in the educational web site of EducarChile (www.educarchile.cl), one of the most visited and used public web sites in the country. After this evaluation, the students redesigned the web site in their final project (keeping the end-users in mind: teachers, students and parents). The final project was presented to a group of professionals responsible for the EducarChile web site from Chile Foundation and the Education and Technology Center, coordinated by the Enlaces Network (www.enlaces.cl) (Figure 5). As a result of this experience, the web page managers redesigned the site to make it more usable, understandable and functional. To do this, the web page professionals created a survey in order to obtain more data and opinions from the end-users (http://www.educarchile.cl/Portal.Base/Web/VerContenido.aspx?GUID=c363e908-c2a3-4b21-bd56-ad0cd6ad6d94&ID=197268).

B. Evaluation

The evaluation of the main concepts studied in the classes is made through the use of the concept mapping technique [14] (Figure 6). In this way, the evaluation is not centered on how much the students remember or memorize, but on how they understand, organize, give hierarchical structure to, associate and relate the main concepts learned in order to construct meaning. Thus it is possible to know the representation of the students' mental conceptual home base for the concepts learned during the course. Each student ended the course with a concept map of the main concepts learned and its associations. This is to say, with a graphic representation of his/her significant learning of HCI concepts.

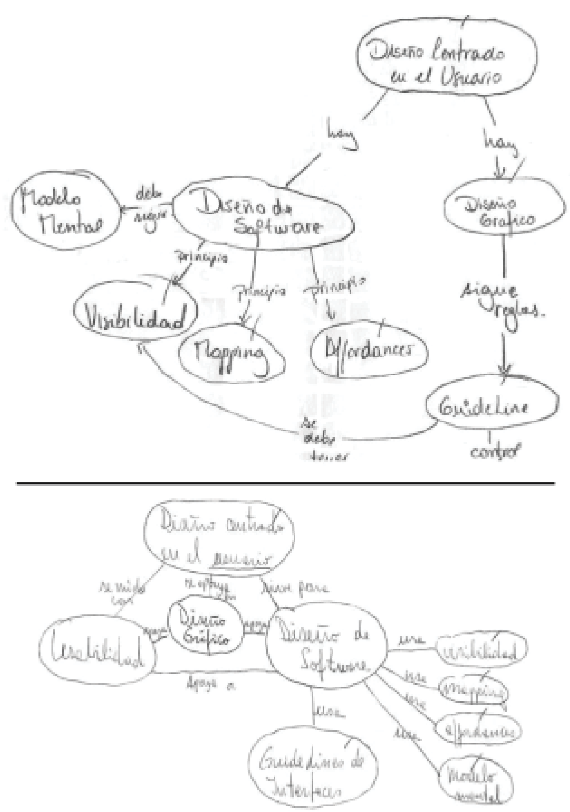

Figure 6. Concept Maps generated by HCI students based on the concepts studied and analyzed in class

Together with the evaluation of the contents seen in classes through the use of concept maps, the students have an intense workload regarding HCI readings. These readings cover the state of the art in the area of HCI and are recent publications from important conferences in the area, such as ACM CHI [3] and IFIP Interact [9], for example. As such, the students are up to date on the latest progress in the area, the latest technology for HCI that is being developed, and on user experience with different systems and applications.

III. OPINIONS OF EX - STUDENTS

There are several interesting and illustrative opinions offered by some students, several of which have already graduated, who took the human-computer interaction course. Regarding the learning methodology, the students stated that it is a distinct method and that it strongly supports the learning of several of the concepts seen in the course. *"It was a pleasure and a privilege to have been able to learn in that way"* (Victor Toledo, ex-student from 2009); *"The HCI course seemed interesting to me in the way that we studied real cases as a course project. It also allows one as a student to have a free reign on creativity and imagine innovative and interesting solutions"* (Juan Pablo Rodriguez, ex-student from 2008). In addition, the students recognize that the methodology utilized allows them to support the development of other skills that are fundamental for today's professionals: *"The Human-Computer Interfaces course is very interesting, in that it allows you to acquire and develop skills that are not common in other Computer Science courses […] the constant debates that are proposed and the presentations in the course allowed me to strengthen my oral communication skills, which is highly valued in the current labor market."* (Angelo Tadres, ex-student from 2007).

In more global terms, on the applicability of the course, students' opinions coincide in that it is a class that provides useful tools for engineers that have already graduated. Angelo Tadres, ex-student from the 2007 generation, says: *"As future engineers, they constantly teach us to design functional and quality software, but they never ask us to think of the users of these solutions. The HCI course gave me the necessary tools to solve these problems, thus creating much more usable and visually attractive interfaces". "In order to achieve a technical back-up to the intuition that I had before entering the University, the work I did in the Computer Science Department helped me a great deal, especially with the course and posterior workshop in the area of HCI. It was a great experience, putting the notion of what a software application does to leave the user satisfied and able to do his tasks into words and action"* (Ivan Galaz, ex-student from 2004).

Other opinions point out that what was learned in the course is useful for their current professional positions: *"The HCI course given by the Computer Science Department offers its students a vision distinct from software engineering, in which the experience of using the software is as important as the technical quality and its development […] In my case, I am in charge of the development of web applications, the usability of which must be strongly considered, because a poor design of its interfaces and interactions causes a loss of productivity in the systems when they are being used"* (Claudio Oyarzun, ex-student from 2004); *"The interfaces course teaches us to concentrate on what the user will end up using, the software interface, the weak point in many of the software applications that I have had to use"* (Mauricio Zuniga, ex-student from 2004); *"[…] HCI sensibility can always be a favorable tool, a plus among the qualities of a development engineer…and that today is quite scarce, and thus quite valued"* (Miguel Elias, ex-student from 2005); *"Up until I took this course, I was used to making programs oriented towards systems, concentrating only on making the program work. This was the first course within my specialty in which the focus was far from programming, but was rather on the end user's experience of using the program. This is a user who is not necessarily a computer expert. […] In my work I develop a lot of web applications, and this course has helped me tremendously in order to discuss important issues with other programmers, for whom it is hard to put themselves in the place of the end user, and who tend to design programs for themselves"* (Thomas Pieper, ex-student from 2002). *"I currently develop web applications, both for private companies and public organisms, and I am mainly responsible for assuring that the end user has the best information available when performing his/her tasks. For example, I assure that the usability level is included among the decision criteria when designing the flow for each task that the user will perform, that the controls for executing the actions are clearly available and that the actions performed by the user have a clear and precise system response"* (Ivan Galaz, ex-student from 2004).

These opinions reflect how relevant having studied human-computer interaction through a constructivist learning focus with application study cases and software interface design projects performed throughout the course has been for these professionals.

There are even some students who do not only adopt the knowledge and the experience learned in the HCI course into their professional lives, but who also use it on a much more personal basis. This is expressed through a higher level of sensibility to issues related to human-computer interfaces: *"At the end of the course I had already internalized the interface analysis into my daily life, not only regarding the web pages that I visit every day, but also regarding devices like MP3 players and cell phones that I use…something that I have continued to apply both consciously and unconsciously to this day"* (Miguel Elias, ex-student from 2005).

IV. CONCLUSIONS

This article presents an active way of teaching and learning human-computer interaction for computer engineering students. The learning methodology of the HCI course that is given in the Computer Science Department of the University of Chile allows for active, wide-ranging, concrete and up-to-date work that leads students to build up knowledge from practice. The course requires the students to constantly apply the knowledge they study in class. As a result, there is a deeper appropriation of the theory and practice of human-computer interaction.

Our end-users are the students. And their reactions and comments support the fact that the focus of the learning methodology is more centered on the practical work of application than on just the presentation and analysis of the course contents. They also highlight how this helps for the transfer of this knowledge to other areas of their lives.

The relevance of an HCI course in the formation of a computer engineer lies in that it provides another perspective on the systems and solutions that these professionals regularly design and develop. In embedding HCI concepts, ideas, theories and models, there can be more certainty that their developments will be used and understood by the end-users, and thus that their work will be more valuable, solid and sensible to them.

History is plagued with examples of technology applications for which use has been impeded because their interfaces are not usable, accessible, understandable, or because they do not represent the end-users' modes of interaction. An HCI course such as the one described in this paper can make all the difference.

email: zaman@bu.edu

Abstract— Engineering education in the developing world is not only necessary for economic growth, intellectual development and innovation, but is also fundamental for national security and short and long-term sustainability. Successful engineering institutions and productive engineers are not only necessary to create knowledge based economies in developing nations, but they are also important players in maintaining economic viability that is tied to national security of immediate and distant neighbors. The necessity for innovation in engineering education and grounding of this training in local needs and markets is true for all forms of engineering, including biological and biomedical engineering that have been rather recent inductees to the engineering education portfolio. Developing countries are taking biological and biomedical engineering seriously to address issues in food and agriculture, processing and nutrition and various aspects of healthcare and medicine. In this paper we address the need, status, challenges and opportunities for the developing world in bioengineering and biomedical engineering education and discuss ways in which the fundamentals of engineering education can be strengthened for a sustainable society.

Keywords: Biological Engineering, Biomedical Engineering, Developing World

I. INTRODUCTION

Engineering education, both in the developed and the developing countries, is intimately connected to not only innovation but also national security and sustainability [1]. The need to address pressing national problems, challenges and threats has always affected the way engineering curriculum is designed, implemented and executed.

While the practice and education of the next generation of engineers has been streamlined to some extent in the developed world, in the developing world, political, social and economic turbulence has affected both the education and practice in multiple forms of engineering. The key problems faced by the developing world are no longer their own problems. Instead they affect mass populations in both the developing and the developed world. Thus higher education in engineering that meets international standards and the local needs is critical to global security and sustainability [2-5].

In this paper, we look at the vision, challenges and future outlook of engineering education in the developing world, with an emphasis on biological engineering. The developing and the developed nations have seen a surge in research activity in biological and biomedical engineering over the last decades. The motivation for improved health-care, better pharmaceuticals, efficient technologies and higher quality of life is shared among the developed and the developing countries. In addition, the developing world faces issues associated with food shortage and public health crises that are less prevalent in the richer nations. Therefore biological and biomedical engineering education in the developing world is tied to national security, survival and sustainability in a way that is unique to these nations. This paper presents a mini-review of the current trends, challenges, opportunities and future outlook for biological engineering education in the developing world.

II. BIOLOGICAL AND BIOMEDICAL ENGINEERING IN THE DEVELOPING WORLD

Biological or biomedical engineering in the developing world can be broadly classified into two categories. The first one is engineering in agriculture and food sciences and includes areas such as genetic engineering and agricultural engineering. This area would also include food processing and food preservation, which are sometimes referred to food-process engineering in certain countries and contexts. The mechanical and electrical equipment associated with efficient food production are also topics of great interest but are outside the scope of this paper.

The second broad area that is of key importance to the developing nations is that of medicine, public health and pharmaceuticals. In general, there is little research on creating new drugs in the developing world, but recently there has been a surge of activity in the pharmaceutical industry in India, which is a notable exception. Other areas of biological engineering and healthcare include engineering approaches to diagnose, detect and combat infectious diseases, infant mortality as well as prevailing epidemics. Additionally, there has been significant activity in the US, Chinese and European research labs in creating low-cost point of care diagnostics for applications in the developing world.

Engineering education in the agriculture dates back to 1960s and 1970s with the appearance of genetically modified crops in the developing nations [6]. As a result, there are a number of agricultural universities in these countries, although the real engineering component of that education varies tremendously. These engineering institutions are also predominantly located in countries where agriculture makes the backbone of their economies [6]. On the other hand, issues related to public health have primarily been dealt with in medical schools and technology development or innovation has been limited. Engineering and medicine have also been kept as two disparate areas of higher education.

Despite a substantial need and dependence of national security, to date, there are no system wide studies of the status of biological engineering education in the developing world. This is probably due to two main reasons. The first one is the lack of appreciation of biological engineering in the general public. Biological or Biomedical Engineering still remains one of the lowest ranked engineering in the developing world. This is due to higher demand and higher paying jobs for engineers in electrical, computer, civil or mechanical engineering. The second reason is the issues of food and to a certain extent public health are not considered engineering problems and have been dealt primarily by economists, policy makers, politicians and bureaucrats. Since these critical problems are not dealt by engineering institutions, the perception among the general public remains the same where medicine and health are considered to be non-engineering disciplines.

III. CHALLENGES IN BIOLOGICAL ENGINEERING EDUCATION

The current challenges facing biomedical and biological engineering education in the developing world can be divided into three categories. They can be summarized as input and output challenges and curriculum and teaching issues including teacher quality, training and retention and research related problems.

A. Input and Output Challenges:

The first major challenge for biological and biomedical engineering education in the developing world can be classified as input and output challenges. These challenges are associated with the quality of students coming into the program, their abilities, aspirations and overall quality. The output of these institutions into the marketplace and the society in general is also linked to the overall perception of the programs and their quality. While the overall level of education in the developing world is highly variable [7], the number of students reaching university is fairly low [7]. In addition, due to economic pressures, students often choose certain areas, including certain engineering degrees, for their majors. Top quality students rarely opt for biological engineering or biomedical engineering as the majors of their choice. There are several reasons for this decision. The salaries associated with biological, agricultural or biomedical engineering are modest in comparison to other engineering fields, particularly computer and electrical engineering [2]. The general perception of the field and the associated parental pressure also plays a role in students opting for areas other than biological engineering. Since historically biological engineering has been associated with agriculture, there are fewer jobs available in the urban areas.

There is also active feedback between the output and the input. Since the input is often of mediocre quality, the output is not particularly impressive either. Due to other factors listed above, including lack of opportunities in the urban areas, the salaries are relatively low and the accessibility to top schools, hospitals and recreational facilities is limited. As a result the system as a whole is unable to perform coherently and the overall quality of the system continues to decline.

B. Curriculum and Teaching Issues:

The problems and challenges are not limited to inputs and outputs. There are numerous fundamental and perhaps fatal problems in the crucible that converts these inputs into outputs. Among these, curriculum presents one of the most fundamental problems. The curriculum is often dated and obsolete. There are few, if any, mechanisms for updating or reviewing it in regular intervals. In many instances, it is not even clear where the curriculum came from and how it was designed. More recent versions of the curriculum are often carbon copies of what is offered in the top institutions of the world with little regard to local needs or problems.

This lack of adaptation has two major consequences. The first is the output of the curriculum is an engineer with little appreciation or knowledge of the local challenges. The second is the inability of proper execution of the curriculum due to incompatibility of resources between the institutions where it was designed and the institution where it was offered.

The teaching staff at most biological and bioengineering institutions in the developing world is graduate of the same system. This cycle, due to low input and output quality, and massive inbreeding, results in continuous deterioration.

C. Research Activity and Research Incentives

The institutions engaged in providing biological engineering education have historically not been particularly research active. One of the main reasons for this lack of activity is limited number of graduate students enrolled in these institutions [8]. Lack of funds and weak industry has also led to disincentive for original research. Publications in peer review journals are also rare. Most of the research is carried out in government labs and in some cases in private industry. This situation contributes to the poor quality outputs from these institutions, and in turn affect the overall performance of the engineering education sector.

IV. Sustaining Biological and Biomedical Engineering Education

The current status of biological and biomedical engineering education in the developing world is far from satisfactory. The success and sustainability of biological and biomedical engineering education would fuel economic growth and substantial improvement in the quality of life. There are three major ways in which quality biological and biomedical engineering education can be improved and sustained in the developing world.

1) *Partnerships*: A large number of international organizations, ranging from WHO to Gates foundation are providing funds to address problems of biological and biomedical engineering in the developing world [9]. These grants are largely focused on pressing problems in food shortage and security and public health. A number of universities and researchers associated with biological and biomedical engineering from across the globe apply for these grants and provide tangible and high impact solutions to the pressing problems. However, very few of these grant and partnerships include active biological and biomedical educational components. The educational components included in some of these grants are also limited to vocational training but exclude areas of higher education and long-term educational sustainability. As a result the experience of the researchers from top institutions in biological engineering, who are also often engaged in educational leadership are never fully utilized.

By encouraging governmental and non-governmental organizations to involve local researchers and universities in their programs would enhance cooperation and give opportunities to local researchers that are otherwise isolated from the biological education and training. Similarly, memorandums of understanding and economic aid packages targeted towards the healthcare problems in developing nations should include teacher training and quality assurance at the higher education level. This can be achieved through engaging researchers, in the developed countries, in the areas of biological and biomedical engineering, who are interested in addressing problems in the developing world. Encouraging educational partnerships, in parallel to research partnerships, would provide a unique and comprehensive understanding of both education and practice of biological engineering to the developing nations.

2) *Teaching grants*: A number of federal and local governments in the developing world offer financial incentives, including grants to address problems in biological and biomedical engineering. However, the incentives to modernize curriculum, train teachers or develop educational components at the higher education level are often ignored. Such mechanisms exist at primary and even secondary education through incentives from international agencies (such as UNESCO and the world-bank) but modernizing curriculum and encouraging debate on curriculum and teacher training at higher education level are overlooked. Since biological and biomedical engineering appears fairly low on the priority list, the issues related to curriculum and teacher training are in worse state than other engineering disciplines. A top-down encouragement, in the form of grants, would allow university professors to take a serious look at the curriculum and encourage discussions. Alternatively, as a number of countries have encouraged research activity through federal grants, incorporating mandatory educational components in those grants would require researchers to think seriously about curriculum and efficient teaching.

3) *Industry Linkage grants*: Private industry in the developing countries or their developed neighbors are often interested in untapped markets. With agriculture and healthcare as key investment opportunities for countries with low-income neighbors, developing local expertise is a cheaper option than importing talent. In this regard, both private industry and local governments have a role to play. These key players should play a more vital role on reviewing the curriculum of local engineering institutions to ensure that the output is cognizant of the local needs and challenges. Industrial teaching internships for professors aimed at making professors aware of the challenges would lead to noticeable changes in the curriculum . With these linkage projects it is likely that the curriculum would adapt to both the fundamentals of biological and biomedical engineering as well as the local needs and challenges. In the long-term this would benefit the private sector by providing it with a work-force that is innovative, fundamentally sound and aware of the challenges faced by the local industries.

V. Conclusion

Biological and biomedical engineering will play a pivotal role in the development, survival and sustainability of the developing nations the in upcoming years. Issues related to food production, safety and security, public health, epidemiology and overall life quality and expectancy are areas where biological and biomedical engineering will play a central role. Increased globalization and rapid growth in these sectors in the developed nations will also have an impact on the practice and education of engineering in the developing countries.

As the government and non-government sectors realize the importance of these areas, more schools, colleges and departments will incorporate biological and biomedical engineering into their mainstream curricula and degrees. In a rapidly changing world, where the issues of food and healthcare are affecting nations across continents and influencing policy debates ranging from national security to immigration, biological engineering will have a central role to play in the developing countries. A shift in perception of biological engineering from a second class engineering to the cornerstone of national security and sustainability will lead to newer challenges in educating the next generation. As we approach that stage, it is more important than it has ever been to focus on quality control in curriculum and teaching and connect the curriculum with national and local needs and challenges. Quality assurance, well organized and up-to-date curricula and partnerships between public and private sector are necessary to shape the landscape of engineering in a way that makes a substantial impact on national security and long-term sustainability of the developed nations.

Abstract— **The Runestone project is a collaborative course currently offered by Universities in Sweden, Finland, and China. The course provides a unique opportunity for third year engineering students from a variety of programs to experience the opportunities and challenges that international teamwork involves. Teams composed of students from two countries work intensively over a 10 to 13 week project cycle to develop a system which allows a user to remote-control a LEGO NXT robot. The teams negotiate the features of their final system with the academic supervisors from the participating Universities, propose a development time-frame and deliverables, and develop and demonstrate a prototype system.**

This paper uses teaching and learning findings from engineering education research. The evidence is used to arrive at an instructional design that aligns learning outcomes, with instruction and assessment to support student's learning outcomes development throughout the course, We also discuss the evolution of the course over the past 12 years as we moved from a pilot version with eight students from two universities to a large scale course with between sixty and eighty students from between three and five universities distributed over three continents and widely different educational and social cultures.

Keywords— **engineering skills, educating the global engineer, global virtual teamwork**

I. Learning Outcomes and Motivations

The quality of engineering education, and the relationship of curricula to competencies valued by industry, is increasingly important as the world moves towards a more student centric and socially relevant style of education [1]. Quality assurance of outcomes is also an important driving force, as many nations transform their education in response to the Bologna process [2]–[6]. One important element in the learning trajectory from novice to expert is experiencing the uncertain nature of problem solving in a loosely constrained environment.

Some common features of professional work that are seldom represented in University classrooms and practical exercises are associated with the more open ended problem specifications that can arise. Equipping students with a range of important professional skills, such as project management, teamwork and cross-cultural communication can be achieved in a carefully managed open ended project course.

Industry problem specifications are often stated in rather fuzzy high level terms. An open problem specification places different demands on learners than traditional practical work or course assignments. The course we describe in this paper scaffolds learners' development in a number of aspects of professional working practice. During the course we mentor students through the analysis of the problem space and proposal of a feasible solution, identification of appropriate tools and techniques with which to solve the problem, managing and working in a team, and learning about working with people from different cultures.

The objectives of the Runestone course are to give students experience with a problem and work situation which requires them develop a greater level of self-reliance, teamwork, negotiation and communication skills, integrate and use theoretical knowledge from earlier courses, and (through experience of a wider systems development project cycle) understand that the theories we teach in subjects like software engineering are not prescriptive and do not always lead to timely delivery and successful products.

Through the Runestone project we provide students with significant and valuable experiences, directly relevant to their future working life, while retaining some of the benefits of a ”safe” educational environment. By ”safe” we mean that students can experiment with applying their theoretical knowledge to a systems development task in a supportive environment where they do not risk losing their job, or failing the course. Students are not, however, left to “sink or swim”, active bi–weekly mentoring meetings (Milestones) are used to support and guide students as they struggle to develop the skills they need.

The assessment criteria are designed to stimulate and reward students who engage in processes and activities that contribute to their development of insight and skills for dealing with the realities of systems development in a globally distributed virtual team environment. This means that a student can complete the course, and gain a pass, even if the system they deliver falls short of achieving the functionality and quality required to release a product. Passing the course depends much more on working processes and sincere attempts to put theory into practice, than it does on developing a successful and robust hardware/software system.

II. Runestone

Research on designing learning situations that help develop professional engineering skills such as teamwork, cultural awareness, and project management is a key area as we design programmes to educate the next generation of engineers. Grandin et al. [7] identify a number of key areas in a recent report where they call for action to address the needs of future engineers. Part of our approach to addressing these educational challenges in the IT programme at Uppsala University is the "Runestone Project", a collaborative course in engineering systems development spanning multiple Universities and cultures. [1] Runestone is based on the well publicised idea of providing motivation and scaffolding for the development of professional skills through open ended group project work [8], [9]. This paper provides an overview of the models [10], [11] educational theory behind the course design and an overview of its current structure. One unique aspect of this course is that is has been offered continuously over the last twelve years, expanding from a pilot course with a single group of students to a full scale collaborative course with 60 to 80 students participating from four nations.

Runestone students complete a team role and skills evaluation exercise at the start of the first week of the project and are subsequently placed into teams by the instructors. Teams have approximately six members from two sites, and are supervised by an instructor from the teaching team, with whom they have regular virtual meetings throughout the course. Assessment and mentoring of the teams occurs in the virtual meetings. Staff and students do not meet physically very often during the course, indeed many of the students might be in another country than the staff member supervising their team.

The course requires students to design and implement a large scale distributed system. The task is closely related to a realistic engineering work assignment [12], and requires knowledge of many aspects of their previous study in distributed systems and network programming. The course provides students with experience of team based product development, in a modern technical work environment where teams are both culturally diverse and geographically distributed.

The course combines application of technical skills with other important global engineering skills: teamwork; negotiation and project planning; and project execution.

Technical

In recent years teams have developed a software system to give users remote control of a robot, build using LEGO NXT, in a location anywhere in the world via the Internet. The project used in the early years was based on custom built hardware. However, maintaining and coordinating acquisition of these systems for all the collaborating sites became too complex after a few years, and we replaced the custom hardware with LEGO Mindstorms robots in 2003. A further transition to LEGO NXT hardware in 2007 was motivated by difficulty of obtaining the, now obsolete, Mindstorms RCX hardware. Wear and tear on the LEGO RCX kits, and the availability of bluetooth communication in the LEGO NXT, replacing the infra-red communication used in the first Mindstorms platform, were other reasons for the change.

The specification has undergone several revisions over the twelve years we have been running the project, but the salient characteristics and their relationship to learning outcomes and assessment policies has remained largely unchanged over the last ten years. The project has a ten to thirteen week timeframe. The activities and deliverables for 2005 shown in 1 are typical. There are slight timetabling variations from year to year depending on the level of synchronisation of the academic timetables at the participating sites.

The current task requires teams to design and implement a software system which allows a remote user to control a LEGO NXT robot (of their own design) in real-time through a web browser Graphical User Interface (GUI). Communication between the robot and server is implemented using the BlueTooth wireless communication protocol. Communication between the server and GUI can be implemented in a variety of technologies. Since a real-time video stream of the robot environment is to be incorporated in the GUI some low level network programming using sockets and the UDP and TCP protocols is also required.

Teamwork

Teamwork and the process of collaboration is closely observed during the project and the teams are required to report regularly. Regular mentorship is a key element of the course [13] and helps the teams to negotiate a range of issues that arise from the technical challenges and personal and cultural differences. Active and regular mentorship feedback is a crucial element of the learning activity in the course, providing information and helping students to negotiate the technical and personal crises that arise naturally during the course.

Development of written communication skills is facilitated through critique of the design documents and bi-weekly reports the teams present. Each report is presented using online synchronous chat, this allows the instructors to evaluate team member's communication skills and ability to organise and use time effectively. The instructors also observe the internal social dynamics of the team, and provide feedback and advice.

Process Management

Problem analysis and specification documents are requested early in the project and critiqued, each deliverable, including documentation, verbal presentation and collaboration processes are incorporated in the final team grade. Teams are also asked to provide an implementation timeline in the form of a "Gantt Chart", in which the major sub-project dependencies should be identified. Instructors use this chart to assessing the team's ability to make progress, estimate time requirements, and adjust work-flows as time mis-estimations become apparent during the project.

[1] The course is a collaboration between Uppsala University, Sweden, Grand Valley State University, USA, Rose-Hulman Institute of Technology, USA, Tongji University, China, and Turku University, Finland.

Project Week	2005 Dates	Activity
0	9-13 Jan	USA Only: Intro
1	16-20 Jan	Intro and Team Building
		Course begins 19/1 in Sweden
2	23-27 Jan	Work on Team Building experience (no IRC[2] meeting this week)
		Prepare Web site and CVS for team
		Work on Analysis and Design
3	30 Jan -03 Feb	Milestone 1: Present Team Web Site(IRC report)
		Present Individual Team members and their profile pages
		Work on Analysis and Design
4	06-10 Feb	Milestone 2: Present Analysis and Design Docs (IRC)
		These deliverables are marked contributing 10 marks
		to the final group grade
5	13-17 Feb	Continue work (no IRC meeting this week)
6	20-24 Feb	Present Milestone 3 (IRC report)
7	27 Feb-03 Mar	Work on project sub-system integration
		Prepare your final presentation materials
8	06-10 Mar	Spring Break in the USA. Sorry Swedes!
		Teams work informally, maybe mostly in Sweden?
9	13-17 Mar	Present Milestone 4 (IRC report)
10	20-24 Mar	Final Presentations

Fig. 1. Project timeline

Instructional Approach

Few resources are provided initially. Students are expected to locate and make choices of the software and operating system to use with the LEGO NXT processing unit, as well as communication protocol stack to handle communication between their software system and the robot. We provide links to some appropriate software, but nothing is specified in the project description. The instructors assess the technical learning outcomes based on the level of sophistication of the software and the complexity of the attempted functionality, as well as the degree to which the software is complete and working at the end of the project.

Development and assessment of skills such as teamwork and intercultural communication are based on continuous online mentoring and discussion in the regular virtual meetings throughout the course. Assessment of outcomes is based on observation of how the teams deal with communication and work process issues in the presence of tight deadlines and high workloads.

Managing this process for a team of instructors also presents challenges. To make judgment of skills and deliverables comparable between instructors the teaching team have regular online meetings, and discuss the interpretation and application of the qualitative grading criteria (see figures 2 and 3 for examples of some of these grading rubrics). Many of the larger deliverables are assessed by several instructors, for instance the design documents and final presentations are usually assessed by the instructors for both the sites involved in each team. Finals marks are discussed if there is a difference of opinion between two instructors. Our experience is that instructor agreement rates are very high, we have never had serious disparities or disputes over marks for design documents or final presentations.

A key element of the Runestone approach is the course assessment framework. Our assessment structure focuses on aspects of the project work including technical achievement, work process, teamwork, and communication and cultural sensitivity which are vital to future practicing engineers. In the following section we examine some aspects of the course structure and assessment activities in more detail.

III. Assessment

The project work-flow and deliverables used to assess teamwork and software development processes are summarised in figure 1. The dates given here are for the 2005 academic year and provide a guide to how the sequencing of courses was managed between Sweden and the USA. Coordination between Sweden and participants in China and Finland is easier as students from the participating universities have had greater flexibility in their study timetables.

Assessment is based on a combination of individual and team achievements in a range of areas. The goal is to provide motivation for students to engage in both the technical and non-technical aspects of the project in order to achieve the desired learning outcomes. Assessment is divided into three primary areas.

Teamwork and Communication :
evaluating the organisational ability of the team and the manner in which the team presents itself and works as a unit to achieve its goals. This includes individual marks for those elements of the reporting for which individuals are responsible, as well as peer

Grade	Classification	Qualitative criteria
0	Missing	No report from group
1	Inadequate	Poorly structured, several required areas missing or incomplete, some material not online prior to the meeting.
2	Poor	Poor to adequate structure of material. some required data missing or hard to find. Confusing presentation and layout of pages hard to read.
3	Adequate	All required information is presented and adequately organised, however, layout and structure make it hard to evaluate the accomplishments of the team since the last report.
4	Fair to Good	All information is supplied and structured according to the reporting requirements. Some areas of the report do not give sufficient relevant information for the reader to assess the progress of the team and the individual contributions of the members since the last milestone.
5	Excellent	All information is supplied in a format and structure that is consistent with the reporting guidelines for the course. Information content is relevant, concise and gives a clear and accurate impression of all aspects of the achievements of the group and individuals within the group since the preceding milestone.

Fig. 2. Criteria for awarding team grades at each project Milestone

evaluation of the contribution of each member by the other members of the team (at the conclusion of the project).

Project Management:
evaluating the interim progress reports and the online meetings in which the team reports on progress. Assessment here focuses on the ability of the team to plan realistically and work towards reaching the milestones they have defined.

Technical Achievement:
evaluating the complexity of the milestones the team set, and the levels of technical achievement reached during the product development process. Assessment is based on professional code development and the sophistication of the final product.

Contributions by individuals and teams in each of the assessed areas are evaluated throughout the course using the following deliverables. There is no written final examination in the course, deliverables in all projects are evaluated throughout the course, and the final project demonstration plays a significant role in determining the final grade. Individual grades are based on the group grade, to which modifiers are applied based on peer and instructor assessments of individual contributions to the project development and ultimate success.

A. Teamwork and Communication (30 points):

- Milestone Meetings (20 points)
  There are four milestone meetings, and at each of these the teams gain between 0 and 5 points depending on the performance of the group. This gives a total of 20 points. After each meeting an online critique of the meeting and report is made available to the team immediately via private pages on the course Wiki. The critique provides written feedback on the presentation, as well as the assessment of the instructor (in the form of a grade on the 0-5 scale).
  The qualitative associations we use to allocate a grade on the five point marking scale are shown in figure 2.
- Individual Achievement (10 points)
  At the end of the course, each individual's contributions to the meetings, and their level of engagement in the project are graded.
  A mark of 0 to 5 is be allocated by the teaching staff on the basis of their assessment of each individual's contribution to the project in terms of attendance and participation in group meetings, and contribution to team spirit and success.
  A further mark of 0 to 5 is be awarded on the basis of the peer reviews of each team member by their teammates. This gives the remaining 10 points in this category. We have studied how students approach the anonymous peer review [14]. In our experience this aspect of the course works well, and students typically give a balanced and responsible assessment of the contributions of the

Max. Points	Criteria
5	Research an area and write-up a report describing what you learned
6	Research an area and include that research in the design document
8	Research an area, include it in the design document, and create a working prototype apart from the project itself
10	Research an area, include it in the design document, integrate it into the project

Fig. 3. Grading criteria for Areas of Excellence

individuals in the team.

B. Project Management (30 points):

The **team progress grade** reflects the extent to which the team has demonstrated good project management practice in their workload allocations and priority setting.

A mark from 0 to 10 is awarded on the basis of the quality of the project analysis and project specification documents prepared by the team.

The remaining twenty marks are earned during the project based on the extent to which the team has achieved its self defined goals for milestones three and four. This mark is based on the demonstrated achievements of the team being consistent with the expectations stated in their development and implementation plan.

C. Technical Achievement (40 points):

Twenty (20) marks are awarded for the final presentation and the product demonstration. Criteria for assessing final presentations are included as appendix A. Two instructors are two teams participate in every one hour video conference presentation slot. The teams make a presentation of their development process, and reflect on their project and what they have learned. Each presentation concludes with a live demonstration of the software, and questions from the other team.

The tools we have used for video-conferencing in the final presentations have varied considerably. In early courses we used a combination of Microsoft NetMeeting. Later versions of the course used either Skype or Marratech. In 2010 we will use Adobe Connect.

Another twenty (20) points are for technical innovation and high quality technical achievements in two nominated areas of “excellence”. As a part of setting milestones or goals, the teams will be asked to identify two areas of the product where they intend to aim for advanced development leading to “excellence” in the resulting technical solution. Marks are allocated in these areas according to the guidelines in figure 3.

CONCLUSIONS AND FUTURE WORK

The Runestone project approach has been incrementally refined over the last twelve years to provide students with global teamwork experience in a realistic project setting. The course has expanded to involve universities outside the original partnership, and now involves up to four universities and between sixty and eighty students annually.

The main contributions of the current paper are to completely describe the current structure and assessment strategy for the course and link this to learning outcomes in communication skills, global teamwork, and virtual collaboration. By publishing this course model we contribute to a growing literature on the use of open ended project work in preparing students to work effectively in the workplaces of the future.

APPENDIX

A. Presentation Grading Scheme

3pts Professionalism in preparation and presentation.
1) Was the team well prepared and organised.
2) Smooth and well rehearsed presentation structure.
3) Use of presentation tools (IRC, NetMeeting, hardware demo)

5pts Use of web and audio-visual presentation technique.
1) Was material clearly presented and easy to understand. (i.e. pictures, good slides, etc.)
2) Is the presentation clear, to the point
3) Does the presentation show off the whole team, and each person’s accomplishments/contributions.

5pts Team Management
1) Division of labor
2) Leadership
3) Time and scheduling difficulties
4) Personality conflicts

5pts Technical Discussion and Demo
1) Design process
2) Coding standards, version control, software management issues
3) Software package and documentation standards
4) Limitations and future enhancements
5) Demonstrated software functionality

2pts Question and Answer
1) Posing good questions to the other team.
2) Responding well to questions from others.

Abstract — **Engineers are among the main agents of promotion of development in the world and the formation of a new kind of engineer is the priority to face the future economical and political market. Nations are recognizing the importance of engineers once they are the ones that make possible the world goes round. Engineering Schools worldwide have implemented more flexible programs, more investments in labs and equipments, promoted more exchanges programs and so on. It is the education evolution in order to adequate the formation of engineers of the 21st. Century. This work discusses an important issue as the engineer formation under the perspective of the international academic midst. COPEC – Council of Researches in Education and Sciences has a history of action in engineering education, conceiving and implementing projects with success. However, more and more it is necessary the permanent attention to the changes in world scenario concerning the political, economical and social aspects of the country and the globe. This awareness helps to develop and implement new programs in order to form the engineer for tomorrow. Although it is not an easy task it is the way to assure the future of engineering as well as the development of science and technology.**

Keywords: Global thinking; local awereness; contemporary paradigm; sciences sdvancement; generalist formation; strong ethics.

I. INTRODUCTION

The discussions about Globalization in general show a bad scenario and the future is unpredictable once it is not possible to foreseen the big players' next movement in such huge business game of fighting for markets. The world is changing quickly, the distances are smaller and so we have a larger number of people moving around, interacting with different cultures and habits and at the same time having a kind of influence. Big corporations are looking for new talents no matter where they are and so more opportunities and the reverse side of the same coin more competitiveness. The history shows an enormous amount of companies and engineers working in different places in the world accomplishing huge projects promoting the development of countries and societies. Now more then ever engineers should pay attention to what is going on worldwide to go for international experiences to improve personal skills and get different opportunities because nothing has more impact than personal experience [01].

It is necessary to promote changes in the way engineers are educated at the present. There is a need to break up the old paradigm of education that perpetuates the mere technocratic formation. Following these thoughts there are some questions to be considered: 1. Does this process of change really occur at the level of modern engineering education and training in different countries? 2. Are the engineering students aware of the contemporary skill requirements of engineering experts? 3. Does any program consider how much the new socio-occupational demands affect the professional formation of future engineers? These are very important aspects to take into account when real actions are taking place in education reforms regard to engineering programs. Although a little slowly the changes will have to happen in order to attend the demands of the 21st. Century [02].

II. COPEC- COUNCIL OF RESEARCHES IN EDUCATION AND SCIENCES

The Council of Researches in Education and Sciences is constituted by scientists of the several areas of human knowledge committed with education and the development of science and technology. Its members believe that education is the main beam in the construction of a better society and that sciences and technology are the big agents in the fostering of progress to promote the welfare of human being.

The history of COPEC has started with an idea shared by some scientists of creating an organization to foster the research mainly in education and sciences. This idea seized proportions and after some meetings the Council became reality. It is a group of scientists, professors and professionals whose vision of future has driven them to start this work. Through its activities COPEC maintains relations between universities, institutions of education, enterprises and the society of the several countries for the discussion of education, technology and sciences directions. It works to stimulate and to foster the efforts to bring an international perspective in education [03].

Constitute powers of the institution:

- General Assembly;
- Deliberative Council;
- Board of Directors;
- Fiscal Council.

III. ENGINEERING IN FOCUS

Sustainable development with social promotion of individuals and society has been the constant search of scientists, educators and some politicians worldwide after the globalization phenomenon has started. Despite the efforts of so many sectors of society the present status of Education in every level in western world is not yet as good as it should be. Education plays an important role in the development of peoples worldwide. It is the key to combat ignorance and consequently the poverty. Science and technology alone can not help. It is fundamental the growth investment in education for all.

Technological power may shift from the west to the east as India and China emerge as big players in the global market. The two countries have the size and weight to transform the 21st global economy. This aspect will certainly have an impact on the education in western world too. Although the reality is that India and China will always have an advantage in their numbers, by the other hand in western world there are the freest markets, the most highly trained workforce, the resources and ability to innovate, and the best universities in the world.

History facts show the innumerous achievements of so many engineers all around the world who have diligently built and transformed the environment to make men's life better. The number of prominent professionals who have been referenced by their accomplishments is uncountable. Based on this it is possible to say that the formation of engineers is fundamental to keep the level of development of humanity in order to achieve the social development similar to the technological. However the present challenges of engineering education institutions are not limited only to the formation of a professional for a new global work market, but also to defeat the crises of education in which they are inserted. The crucial problem is the necessity of think again the kind of education which has fragmented knowledge that drives people to an inability of articulating its several parts. Education must promote the natural ability of the mind to set and to solve problems and by inter-relation to stimulate the full usage of general intelligence [04].

IV. THE ROLE OF UNIVERSITY

People live today in a world of no frontiers, with new complete new values and different social relations. All these aspects promoted by the development of science and technology have modified deeply people's life in all levels of the so-called "Global" society. Education institutions are challenged once more, to provide for the society the new citizen forming the professional prepared to face the unpredictable challenges of the future and to be a winner.

University has an important mission that goes through the centuries, from past to future, passing through present. This mission is essentially the conservation of cultural inheritance generating ideas, values and knowledge. This same University has to defeat the challenge of present world serving the contemporary society viewing the future.

New World order demands a new kind of professional, capable to think global without loosing the dimension of local peculiarities and vice-versa. It is not easy to form this kind of professional although it is known exactly what is necessary. With the goal to defeat this challenge COPEC has implemented many projects in different Engineering Schools that were very challenging. They were programs that required the full commitment of the school team. Others that required substantial financial investment in new equipments but all of them were accomplished with success [05].

V. AN OVERVIEW OF SCIENCE, TECHNOLOGY AND ENGINEERING

As any Country Brazil has recognized the importance of engineering in world scenery and so it has been working to get the competitiveness of national goods and services by means of incentive to create projects of qualification of professionals through continuing education for example and others. Leaderships, many representative groups, and agencies have been implemented programs to prepare the engineers to increase the efficiency of research system, experimental development, engineering, producing system and market.

All these efforts have been having a kind of smooth effect once it is one of the most difficult programs of College level and expensive that does not help very much the inclusion policy. However, some Colleges have opted for a softer engineering program offering them in the evening. These programs are lighter, more focused in technical knowledge, and less focused in basic sciences. The students in general work all day and choose engineering programs because it is a way to be promoted at work [06].

A third degree diploma opens some doors, it means not only the possibility of earn more money but also to reach an upper status, socially speaking. It is a fact that even being a lighter program for the students it is very hard and in general it takes them more than five years to finish it. The diploma has the same value of a program that prepares engineers of conception. In certain way it helps the inclusion policy of education although the number of engineers has been decreasing considerably in the last 10 years [07].

VI. ENGINEERING EDUCATION PROJECTS DEVELOPED BY COPEC

COPEC is an organization that develops many activities on several fields of sciences like environmental, healthy, oceanography, computer sciences and others. The group that is involved with engineering education is very active and counts with a profile of many positive achievements. Along almost 5 years the group of engineering education researchers has developed many successful innovative programs that were implemented in different universities. Some of them were in under graduation level such as:

Fishing Engineering – it was a five years program, which main characteristic is the inclusion of extra classes specially selected as aquiculture and business management and the effective work in projects. The work in projects was developed in a fishing community or in fishing caught industry, supervised by a professor.

Computer Science Engineering – five years program, totally ministered in a traditional way with the insertion of Digital Systems course taught at distance in a first moment and lately with the introduction of Communication Systems course. They were available in punctual and non-punctual systems with tutors to help to solve doubts and intermediate the student – professor interaction.

Electrical Engineering – five years programs that had what was called "free period" that was a time when the students could attend classes in the several areas of human knowledge, in one of any other college department of the university. They could choose as many areas as they wanted along the five years, at least one per two years; at the end of the each period they have to present a report about their development. The report was showed and discussed with a council compounded of a psychologist, a pedagogue, an engineer professor and the coordinator of the program.

Environmental Engineering – five years program designed to have modular periods; the "theoretical module" and "research module". The theoretical basis of the researches that the students developed was given to them during the "theoretical module" and the two modules happened in alternate periods. It is as follows: at the fourth year the class was divided in two groups of students half in "theoretical module" and half in "search module" and they shifted at the following period of four months. At the end of each "search module" the student's performance was evaluated so that the following module approach could be in according to the necessities of the students.

Biomedical Engineering – five years program that included the "Challenge Cycle", which is a period of four months at the end or in the beginning of the last two years. It was a period when the students worked effectively in a hospital or research center. A professor altogether the supervisor of the institution supervised the students' work in part of a project. They had to accomplish their work so that another student that would replace her/him in the project could perform the next step. At the end of the program the student was a professional with full formation in electrical engineer, with strong knowledge in bioengineering, medical and health.

Electrical and Civil Engineering – five years program, the curriculum was elaborated in a way that the experience in "Scientific Introductory" was part of the program as a course. It is a way to form the Engineers in which the students since the first year of the program had to develop projects and to present them at the end of the each year for an audience. They had also to develop prototypes of devices and show them working. Their scores were based in the design, the prototype performance and the student presentation. Every year it resulted in proceedings edited and distributed by the university.

Environmental Engineering II – five years program with the adoption of new courses to improve the formation of future engineer. The courses were offered along the five years of course distributed as follows: Philosophy in the first and second years; Assisted Training Period since the third year to the last one; Human Resources and Management Strategies in the third and fourth years; Development of Projects in the fifth year. The suggested distribution of the courses was conceived taking into account the considerable number of Basic Science, Basic Science of Engineering and specific courses of specific areas of engineering which were essential.

Electrical Engineering II – five years program, the curriculum was elaborated in a way that the students had before the beginning of the classes four weeks of intensive courses of calculus (to review and to learn what is necessary to have a good performance during the first year of the program), dissertation (to learn how to write reports) and scientific methodology (to learn how to use the scientific method and propose some hypothesis).

Besides the programs COPEC has implemented some other projects to foster the formation of the new engineering. They are projects designed to serve engineering students of any engineering school of the region. The objective is to offer opportunities for students to get better experiences and enrich their formation.

Civil Engineering Internship Project – It is a partnership of COPEC with Construction Companies of the region to provide proper internships for civil engineering students. It is offered to students of 4th and 5th years of civil engineering programs of any engineering school of the region. The student is hired as assistant and s/he has the opportunity to experiment all the phases of a construction site from the blue prints to the final touches of the building.

The Engineering Educator Graduation Program – The PEE Program offers two graduate degrees: the Master of Science and the Doctor of Philosophy. It is a very dynamic and rich program, developed in modules, following the trend of global formation of professionals, mainly to attend the need of a prepared engineering educator to act in the several different cultural environments, which mobility has imposed as a fact of life for researchers and teachers at graduation level. Not to mention the necessary new competencies of educators such as: evaluation management; development competencies; communication skills; teamwork; ethics and intercultural competencies. So this program has been designed to fulfill this lack of engineering educators.

The Port Engineering Program – The most recent one developed and implemented by COPEC's team, which is a program designed and implemented at Master of Science and the Doctor of Philosophy level very proper for the time and geographical region once there is the largest seaport of Latin America [08].

VII. Study Abroad

In Brazil: It is a project that brings to Brazil students from abroad in a program of 15 days (can be more or less) when they have academic, social and cultural activities. It is very intensive period when the students visit 5 of the 9 cities of Atlantic Forest Region at the sea shore of Sao Paulo state, as well as visit to different industries and universities.

Abroad: It is a project that brings students to USA and Sweden in a program of 15 days (can be more or less) when they have academic, social and cultural activities. It is flexible once it is designed in according to the group needs. It is a way to provide students a good international experience.

All the programs and projects of engineering education that were implemented showed that it is possible to innovate and change the formation of engineers and so to provide them the tools that they will use as professional and as researcher.

COPEC understands that the programs should provide the future engineers a generalist formation and to instigate the development some skills such as: communication, knowledge of foreign languages, environmental awareness, and ethics among others in order to be prepared to face the contemporary work market in a world of no borders so extremely competitive and challenging.

All the programs are customized and the students receive a diploma with hours that can be used as ECTs in their University of origin [09].

VIII. The Formation of the Engineer seen by COPEC

COPEC as an organization that works for the future of education has established some guide lines to be applied on the design of engineering programs. The guide lines are the result of researches as well experience designing and implementing engineering programs [10].

- The programs should be flexible;
- Have more practical activities;
- Internships as a way to provide real experience in engineering.

The formation of the engineer must consider above all the strong basis in basic sciences and basic sciences of engineering and the programs should instigate the students the willing to develop some skills such as showed bellow:

Basic Sciences

\+

Basic Sciences of Engineering

\+

- Aptitude to conduct and implement projects
- Responsibilities for actions and results
- Creativity and innovation potential
- Mastering technologies' evolution
- Positive attitudes and behaviors
- The willing to learn all life long
- International experience
- Entrepreneurship mind
- Respect to diversity
- Communication skills
- To work in teams
- Strong ethics.

These capabilities can be instigated in the students by means of new education proposals, exchanging programs, international experiences, double diplomas, internships, technological initiation and other feasible implementation at the engineering programs [11].

IX. Final Considerations

Education comprehend the process of teaching/learning that happens not only inside a classroom but in any opportunity when the knowledge (whatever it is), is transmitted from one source to a receptor. Real learning happens when the mind is capable to situate any information in a particular context and if possible, in the universe that it is inserted. The fragmentation of the complex world in separated pieces, breaks up the problems restraining the multi dimensional aspects and it has as result the decrease of the possibilities of comprehension and reflection, eliminating the opportunities of real learning. The science has developed itself in this kind of knowledge fragmentation, generating the super specialties, divorced from the global context that they are part, atrophying the ability of integrating and evaluating the issue in its context. There is a loss of long-term prognoses, which has a straight incidence in the decisions and choices, when they are necessary. The New World order demands a new kind of professional, capable to think global without loosing the dimension of local and vice-versa. It is not easy to form this kind of professional although it is known exactly what is needed.

The contemporary paradigm of education preaches among other requirements the international experience as one of the most important skills in the formation of the new engineer. The environmental consciousness, the willing to work in teams, and etc, it is a long list but the most important aspect of engineering formation is the strong knowledge of basic sciences and basic sciences of engineering because these are the tools that will enable the future engineer to perform successfully and more over it will give them the self confidence necessary to win.

For high education institutions the necessary changes are immediate. New ways and approaches to form the professional have to be implemented because the university is the institution responsible for the final product of the long educational system in any country. With weak or good pupils the mission is to prepare the engineers to work and make the world goes round using new technologies and promote the advancement of sciences.

Summarizing the formation of engineers should focus on the generalist formation and to stimulate in the students the capability to develop their creativity; to teach them how to use the information to improve their work as well as to commit with environment; and above all to adopt a strong ethics.

The majority of the programs developed by COPEC Team of education were implemented in different Universities in the region, which has 9 universities. At present moment COPEC has started its own Institute of Education starting with 3 different programs, one in Dentistry and 2 in engineering.

Abstract—**The development of internet technologies leads to recent trends of online based education in universities. Remote experiments give the students the possibility to experience real physical situations and compare their experimental results with those of the physical models (simulation). Online learning based on remote experiments is capable of diminishing the scantiness in practical courses in the universities. In this work we present an online practical course based on Remote Experiments (OnPReX), interactive graphics and an online tutoring system organized at the Technische Universität Berlin. Furthermore we give background information about the development of our remote experiments. The remote experiments are real–life settings, designed and engineered at the solid-state physics department of the Technische Universität Berlin. We describe the development of two online practical courses, focusing on classical and modern physics, addressed at undergraduate engineering students. We ran the online practical course based on Remote Experiments in two test phases over two semesters and conducted an evaluation from which we improved technical and pedagogical aspects of the experiments and the course.**

Keywords- Remote experiments; online tutoring; online course; Physics in engineering education

I. INTRODUCTION

Learning by experimentation is a fundamental element in natural and engineering sciences. The involvement of science and engineering students in practical work is a fundamental precondition of understanding the concepts and processes of science. A practical course in undergraduate engineering and science studies requires large amounts of resources, equipment and manpower. Unfortunately many universities are not able to provide in engineering education the laboratory capacity for the numerous undergraduate students due to the high costs involved. At the Berlin Institute of Technology there are more than 500 students in an undergraduate physics course. In the learning process of physical phenomena elements of physics theory, physics models and practical experiments must be involved. Often theory, models and experiments are offered separately, with time shifts in the curriculum, leading to a discontinuity in the learning process. Also there is a set of physical experiments not included in physics curricula, because they have a unique or expensive setup (e.g. Raman spectroscopy). Some other experiments are too dangerous to be conducted by beginners (e.g. the experiments with radioactive sources). Due to the lack of possibilities to provide a practical course for these students we organized an online practical course based on Remote Experiments (OnPReX). Our Online practical course is a combination of the remote experiments with an e-learning software platform called Moodle [1]. Remote experiments are real-life settings, built up at the TU Berlin and connected to a PC. We named this setting Remote Farm [2]. These computers are also used as web servers, so everybody can get access to the experiments through a free browser plug-in and gain control over all devices. All data recorded during the experiment is stored online and is accessible for users. The course schedule can be explained briefly as following. After studying the fundamentals of physical phenomena the students perform the experiments in small groups with the help of available literature and an online tutoring system in an online learning platform (ISIS) [3]. The acquired data can be evaluated and analyzed with suitable data processing programs. The reports have to be sent for correction via email to a lecturing tutor (see II.B). The OnPReX participants have, due to the online character of OnPReX, the possibility to take part in the practical course at any time and anyplace. Khachadorian et al. [14] showed that the OnPReX course matches with the authentic online learning environment characteristics explained by Herrington et al. [5].

II. THE COURSE

Any effective learning process in science should be based on the theory, physical models and experiments. In general these three elements are offered in separate courses and consequently the learning process of theory and experiment lacks cohesion. The online practical course based on Remote experiments (OnPReX) offers the possibility to deal simultaneously with theory, experiments and also physical models producing deeper understanding of physics. The elective OnPReX is an optional course for bachelor and intermediate diploma students. The OnPReX course (see Figure 1) contains classical physics and modern physics parts. The duration for each of these courses is one semester and is offered by the Department of Solid-state Physics at the Berlin

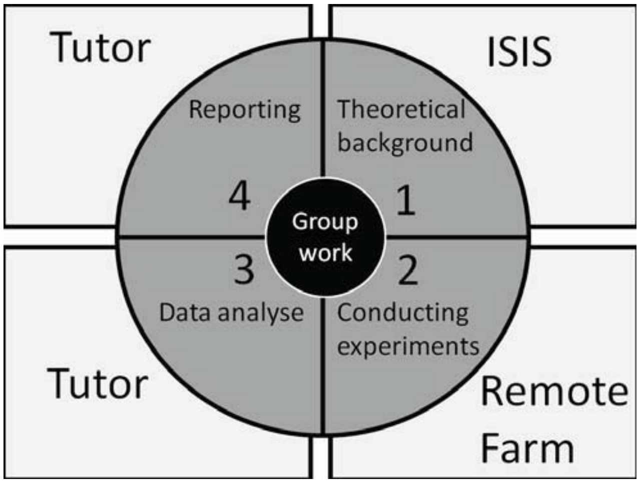

Figure 1. The four steps in OnPReX-course work flow are learning the theoretical background of experiments by information system for instructors and students (ISIS), conducting experiments via the web page of Remote Farm, data analysis with assistance of tutors and other work groups, and finally presenting the results of the experiment in form of a report

Institute of Technology. The OnPReX-course was tested over a period of two semesters, and it has been operational for one year in a regular setting. The participants of this course, which are mostly undergraduate engineering students, work in groups of three. Each group conducts six remote experiments (via the Remote Farm [2]), analyzes the data obtained from experiments and writes six reports. Additionally every participant must take an oral exam to get the three ECTS (European Credit Transfer System) points. These courses are a challenge in the organizational and managerial sense. We offer the engineering students the opportunity to work at the same time with the physical phenomena through self managed learning and by means of theory, physical models (simulation) and experiments (remote experiments), whereby similarities and differences between the theory, the simulated model and the experiment can be studied. This leads to a better understanding of a given physical phenomenon through the analysis from various perspectives. The participants of OnPReX gain the following skills and abilities, which are qualified as the general goals:

- Learning of the fundamental physical phenomena by experiments and simulations.
- Learn to deal with remote-controlled experiments and with practice-related problems during the experiment.
- Learn to deal with text-editing and data processing programs.
- Improving the skills related to the IT communications and online competence and their integration in team working.

In Section V we show by means of an evaluation if the general goals of OnPReX are achieved.

To manage the OnPReX-course we needed two tutor teams: the technical support team and the teaching tutor team:

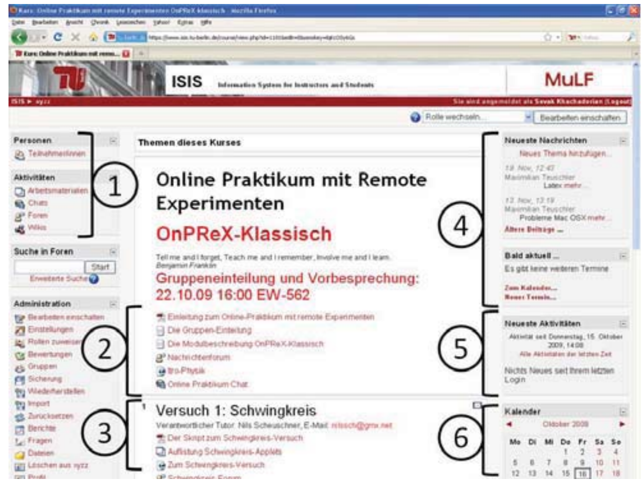

Figure 2. Information System for Instructors and Students (ISIS)-learning platform of OnPReX classical on the web page of TU Berlin. In OnPReX classical platform field showed with 1 to 6 are the list of participants, the general platform to the chats, forums and the wikis(1), general information about the course, the list of the participants groups, some organizational information and a forum and a chat room for the whole course (2), the field dedicated to first experiment explained in III.A.a) (3), the field for the coming appointments and latest news (4), latest activities field (5) and the course calendar (6).

A. Technical tutors team (Remote Farm):

The tutors of this team design build and program the experiment. The maintenance of existing experiments and debugging the technical problems are part of their duties. This team consists of three tutors and two of them deal with the programming and the electrical part of experiments and one of them deal with designing and building the mechanical setup of the experiments. This team is responsible for the activities in the Remote Farm and work under supervision of a team leader.

B. Teaching tutors team (ISIS platform):

This team consists of three tutors. Every tutor is responsible for two of the remote experiments. The teaching tutors provide support to the OnPReX participants, understand the theoretical background of the experiments, analyze the data, and write the reports. They also correct the reports and consult the students to solve the problems. These tutors must answer the student's questions in the forum regularly. This team works under supervision of the course instructor. The teaching tutors work in the ISIS environment.

III. THE COURSE CYCLE

The course cycle of OnPReX, as shown in Figure 1, contains four sections or four steps that the participants need to go through. The sections represent different learning activities: the first step focused on the theoretical background of the experiments using the Moodle [1] learning environment. Steo two is conducting experiments in the Remote Farm [2] via the Internet. Step three is the analysis of the obtained data in cooperation with the other group members and the tutors and step four is writing the scientific reports with the help of the tutors. We explain these processes below.

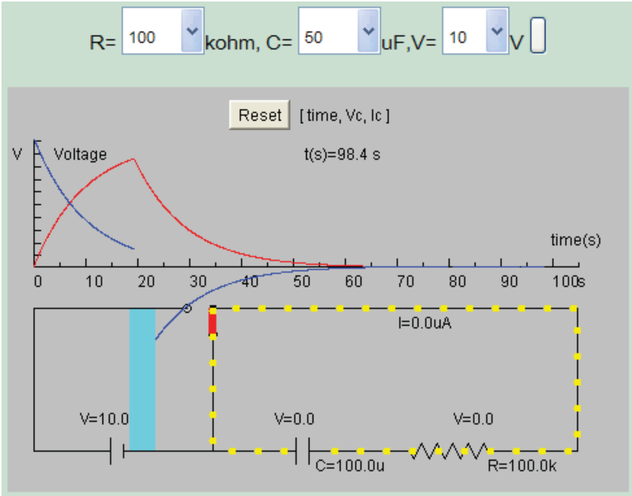

Figure 3. The simulation of a parallel plate capacitor taken from [4]

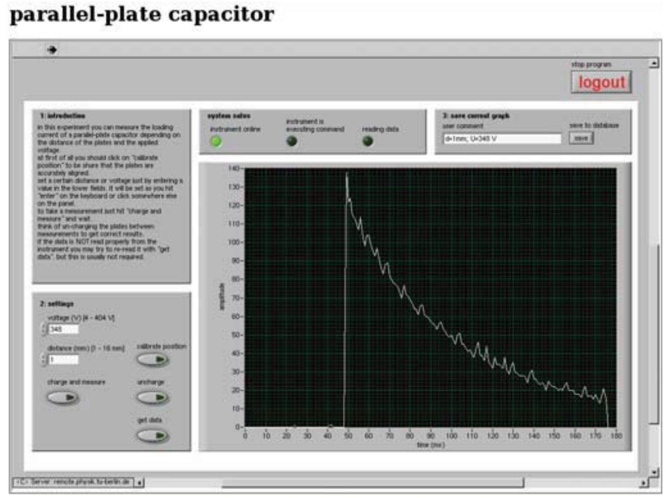

Figure 4. Front-panel of the Remote Experiment "parallel-plate capacitor". The graph shows the discharge curve of the capacitor for a given plate-distance.

A. Learning the theory: Step 1 in the course cycle

A well organized online course requires an efficient learning management system (LMS). We chose Moodle as our Virtual Learning Environment. The educational roots of Moodle as a learning management system is the "social constructionist pedagogy" [1]. Moodle is designed to help teachers create online courses with opportunities for improved interaction between students and tutors. The advantage of Moodle is that it is very flexible and can easily be deployed to thousands of students. Many institutions use it as their platform to conduct full online courses. Moodle offers series of activity modules such as announcements, course contents, documents, groups, project calendar, forums, wikis, databases to build richly collaborative communities of learning around their subject matter (in the social constructionist tradition). In Berlin we use a modified version of Moodle, called ISIS (Information System for Instructors and Students). The ISIS platform offers for each course an environment, where the whole course organized. We use two separate Moodle (ISIS) course environments, one for OnPReX classical and one for OnPReX modern. The ISIS environment in general on one hand due to its functionalities such as forums, wiki's and chat and on the other hand the various learning resources offer an efficient learning platform for the participants. The first step in the OnPReX course cycle is learning the theoretical background of remote experiments (see Figure 1). In Figure 2 we show the web page of ISIS for the OnPReX-modern physics. Each course management environment was divided into six parts. Every part, leading to a remote experiment contains the following learning resources and functionalities:

a) Learning resources:

The learning resources are listed for each remote experiment separately in the ISIS platform (see Figure 2). This includes the following elements.

- Script: a script contains the theoretical background of the experiment, the experimental setup, a guideline to conduct the experiment and the experimental tasks to be done. These scripts are an initial help for students and should facilitate the process of conducting experiments, data analyzing, and reporting.

- Simulation: Simulations of the remote experiment produce the same physical quantities for measurements as in real experiments. The theory, demonstration of similarities and differences between simulation and the experiment results in better understanding of the physics behind the experiments [11]. In Figure 3 we show a simulation related to discharging and charging behavior of a parallel plate capacitor [4]. The association of this simulation with the parallel plate capacitor remote experiment offered in the Remote Farm helps to understand the similarities and differences between simulation and real experiments.

- Remote experiment: The link from ISIS to the remote experiment. The remote experiment is the central point of the OnPReX. The course participants run the remote experiments through the web page of Remote Farm [2], which will be explained in Section III.B and IV.

b) Functionalities:

As shown in Figure 2 the ISIS platform of OnPReX classical [3] has some functionalities listed below.

- Forum: Each experiment has a separate forum, where participants discuss the experiment, its theoretical background and the experimental issues and problems. The questions and the comments can be edited and categorized every semester. The result of discussions can be also added to the wiki.

- Wiki: Every Experiment has a wiki page. This gives the participants the possibility to create and edit the contents and their gained know-how related to the experiment. With this functionality we aimed to provide the opportunity for participants to have a role not only as an user of learning resources but also as a content provider (a characteristic of the authentic learning environment [5]). These wikis should emerge as collections of learning resources and simulations and information about the theoretical background of experiments. The teaching tutors mentioned in Section II.B moderate the formation of the wikis in terms of categorization and sorting and also the editing of the contents provided by the students.

- Chat: Each experiment field has a chat room, where the student can chat about the experiments. We added this functionality to the ISIS page and motivated the students to use it and find out if this functionality is convenient for use in OnPReX. The evaluation of the course shows (see Section V) that this functionality is not used often by the participants. The participants of the course prefer to communicate via email, the forum or chat using other instant messaging services like Skype, Yahoo Messenger, etc.

B. Conducting experiments via Remote Farm: Step 2 in the course cycle

The second step in the course-cycle (see Figure 1) is conducting the experiments. The students use their web-browser (i.e. Firefox or Internet Explorer) to perform the experiments. The experiments of the Remote-Farm are real-life setups hosted at the TU Berlin. All variables can be manipulated via the server controlling the setup, which is realized by digital to analog converters, relays, stepping motors etc. For most of the experiments we also offer a video stream over the Internet to view the changes in the setup on-line. In Section IV we give a more detailed introduction to the implementation of our remote experiments. The control of the experiments, web-server and the browser plug-in are provided by a software called "LabView" [6] (by National Instruments). The plug-in is freely available over the Internet and is compatible with common operating systems (Windows, Mac and Linux) and browsers. So far the Remote-Farm offers 12 experiments with two additional setups in the construction-phase. One of the recently developed setups is the parallel-plate capacitor. In this experiment the students can study the discharging behavior of a capacitor with variable plate distance. Figure 4 shows the control-panel of this remote experiment. The setup of the experiment (shown in Figure 5) consists of two circular shaped aluminum plates with a diameter of 20 cm. The plates can be charged by applying voltages between 4 and 400 V. The capacity can be varied by changing the distance between the plates in a range of 1-16 mm. The students have to record discharging current curves, in order to determine the capacity for the given distance. The results can be compared to the theory studied in the first step of the course cycle or to related applets available on the Internet.

C. Data analysis: Step 3 in the course cycle

The ability of acquiring real experimental data is one of the many advantages of remote experiments. The ability to collect, analyze, and interpret data are the core-skills for scientists and engineers. Moreover, the engineers must learn to form and

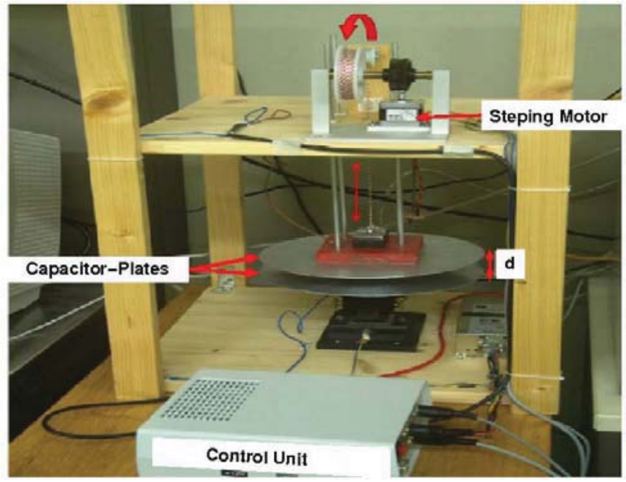

Figure 5. Photo of the parallel-plate capacitor. The circular plates are visible in the center of the image.

support conclusions and make order of magnitude, judgment and use measurement unit systems and conversions. This is important when reviewing experimental results and others work. Analyzing and representing the experimental results are one of the key skills taught in this course (see the OnPReX general goals in Section I). The measurement data must be evaluated and analyzed with the suitable data processing programs. The experimental data from the remote experiments are afflicted with experimental errors. The calculation of these errors, identifying unsuccessful outcomes due to faulty equipment, construction, process or designs are also skills that the students learn through OnPReX. To make the learning of "data analyzing basics" for OnPReX-participants easier we prepared an introductory script where the basics of data analysis and some data analyzing software products are introduced (see Section III.A.a)). As shown in Figure 1 (fourth step in the course cycle) we support the learning of data analyzing skills by online tutoring. As pointed out in Section II.B the teaching tutor team supports the OnPReX participants to solve the problems due to the data analyses. The OnPReX-participants exchange information and know-how among each other and also with the tutors via email, forum, chat and the wiki. The communication of the tutors and the students becomes easier through the ISIS Platform.

D. Reporting: Step 4 in the course cycle

The main purpose of writing scientific reports at universities is to communicate the results of experiments. The process of writing a scientific report also includes valuable practice in articulating the theoretical and empirical basis of a particular experiment, and the significance of the interpretation of results. With this training the undergraduate students are well prepared to produce reports for postgraduate studies and communicating their findings to the scientific/technical world. In an introductory script we give a general idea of the sections of scientific reports. The rest of this skill can be learned in the form of learning by doing with the assistance of tutors (teaching tutor team Section II.B).

IV. TECHNICAL DETAILS ON REMOTE-EXPERIMENTS

Our remote experiments are controlled with commercial software called LabView [6]. We currently use the version 8.20, which is not the newest version available. All devices manipulating parameters in our experiments are not directly connected to the server. For safety reasons we installed an additional microprocessor-board for each setup, which checks all critical parameters and is such able to prevent the setup from being damaged. The collection of data is in some cases performed by these micro-controller boards (connected to the server via RS 232), in other cases we use commercial meters controlled over RS232 or similar industrial standard interfaces. Examples for these meters are voltage, current, Geiger-Müller counter or charged coupled devices (CCD). A very important part of remote experiments is the ability to observe the experiment on live-pictures. To actually see the changes being made is one key learning experience. On the other hand, the live-pictures are the most important proof for the existence of real experiments. Most of the effects that can be studied with our experiments could be simulated by applets. We spent a considerable amount of time on the installation of a reliable video-system. After initial experiments with USB web-cams and software streaming solutions, we switched to commercial surveillance systems. The “AXIS 241Q Video Server” is a 4-channel video server providing Motion JPEG and MPEG-4 streams. It also provides JPEG still-images which we include in some of our LabView [6] front-panels, shown in Figure (control panel).

V. COURSE EVALUATION

The practical course with remote experiments is a relatively new type of course, which still needs improvement. There is proof that student evaluations are good indicators of effective teaching (see, [7] and [8]). The process of (a) gathering information about the impact of learning and of teaching practice on student learning, (b) analyzing and interpreting this information, and (c) responding to and acting on the results, is valuable for several reasons [9]. We present the outcome of the evaluation for the 2008 to 2009 winter-semester. In this evaluation the questions are divided in two categories. In the first category we tried to find out if the general goals of OnPReX are achieved and in the second category of questions we tried to get responses from the participants in order to further develop and improve the OnPReX course. We used online evaluation software (Unizensus) to evaluate the OnPReX courses [13]. Unizensus is an evaluation-software, which has been used in the Berlin Institute of Technology (Faculty of science) over years. We present the major results of the evaluation in Table 1. 91% of the interviewees have not passed any physics practical course before and 63.5% had no experience with writing a report. This shows that the participants were beginners and were short on experience due to physics practical course. 81% and 55% of interviewees believe that the OnPReX helped to improve their text editing, and data processing skills, respectively. 73% of the participants believe that their online competence ameliorated through OnPReX. 64% of the participants believe that the skill of dealing with remote experiments is "very important" for a future occupation as engineer. They believe that this skill has real world relevance. The fact that the remote experiments can be conducted at any time and any place is considered "very important" by 73% of the interviewees. Finally 82 % of the interviewees would recommend OnPReX to other students. From the results and the comments of the evaluation we also learned, that some of the remote experiments were unstable. The control panels of some other remote experiments were rated as user-unfriendly. On the basis of the feed back from the participants we developed some solutions and modifications e. g. reconfiguration of control-programs, exchange of live stream structure, designing more user-friendly control-panels for remote experiments. Remote experiments are advantageous especially where the experiment is dangerous for the experimenter. For example 37.5% of interviewees raise concerns over working directly with dangerous experiments such as radioactivity. 62.5% of interviewees prefer to work with the remote experiment over the real experiment since in the case of remote experiments no device-damage can be inflicted. We mentioned the OnPReX general goals before (Section I) and in the first category of questions listed in Table 1. We show that the general goals of OnPReX, namely the improvement of text editing skills, improvement of data processing skills and the learning of the standards of reporting are partly achieved. These results show that the OnPReX must further be developed to provide better conditions for the students improving their text editing (mean value: 2.7) and their data processing (mean value: 3) and reporting (mean value: 3) skills.

VI. ONPREX AND LILA

Lila (Library of Labs) [10] is a project co-funded by the e**Content***plus* program of the European Commission. The major goal of this project is the development of an integrated platform for remote experiments and virtual laboratories. Eight European universities are involved this project and three companies. The project partners share their remote experiments, virtual labs and the learning resources in the LiLa platform. The LiLa project aims to create a repository of remote and virtual laboratories and develop educational formats and supporting media to ease the use of the repository and guaranty smooth access by means of a retrieval and access control system. Any user with a Lila account can have access to the remote experiments in the Remote Farm and related resources. This platform provides an efficient framework for online collaboration between the users and the instructors of online courses in each partner university. Through the LiLa platform the users will be guided by the educational support system to use the database of learning content. By means of the integration of OnPReX resources in LiLa on one hand we will be able to offer the students a better and a more diverse collection of remote experiments, simulations and learning resources and also gain through the collaboration and cooperation with the other LiLa partners more technical and didactical know-how for further improvement of the OnPReX. In particular our benefits as instructors of OnPReX from the integration in LiLa will be to use the Lila platform as a central starting point for finding remote experiments and virtual labs with the intent to implement them in the OnPReX. Secondly, get didactical support using the educational format and supporting media of this platform and thirdly getting new ideas from the use cases in the LiLa platform.

TABLE I. THE RESULTS OF EVALUATION: THE QUESTIONS ARE DIVIDED IN TWO CATEGORIES. IN THE FIRST CATEGORY WE TRIED TO FIND OUT IF THE OBJECTIVES OF ONPREX ARE ACHIEVED AND IN SECOND CATEGORY OF QUESTION TRIED TO GET RESPONSES FROM THE PARTICIPANTS IN ORDER TO DEVELOP THE ONPREX COURSE FURTHER.

Nr.	Question[a] (objectives)	mean value
1	improvement of text the editing skills	2.7
2	improvement of data processing skills	3
3	learning the standards of reporting	2.6
4	the importance of dealing with remote experiments as engineer	2.3
	Question[a] (experiences)	
1	usefulness of introductory script	2.5
2	usefulness of simulation, animation and interactive graphics	2.2
3	user friendliness of Remote experiments	2.4

a. Rating scale: 1= Excellent, 2 = good, 3= satisfying, 4 = acceptable, 5 = poor

VII. CONCLUSION AND OUTLOOK

Presented was an online practical course with remote experiments for bachelor and intermediate diploma engineering students. We showed that the association of the remote experiments, online literature and simulation with an online tutoring system can result in an online practical course, which can be very useful in engineering education. We believe that the OnPReX can be very helpful for the engineering students through their academic studies and their career as an engineer. Clearly OnPReX support self managed online learning, as a valuable learning experience. Definitely we need to further develop OnPReX. Firstly the existing remote experiments need to become more stable and we need in parallel to design and build new experiments. Secondly we need to test the capacity of OnPReX concerning the number of participants to be served in a semester. In winter-semester of 2009 to 2010 we are aiming to offer the OnPReX as a compulsory subject choice for the students of "Natural Sciences in the Information Community". This is a bachelor course of studies where the students should pass during the first and second terms two physic practical courses with 12 ECTS points. We offer the students in the first term the OnPReX classical and modern course for 6 ECTS points. In the second term the students take the regular physics practical course offered by their faculty. Herewith we are going to test the capacity of OnPReX concerning the number of the participants. Further evaluation is needed to uncover if the OnPReX upgrades after the first evaluation were sufficient. We need to provide a simulation for every remote experiment to make the comparison of obtained data from remote experiments and simulation possible. Within the LiLa project we are aiming to get access to additional simulations and experiments in order to further improve the OnPReX course.

ACKNOWLEDGMENT

Authors thank S. Morgner for helping to organize the OnPReX.

Abstract— **The LiLa (Library of Labs) project goal is to combine virtual laboratories and remote experiments spread out over Europe, which will be shared and exchanged among educational institutions in the form of reusable learning objects. This work addresses the needs of authentication and authorization when reusable learning objects are exported from an *experiment provider* organization to *an experiment user* Learning Management System. The paper discusses possible solutions based on using the SCORM run-time environment specification as a framework for learning objects and Shibboleth as a framework for a federated authentication and authorization.**

Keywords-virtual laboratories; remote experiments; authentication; authorization; learning objects

I. Introduction

The objective of the Lila project is to combine virtual laboratories and remote experiments (i.e. simulated experiments and experiments which are controlled remotely by computers) spread out over Europe, making them reachable in an environment with central retrieval and access facilitating synchronous collaboration and user generated production. The goal of this project is not only to integrate experiments and laboratories into a software infrastructure, but also to build a virtual portal in which experiments and laboratories are provided, including an on-line course system which guides users through experiments.

From the technical point of view, the LiLa portal is a repository of virtual laboratories and remote experiments on a central server, which will make it possible to include meta-data in laboratories and experiments to integrate them in library search engines and link-resolver technology. Basically, this means that virtual laboratories and remote experiments become learning objects, including learning object metadata as defined in [1]. A LiLa Learning Object (LLO) is then defined as a learning object with functionality and data elements which are specific to the access and use of virtual laboratories and remote experiments. The Lila portal gives access to these LLOs in an integrated environment, which includes a tutoring system for students and access to the 3D-engine Wonderland as a collaboration environment for students, teachers and researchers, providing users an organizational framework for online collaboration, for the transfer of virtual laboratories and connected support-services as well as for access opportunities to remote experiments.

In order to adequately exploit these learning resources, one of the objectives of the Lila project is to provide a well defined access control to laboratories and experiments. This work addresses the needs of authentication and authorization when reusable learning objects are exported from an *experiment provider*, that is, an experiment repository or a LMS (Learning Management System) of an institution providing access to resources for virtual laboratories or remote experiments, to an *experiment user* LMS, that is, the LMS of an institution which includes the learning objects as part of the curriculum for its students. In this context, the LiLa portal will act as a platform that will integrate different modules for laboratory and experiment searching, scheduling, authentication and authorization, and LLO importing and exporting. This paper discusses possible solutions based on the use of the SCORM [2] run-time environment specification as a framework for learning objects and Shibboleth [3] as a framework for a federated authentication and authorization.

II. Technology Overview

A. SCORM technology

Sharable Content Object Reference Model (SCORM) is a set of technical standards, specifications and guidelines designed to meet the functional requirements of the Advanced Distributed Learning (ADL) initiative. These standards are aimed at e-learning products like LMSs. SCORM is exclusively a technical standard, not pedagogical.

SCORM specifies that content should be packaged in a ZIP file and described in a XML file, named imsmanifest.xml (the "manifest file"). The XML file contains all the information the LMS needs to deliver the content, like information about how to launch each SCORM learning object (SCO) and, optionally, metadata that describes the course and its parts.

In LiLa, a LiLa Learning Object (LLO) is a SCO with additional constraints extended by additional metadata. Specifically, LLOs should obey the SCORM standard for learning objects, and are packaged in ZIP containers similar to regular SCOs. A LLOs is specific for one experiment or virtual laboratory, so a LLO will render a single web page, i.e, it will be a single (not composed) SCO with only a single href (html-file). Since most of the existing laboratories and experiments

This work was partly funded by the eContentPlus EU project ECP-2008-EDU-428037 'LiLa' (Library of Labs: Dissemination of Remote and Virtual Laboratories for Natural Sciences and Engineering).

use applets, a typical LLO will embed an applet providing access to the virtual laboratory or the remote experiment.

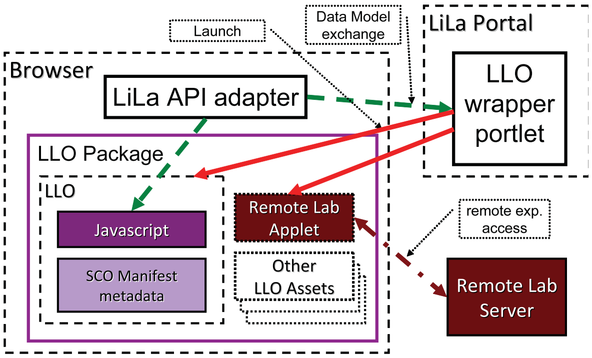

Figure 1. LiLa learning Object components

Fig. 1 shows the internal components of an LLO and the relations between an LLO, the LiLa Portal and a remote laboratory.

The LiLa portal will be based on portlet technology [4, 5], to take advantage of available functionalities such as collaboration, content management, groupware management, etc. On the other hand, there are no available portlets to display SCORM content. Having LLOs based on SCORM is important, because then it will be possible to deploy LLOs in all SCORM compliant LMSs. In LiLa a LLO wrapper portlet will be implemented to render the content that is uploaded to the portal as LLOs. This LLO wrapper portlet will be in charge of launching the LLO html page in the user browser, providing the adequate SCORM runtime environment – simplified, through the LiLa API adapter and of providing and launching the Remote Laboratory Applet, that in the case of remote experiments will have a client/server relationship with a remote Laboratory Server.

B. *Shibboleth*

The Shibboleth System is a standards-based, open source software package for web single sign-on across or within organizational boundaries. It allows sites to make informed authorization decisions for individual access of protected online resources in a privacy-preserving manner.

Shibboleth allows the deployment of a federated identity management system, in which the components of the identity management system are distributed across organizations, with each organization trusting the other to perform the functions of the components they host. There are two roles in this kind of systems: organizations providing identities, that would like to provide applications only the information required to make authorization decisions, and organizations providing applications or services, that would like to manage only the identity information required for their applications, reducing the risk of storing or accidentally releasing sensitive information they do not need.

The functional components of a Shibboleth implementation support these two roles. There is an identity provider (IdP) component, which has been implemented as a J2EE component, and a service provider (SP) that has been implemented as a C++ Apache module. There is also an optional "Where are you from?" (WAYF) service, that allows to redirect users to the right IdP.

The LiLa project has selected Shibboleth as the authentication and authorization technology for the virtual portal, due among other reasons to the wide deployment of Shibboleth in educational organizations in Europe. This will facilitate the creation of a federated identity management system comprising the organizations providing virtual laboratories and remote experiments and the LiLa project as the organization that will provide a repository for experiments and laboratories, enhancing their use by including services based on the inclusion of metadata (search and catalog creation), a tutoring system for students, and collaboration services including access to the 3D-engine Wonderland.

III. AUTHENTICATION AND AUTHORIZATION

A. *LiLa Authentication and Authorization Architecture*

Shibboleth is the authentication and authorization technology used in LiLa to control the access by registered users to the portal as well as to control the access to experiments and remote laboratories, contained in LLOs.

As regards authentication and access control, the general portal software architecture is shown in Fig. 2.

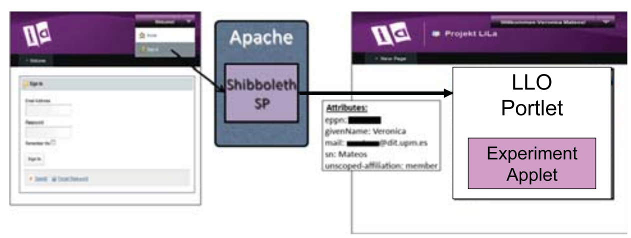

Figure 2. Shibboleth Authentication in the LiLa Portal

The general process is the following:

- A user goes to the home page of LiLa Portal. In this page the user can see some portlets.
- To access the LMS and experiments, the user has to log in the portal and go to LiLa Project page. Sign in functionality allows user to log in.
- User authentication is done using Shibboleth. As a result of the authentication process, the Shibboleth's Service Provider (SP) obtains a set of session attributes. These attributes are used to allow or deny user to access to protected resources. Also, the attributes could include information for authentication and authorization related to the LLOs which are rendered by using a portlet.
- If a user is shibboleth authenticated and she has the required permissions, she will go to the LiLa Project page, where she will see the portlets giving access to experiments and will be able to access them.

B. *Learning Object Authentication and Authorization*

The LiLa Portal is able to check the schedule and user permissions for experiments that are contained in a LLO as far as the LLO is launched in the LiLa Portal itself. However, downloading LLOs to a LMS would bypass the portal mechanism used to check the availability of a reservation for an experiment by a user. This section discusses the authentication and authorization mechanisms used in LiLa and possible solutions to overcome this problem.

The LiLa Portal uses Shibboleth for authentication and authorization, which for the purpose of the following description means that the portal will need to have a Shibboleth Service Provider installed, which will be in charge of redirecting the requests for AA to a Shibboleth Identity Provider, that can be located elsewhere.

One possible solution to “export” the LiLa authorization and scheduling infrastructure of experiments to other systems is to both a) integrate scheduling information and Shibboleth, and b) include some way of checking AA and scheduling information within a LLO.

Fig. 2 depicts the scenario in which Shibboleth is used to perform User Authentication and Authorization, while the authorization related to a LLO is carried out by a specific “Token based LLO Authorization Server” (TLAS).

A LLO includes some information or security token, the LLO AA Token, for example in the SCO Manifest *adlcp:datafromlms* data element. LiLa could update *adlcp:datafromlms* “on the fly”, if needed, when the LLO is downloaded to be included in an external LMS. A LLO is designed to get this information before launching the Remote Laboratory Applet, by retrieving the value *cmi.launch_data*.

Once the LLO AA Token is retrieved, the LLO will contact the TLAS using the token and in return, the TLAS will provide some piece of information which is needed to start the virtual experiment / remote laboratory applet. This piece of information will be passed as a parameter to the applet when launched. In the case of a remote laboratory applet, the parameter could be the url needed to contact the remote laboratory server, which might include authorization parameters depending on the level of integration of the remote laboratory with LiLa authorization and scheduling mechanisms. In the case of a virtual experiment, in which the applet is does not need access to a server, the parameter could be some access code needed to unlock the virtual experiment. The communication between the LLO and the TLAS will be based on AJAX, using the XMLHttpRequest object.

The task of the Token based LLO Authorization Server (TLAS) will be aided by Shibboleth. This server will be accessed through an Apache httpd server and protected by a Shibboleth Service Provider. This means that the TLAS will be able to perform the LLO authorization task using the user AA data provided by Shibboleth. This will make it possible to have an authorization schema where a LLO is only authorized if the user belongs to a certain organization that has obtained the access rights to the LLO. In this schema, the AA token includes information that links the LLO and the organization.

In the case of an experiment for which previous reservations are required, the TLAS could also be linked to the LiLa scheduling infrastructure, in order to only give access to the applet in case there is a valid reservation for the user. This would benefit remote laboratories that could use the LiLa reservation system even when the LLOs are used in external LMSs.

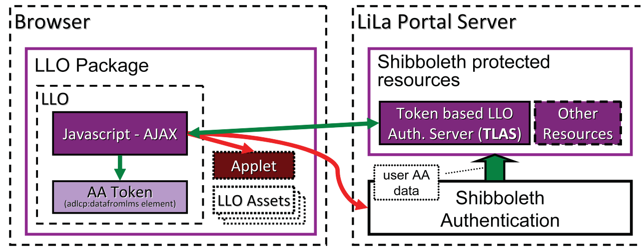

Figure 3. Authentication and Authorization for LiLa Learning Objects

Other alternatives have been considered. For example, AA attributes and scheduling information could be provided exclusively through Shibboleth. However, this would mean that in order to take advantage of remote laboratory reservations, external LMS would need to include a Shibboleth Service Provider.

Another alternative is to include the functions to check AA and scheduling status in the *LMSInitialize()* function that will be provided by the LiLa API Adapter in the LLO wrapper portlet. In this case, a LLO does not need to include any specific javascript code to perform the authentication and authorization, but when it is used in external SCORM compliant LMSs systems, no AA status check would be made unless the LMS own *LMSInitialize()* function is also modified. This could be an interesting alternative, since some of the most popular LMS are open source and LiLa could integrate the LLO AA and scheduling mechanism in LMSs such as ILIAS or Moodle.

IV. CONCLUSIONS

The paper discusses a solution for the authentication and authorization needs of learning objects used to access virtual laboratories and remote experiments in the context of the LiLa project.

The software architecture used in LiLa requires that the virtual laboratories and remote experiments are provided as LiLa Learning Objects (LLO), which are an special SCORM encapsulation including access control functionality for interacting with the Virtual Portal authentication components in order to force that the experiments are only executed by the adequate authorized students. The objective is to enforce access control to the experiments provided by LLOs not only when LLOs are deployed on the Virtual portal, but also when they are deployed on external LMSs, taking advantage of the functionalities offered by the Shibboleth system, that allows to build a federated authentication and authorization infrastructure for web applications.

The authors are currently working on implementation of the whole system that will help confirm the viability and expose possible problems of the proposed solution.

Abstract— **Over the past couple of years we have defined and implemented a variety of tools and instruments for supporting technology-enhanced teaching within the field of Nanoscience. Among others, the Nano-World showcase suite developed includes the following: a collaborative simulator for learning the basics of atomic force field microscopes; a remote laboratory which offers real-world access to experiments at the nanoscale level; software infrastructure for remote control and steering of ongoing experiments using mobile devices; interactive courseware that teaches the basic laws of physics such as force fields; a web-based platform for 3D visualizations of data collected via nano microscopes; and an interactive game for getting first impressions of atomic manipulations.**

In the paper we describe the different components and report on lessons learned from using the showcase within the university curriculum as well as an information medium for schools and public audiences. We also report on plans and first steps to interface the showcase suite with LiLa – the forthcoming library of labs.

Keywords: Remote Laboratory, Virtual Experiments, Nanoscience, 3D visualization, Collaborative Learning Environments

I. Introduction

In recent years, nanometer-scale science and technology has gained a lot of interest among researchers and the public. Boosted by the development of the scanning tunneling microscope (STM) [1] by Nobel laureates Gerd Binnig and Heinrich Rohrer at the IBM Zurich Research Laboratory, the fascination of investigating and manipulating material at the nanoscale level has attracted a large number of research groups.

At the level of atoms and molecules, we see a blurring of boundaries between classical disciplines such as physics, biology, and chemistry. Therefore, training in this new field is not only important for the different curricula involved, but is also a challenge due to its highly interdisciplinary nature. Future nanotechnologists need training in solid-state physics, molecular chemistry, analytical chemistry, and engineering.

The Virtual Nanoscience Laboratory of the University of Basel [2] consists of virtual and remote experiments, collaborative 3D visualization tools, interactive game-based learning methods, and an infrastructure that offers mobile access to remote and virtual experiments [3].

Hands-on examples, course materials, and simulations give an insight into the methods of Nanoscience and nanotechnology for undergraduate students of different disciplines.

II. Virtual Experiments: NanoSimulator

A. Content

With the STM as the first Nanoscience tool accessible to researchers, it was possible to make nanostructures visible that had previously been inaccessible to sensual perception. Nano tools also allow the investigation of additional physical properties such as normal and lateral forces or optical properties. All technical approaches are based on raster scan technology: line by line, a sensor rasterizes the surface and records information, very similar to a blind person who is scanning a text written in the Braille code.

Our NanoSimulator, a simulator for learning the basics of atomic force field microscopes, is based on five virtual experiments using the raster scanning method mentioned before. Experiments implemented include friction, electrochemistry, fluorescent dipoles, imaging technologies, and non-contact AFM on Si(111)7x7 surface [4]. As the friction module is the NanoSimulator experiment with the highest usage ratio, we have a closer look at it.

Friction is one of the oldest well-observed phenomena in the history of mankind. It appears in every technical application, whenever parts are in motion. Without friction we could not walk and no moving body would come to rest, for example. Recent research could prove that it is possible to move a weight over a surface without the dissipation of energy [5]. The virtual friction experiment (see Fig. 1) can simulate this recently explored behavior, as well as the well-known stick-slip behavior at the atomic scale.

The NanoSimulator allows the direct change of the specific parameters in every experiment. The simulator can be driven in collaborative mode: all students connected are able to simultaneously view any adaptation of parameters and the respective reaction of the simulation. By adjusting the scan size, for example, it is possible to zoom into a specific region. By increasing or decreasing the spring constant of the sensor, the contrast mechanisms can dramatically change, just like in the well-studied real experiments [6].

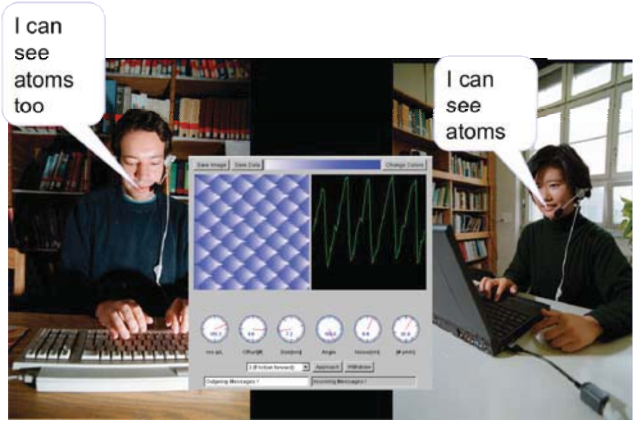

Figure 1. Friction mode of the nanosimulator. Two students observing stick-slip phenomena between a tip and an ultra flat NaCl surface. The simulation window contains several wheels for parameter settings as well as measurement results including visualizations.

B. Educational approach

All five virtual experiments follow a problem-based approach. Depending on individual skills, students get specific tasks or learning scenarios they have to fulfill using the simulator. They can act in the role of scientists and explore phenomena with virtual experiments in a similar way researchers did it a decade before in their top research environment.

The simulator makes simplifications of real-world effects, but it is close enough to practical usage. The friction mode of the NanoSimulator, for instance, allows the observation of atomic stick-slip phenomena [7] described by many researchers around the world. In addition, the NanoSimulator also correctly describes the recently investigated phenomenon of ultra-low friction [8].

Nanoscience experiments can be very expensive, which hinders their usage in education. By simulation instead, they become accessible at greatly reduced costs. Similar to aviation environments, Nanoscience students receive their basic training in a simulator context.

C. Technical aspects

All virtual experiments can run as Java stand-alone applications, Java applets or as client-server applications (Java servlets) for the collaborative mode. In the case where the actual simulation and the virtual experiment user interfaces are distributed over a network, the continuously calculated experiment data is streamed to all connected clients. Events exchanged between the client sites and the server ensure the synchronization of the application.

The virtual experiments are based on the open source virtual experiment framework vexp [9]. By using the modular and object-oriented vexp framework, new virtual experiments can easily be developed by extending the Simulator class.

D. Lessons learned

The planning, implementation, and testing of new virtual experiments are a time-consuming task. However, state-of-the-art languages such as Java have rich class libraries that support developers by providing solutions to generic problems like parameter exchange and data visualization.

Nanoscience students use simulators only if they are assigned specific tasks that they must complete and report on. In our setting, students that had to write a protocol to document their work have spent more time using the simulator.

III. Collaborative Web 2.0 Components: Nano3D

Nano3D is a collaborative Web 2.0 tool for the visualization of nanoscale measurements. It was developed to aid researchers in creating high-quality images and videos of their measurements (see Fig. 2) and to allow students to interactively explore atomic structures. The visualization of nanoscale worlds and the analysis of atoms and molecules offer scientists important new insights, since the function of an object is often determined by the fine details of its structure [10].

A. Content

An important goal of Nano3D was to provide researchers with a collaborative visualization platform. Nano3D allows users to easily create both individual and shared workspaces. In every workspace, they can handle the measurements uploaded, and access all visualizations previously created. The concept of easily accessible workspaces is also practical for the use of Nano3D in education. Students and pupils can be provided with a default workspace that already contains various measurements and visualizations. They can directly begin to explore the possibilities of visualizing measurements, without having to deal with importing measurements and setting up a work environment for their visualizations, as they would typically have to if they used a local installation of a visualization platform that is not web-based.

The measurements mentioned are essentially height maps of atomic surfaces created from data captured by a raster probe microscope. Various tools exist to create 3D representations of such height maps. POV-Ray [11] is a very popular tool, both because it is very powerful and freely available. Height maps can be imported and visualized from arbitrary points of view, allowing full freedom in the representation of the three-dimensional structure. However, POV-Ray is rather complex to use. The rendering of the scene is specified in the Turing-complete Scene Description Language. Text-based description of objects situated in three-dimensional space is not intuitive, and requires not only programming skills, but also good spatial sense. And even for researchers that have these abilities, creating visualizations with POV-Ray remains a time-consuming and problematic task. If not only still images, but movies should be created, additional knowledge about video encoding and publishing is required. Nano3D hides the complexities of the tool chain by using a set of flexible, parameter-oriented scene descriptions created by visualization experts. Users can control the parameters, such as viewpoint, coloring, scaling, light and orientation not via textual input, but through interactive components (HTML forms and Java applets) that allow an intuitive understanding. Selecting the viewpoint, for example, requires just clicking a point in a three-dimensional space; choosing height-dependent coloring is supported by selecting from a display of various color gradients.

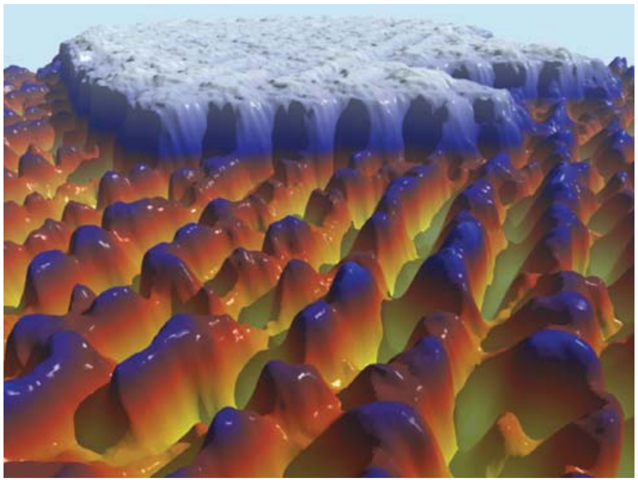

Figure 2. 3D visualization of a NaCl nano structure, created with Nano3D. The corrugations in the front represent individual atoms, the white plateau in the back is a mono-atomic ultra-flat terrace.

B. Educational approach

Nano3D allows students to work on real experiment data. However, they do not have to download and possibly preprocess this data, as they would have to if they used their own visualization solution. Real-world data is already available in the Nano3D workspace, and students can directly start exploring it through visualization.

By hiding the complexity of the tool chain necessary for creating visualizations, Nano3D allows students to focus on the cognitive impact of exploring scientific data through 3D visualization. Especially for undergraduate students whose technical skills are not that advanced, Nano3D offers the possibility to work with computer-based methods in the scientific process.

C. Technical aspects

Nano3D has two main components: a web front-end and a visualization back-end. The web front-end provides users with means to create their workspace and to upload their measurements (workspace organizer). Interactive components give the user intuitive aid in selecting appropriate parameters for the visualization. The user can edit the parameters and create and preview the respective visualization in an integrated view called render editor. The visualization back-end makes use of the ray tracer POV-Ray to generate renderings. Visualizations are created either as single images or as image sequences that are encoded into video using the open source video player MPlayer [12]. After the visualization has been created, a preview is displayed in the render editor, and the high-resolution image or movie is available for download in the workspace organizer.

Nano3D requires a Java Servlet container (we have used Apache Tomcat [13]) and an installation of POV-Ray and MPlayer (video support can also be disabled). The application has been successfully tested on Linux (Fedora Core 5) and Windows XP. The productive deployment of the application has been running on a Linux server for over two years.

D. Lessons learned

Nano3D is in productive use since January 2007, with a total uptime of 99.8%. The Linux-based server has been running for 626 days. The main users of the service were researchers and students from the University of Basel. However, statistics show that Nano3D has received regular traffic from several German universities. The German Museum in Munich has integrated Nano3D in its exhibition about Nano and Biotechnology [14].

Nano3D is included as a component in the curriculum of Nanoscience studies, where students can get a first impression of working on measurement visualization and exploration. It is also used in events addressed at pupils and prospective students. In research weeks for pupils organized by the Schweizer Jugend Forscht (SJF) foundation, Nano3D is used to help students understand the nano-scale world of modern physics.

Nano3D has also been used in science media communication. High-end visualizations have been produced for the University of Basel's research magazine UNI NOVA [15] and for the "Small is Great" brochure of the National Center of Competence in Research Nano [16].

IV. Interactive Insight Learning Elements: Nanojoystick

Undergraduate students of various fields making use of nano technology need a motivating but also simple introduction into the world of Nanoscience. Nanojoystick follows a game-based learning approach by offering a simplified simulation of a nano-scale environment. Users can move elementary building blocks of matter (molecules and atoms) and form new nano structures.

A. Content

Building new molecular structures atom by atom has been a strong wish in chemistry and physics for a long time. With the help of the new nano tools created in the last two decades, first steps in this direction have been taken. Notably, Wintjes et al. have demonstrated a nano-switch [17].

This recent development is brought to life in the Nanojoystick application. It allows students to directly manipulate a simulated atom-level environment.

Students control the movement of the tip of a scanning tunneling microscope in x and y direction via a joystick. In the virtual environment, they are given a nearly complete line of molecules. One molecule is displaced, and the task for the students is to fill the gap in the line by moving the displaced molecule with the tip.

Students can control the point of view, the movement of the microscope tip and the zoom level via the joystick. The joystick provides a very direct control that many of the students already know from computer games. The time required for completion of the task is measured, and a ranking listing the three fastest students is displayed. If several Nanojoystick stations are present in the same network, they exchange scores and create a network-wide ranking.

B. Educational approach

The game-based approach allows an intuitive first contact with the field of Nanoscience. However, the use of a joystick is motivated by the practice in the scientific community. Real scientific molecule manipulation experiments needs precise planning and must be performed very carefully. Joysticks provide the necessary high-precision user interface.

In the context of science communication events such as the Sciencedays in Germany [18], the Nanojoystick is an ideal demonstrator to invite scholars to get in touch with science (see Fig. 3). The use of several stations with competition through a global ranking is well suited to involve not only single, but small groups of visitors. The high-precision control of the tip via the joystick has been appealing to both girls and boys.

Figure 3. Youngsters making their first manipulation experiments at the nanoscale level. Three interconnected Nanojoystick stations were presented at the Sciencedays in Rust, Germany, attended by nearly 20.000 prospective students.

C. Technical aspects

Nanojoystick is a stand-alone 3D application that makes use of modern graphics processing unit capabilities. It is written in Java and uses the JMonkey Engine [19], an open source scene graph for Java. The engine provides an API for physics simulation, which provides the rule set for the Nanojoystick environment.

D. Lessons learned

A game-based approach to science is very attractive for young people. Experience from several public events, most notably the Sciencedays, has shown that the interest of youngsters in a complex subject can be initially stimulated by providing a playful entry.

Also, providing several stations and thus allowing small groups to concurrently experience the application has proven valuable. The addition of a networked ranking system additionally stimulates the interest of the visitors.

V. MOBILE E-LEARNING: NANOMOBILE

A. Content

NanoMobile is a system that uses mobile devices for monitoring and controlling scientific experiments. The experiments can be both real and simulated. The system is designed to take into account the limitations of mobile devices: it does not require much user input and the users do not have to read a lot of text. It is also easy to learn how to use the software through a common user interface applicable over a wide range of real experiments and simulations (see Fig. 4). Moreover, the system optimizes the data with respect to the client device properties such as screen size and sends the data to the client in a bandwidth-saving manner.

Complex scientific experiments can run for hours or days. Supervisors of the experiments may only need to take action or monitor the ongoing experiment every once in a while. Our system aids students and researchers in using their time efficiently. They are not required to stay in the lab during the entire experiment, but are still able to monitor and control the experiments. We see several advantages such as:

- Monitoring an experiment from anywhere, at any time. Researchers and students might not always have access to a desktop computer (they may leave the lab or even the campus), and under certain circumstances, it may be impractical to carry a laptop. PDAs and mobile phones, however, are usually available all the time and are always ready to use. This makes it possible to observe an experiment while users are on the move.
- Steering of remote experiments. When errors occur, users are not required to go back to the lab to solve the problem. They can use their mobile device to restart experiments, adjust the experiment parameters, and so on. This is especially useful for long-time experiments.
- Receiving instant notification from collaborators, tutors, and experts. Simple notifications can be sent by pressing a single button. Measurements can be shared with other users instantly and regardless of their location, given that they have the client application on their mobile phone.
- Self-tests and automated notification. After setting up an experiment, a user can focus on other tasks and only go back to the experiment when notified via email or SMS

that she needs to take action. Human supervision is only necessary in case of malfunction, extraordinary events or termination of the experiment. The mobile client and a notification system allow students and researchers to supervise their experiment in the most time-efficient manner.

Figure 4. NanoMobile remote steering interface on a PDA. Left: View of an observed surface with atomic resolution. Right: List of gauges to view and adjust experiment parameters.

B. Educational approach

We illustrate the educational approach of NanoMobile by describing several learning scenarios in which NanoMobile is used.

Scenario 1: Virtual experiments and mobile learning

We have stated that learning through virtual experiments is an important component of the Nanoscience curriculum. Many experiments take a long time to complete. If students are required to remain at the location where they have started the experiment, or if they only are able to access the running experiment when they are in proximity of suitable computing infrastructure, the motivation for persisting efforts in the virtual experiment suffers. If they are able to use their mobile devices to monitor experiment progress and take action when necessary, they can integrate the experiment supervision in whatever other activities they pursue during the day.

Scenario 2: Ad-hoc collaboration

NanoMobile allows ad-hoc collaboration in the context of an experiment. If a student conducting an experiment is unable to resolve an issue, she will typically require assistance from either a fellow student or from a tutor. NanoMobile enables instantaneous notification of other students or tutors via the clicking of a single button. The user notified can view the parameters and problems of the ongoing experiment on her mobile device and is able to directly resolve the issue. The ad-hoc nature of collaboration in NanoMobile makes involving fellow students and tutors in one's own learning effort much simpler and convenient.

C. Technical aspects

NanoMobile consists of client software for the PDA and server software that acts as a middleware between the client devices and the actual experiment.

The mobile client has four important modules. The monitoring module is responsible for visualizing measurement data. The command module allows the user to actually steer the remote experiment. The user can start, stop and pause the experiment as well as change the current experiment parameters. The notification module is a communication service that enables the user to inform other mobile users about the experiment. Several types of messages such as alert, special interest, or help requests can be sent to a specified list of receivers. Finally, the viewer module is used to toggle between views of attached web cameras. This module is of crucial importance, since it allows users to not only monitor a set of predefined parameters and conditions, but to actually see the ongoing experiment from various angles.

The four modules communicate with the experiment via the middleware layer. The middleware layer is implemented as a Java web application using the Java 2 Enterprise Edition (J2EE). The client and the middleware exchange messages via HTTP.

Clients request visualized measurement data via HTTP GET requests. To save expensive GPRS bandwidth, only the updated parts of the measurement data are sent. The measurement data in scanning type experiments (e.g.: scanning probe microscope experiments) is generated line by line. On stable network connections, there are many requests per unit time for very thin slices. This yields very good real-time visualization of the experiment. When the GPRS signal strength is bad, the delay between transmissions can be a few seconds. If the delay time is longer than the scan duration for the complete image (around 60 s), the client gets the image in one chunk.

A request contains several parameters such as start and stop line of the current slice, scaling factor and device type. Parameters are sent to the middleware as URL-encoded name-value pairs. Control commands for the experiment server are sent in the same way. The measurement data is received at the mobile client as an HTTP response. Image parameters and command responses from the experiment are included in the HTTP response as custom headers (e.g.: startline: 12, scanrange: 50). According to the image parameters (startline and stopline), the image slice is superposed to the image shown to the user. The user gets the impression of watching an evolving scan image as if she sat directly in front of the microscope.

The experiment continuously streams out raw measurement data on many channels. This image data flow can be as high as a few hundred kbps depending on the scan speed and the number of channels. As middleware and experiment server are usually located in the same LAN, only the transfer speed of the LAN connection sets a limit to the raw data stream.

To reduce the workload on the mobile client, only the data that the user wants to see at a given time is sent. To be able to react immediately to the demands of the user, it has to keep an up-to-date set of the uncompressed raw data matrix. The middleware component includes an image generator that creates raster images from the raw data (scaled to the client screen size). This ensures that measurement data is sent to the wireless client in a bandwidth- and transmission-cost-saving manner.

The J2EE technology provides scalability for the middleware layer to support many simultaneous clients. It also enables rapid implementation of an additional web application to control the experiment server. Web browsers of all computer platforms can display the HTML view of the servlet.

D. Lessons learned

Conducting experiments (be they virtual or real, in an educational or scientific context) has two important aspects: the required efforts can be sparsely distributed over time, and synchronous and asynchronous collaboration is often necessary. Obtaining information from and steering experiments not in situ, but from remote locations, is an important progress. By providing such remote control for ultra-mobile platforms, i.e. platforms that are always available to the user such as PDAs and smart phones, we achieve maximum efficiency in organizing experiment supervision and collaboration.

VI. Conclusion and Outlook

Our showcase demonstrates how the Nanoscience curriculum can be enriched through the use of advanced learning technologies. The simulation of experiments makes them much more accessible to students. Simulated experiments are much cheaper, can be repeated arbitrarily and require less prior knowledge than real experiments. Students can train under conditions that they will later experience in their real lab work.

Accessibility not only on a technical, but also on a conceptual level is facilitated through the use of advanced visualization and interaction techniques. Nano3D allows students and researchers to explore their measurements in three-dimensional representation. The high-end nature of the visualization makes Nano3D a valuable tool not only in exploration and interpretation, but also in publishing about the experiments. The Nanojoystick is focused more on prospective students and aims at providing a playful and intuitive access to the world of nanostructures. Experience from public events shows that the Nanojoystick is well suited for providing an interactive entry point for children in small groups. Finally, NanoMobile is a valuable tool for overcoming the restrictions that long-time experiments impose on collaboration and freedom of the supervisor. Through NanoMobile, students and scientists can monitor and control experiments collaboratively and completely independent of their location.

In a broader perspective, the most important feature of the Nano-World suite is virtualization. First, real-world experiments are virtualized in simulations. Second, the presence of users is virtualized through networked communication technologies. The result of the virtualization is a much broader availability of experimental and collaborative tools. An interesting challenge is the bringing together of the developed approaches in a single virtual space. This is the goal of the LiLa (Library of Labs) project [20].

VII. Acknowledgments

Nano-World has been developed within the Swiss Virtual Campus Inititiative. The authors would like to thank Robert Frank and Prof. Dr. Ernst Meyer.

Generalization of an Active Electronic Notebook for Teaching Multiple Programming Languages

Mohsen Torabzadeh-Tari, Peter Fritzson, Adrian Pop, Martin Sjölund
PELAB – Programming Environment Lab, Dept. Computer Science
Linköping University, SE-581 83 Linköping, Sweden
{mohto, petfr, adrpo, marsj}@ida.se

Abstract **— In this paper we present a generalization of the active electronic notebook, OMNotebook, for handling multiple programming languages for educational purposes. OMNotebook can be an alternative or complementary tool to the traditional teaching method with lecturing and reading textbooks. Experience shows that using such an electronic book will lead to more engagement from the students. OMNotebook can contain technical computations and text, as well as graphics. Hence it is a suitable tool for teaching, experimentation, simulation, scripting, model documentation, storage, etc.**

OMNotebook is part of the open source platform OpenModelica. It is already used for the course material DrModelica in teaching the Modelica language but can easily be adapted to other programming languages which is also shown in this paper. The notebook can also be adapted to other areas, such as physics, chemistry, biology, biomechanics etc., where phenomena can be illustrated by dynamic simulations within the notebook.

The idea behind this paper is to show that by using a standardized interface the notebook can be extended to any computer language, i.e., being language independent. This is shown in the form of an implementation and adaptation of the notebook to support the Scheme language.

Keywords- OpenModelica, Scheme, DrModelica, Eletronic Notebook

I. INTRODUCTION

In this paper we introduce a research project for generalizing the modern object-oriented equation-based modeling and simulation environment OpenModelica towards also supporting other programming languages than Modelica, [1]. In this way the active student has a common platform for learning programming languages as well as given the opportunity to experiment with physical phenomena by using interactive electronic book, OMNotebook, [2].

This kind of interactive courses based on electronic books allows experimentation and dynamic simulation as well as execution of computer programs. The OMNotebook can contain program code, text, links, pictures, video, virtual and scientific visualizations. OMNotebook is an active electronic book that makes it is possible to integrating applied sciences in physics, human biology [3], mathematics and computer science.

This work was supported by the EU project Lila and by the ITEA2 OPENPROD project.

II. TECHNOLOGY

A. The Modelica Language

In the late 90th people from both the academic community and industry joined forces to define and standardize a multi-domain modeling language, Modelica, [1]. The object-oriented approach for modeling the dynamic behavior of engineering systems was adopted for Modelica, partly based of earlier prototype languages by the designers. In September 1997, version 1.0 of the Modelica Languagewas published on the web. Since then, the Modelica design group has had many meetings, resulting in new versions of the Modelica language.

The freely available Modelica Standard Library (MSL) contains many model components and examples from different application domains. Such components can be easily adopted by the modeler and integrated in his/her own application model. The inherent acasual capabilities built into the language lets the user express relationship between variables which gives more reusability compared to software based on assignment statements and related constructs as in conventional programming languages. A general type system including a general class construct unifies object-orientation, multiple inheritance, components/connectors, and templates/generics.

Furthermore, models in Modelica are described mathematically by Hybrid Differential, Algebraic Equations Equations (HDAEs). The hybrid is referring to the fact that both continuous-time and discrete-time models are handled, [4].

B. The OpenModelica Platform

In 2002 an initiative was taken by PELAB, [2], to develop an open source platform for the Modelica language based on more than 20 years of in-house experience of research in compiler construction. This effort was gradually expanded, and in 2007 an international consortium was formed to support the open source effort. Previously, the only option for the Modelica community, i.e., Modelica users, for simulating Modelica models was to use commercial tools.

The main goal for this open source platform is to create a complete environment for modeling, compiling and simulating Modelica models based on free software. Both the source code and the binaries are freely available and supported for a variety of intended uses in research, teaching as well as in industry.

The platform was originally written in a language called RML (Relational Meta Language), which is a popular formalism for compiler semantics. This formalism allows efficient compilation combined with optimized C code. This was later (2006) replaced by an extension to Modelica itself, MetaModelica, and the whole compiler was migrated to MetaModelica

The OpenModelica environment compiler translates the Modelica model into a flat Modelica code first and then into C code after a couple of more steps. Also an interactive command handler, i.e., a shell, for executing Modelica scripts and functions etc., is also provided in the environment.

The OpenModelica environment, shown in Fig. 1, consists of several interconnected subsystems. The debugger currently provides debugging of an extended algorithmic subset of Modelica, MetaModelica.

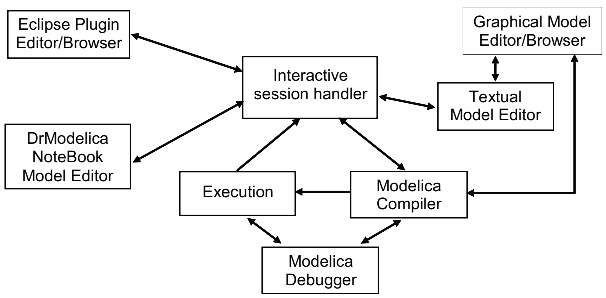

Fig. 1. Illustration of communication between different parts of the OpenModelica platform.

The interactive session handler interface is used in this paper for communication between the OMNotebook and the Scheme interpreter.

C. *OMNotebook – the Active Electronic Notebook*

The OpenModelica Notebook editor, OMNotebook, provides an active electronic notebook including an editor. The notebook is active in the sense that models inside the book can be changed and executed, it is not just a passive textbook or html page. This is one of the first open source efforts that makes it possible to create interactive books for educational purposes in general, and more specifically for teaching and learning programming. This functionality allows the usage of interactive hierarchical text documents where underlying chapters and sections can be represented and edited. OMNotebook supports functionality for Modelica model simulations, text, images and interactive linking between those. Furthermore, via the external interface, Scheme programs and other codes can be evaluated.

The notebook is currently being used for course material (DrModelica) in teaching the Modelica language and object-oriented modeling and simulation, (see Fig 2), but can easily be adapted to electronic books teaching other programming languages which is demonstrated in this paper. OMNotebook can also easily be used in other areas such as physics, biology chemistry, biomechanics etc., where phenomena can be illustrated by dynamic simulations within the book.

Traditional teaching methods with lecturing and reading a textbook are often too passive and don't engage the student. The option presented in this paper with an active notebook, however, facilitates the learning process, e.g. to run programs and exercises within the book, and mix lecturing with exercises and reading in the interactive book.

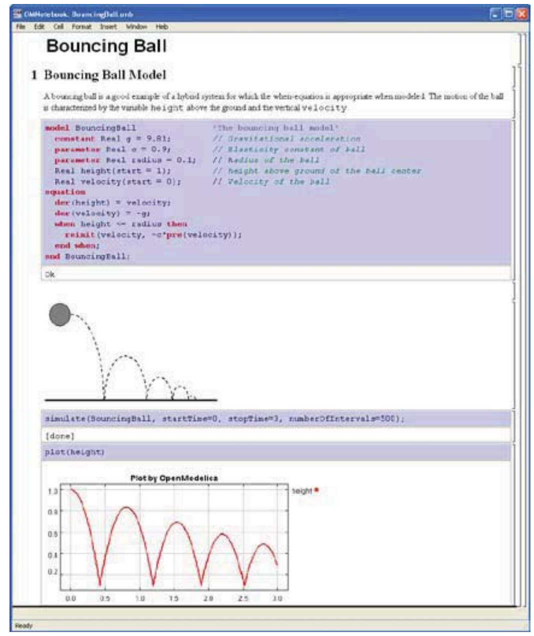

Fig. 2 Bouncing ball example with movement animation in OMNotebook

The hierarchical structure of traditional documents, e.g. books and reports, can also be applied to the notebook which means basically that the book is divided into sections, subsections, paragraphs, etc. This makes the navigation in the book sections easier.

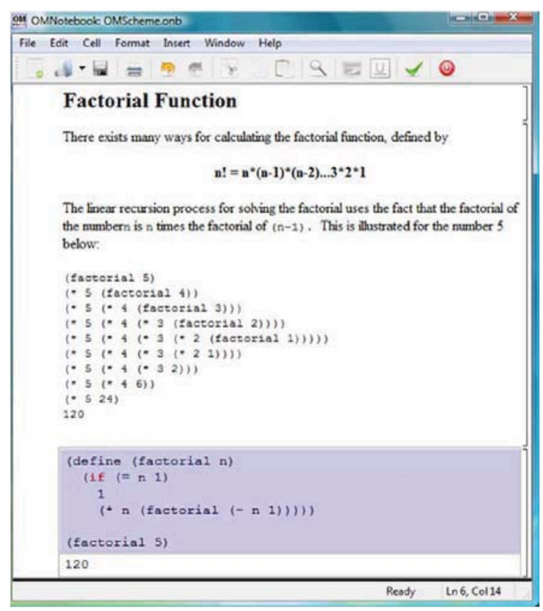

Fig. 3 Factorial function illustrated in OMScheme

In the OMScheme extension of the OpenModelica platform the interactive notebook has been further developed and adapted to the Lisp dialect, Scheme, for creating a suitable educational environment, where students don't have to focus on different tool and technology but instead focus on the information. An implementation of the factorial function using OMScheme is shown in Fig 3.

D. PLT DrScheme

The PLT Scheme is a dialect of the Scheme programming language, [5]. MzScheme is the interpreter behind the PLT Scheme for compiling syntactically valid programs into an internal bytecode representation before evaluation. The graphical user interface toolkit is named MrEd. DrScheme is an integrated development environment based on MzScheme, i.e., a MrEd application, with support for embedding third-party extensions. DrScheme provides developers with modular development tools, e.g. syntax or flow analyzers. The C API provided by this environment is embedded in OMNotebook and used in this paper for evaluating Scheme programs.

III. Conclusions

In this paper we outline the basic ideas of an active notebook for educational purpose intended for handling multiple programming languages. An early prototype is being developed for the Lisp dialect Scheme. This interactive E-book, OMNotebook, has been used successfully in both graduate and workshop courses for the Modelica language. OMScheme takes this idea further, combining an additional programming language with innovative teaching concepts.

Abstract— **Use of leading industrial technology in 'remote experiments' and 'virtual laboratories' delivers authentic experiences to engineering students. Both types of learning resources can easily be shared between universities or industrial partners, leading to dramatic reductions in the costs associated with development, construction, operation and maintenance of traditional laboratory set-ups; however, each is characterised by inherent advantages and disadvantages. We compare and contrast remote experiments and virtual labs, using two case studies: 'Cambridge Weblab', a remote experiment built by the Computational Modeling (CoMo) Group at the University of Cambridge and 'SRM web-suite', a virtual lab developed by CMCL innovations. The Cambridge Weblab remote experiment uses a Siemens SIMATIC PS7 industrial interface to control a chemical reactor, yielding authentic experiences of industrial practices for students. A variety of pedagogical approaches employed by institutions using the Weblab are also discussed in this paper. The SRM web-suite uses an advanced engine design tool that simulates fuels, combustion and emissions in conventional and advanced internal combustion engines. The detailed simulations have been precisely tailored for training and educational settings. The web-suite labs provide students and engineering professionals with experience using the latest industry-standard technology, whilst supporting a wide range of educational goals e.g. undergraduate courses in combustion engines or chemical reaction engineering and advanced courses in futuristic fuels or powertrain engineering. We also assess the potential impact of these learning resources within the pan-European Library of Labs (LiLa) framework. Ultimately, we demonstrate that remote experiments and virtual laboratories are complementary, that there is significant potential for future integration of the two technologies, and that both can benefit from the latest industrial technologies.**

Keywords- Library of Labs (LiLa); remote experiments; virtual laboratories; chemical process control; advanced combustion engines

I. INTRODUCTION

A. What are e-labs?

This article compares three types of laboratory setups: conventional laboratories, remote experiments, and virtual laboratories. In a conventional laboratory, students are physically present in the laboratory, interacting directly with laboratory equipment and communicating face-to-face with classmates and instructors. In contrast, a remote experiment is performed on physical equipment housed in a laboratory, but is controlled by the student remotely, typically communicating with the laboratory equipment across the Internet. The software interface providing the controls of the remote experiment may be custom built [1, 2] or designed using a number of commercially available solutions [3, 4, 5, 6, 7]. Finally, virtual laboratories simulate the physical phenomena of a laboratory setup with a software on a computer and do not make use of any laboratory equipment. Students perform virtual experiments by interacting with the control interface of the software and observing the simulated results. Collectively, remote experiments and virtual laboratories will be referred to as e-labs throughout this article. The e-labs concept has also been discussed at several conferences dedicated to the subject, such as REV and ASEE/IEEE frontiers in education.

B. The Need for e-labs

E-labs are a well established resource for learning and are now becoming widely adopted [1]. The University of Cambridge WebLabs [8], CMCL SRM web-suite, MIT iLabs [9], TU Berlin Remote Farm [10], University of Stuttgart VideoEasel [10], and University of Basel NanoWorld [11] are examples of the e-lab learning materials presently available. There are many factors motivating the rise of e-labs including concerns over the cost, space, and staff requirements for conventional labs, as well as health and safety risks. Using e-labs can enrich curricula by providing students with experiences that would be too hazardous or prohibitively expensive in a conventional setup. Furthermore, simulations can use unique visualizations to provide insight not available in conventional labs; this is particularly the case for phenomena that are not directly observable. For example, the "Falling Coil" simulation at MIT [12] allows students to see changing magnetic fields and current as a ring falls towards a magnet, thereby illustrating Faraday's and Lenz's laws.

C. E-labs vs Conventional Labs

Below we present a comparison of e-labs and conventional labs by examining a remote experiment case-study and a virtual laboratory case-study. We propose that conventional labs, remote experiments, and virtual laboratories can all be important assets in curricula; viewing these methodologies as complementary, we identify suitable applications of each. Previous research has demonstrated that e-labs can be equally effective as conventional labs, in terms of understanding of course material, and that students do not express a strong preference for conventional labs, sometimes preferring e-labs as scheduling and time constraints can be alleviated [13].

Some key issues in the debate about e-labs versus conventional labs are: collaboration, analysis of experimental data, learning by trial-and-error, guidance from instructors, familiarity with laboratory equipment, and authenticity of experience [13]. The resolution of these questions is a matter of implementation, with a few exceptions. For example, both e- and conventional-labs can support collaboration, with e-labs using text, voice, and even video to link students. The same tools allow instructors to provide guidance and assistance during e-labs. Students gain experience working with experimental data through both remote experiments and conventional laboratories, but not with virtual labs. Whether learning by trial-and-error is supported can vary across all three types of lab. In conventional labs, time, costs, and safety concerns are all constraints; in e-labs the parameterization of the interface may be a limiting factor.

In some subject areas, only conventional labs can provide "genuine" experience with laboratory equipment and practice, so some conventional laboratories must remain in the curriculum. This is particularly the case for labs that involve a kinesthetic element and require the development of specific motor skills to ensure success; where this is not the case, a high quality interface, simulating the controls on laboratory equipment, can do a great deal to enhance a student's feeling of immersion in the lab and familiarity with laboratory equipment [2].

Finally, the authenticity of a lab is significant in preparing students for industry, motivating theoretical learning, and promoting student engagement. All three types of labs can provide an authentic experience as illustrated by the case studies below. The SRM web-suite case study demonstrates that a virtual laboratory can provide an authentic experience, an observation that, to our knowledge, has not been demonstrated previously.

II. THE CAMBRIDGE WEBLABS

A. Background

The Cambridge WebLabs were set up using funding and support from the 'Cambridge-MIT Institute' initiative which was carried out between 2000 and 2006. During the development of the 'iLabs' network [9] between 1999 and 2006, the Massachusetts Institute of Technology (MIT) obtained significant experience in using remote experiments for practical teaching of Engineering and Physical Sciences subjects. The Weblabs project itself started in 2003 after a Cambridge student who had visited MIT suggested that the Department of Chemical Engineering at Cambridge should develop remote experiments of its own. Within two years, Cambridge had developed an advanced remotely operated apparatus for teaching of Chemical Engineering and was exchanging usage of its new facility for usage of similar apparatus at MIT [14]. The apparatus has since been utilised successfully by a number of institutions within the UK.

B. Laboratory Setup

The Cambridge WebLabs teaching rig (Fig. 1) consists of a stirred reaction vessel with three pumped feed lines and an adjustable outlet overflow. The feed pumps and stirrer are controlled by a SIMATIC™ PCS7 interface (Fig. 2), which was donated together with the control software and hardware by Siemens Automation and Drives. The Siemens software and hardware is extensively used within industry and was chosen to help deliver an authentic educational experience.

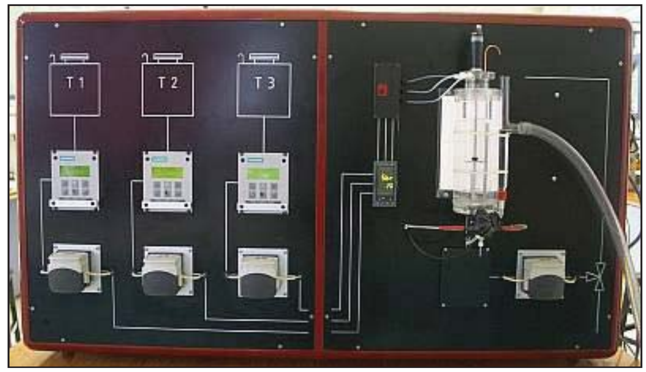

Figure 1. Hardware used in the Cambridge WebLabs

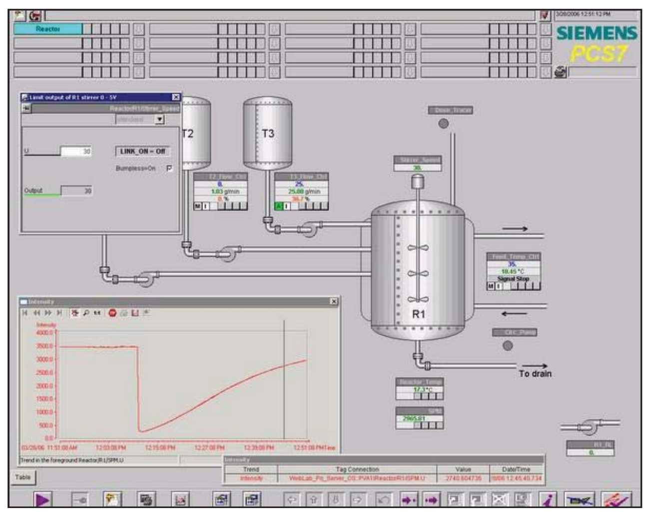

Figure 2. The SIMATIC™ PCS7 interface

So far, two WebLabs experiments have been developed: one on chemical reaction engineering and one on process control. The reaction WebLab was developed by Cambridge alone, but the control WebLab was developed as a result of collaboration with the Chemical Engineering department at Imperial College, London. Both experiments make use of the slow equilibrium reaction between aqueous phenolphthalein and hydroxide ions which is observed at high pH and results in increased or reduced intensity of the characteristic pink color of the solution:

$$\underset{\text{(pink)}}{PHEN^{2-} + OH^-} \underset{r_2}{\overset{r_1}{\rightleftharpoons}} \underset{\text{(colorless)}}{PHENOH^{3-}}$$

The intensity of the color of the solution is monitored by a photospectrometer and the readings can either be used diagnostically in the reaction experiment or for control purposes in the control experiment.

C. *Usage*

Since 2006, the WebLabs have been an assessed part of the Chemical Engineering course at Cambridge. In the case of the reaction engineering WebLab, students are required to complete a series of challenging theoretical exercises before they are permitted to use the apparatus. The exercises are designed to provide direction and focus to the experiment so that students can see their predictions tested and validated by following a rigorous procedure. In the process control WebLab, the preparation exercises are much simpler and students are given the freedom to try out a wide range of control parameters. The two experiments therefore use two very different pedagogical models.

So far, the WebLabs have been adopted in undergraduate teaching at the UK universities of Birmingham, Newcastle, and Surrey and Imperial College, London. The collaborating institutions have generally made use of the same supporting material and exercises as Cambridge.

D. *Student & Institution Feedback*

Student feedback on the Cambridge WebLabs (Figs. 3-6) has generally been good. The data in Figs. 3 & 4 use the Likert scale (1 = strongly disagree, 7 = strongly agree) and were collected for the class of 2008/2009. Most students responded that the WebLabs met their educational learning objectives and that they were a beneficial learning experience. However, the WebLabs proved less successful in capturing students' imaginations, as most users did not find either exercise significantly more (or less) enjoyable than other course work at a similar level. When used at other institutions, feedback on the WebLabs was mixed; in those cases, some students struggled to complete the preparatory exercises, which are tailored specifically to the Cambridge course.

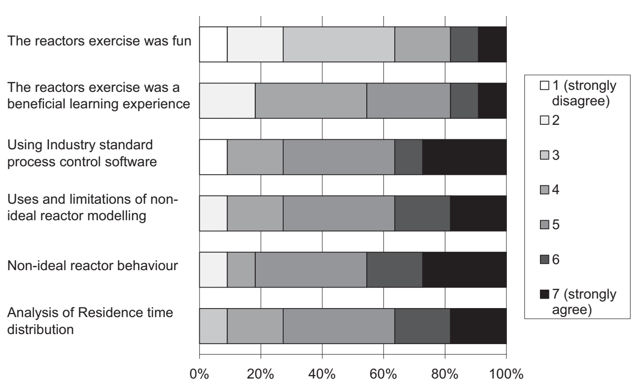

Figure 3. Feedback from the reaction engineering exercise

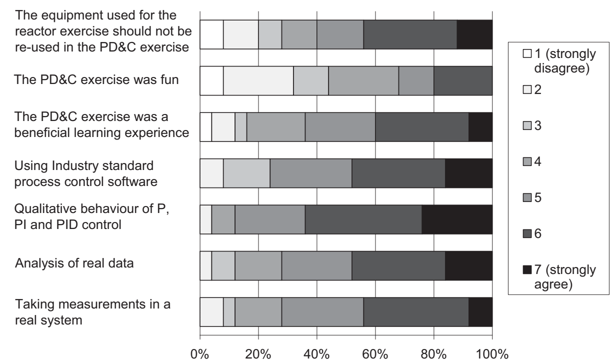

Figure 4. Feedback from the process control exercise

E. *Sustainability*

The concept of online learning through remote experiments has been demonstrated to be technically viable, but experience running the WebLabs at Cambridge has highlighted that the following problems need to be mitigated to ensure their sustainability:

- Unlike virtual laboratories, remote experiments have significant maintenance costs.
- It can be difficult for other institutions to use remote experiments as coursework exercises because it costs time and money to integrate them into their curricula.
- Universities' teaching times often coincide, meaning that only a small number of institutions can use a given remote experiment as part of their undergraduate course; the fact that only one user group can operate the experiment at a time is a significant limitation.
- Although interested in using each others' remote experiments, institutions may initially be unwilling to pay for that use, because e-labs are not yet a well established component of coursework.

Remote experiments are therefore most likely to be adopted by sharing facilities between a number of institutions that have the resources to develop them. It is also desirable to build experiments which have value for industrial research or testing, as rental of facilities to companies during universities' holiday periods could play a major role in ensuring sustainability.

III. The SRM Web-Suite Virtual Laboratories

A. *CMCL Virtual Laboratory Methodology*

The SRM web-suite is a series of virtual laboratories, developed by CMCL innovations, that focuses on combustion in engines, enabling insight into state-of-the-art combustion processes and futuristic fuels. The key innovation of the CMCL methodology for virtual laboratories is its basis of virtual labs for education using industry-standard research and development (R&D) tools. The simulations in the SRM web-suite use the same technology as CMCL's SRM suite [15], which has been adopted by R&D teams at engine manufacturers in order to improve engine performance and emissions and streamline the development process by reducing the number of costly experiments performed.

The SRM web-suite represents a new development in e-learning tools by being simulation-based yet providing students with an authentic experience. Simulations for virtual laboratories are usually developed strictly as educational tools, simplifying many details to ease the implementation or emulating simple experiments that students could have carried out in a conventional lab. Thus, the authenticity of a student's experience is sometimes diminished through the use of a virtual laboratory. In contrast, the SRM web-suite offers students experience with real industrial tools used in combustion, emissions, and engine development research. Moreover, the SRM web-suite provides students with the opportunity to perform experiments that would be otherwise inaccessible due to the safety, cost, and time constraints associated with an equivalent conventional lab. For instance, studying the characteristics of an unstable engine mode such as "knocking" in a conventional engine lab set up can be potentially hazardous because of the possibility of severe engine damage. The same phenomenon can be studied in a cost-effective and safe manner using the SRM web-suite.

B. *Technical Architecture of the SRM web-suite*

The architecture of the SRM web-suite is based on a client-server model in which simulations run on a remote server, either one of CMCL's servers or a licensed server deployed at an academic institution. Students then interact with a lightweight web-interface implemented as a Rich Internet Application (RIA). The only requirement for a student's system is a Javascript enabled web-browser, allowing any platform to be used, including mobile devices. This flexibility and convenience may encourage students to make more use of any optional laboratory components in a course. For example, enthusiastic students could entertain and educate themselves by carrying out SRM web-suite labs using their smartphones, whilst waiting for a bus. The client server-architecture and lightweight RIA interface allow new customized interfaces to be deployed easily to support new educational modules, while employing the same underlying simulation technology. This means that a larger portion of development time can be spent creating valuable supporting materials, rather than being consumed by technical developments.

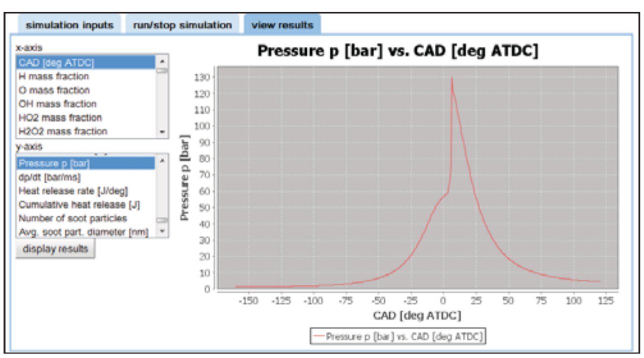

Figure 5. Screenshot showing simulation data from a web-suite laboratory

C. *Pedagogical Methods*

The methodology and architecture described in the previous section provide the SRM web-suite virtual laboratories with a flexible structure that can accommodate a range of pedagogical models and educational goals. The same simulation technology, provided with different user interfaces, can be used to teach introductory undergraduate courses on combustion engines and advanced seminars on future fuels.

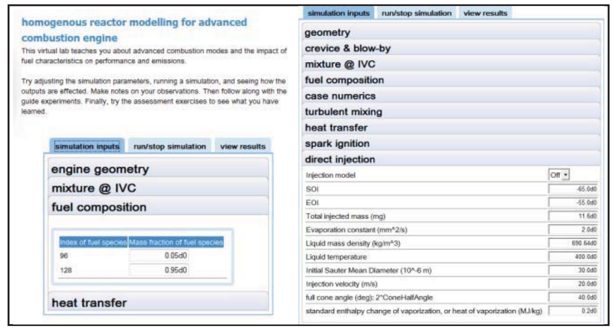

Figure 6. Web-suite interfaces for an introductory lab (left) and an advanced lab (right)

One key feature of the SRM web-suite virtual laboratories is that students can learn by trial-and-error, using the "productive failure" pedagogical method. Recent research has demonstrated that students retain a significantly higher portion of content using this methodology [16,17,18,19,20] in which they are first posed with an undirected task that they *attempt* to solve through experimentation and observation, followed by periods of increasingly guided learning during which their success rate increases. The web-suite labs enable a productive failures methodology to be used because there is no limitation on the number of times a student can run the simulation and no significant growth in cost with the increasing number of runs.

In the case of a conventional or remote experiment, there is often a cost (in materials and/or manpower) associated with each time the experiment is run; this requires that limits be placed on the extent to which trial-and-error learning can be employed. For example, each run of an experiment on the Cambridge WebLabs reactor uses chemical supplies which must be purchased and maintained by laboratory staff. Scheduling also constrains the use of trial-and-error learning in conventional and remote experiments, because access to laboratory equipment, whether direct or remote, must be shared between students. This is not the case with the SRM web-suite virtual labs, since students can perform the experiment at their convenience, repeating it as many times as they need, and any number of students can be performing the experiment simultaneously (up to the limitations of the server running the simulations). The ability to repeat experiments or perform them at a slower pace may also benefit students with different learning styles or rates.

In addition to use in a productive-failure framework, the SRM web-suite virtual laboratories are also ideally suited to more traditional guided methodology, or for demonstrative purposes as a part of lectures. The client interface can be augmented with guided interactive support at various levels, to provide additional information or to take the student through an experiment step-by-step. The design of the client interfaces for the web-suite labs makes it easy to embed them into larger modules and to incorporate a range of supporting materials such as videos, diagrams, and assessment exercises.

Finally, the SRM web-suite can be used for collaborative student work; however, collaboration tools are not currently a core feature in the virtual laboratories. Collaboration features are being included as part of the European Commission's Libray of Labs (LiLa) portal through which the SRM web-suite can be accessed, as described in Section IV.

IV. Remote Experiments or Virtual Laboratories – or Both?

A. Pedagogy

The pedagogy which is usually associated with remote experiments is very different from that associated with virtual laboratories. In remote experiments, students are usually required to follow strict procedures in order to complete an experiment safely and on time. This promotes strong organizational skills, can be used to enable team working skills, and helps to develop students' intuitive understanding of the physical world through interaction with the equipment. Virtual experiments have few constraints with regard to time and safety, and are well suited to an exploratory style of learning, which teaches fundamental concepts and improves theoretical understanding. Nevertheless, more advanced virtual laboratories, such as the SRM web-suite, can offer a good compromise between remote experiments and historical virtual laboratories. They require significant computing power, so run times are not insignificant, but are highly realistic in terms of the data generated and their relevance to industry. This means that they have many pedagogical similarities with remote experiments or real laboratories.

B. User Experience

It has been argued by some [13] that for many applications, remote experiments can provide learning outcomes which are of equivalent value to conventional laboratories. Others [2] broadly agree with this conclusion, but would insist that a balanced approach is still valuable as simple hands-on experiments can allow better collaboration and interaction with the equipment. They would nevertheless advocate remote operation if there are compelling pragmatic reasons (see section IV-C).

Student feedback from the Cambridge WebLabs suggests that the typical user is indifferent to remote experiments in terms of their enjoyment, although they are usually satisfied with the learning outcomes that they deliver; the findings of [13] would support this conclusion. It must also be stressed that the usage of an industrial interface was generally appreciated by the users of the Cambridge WebLabs and to some extent mitigated the students' negative views.

According to an old view which is perhaps becoming outdated, virtual laboratories are much easier to package in an attractive and exciting user interface which promotes user engagement, however their lack of relevance to the physical or commercial world limits their value as a learning tool for higher education. The next generation of virtual laboratories (e.g. the SRM web-suite) is designed to address these weaknesses by aiming for a higher overall level of authenticity.

C. Technical requirements & Sustainability

Virtual laboratories offer a major advantage over remote experiments in that their design costs are lower and that their maintenance costs are almost non-existent. By contrast remote experiments can be relatively expensive to set up, even when resources are shared between institutions, and maintenance costs are significant and ongoing. Furthermore, remote experiments are much more likely to experience 'downtime' than virtual laboratories. Virtual laboratories are therefore inherently more sustainable than remote experiments.

In the case of experiments which involve sophisticated equipment and are a standard part of a taught course, there is are strong pragmatic reasons why universities may wish to pool resources by using remote operation. As well as reducing costs, this reduces the risk that equipment will be left in a poor state of repair, thus allowing students to focus on the scientific aspects of their experimental work.

D. Usage & Integration into Curricula

It has been suggested [10] that there are significant benefits associated with combining remote experiments and virtual laboratories. By comparing real experimental and virtual experimental results, it is possible for students to gauge the strengths and weaknesses of different modeling techniques, thus creating a very powerful teaching tool. Design of these combined experiments is time-consuming and expensive, but the potential for sharing resources between institutions may well make this approach viable if there is sufficient interest. Although the Cambridge WebLabs have not yet reached this state of development, the combination of in-depth theoretical pre-preparation and practical experimentation is a step closer to the goal of combining remote and virtual experiments.

V. Future Work

A. The LiLa Project

The Library of Labs (LiLa) project is a pan-European initiative to develop a network of e-labs and supporting materials aimed at undergraduate and graduate students; the LiLa project is co-funded by the European Commission in the context of the eContentplus programme. Among the scheduled developments in the LiLa project is the LiLa web-portal, the entry point for access to the e-labs and other content in the LiLa network. The LiLa portal will provide supporting infrastructure for e-labs such as search and retrieval functions to find appropriate e-labs and related content and a booking and access control system to share and protect the equipment in remote experiments. Pedagogical support provided by the LiLa portal includes collaboration tools and a tutoring system to guide students in their studies and suggest related. The collaborative aspect of the portal will enable group work and interaction between students, but will also increase student interest by taking advantage of the social habits and technologies of the Web 2.0 generation. LiLa content will be delivered as SCORM packages, allowing integration into local learning management systems (LMS).

B. *Projected impact of LiLa on WebLabs and SRM web-suite*

Participation in the LiLa network will benefit developers of e-labs in a number of respects. Firstly, the infrastructure and pedagogical functionality in the LiLa portal can be used to enhance e-labs. For example, one of the difficulties that Cambridge faced, when its Weblabs were used at other institutions, was a lack of appropriate supporting materials; the materials provided were not necessarily appropriate for use at other institutions. Through the LiLa network, lecturers and institutions can develop and share supporting materials for e-labs, reducing the initial cost of integrating an e-lab and ensuring that a range of supporting materials are available. Looking at the CMCL case study, users of the SRM web-suite labs will benefit from the collaboration tools, additional resources, and community support offered by the LiLa network. The development cost of these tools for a single e-lab would in many cases prove prohibitively expensive, but becomes viable when shared between many users.

In addition to the resources provided by the LiLa network, its user-base may also be beneficial for e-lab providers. One of the major difficulties with e-labs is balancing their high costs in the case of under-utilization. By opening up an e-lab to a wider audience, its utilization can be drastically improved; greater usage lowers the per-user running costs, which can potentially be distributed over a number of institutions using the e-lab.

VI. Conclusions

A comparison between a remote experiment, ‘Cambridge Weblab’ and a virtual lab, ‘SRM web-suite’ was presented in this paper.

It is almost certain that virtual laboratories will continue to play a major role in the teaching of engineering and physical sciences in the future, due to their convenience and low costs. Educational applications of more sophisticated virtual laboratory technology, such as the SRM web-suite will ensure that students are well prepared for industry, which is making increasing use of simulations to reduce the need for expensive and time-consuming experimental programmes. Nevertheless, this approach also entails that the students need to know the limitations of different modeling and simulation techniques if they are to successfully apply them.

Remote experiments can provide authentic laboratory experiences, essential for student’s educational development. Many universities will struggle to find the resources to provide more than a small number of conventional experiments, so remote operation of others’ facilities is a potential solution to this problem.

Initiatives such as the LiLa project are essential in order to provide a systematic framework for enabling a collaborative usage of remote experiments and virtual laboratories to meet the educational needs of today’s students.

Acknowledgment

We acknowledge the support of Siemens Automation and Drives in the development of the Cambridge Weblabs, the provision of facilities by the University of Cambridge and the financial support of the EU eContentplus program, as provided through the LiLa consortium.

***Abstract*—Experiments play a vital role in undergraduate engineering education: They allow students to learn the foundations of engineering in practical hands-on courses. However, lack of funding and increasing costs for equipment makes it harder and harder to supply a complete pool of experiments for large student classes. The EU funded "Library of Labs" project aims to counterbalance this development by creating a EU wide network of remotely controlled experiments and virtual laboratories. Remote experiments are here real experiments remotely controlled over a network, virtual laboratories simulation environments using the component metaphor of a real laboratories.**

In this paper, we introduce such a virtual laboratory developed at the University of Stuttgart; the aim here is to help students, here participating in the undergraduate physics course for engineers, understanding abstract phenomena by visualizing the underlying mathematics. We demonstrate this in a particular use-case, the wave equation and phenomena related to it, as they are discussed in undergraduate physics, and show how to implement this as a simulation in the virtual laboratory.

In cooperation with the physics department a deployment plan for this experiment and related experiments has been created for the lecture "Physics for Engineering" which shall also be presented and discussed.

I. Introduction

Recently, Germany's university system has been changed from the Diploma model to the two-tier Bachelor/Master program: In this study system, following the US university system, students first study a six-semester Bachelor course granting them already access to fundamental skills in their studies and early job opportunities. A successful Bachelor study is the requirement to apply for the second, extended Master studies. Due to this change, many foundational courses in the Bachelor program had to be streamlined and shortened to leave room for courses that would have been taught later in the old Diploma system. As a consequence of this streamlining, courses as fundamental as elementary experimental physics for engineers have been cut down from two to only one semester, and no time is left in these courses to provide students access to practical laboratory hands-on courses in the first semester. The first time students do have contact to real labs is delayed to the second semester where admission to the labs is granted by passing the exams in the first semester.

Unfortunately, this is a very traditional way of delivering physical content: Theoretical background is taught first, followed by practical hands-on courses allowing students to get in touch with practical aspects; the gap between theory and practical applications is here rather extreme, lots of background is simply forgotten in six month. As described in [2] this is so far unfortunate as typical students in a traditionally taught course are learning mechanically, memorizing facts and recipes for problem solving, not gaining a true understanding. Wieman and Perkins note furthermore that most people ("novices") see physics more as isolated pieces of informations handed down by some authority and unrelated to the real world [1].

In reaction to these deficiencies, Schauer introduced an alternative strategy based on integrated e-Learning, defined as "interactive strategy of teaching and learning based on the observation of the real world phenomena by the real e-experiment and e-simulations", see [2]. The procedure here is first to observe the real world phenomena, search for proper information, collect and evaluate data, then present and discuss data and results. Only then comes the explanation and the mathematical formulation of generalized laws and their consequences. The advantage of this procedure is that students have to take an active part in the teaching process. Effective tools for observing the real world are remote experiments and simulations. For studies about the effectiveness of simulations, see [1].

Building a pool of experiments sufficient to cover all of undergraduate physics is of course not an easy concern either, and a rather overwhelming task for a single university. To this end, the University of Stuttgart and ten other European institutions formed the "Library of Labs" network [3], supported by the eContent*plus* programme of the European community. The aim of this network is to setup a common infrastructure to mutually grant access to and share lab experiments and simulations available at the partners, and thus gain access to a sufficiently large pool while sharing the costs and the infrastructure.

II. On Remote Experiments and Virtual Laboratories

Within LiLa, we roughly distinguish between two types of interactive content: So called "Remote Experiments" are remotely controlled physical laboratories, hosted and maintained by one of the participating institutions. Being a scarce resource, remote experiments must be reserved and booked, and only a single student or student group can access them at a time. The University of Stuttgart does currently not provide any remote experiments, but depends on the contributions of parters, for example on the WebLab of the University of Cambridge, or the remote experiments installed at the Institute of Technology in Berlin.

“Virtual Laboratories”, however, are computer simulations that follow the metaphor of a physical lab and form a framework for manifold simulations. An experiment consists here of one or many components grouped together to form a complete simulation of a physical or mathematical phenomenon. The behavior of the simulation again is measured by one or several meters, where both — the experiment and the meters — are computer algorithms. These algorithms can be either taken from a pool of already prepared experiments, or can also be modified or created by the students as required. Examples for such virtual laboratories are the “Modelica” system developed by our partner, the University of Linköping in Sweden, capable to simulate any coupled system describable by differential equations, the Easy Java Simulations (EJS) project [9], [10], or the VideoEasel system maintained and developed at the University of Stuttgart; the latter laboratory is specialized for simulating many-body particle systems, systems that are described by simple microscopic rules from which complex and often surprising macroscopic behavior emerges. A typical example for such emerging behaviour is that of “phase transitions”[4], the sudden change of a physical quantity under the change of a parameter of the system, as for example boiling of water at $100°C$. Experiments on such phenomena using virtual laboratories have been described in the past by one of the authors[5].

The common aspect of Virtual Laboratories is that, instead of only presenting a fixed, pre-programmed simulation, they reveal parts of the simulation engine and allow their users to *program* or *model* the dynamics to be simulated, and not just interact with the simulation as an electronic model of a physical experiment. Virtual Laboratories are, hence, a considerably flexible environment *for* simulations than just a specific simulation. While the underlying principle of EJS or Modelica is to describe physical processes by differential equations, VideoEasel only considers very simple time- and space discrete automata. Besides this simplicity, the large number of such simple systems coupled together generates interesting complexity and phenomena worth studying.

Even though the focus of the VideoEasel system is that of many body systems and how complex macroscopic behavior emerges from simple microscopic rules, we shall here describe a group of experiments not based on statistical mechanics, but one of the fundamental equations of physics, the wave equation. It describes spreading of all types of waves, let it be sound, water waves; phenomena like reflection and refraction are described by the same set of equations. Maxwell's equation of classical electrodynamics can be simplified to wave equations of the electric and magnetic field under certain conditions[6], and the Schrödinger equation of quantum mechanics also behaves like a wave equation with a specific diffusion relation. The latter has important consequences in physics, namely that phenomena like interference patterns known from light are also observable for rays of material particles. It is one of the fundamental experiments of quantum physics to measure this pattern which is not explainable by the model of classical particles otherwise.

These experiments, their simulation, and many other related, will be described in the section IV below.

III. Mathematical Background

In this chapter, the elementary mathematical background on the wave equation is given. Its properties discussed in this section are typically taught in undergraduate physics classes and hence need to be addressed by any type of simulation; specifically, they must be reproduced correctly to provide sufficient insight into the behaviour of waves.

The (scalar) wave equation is the following second-order hyperbolic differential equation:

$$\frac{\partial^2 \psi}{\partial t^2} = c^2 \triangle \psi \tag{1}$$

where ψ describes the *amplitude* of the field and c is the speed of the wave propagation. The wave equation describes phenomena like sound waves, electromagnetic waves or, in the approximation of small amplitudes, water waves. More important than the equation itself are, however, its properties every student of physics or engineering should be aware of, and that a suitable simulation must be able to reproduce:

- The wave equation is a linear equation; this has the important consequence that the sum of two solutions ψ_1 and ψ_2 is again a solution, i.e. $\psi_1 + \psi_2$ solves the wave equation as well. That is, the *superposition principle* holds: Waves from two sources simply add linearly without interfering each other.
- The wave equation has two noteworthy special solutions: First, *planar waves*

  $$\psi(\vec{r}, t) = A \cos(\vec{k} \cdot \vec{r} - \omega t + \phi) \ ,$$

  where $\vec{k}$, the so-called *wave vector*, points into the traveling direction of the wave, ϕ and A are arbitrary and $|\vec{k}|c = \omega$ holds. Second, for the special case of three dimensions, *spherical waves*

  $$\psi(\vec{r}, t) = \frac{1}{|\vec{r}|} \left(A_{\text{out}}(|\vec{r}| - ct) + A_{\text{in}}(|\vec{r}| + ct) \right) \ ,$$

  where A_{out} and A_{in} are arbitrary functions and describe waves outgoing from and ingoing into the origin. A spherical wave created by a harmonic oscillator at the origin would correspond to the solution $A_{\text{out}}(u) = \cos(u + \phi)$ and $A_{\text{in}} = 0$, for example. Unfortunately, a spherical wave solution of similar simplicity does not exist for two dimensions (or any even dimensional space), which is, however, the case covered by the simulation. In this case, one only has

  $$\psi(\vec{r}, t) = c \int_0^{t-1/c|\vec{r}|} \frac{cos(\omega t' + \phi)}{\sqrt{c^2(t-t')^2 - |\vec{r}|^2}} \, dt' \ ,$$

for the initial condition of a harmonic oscillator at the origin that starts oscillating at $t = 0$. Unlike the three-dimensional case, the solution due to a short excitation at the origin does not stay on the light cone, but fills the inner of the light cone.
The important lesson is, nevertheless, that all these solutions form only different generating systems of the solutions of the wave equation, and one can, for example, generate a plane wave by a suitable linear combination of spherical waves. This is also known as *Huygens' Principle* and one of the important topics covered in undergraduate physics.

- A third important property is the conservation of energy: That is, the integral of the square of the amplitude over the whole space remains constant. The square root term in the two-dimensional solution or the $1/r$ term in the three-dimensional solution can be understood as manifestations of this principle: As a spherical wave propagates from the origin, its square amplitude must dilute proportionally to the surface of the sphere, i.e. $1/r^2$ in three or $1/r$ in two dimensions.
- The above solutions of planar and spherical waves hold only in free space; if the wave is confined by obstacles or walls, these are mathematically described by boundary conditions that need to be satisfied by the solution. While many possible boundary conditions exist, two special choices are of primary interest: First, the so-called *Dirichlet* boundary condition which requires ψ to vanish at the edge of the domain, and which describes a fixed end; and the *Neumann* boundary condition at which the spatial derivative of ψ in normal direction vanishes, also denoted as "loose end". The important properties are here that upon reflection on a fixed end, a wave is reflected back with its amplitude reversed, whereas on reflection on a loose end the wave traverses back without a phase change. A simulation of the wave equation should also reproduce these effects correctly.
- Waves interfere, creating interference patterns or standing waves; a wave reflected by an obstacle and reflected back will, for example, interfere itself and will create nodes and anti-nodes in the medium at fixed (non-time-depending) positions. This effect is called "standing waves". A simulation should also be able to demonstrate this effect.
- Waves are diffracted at obstacles. Quite unlike classical particles, waves can partially travel around obstacles, and only obstacles larger than the wavelength can severely impact the propagation of waves. One particularly important experiment on diffraction is the double-slit experiment, creating a very typical interference pattern. The very same interference pattern is, surprisingly, also visible for particles, showing that particles also have a wave nature. This is one of the very fundamental principles of quantum mechanics.

A. A Discretization of the Wave Equation

The VideoEasel system introduced above is only capable of simulating discrete systems, i.e. systems that are discrete in time, space and states; continuous differential equations are out of question. While software exist capable of solving such equations, for example in the form of the "Modelica" toolkit provided by the University of Linköping, their complexity is beyond the all-purpose approach of the virtual lab designed in Stuttgart. Hence, the goal is a suitable discretization of the wave equation (1) that is able to reproduce the phenomena described above, and is hence both didactically suitable and mathematically correct.

At first sight, a suitable approach would be the straightforward discretization of the wave equation by a discrete Laplacian and a discrete time derivative, hence replacing it by a scalar second order difference equation. However, it turns out that this approach is not particularly useful, especially energy conservation is considerably hard to ensure in this approach. A considerably more interesting and fruitful approach is that of proposed by H.J. Hrgovčić[7] in his thesis: Similar to the Dirac equation replacing a scalar differential equation by a vectorial equation, Hrgovčić replaces the scalar amplitude of the wave equation by four flux components that describe the field flux into and out of vertices in a quadratic lattice.

In this approach, the wave equation is replaced by a difference equation that operates on the dual lattice of a spatial quadratic lattice, i.e. on the vertices that connects lattice points with their four nearest neighbours. Let $\vec{r}$ be a point on the original spatial lattice, then the vectorial field $\vec{f}$ describes the four components of the field flux running into location $\vec{r}$ coming from the left, right, top and bottom neighbour. We write the four components as

$$\vec{f}(\vec{r},t) = \begin{pmatrix} f_{x,+} \\ f_{x,-} \\ f_{y,+} \\ f_{y,-} \end{pmatrix} (\vec{r},t) \quad \vec{r} \in \mathbb{Z}^2$$

keeping in mind that $f_{x,+}$ is the flux ingoing into the vertex at location $\vec{r}$ from its right neighbour, etc. Let $\vec{g}$ now the vector of the outgoing fluxes from vertex $\vec{r}$ to its neighbours, i.e.

$$g_{x,+}(\vec{r},t) = f_{x,-}(\vec{r}+\vec{e}_x,t) \qquad g_{x,-}(\vec{r},t) = f_{x,+}(\vec{r}-\vec{e}_x,t)$$
$$g_{y,+}(\vec{r},t) = f_{y,-}(\vec{r}+\vec{e}_y,t) \qquad g_{y,-}(\vec{r},t) = f_{y,+}(\vec{r}-\vec{e}_y,t)$$

then the following matrix equation describes the fluxes under the wave equation:

$$\begin{pmatrix} g_{x,+} \\ g_{x,-} \\ g_{y,+} \\ g_{y,-} \end{pmatrix} (\vec{r},t+1) = \tag{2}$$
$$= \frac{1}{2} \begin{pmatrix} -1 & 1 & 1 & 1 \\ 1 & -1 & 1 & 1 \\ 1 & 1 & -1 & 1 \\ 1 & 1 & 1 & -1 \end{pmatrix} \begin{pmatrix} f_{x,+} \\ f_{x,-} \\ f_{y,+} \\ f_{y,-} \end{pmatrix} (\vec{r},t) \,.$$

This equation is now finally suitable for its implementation in VideoEasel. For visualization efforts, it is also often useful to display the field amplitude directly: It is given as the sum of all four incoming fluxes; the intensity resp. the energy of the field is given as the sum of the squares of the components. It is now readily seen that the matrix in equation 2 is orthogonal, hence preserves the lengths of vectors, and by that also the energy of the field, as required. Some additional modifications not to be discussed here also allow the simulation of reflection on loose or fixed ends, and — as surprising as it may sound — even though the underlying lattice is clearly not isotropic, the simulation generates almost perfect spherical waves. Needless to say, as the equation is linear, the superposition principle holds, and effects like the construction of planar waves from spherical waves can be demonstrated. Examples will be shown in the next section.

IV. Experiments

In this section, a couple of typical experiments shall be shown to demonstrate the usefulness of the Virtual Laboratory. Fig. 1 demonstrates the linear superposition of two wavefronts generated by two point excitations and the spherical wave created by an oscillator in the middle of the screen. The superposition principle is due to the linearity of the wave equation; in this simulation, linearity also only holds approximately because amplitudes of the excitation are limited; consequences from this limitation remain rather limited, though. It is further interesting to note that the generated waves are almost spherical, despite the simulation running on a square lattice.

The second set of figures (Fig. 2) demonstrates Huygens' Principle: A row of point-wise oscillators generates a wavefront that is almost planar by superimposing the spherical waves seen in Fig. 1. On the right hand of Fig. 2, a planar wave travels partially around a vertical obstacle, generating two spherical wave fronts behind the obstacle: This wave pattern can be understood by being generated by a vertical row of oscillators similar to that constructed in the first experiment, though interrupted by the obstacle in the middle. The oscillators at the top and bottom edge of the obstacle are then generating the spherical waves traveling into the "shadow" of the object which blocks the incoming planar wave. It is also interesting to note that the planar wave reflected back by the obstacle interferes with the incoming wave, forming a standing wave. Node lines become much more visible in the real animation than on the picture, though.

The third example shows the famous double-slit experiment (cf. Fig. 3): An incoming planar wave is blocked by a double slit, forming a typical interference pattern behind the slit. In a true-life experiment, laser light detracted at a double slit generates the very same pattern, becoming visible on a screen placed behind the slit. What is remarkable on this experiment is that a very similar pattern is also observable if the laser beam is replaced by a particle ray, quite contrary to common intuition. It is one of the elementary experiments in quantum physics. Following Huygens' principle, the very same interference pattern is of course generated by two oscillators placed at the position of the slits, as shown in the right-hand side of Fig. 3.

V. Integration of Virtual Laboratories and Remote Experiments into Lecture

The aim of LiLa is to share all the experiments participating institutions have to offer, enabling lecturers to select from almost unlimited resources for their lectures. The topic to be discussed in the following section is hence how to optimally integrate such resources into lectures, to mention potential challenges and how to overcome them, or in short, to give interested lecturers guidelines for optimal deployment of the LiLa material.

We are developing these guidelines again from our experiences using remote and virtual experiments in the lecture "Physics for Engineering", one example being the wave equation introduced in the sections above.

A. Initial Situation in "Physics for Engineering"

"Physics for Engineering" is a first year freshmen course taught to students of all kinds of engineering studies, including mechanical engineering, aerospace engineering and many others. Currently about 1300 students are attending the course. Due to the high number of participants and limited room capacity, lecturers are giving the same course twice a day, giving all students a chance to attend. The curriculum, recently modified to a Bachelor-Master study program, does not include any mandatory exercises for this specific lecture, nor does the tight schedule allow room for a mandatory lab course. However, experiences have shown that students participating in optional homework exercises handed out by the lecturer have a considerably higher chance passing the final written exam. Hands-on lab courses have not been part of these homework exercises, so far, however; the aim of this first pilot study is to offer students optional learning alternatives to the also optional pen-and-paper exercises.

The University of Stuttgart already offers an electronic Learning Management System (LMS) which provides information on the lecture, forums, questionnaires and material for self-study for this and many other lectures offered by the University. It is a well-accepted system known to both lecturers and students. Clearly, the LiLa experiments will be integrated into this system, here as applets running in a browser. This interactive content is then either used for self-study, or — in this starter project — in small student groups of at most 12 people a time, supported by teaching and technical staff of the physics department and the computing center.

We first performed an initial questionnaire to evaluate the motivation and interest of students in such optional courses, and to find out how much time they would have available for such additional courses. Around 87% are interested in participating in optional lab exercises, 23 % are willing to spend between half an hour to one hour for doing the exercise, 37,5 % are willing to spend one hour to one and a half hour and 30 % are able to spend one and a half hour to two hours. The remaining students may either have less than half an hour or more than two hours available for such courses. Apparently, the interest in such optional experiments is rather high, and the time students are able to invest into such courses is between half an hour and two hours.

B. Deployment Plan for the Exercises with Online-Experiments

The first step to do is to evaluate which experiments, virtual or remote, fit best into the content of the lecture. For that we

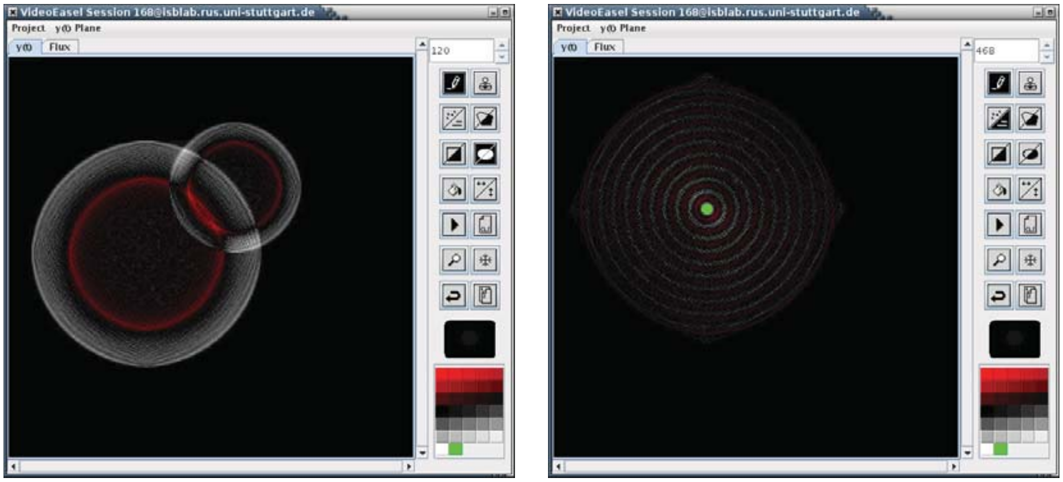

Fig. 1. Superposition of two point-excitations (left) and a spherical wave created by an oscillator (right)

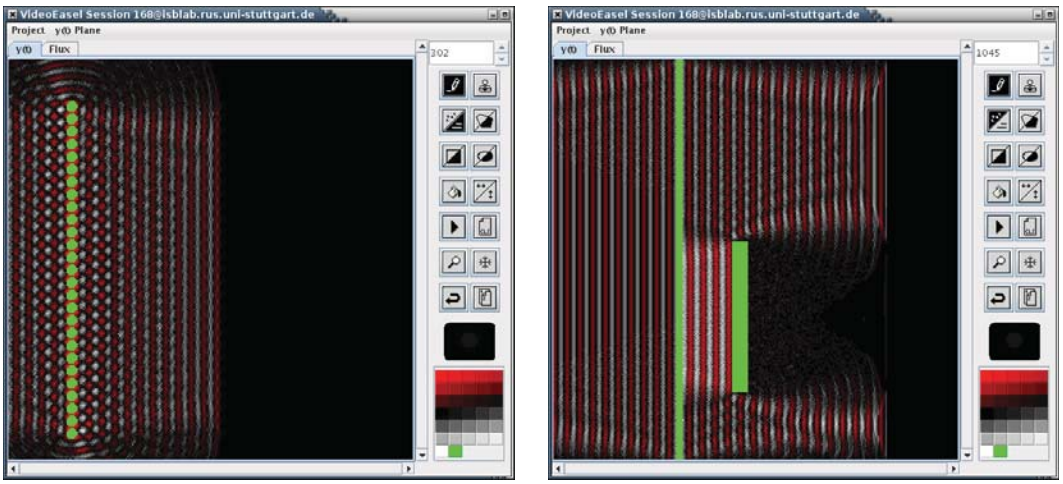

Fig. 2. Demonstration of Huygens' Principle (left), and a planar wave being blocked by an obstacle. Note that spherical waves travel into shadow of the obstacle.

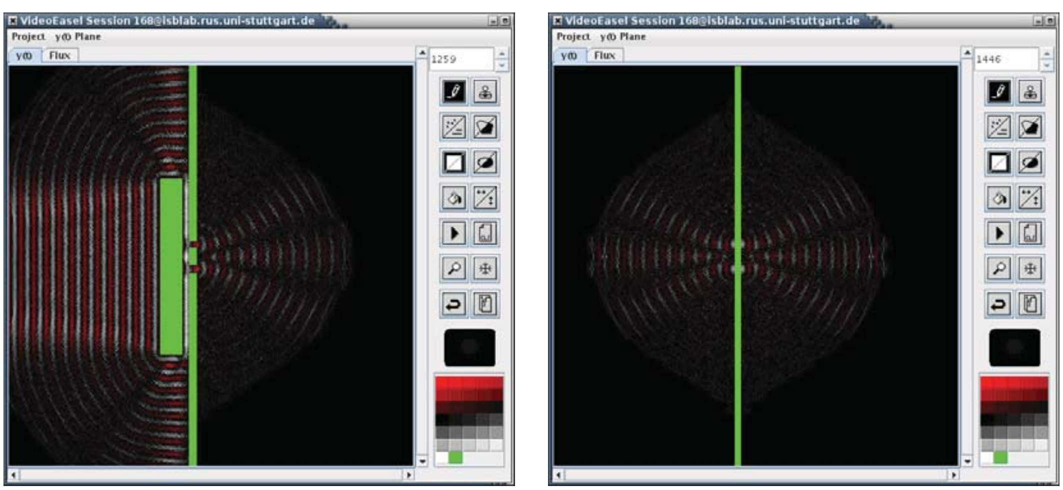

Fig. 3. The famous double slit experiment (left). The same interference pattern is generated by two oscillators replacing the slits (right).

compared the existing contents of the lecture with experiments available in Stuttgart and Berlin. For a first pilot phase we wanted to set up a manageable amount of experiments and decided to restrict the number of experiments to one per month.

Afterwards, we had to develop a structure for each of the experiments itself; this includes a both the organizational framework for the experiments as well as its technical realization which should fit into the Ilias LMS. We agreed on structuring experiments into the following three phases:

- **Orientation Phase:** This first phase allows students to familiarize themselves with the online experiment; an abstract on experiment is presented that contains a short description of experiment and the task to perform, the definition of the learning goals that should be reached, and a small pre-test evaluating the knowledge of the students.
- **Execution Phase:** This is the main phase of the exercise. Here the given tasks should be mastered by the students, i.e. running the experiments and measuring the results.
- **Review Phase:** The purpose of the last phase is to check the progress of the students. They pass again a small test, evaluating the knowledge obtained from running the experiment.

In the pilot, we also included an additional questionnaire in the review phase to gain some understanding on how students think about these exercises. Specifically, we want to know whether they believe to learn better with online experiments and whether their motivation looking into physics is increased by running experiments. Results of this questionnaire are not yet available and will be evaluated at the end of the winter term.

C. Motivational Aspects

Providing additional learning material helps little if students aren't motivated to use them; in this section, possible stimulations shall be discussed to optimize the impact of the provided material.

While providing experiments, and hence a chance to work actively instead of consuming content is a motivation by itself, realistically speaking this type of motivation might only work for students that are intrinsically motivated already. However, freshmen are very busy and the course schedule for the first year is already very packed by lectures and courses of manifold kind. This leaves, unfortunately, only very limited time for *optional* exercises, and it seems also very unrealistic to change this situation in short-term; hence, we face a situation that makes it considerably hard to clarify the importance of additional work to be performed by students.

Currently, we consider the following mechanisms to build up an additional force to drive students:

- Students participating in online experiments gain extra points for the final exam at the end of the course. While in this strict sense legally problematic — an *optional* course element cannot become a requirement for passing the exam — a potential modification would be that points collected from running experiments are bonuses that can cancel errors made in the written exam while leaving the error thresholds for the grades otherwise untouched. That is, a 100 % error free exam would still count as an A grade, regardless of whether experiments have been performed or not, but a lower B grade could be improved by having participated in lab courses. Collecting bonuses for the exam is an already accepted and tested mechanism in other lectures.
  What might be problematic is testing students for continuous attendance of the lab courses; while less a problem for tutored courses, it is more a problem for students that use experiments for self study at home. The former type of student support remains, however, only available as long as we have funding from the LiLa project and might be not available beyond the pilot phase.
- An additional source for motivation might be the integration of a contest into exercises, asking students to provide answers or experiments for an open ended question. Such a question could be to provide an experimental setup that demonstrates interference of waves, or the relation of the strength of a wave from the distance of its origin, etc. At the end of the term the best student would be granted a price, e.g. a free iPod.
  Clearly, such a contest can never be completely objective or completely fair for the suggested open-ended exercises; results might be copied from fellow students as in exams, but we have a much less controlled environment here where chances for intellectual theft are considerably higher.

In our current planning, the wave equation experiment will provide a good framework for interesting open-ended questions to be posed that requires students to perform the experiments by themselves. The next section will propose a couple of exercises and questions we plan to provide. Unfortunately, results are not yet available at this time.

D. Deployment and Scheduling

In our current planning, the wave equation exercise is scheduled to the end winter term, following the schedule of the lecture; it is likely the last and final exercise in this course, and thus offers a good opportunity to state open-ended questions as mentioned in the paragraph above.

One of the challenges we have to face is the rather high number of participants; as mentioned earlier, we expect roughly 1300 students in the winter term. While we definitely hope that most of them will participate in our hands-on course, checking their solutions for correctness is a major hassle for a small team of assistants and tutors. We propose the following solutions to address this problem:

- Automatic testing of results by the Ilias learning management system. This requires, of course, that exercises are stated in a way that allows automatic testing, e.g. by requiring students to find a numeric value by measuring a phenomenon, or by stating multiple-choice exercises. A potential exercise here would be to ask students to measure the amplitude of a spherical wave as a function of the distance from the oscillator; it can be seen from the explicit solution above — or by considering the conservation of energy — that the amplitude must decay as $1/r$. Since our laboratory also includes a SCORM integration, such exercises could also be stated within the laboratory system itself, forwarding any measurement results directly to the Ilias system.

- Peer reviewing. Here experimental setups created within a small group of students, say two to three, are reviewed by a second, independent team. Each group would have to prepare a report about their findings and experimental setups which is then checked by peers. A possible task would be to design an experimental setup demonstrating Huygens' principle and report on the results.
- As a modification of the above ideas, small modifications of the same assignment could be handed out to individual students instead of student groups; alternatively, combinations of the ideas above are possible were a first student group built the experiments and a second group checks for proper results and enters the measurement results into the Ilias system.

The aim of all exercises is of course to ensure that students gained insight into the wave equation while keeping them motivated to participate. Peer reviewing imposes the risk of students dismissing reports from their fellow students, or creating unfair review results due to varying background knowledge at the reviewers themselves. However, it also creates an additional learning effect by requiring student reviewers to go over the material once again. At this time, we do not yet know whether our ideas will work and we cannot yet present results, however, we surely never find out without trying. First experiences will become available end of the winter term.

VI. Results and Future Prospects

While we haven't had the chance to use the virtual laboratory for students, we nevertheless already run an initial test-case with a simple flash-based experiment created by the University of Colorado [8], and used here as a "warm up"; about 250 of 1300 participated in this test case, but the first results look very promising: A first analysis of the online-questionnaire shows that around 90% of the students enjoyed the exercise with an online-simulation. Also around 90% of them stated that they are more motivated to deal with the content of the lecture due to the online-simulation. Around 85% were thinking that their learning success will be higher with doing these exercises. For around 90% of the participants the content of the exercise was easily comprehensible.

Unfortunately, instructions how to handle the online experiment were not yet sufficient; about 45% reported insufficient instructions, requiring us to enhance the descriptions and being more precise on the expected tasks. For example, we gave no information how to round the numerical results, and the Ilias system was not flexible enough to accept results rounded to a different number of digits than we expected, causing it to rate some of the results as incorrect, and hence demotivating students. Of course, once we would have built up a working and tested corpus of online experiments, such problems will be avoided; what we should learn here is, however, not to underestimate the effort that needs to go into testing.

Exercises were accompanied by online questionnaires to be filled out by students using the exercises for self-study; additionally, we were able to reserve work-stations for groups of twelve students in the computer department on campus, allowing them to meet with tutors and experts to help them with their tasks. While it is unclear whether we will be able to offer on-site help in the future, it did allow us now to interview the participants directly, and we will be able to report our findings at the end of the term as soon as the data is collected and analyzed.

Concluding, we hope to be able to enrich the engineering studies by providing exciting, entertaining and instructural experiments students are able to perform at home any time they like; however, as we have already seen, providing just the experiments themselves is insufficient: they need to be embedded into a pedagogical strategy and must be complemented by sufficient instructional material telling students what the experiments are about, how to perform them, and which results we are expecting from them.

VII. Acknowledgments

This work was funded by the eContent*plus* program of the European Union as part of the LiLa (Library of Labs) project. The authors appreciate the support of the Computing Center of the University of Stuttgart and the kind cooperation with the Department of Physics, Dr. Jetter.

Abstract— **Universidad Carlos III de Madrid is one of the six main participating institutions in the eMadrid excellence network [73], as well as its coordinating partner. In this paper, the network is presented together with some of the main research lines carried out by UC3M. The remaining papers in this session present the work carried out by the other five universities in the consortium.**

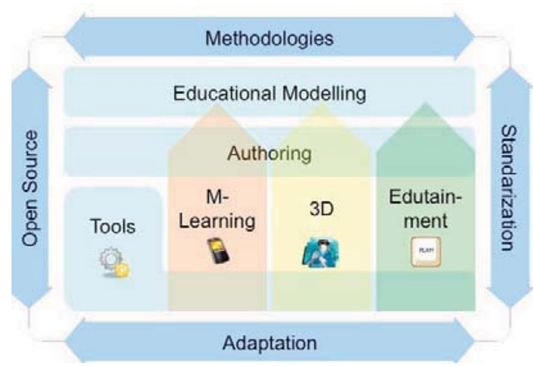
Keywords- e-learning, technology enhanced learning

I. INTRODUCTION

eMadrid [73] is the name of the Excellence Network about e-learning funded by the Regional Government of Madrid. Its members are the Universidad Carlos III de Madrid (UC3M), who acts as a coordinator, Universidad Autónoma de Madrid (UAM), Universidad Complutense de Madrid (UCM), Universidad Politécnica de Madrid (UPM), Universidad Rey Juan Carlos (URJC) and Universidad Nacional de Educación a Distancia (UNED), together with a large number of associated companies and educational institutions. The aim of the network is to provide leadership and perform advanced research in the area of e-learning.

Much progress has been made in recent years in the field of e-learning, but important challenges lie ahead for this technology to maximize its impact. Questions such as the following are of great interest for the future: What authoring tools may be provided so that creating educational material is as smooth and simple as possible, so that authoring can be incorporated into the educational process by all agents involved in it, including the students themselves? What impact do recent advances in web technology, such as the web 2.0 and semantic web technologies, have on education? How can the open source approach boost learning management systems? What new teaching models and methodologies can be supported by educational tools? What role does standardization play for e-learning formats and tools and how it can advance the state of the art? How can the integration of games, that are having such a success among the young, impact learning? How can we support formal and informal learning with the use of mobile devices, which are in the pockets of almost everyone?

Although the research to be carried out is intertwined and related, the consortium has organized its work around the following research lines: (1) Educational modelling (including collaboration & virtual communities), (2) Educational methodologies based on ICT, (3) Standardization of tools and educational content, (4) Platforms and tools for e-learning, (5) Adaptation, adaptability, and accessibility, (6) Immersive 3D learning, (7) Edutainment (Integration of games and simulations in Virtual Learning Environments), (8) M-learning (Mobile and ubiquitous learning), (9) Authoring & Applications of Web 2.0 and Web 3.0 to e-Learning, and (10) Free and Open Source Software. This figure shows the relationship among them:



We distinguish 3 main phases in the educational process: the phase of educational modelling, where the learning process is planned, the authoring of the needed learning material and assessment, and finally the tool-based deployment and enactment. For each of these main phases, we have one research line. But apart from the mainstream application areas, there are 3 promising areas, which deserve particular attention. These are m-learning, 3D virtual worlds, and game-oriented learning, which cut across the main areas. Due to their future importance, we study them in detail in independent research lines.

All this is framed by educational methodologies (giving a pedagogical underpinning to the learning process), standards (enabling interoperability among tools), adaptation in the most general sense (to classes of users and their abilities and context), and development principles (among which we concentrate on open source).

This paper is the first in a special session about the eMadrid excellence network. The remaining 5 papers by the other consortium partners touch upon several of the research lines mentioned. The paper by UCM describes their approach to introduce educational games in the learning flow. URJC presents the influence of libre software in education on the basis of a case study. Apart from open source programs, open educational resources are acquiring increasing importance. The paper by UPM covers a proposal for the use of semantic web techniques for making their discovery more effective. UAM describes how virtual 3D technologies can be used for learning. UNED's paper proposes a new paradigm for authoring that takes advantage of semantic web techniques.

The Universidad Carlos III de Madrid participates in all 10 research lines identified for the network, but, for the purpose of this paper, we will have sections about all the topics except two: the one on edutainment (we will make some reference to it in the section about 3D worlds) and the one on open source software, although most of the developments carried out are open source software. We will refer to them in several sections, most notably in the one about frameworks and tools.

II. EDUCATIONAL MODELLING

Learning scripts are external representations of the procedures and relations among participants and elements in a learning flow. Based on instructional design techniques to translate pedagogical models into a structured plan of activities and materials, scripted courses help students to focus their attention on relevant resources and activities [1]. There are several formats to deliver structured learning flows, ranging from pure text based instructions to graphics and diagrams of activities. Even if the structure is the same, different delivery methods may affect students' performance on the course.

On the way to capture all the richness of human interactions into a learning design, authoring tools promote Domain Specific Languages [2] such as IMS Learning Design [3], LDL or LAMS. The use of modelling languages implicitly imposes three phases in the course life-cycle: authoring, deployment, and enactment. For authoring, modelling languages allow instructors to define all interactions and resources in the course in a computer-readable way. Deployment is devoted to allocate resources and assign actual course participants to the abstractly defined roles. The course starts at the enactment phase, where instructions given by the script are delivered and interactions among course participants take place.

The number of tools aimed to support the course life-cycle for educational modelling languages designs is increasing rapidly and the market is willing to adopt new techniques of learning delivery. Despite these significant efforts, there still exist open issues in the field, requiring further research to be addressed. Main open questions include usability of the different approaches and its relationship with technology adoption; identification of patterns and its expression in form of scripts; and support of emerging learning techniques related with the wide acceptance and potential of Web 2.0 tools in the field of collaboration and course adaptability.

IMS Learning Design [3] is considered the *de facto* standard for educational modelling. It is intended to support a wide range of pedagogical models. General-purpose authoring tools such as RELOAD, COSMOS or CopperAuthor offer a close-to-specification interface which cannot be used by non-experts in the field. As a result of the difficulties shown during course edition, there is still a low level of adoption of the specification. Current research guidelines promote the inclusion of a new abstraction layer to reduce the gap among the technologies and the practitioners.

A different approach to improve usability of authoring tools and therefore to increase the adoption of IMS Learning Design relies on the identification of patterns of interaction [4]. Patterns are widely accepted in the field of collaborative learning and, in the long term, allow instructors to identify best teaching techniques.

Script-based learning, as well as the whole area of e-learning, has recently received the positive impact of the success of Web 2.0 techniques, whose tools promote participation, interaction, and new forms of communication among users [5]. The inclusion of emerging modes of interaction on educational patterns presents a challenge that can be faced from different perspectives. On the one hand, there is a great potential on the development of new learning strategies that rely on emerging web features. On the other hand, the distributed nature of the web hinders the creation of scripted courses due to the difficulty to express during authoring how course participants will interact with a service, whose nature and usage details would (and will) change on time.

The UC3M group contributes to the adoption of IMS Learning Design with GRAIL, a compliant runtime environment integrated with the .LRN Learning Management System [8]. We considered that the strict division of the course life-cycle of authoring, deployment, and enactment imposes a severe drawback for the adoption of the specification. Current developments are focused on the provision of an authoring-phase functionality once the enactment phase has started. Following the metaphor of a cockpit, the tool incorporates facilities for actions such as editing existing resources, creating new ones, or modifying conditions imposed to the course. Another research line that makes use of GRAIL is focused on service integration within structured scripted learning flows. The UC3M group studies the impact of the inclusion of third party services in the course life-cycle and develops models to perform the actual integration [7]. Software components built on top of GRAIL allow the evaluation of the proposed solution.

III. ICT-BASED EDUCATIONAL METHODOLOGIES

The introduction of Information and Communication Technologies (ICT) in the educational setting opens a wide range of learning possibilities. Flexibility, both regarding temporal as well as spatial constraints, is traditionally awarded as a key advantage of the use of ICT in learning. ICT facilitate the delivery and accessibility of learning resources, the use of richer multimedia and helps fostering collaboration and interaction between students and teachers, as well as between students themselves. Thus, far beyond the direct translation of traditional face-to-face methodologies, ICT bring a rich set of expectations for adapting such methodologies and introducing new ones to motivate the students and improve their learning outcomes.

Learner's assessment is perhaps one of the areas where this combination is proving to turn into a richer symbiosis. ICT strongly facilitate the management of the assessment process, leveraging the teaching burden associated to it. But apart from the logistic support, ICT empower potential benefits of the assessment process (for example, fostering immediacy of feedback) as well as open new scenarios for student evaluation.

Systems based on multiple-choice questions (MCQ) are the most extended Computer-assisted assessment method. Most Learning Management Systems, such as .LRN [8], Moodle [9], Blackboard [10], etc., include the possibility of writing and taking MCQ tests as part of their functionality. In [11], a thorough analysis of MCQ from a pedagogical assessment standpoint is provided, together with an assessment framework and a set of feedback principles for improving their effectiveness. From a didactic point of view, immediacy is one of the key advantages of MCQ, as automatic feedback can be provided to the learner instantaneously. Such immediacy is considered a critical requirement for successfully supporting the student learning process. Despite of their wide use, MCQ suffer from some limitations as stated in [11] and alternative methodologies can be considered more appropriate depending on the learning outcomes to be assessed.

Web 2.0 applications in learning are based on constructivist theories. Web 2.0 technologies allow the students to actively participate in the learning process, interacting with their peers and the instructor and even collaborating in the generation of learning materials. Moodle is an example of LMS inspired on constructivism. The use of Web 2.0 technologies for assessment focuses typically on the use of blogs [12] [13] and wikis [14] [15], as simple but flexible portfolios, which provide an easy-to-use framework for personal reflection, discussion and collaboration.

Pedagogic theories advocate the active involvement of the student not only in the learning process, but in the assessment activities too [16]. This objective is easier to achieve with ICT, using collaborative tools for discussing and agreeing rubrics and assessment criteria or peer assessment systems for involving the learners as assessors themselves [17].

Finally, existing online video-conference technology allows for the deployment of richer interactions, close to face-to-face ones. Remote presentations and questioning can be easily deployed today with minimum technological infrastructure (a simple webcam and web-based software). Viva exams are an example of a traditional methodology that can be directly translated to the virtual world using this technology. But ICT can also help to overcome traditional disadvantages of viva exams, such as the lack of persistence or the difficulty of applying homogeneous qualification criteria. Regarding the first point, online meetings are easily recorded, allowing the archive of evidences in a similar way to written exams. Such archives can be then used for future review, potential reclamations or simply as a reference for future students. They can also help to improve the quality of the assessment process, providing a set of samples that can be referred to as examples of how a concrete case should be evaluated. This is one of the objectives of the WebCEF project [18], where a showcase of video samples is being built for assessment of English as a second language according to the European CEF competences reference framework.

Lastly, some concerns related to the use of ICT for assessment should not be ignored. Security remains to be an active issue regarding the deployment of e-assessment formally. Potential risks include impersonation and cheating as major problems. Current solutions are typically based on the existence of a controlled environment for the assessment. Nevertheless, as such a requirement implies face-to-face settings, an intense research activity is going on to alleviate such security issues while maintaining the e-learning facilities and advantages, based on the use of video images, motion control etc.

UC3M is actively exploring new assessment scenarios and methodologies based on the use of ICT, mostly in the context of the iCoper European Best Practices Network. In this sense, we have focused particularly on two main research lines:

The work developed on adaptive peer review methodology [19] addresses the combination of active participation of the student in the assessment process together with adaptation to foster the motivational and pedagogical effectiveness of the task. ICT is here applied both to support the process logistics and, mainly, to perform the adaptation to the students' profiles.

In collaboration with the Knowledge Media Institute (The Open University), the use of online meetings and video-conference for assessment in different domains, courses, levels and countries is being explored at UC3M. The analysed case studies cover a complete set of situations, ranging from formative to summative purposes and from individual to collaborative (team-project) assessment.

IV. Learning Content and Tools Standardization

Nobody denies the importance, even more the necessity, of the existence of standards to organize any particular technical field to allow the interoperability of tools. Standards make data independent of concrete tools: they unfasten data from tools. The main objectives of standardization can be summarized in the following points:

- Enabling interoperability among platforms
- Protection of investment on content development
- Exchange of content locally and globally

In the context of e-learning content, several standards have been developed in the recent past. IEEE LOM [22] is a standard that specifies the syntax and semantics of Learning Object Metadata, defined as the attributes required to fully/adequately describe a Learning Object. Learning Objects are defined as any entity, digital or non-digital, which can be used, re-used or referenced during technology-supported learning. SCORM [20] is a set of technical specifications for e-learning software products. It tells programmers how to write their code so that it can "play well" with other e-learning software. Specifically, SCORM governs how online learning content and Learning Management Systems (LMSs) communicate with each other. SCORM does *not* speak to instructional designs or any other pedagogical concern, it is purely a content-oriented standard. There is also a large group of specifications from the IMS Global Learning Consortium (IMS GLC) [21]. Some IMS specifications are: Questions and Test Interoperability (QTI) for assessment purposes, Learning Design (LD) concerning the instructional model, Common Cartridge (CC) to package learning contents using Content Packaging (CP), Learning Information Package (LIP) for learning information and Reusable Definition of Competency or Educational Objective (RDCEO) related to competences. Most of these have not acquired the status of a standard given by a standardisation organization, but in their absence have acquired wide-spread use.

Andrew S. Tanenbaum [24] highlighted the importance of standards in a comical way by saying "the nice thing about standards is that there are so many of them to choose from." And this is exactly the key to success. Too many standards for the same topic, implies that there is no agreement and therefore the power of standardization is lost again. There have to be as few as possible standards that are as good as possible. But what does "good" mean, from a general point of view? Different users and tool vendors might need quite different applications of the same format. With the aim to fulfil users' and stakeholder's requirements, standards tend therefore to become quite extensive and complex. But then we arrive to another problem: since the standards are so complex, only subsets are implemented in tools. And again different subsets of the same standards, means again no standard and no interoperability.

We believe that standards should be designed to be *robust* against subsetting. This has several implications. One is that a particular concept should be expressible in just one possible way using a selected standard. This is why a good conceptual model is essential from the very beginning. Besides, standards should not be considered complete when experts just defined them; they should incorporate some kind of feedback on how implementations are done, adapting them to real market. Adoption of a standard is a social process that should be planned. It is sometimes easier for a specification to achieve successful adoption if it is presented as a set of small related formats, that each solve a concrete specific topic, than a monolithic format that tries to cover a large field.

Nowadays, assessment interoperability is being identified as one of the barriers to overcome to facilitate reusability in e-learning environments. Content reuse has always been identified as one of the big advantages of using standards. Assessment is a special case where content reuse makes even more sense [23]. Another important field of research is competence-based learning. Efforts are been carried out to clarify the link between learning content and competences. From the assessment point of view, ePortfolio is a tool of great interest to represent achieved learning outcomes and the evidences that sustained them.

UC3M is working towards the study of better standards and specifications in the context of the iCoper project [25]. As part of its objectives, iCoper will provide a Reference Model and mechanisms to ensure European-wide user involvement, cooperation, and adoption of standards in the educational framework. To accomplish this goal, the project will systematically analyse the specifications and standards available and in use, to draw conclusions on their validity. In the context of the iCoper project, an effort is under way to detect and solve the QTI interoperability problems by helping to complete the available tools to guarantee a robust exchange of assessment material. Related to assessment interoperability between some LMS (Moodle, .LRN and CLIX), some modules have been developed to enable this interoperability. These modules support importing and exporting assessment material between LMS and they are implementations of QTI 1.2.1. iCoper also deals with the link between IMS LD Units of Learning (UoL) and learning outcomes (including knowledge, skills, and competence), using HR-XML [26] as basis. On the other hand, the link between assessment and learning outcomes (through evidence records) is being investigated as well.

V. E-Learning Frameworks and Tools

It is well known that e-learning frameworks and tools are a critical asset for entities involved in the fields of learning, education, and training. These applications are of importance not only to bridge the physical gap between distant learners and the teacher, but to improve the learning experience and outcomes by providing support for other needs like collaboration, personalisation, adaptability, and new approaches of interaction with both learners and teachers.

The development of e-learning applications and platforms has been deeply affected by the present relevance of Web 2.0 tools and social networks that provide new ways for learners to collaborate in a more dynamic way. Systems such as LearnLand [27] and SciSpace [28], both based on the social platform Elgg [29], provide a high level of collaboration among the participants of a course through the utilisation of social tools. The provision of adaptation and personalisation form another area of interest in this field; as a proposal, [30] presents a way to personalise a virtual learning environment through the display of indicators within the LMS interface, while [31] describes an approach for providing an adaptive LMSs based on a standardised user model. In addition, another approach observed is to combine the use of more immersive user interfaces in combination with an LMS, an example of this is the Sloodle platform [32].

Current open research problems include the improvement of the level of adaptability of e-Learning platforms in order to enrich the learning experience. Another line of study is the use of non-traditional tools in the field of e-learning [33] that could lead to the interaction with external services, which requires an exchange of data providing the security and privacy that are taken as granted in any learning environment.

The UC3M group works with the .LRN framework, mainly through the provision and current maintenance of the GRAIL package, an IMS Learning Design RTE. Currently, this player is being enhanced with edition functionalities in order to provide flexibility at the deployment phase. Also, the accessibility has been improved. It has become a permanent requirement within its development. The research group has also provided an assessment package compliant with the version 1.2 of the IMS QTI specification; and by taking advantage of this compliance, current developments are taking place in order to provide assessment interoperability between the .LRN and Moodle frameworks.

VI. Adaptation, Adaptability, and Accessibility

Adaptive educational systems [34] in general appear in opposition to the "one-size fits all" paradigm for educational environments. When a learning experience is deployed, learners may have significantly different experiences depending on a variety of factors. The definition of an ideal adaptive system would be the one that provides to each learner the most appropriate environment. By environment we understand the context, resources, sequencing, evaluation, communication, support, and any other aspect that shapes a learning scenario. But as remarked in [35], adaptive tools have a poor presence in the LMS market mainly due to their lack of integration capabilities. Brusilovsky analyzes this issue in greater depth in [36] and points to the lack of integration as one of the reasons for this situation.

Thus, adaptation in general is a fairly wide and complex area, because it touches on the multiple aspects that affect a learning scenario. The proposed approach to deal with this complexity is to categorize the techniques for adapting a learning experience. The proposed categorization is:

1. Change the resources used in an experience, its order, its shape, delivery method, etc. depending on observations previously obtained from the user. We call this "Adaptive Choreography". For example, a learning experience may choose to deploy a group discussion or a set of individual exercises as the next activity in the class depending on some observations previously obtained from the experience.
2. Change the appearance of the platform (not the learning resources) to provide a more appropriate environment. In this category we would have techniques applied to change the appearance of a community, the auxiliary menus shown by default, changing the subscription policy in a forum, etc.
3. Adaptation in the context of accessibility. That is, the entire platform needs to change to any disability. For example, offer a larger font for the visually impaired.

The first category is intrinsically related to a learning environment, whereas the last two are generic to web applications. Any web-based application may need to adapt its appearance.

A. Adaptive Choreography

This type of adaptation has received an important push in recent years. The area of Intelligent Tutoring Systems offers a very rich landscape where numerous tools have been proposed. From the very early tools that were stand-alone and highly specialized in a context, today we can see proposals such as "KnowledgeTree" [36], where the emphasis is in integration with current LMSs using a set of "intelligent educational activities" with a distributed connection scheme.

A formal approach to adaptation has been taken by the IMS Learning Design specification [3]. This specification has been conceived as a formal framework to capture the structure and interaction in a learning experience including (a limited but) specific formalism to capture the interaction with services external to a LMS. Using Learning Design a so called "Unit of Learning" can be described including the set of resources that are to be used, the set of roles assigned to the participants in a learning experience (both staff and learners) and the interactions that are supposed to take place.

The specification is divided into three levels. Level A includes the description from a purely structural form of the set of resources needed by the learning experience. A UoL contains a "play", which is divided into "acts", and each act contains a set of learning activities. At any point in time, one act is "active". Level B of the specification is the one directly related to adaptation. A set of properties with different scopes (a role or set of users, a single user or a global property) can be defined and assigned values. Furthermore, a set of if/then/else clauses may be defined to change the appearance, visibility or structure of an activity based on the values of these properties.

Since the publication of its initial version in 2003, there have been several tools that appeared both in the authoring context [37, 38] as well as the execution context [38, 39]. In theory, a UoL captures all the requirements and pedagogical aspects of a learning experience such that it can be reused multiple times in different contexts.

In reality, adaptive learning with Learning Design has been shown to be fairly complex. Although this complexity could be assumed by instructional designers, its adoption threshold is higher than desired for other member of the teaching staff.

B. Adapting the platform appearance

Here we include the adaptation that needs to happen outside the learning resources of the educational experience more related to the platform in which they are hosted. Most of the current LMSs include a customization layer that allows rearranging the structure of the pages hosting a course to better adapt to the particular needs of a specific audience.

In Moodle [9] or .LRN [8] (to mention just two examples of open-source LMSs), the community page hosting a course offers a customization menu where the structure of the portlets can be re-arranged. This functionality is included in virtually any LMS. The importance of this adaptation is specially needed when deploying learning experiences with an audience with small experience in the use of LMSs or computers.

C. Accessibility issues in learning platforms

As in any other web platform, LMSs also face the challenge of adapting its content to people with different disabilities. Fortunately, this type of adaptation has been studied by international bodies such as the WWW Consortium, where the Web Content Accessibility Guidelines have been recently upgraded to version 2.0 [40].

In the context of learning, this problem becomes more challenging when creating learning content. An LMS may offer a perfectly accessible environment, but the learning resources that are usually produced outside of the LMS and created by teaching staff (not web designers) may not comply with these guidelines. In Section IX this problem is described in the context of authoring tools.

VII. 3D Social Virtual Environments for Learning

Advances in information and communication technology not only arrive ever more rapidly to our lives, but also produce a tremendous impact on the way we behave. Among the many consequences of these advances, we have a new generation of learners, so-called Digital Natives [41] with different patterns of work, attention, and learning preferences [42]. Digital Natives usually seek instant gratification, perform several activities concurrently, and behave efficiently in achieving their goals when motivated. Although Digital Natives are not characterized by being empathetic, they easily create new relationships within their own age group and mobilize people for a given purpose [42]. Thus, our main concerns are how to motivate students to learn and how to support teachers to apply instructional strategies adapted to this new generation of learners. In order to achieve our objectives, we explore technologies such as 3D virtual words, game design, social computing and e-learning.

A. Contributions from 3D virtual worlds

3D virtual worlds have a set of elements –also present in video games– that may help to seduce students into learning. The use of avatars as representations of students and instructors and the possibilities for customizing avatars, enhance the degree of realism and permit the subject to immerse him/herself in the 3D virtual environment for learning. The 3D scenarios also help to the sense of immersion and open up options of discovering new knowledge by exploring virtual worlds. The ability of avatars to interact with virtual 3D objects in collaborative environments offers new possibilities for the use of learning theories such as experiential learning, discovery learning and constructivism [43][71].

B. Contributions from game design

Games [44] use action instead of explanation and provide interactive content, therefore bring new ways of using teaching strategies [72]. Class activities such as presentation of a lecture can be done by an NPC (non-player character) representing a tutor or several NPCs playing situations that show students a given technique. NPCs can improve immersiveness by acting in plausible ways; their activities can be programmed using artificial intelligence (AI) methods. Deterministic AI techniques such as finite state machines, decision trees or even fuzzy logic are currently being used in video games and non-deterministic techniques such as Bayesian networks, neural networks and genetic algorithms are starting to be exploited in these games [45]. Our 3D virtual learning environments should find which kind of synthetic characters can be used and what AI technique can we apply for programming their behaviors.

Probably the main contribution of game design [44] is the use of rules to achieve specific outcomes to learning experiences, instead of using them with entertainment purposes. Rules are a crucial element in motivation in these virtual and social environments, they can be used to guide students towards acquiring new knowledge as well as for direct the community toward joint learning efforts.

C. Contributions from social computing

The new generation of learners demands social environments where they can explore knowledge by themselves, connect, communicate, and collaborate with other people in natural ways. Social incentive mechanisms must be used to encourage Digital Native's participation in collaborative tasks. Web 2.0 has opened new ways of communication and collaboration through techniques such as wikis, forums, collaborative tagging, and tag clouds that now must be adapted to 3D interfaces. Social visualization can relate academic performance to status in peer-group and also stimulate social comparison and competition.

D. Integration with learning management systems

A 3D social virtual environment is able not only to integrate a wide spectrum of instructional strategies that engage students in critical thinking learning activities, but also to motivate students, promote wide participation and make subjects easier to learn. Nevertheless, its impact as a pedagogical tool can be enhanced by embedding it in a Learning Management System (LMS) that manages the units of learning created in these learning environments.

E. Technological feasibility and work done

Open Simulator [46], Croquet [47], and Wonderland [48] are open source platforms that are suitable for creating collaborative 3D virtual worlds. They provide features such as avatars, NPCs, text and audio communication, sharing virtual objects and desktop applications and the possibility of transporting avatars between virtual worlds. From a previous study [49], we have decided to choose Wonderland as development platform, because it offers more possibilities for extensibility and has developed its immersive audio capabilities in a more advanced way.

A first collaborative experience was deployed. It consisted of a 3D virtual world, where avatars from several teams explored the world searching for the information a tutor asked them to find. The information was provided for NPCs that performed different dialogues for each learner team. The students were supposed to interact with members of other teams looking for missing information. Finally, the assessment consisted of a test to determine whether the students acquired the academic knowledge and social competences required.

VIII. M-LEARNING

With the steady improvement in the computational capabilities of mobile personal devices and the increasing needs for specialized and personalized training, new m-learning architectures and environments are being defined and used in different ways [50]-[54]. M-learning (and pervasive learning in general) scenarios enhance traditional e-learning scenarios by adding some new important dimensions to the e-learning process such as the anytime, anywhere space-temporal dimension. These new dimensions extend the e-learning concept to a new way of improving the learning experiences by the introduction of personal, context-aware, pervasive services. M-learning provides an "always on" user-context enhanced learning process. As Siobhan Thomas [52] states, m-learning leverages four components in the learning environment:

community driven learning, learning autonomy from the student point of view, location independency and context driven learning. It is therefore not surprising that some projects such as [55] are using mobile devices for e-learning. As Timothy R. Hill states in [56] "emerging mobile technologies hold great promise for educational institutions seeking to extend the learning experience to an increasingly nomadic and time-challenged student community, especially at urban campuses where both faculty and students typically commute to school and struggle to multi-processes work, study and family time and location demands."

Although there have been significant achievements both in m-learning theory and practice during the last decade, there are yet many open issues that need to be addressed. Some of them can be categorized as technology related, some as pedagogy related, while others can be associated to the motivational impact that the use of mobile devices and pervasive environments have on the student. Technological challenges in m-learning comprise the improvement in the computational capabilities of mobile devices, the increase in mobile network capacity, the improvement in programming languages for mobile devices, the use of embedded sensors, the integration of multimedia content and the ability to interact with smart environments. Pedagogical challenges encompass the use of mobile devices to support face to face activities, the use of mobile technology to reinforce traditional e-learning processes, the use of mobile devices as an always on channel to provide immediate and personalized feedback, the possibilities to control the learning process by learning using mobile devices, the use of a mobile device to support meta-cognitive activities or in social learning environments, or how to use the physical learning context in the learning process in either formal or informal learning environments. Motivational challenges include how to use technology to enhance the motivation of the students, how the increase in the control of the learning process motivates them and how the interaction with smart objects using mobile devices can also be a motivational factor for the student.

Among the different challenges previously mentioned, the UC3M group is currently focused on analyzing, synthesizing and proposing solutions for the use of mobile technologies as a "motivation factor", as a support framework of new learning scenarios in contextualized learning and for creating adaptive units of learning with flexible learning paths and as a support for meta-cognitive activities such as time management and process awareness. The group develops technological components and deploys them in real scenarios inside UC3M. The components use different types of networks to interact with the learning environment such as NFC and Bluetooth. The real experiments with students measure learning gains as well as motivational impacts.

The UC3M group is currently participating and actively leading some of the activities in two technology enhanced learning research projects: Learn3 and SOLITE. The Learn3 project is exploring and exploiting the synergies in the research work done by the UC3M e-learning group and the GTI group of the Pompeu Fabra University. Some joint m-learning experiments are being carried out with students in both universities gathering data of individual and collaborative interaction patterns with physical learning objects embedded in the student environment. The SOLITE project aims to align the research of some of the major e-learning research groups in Spain, Portugal and Latin-America. The UC3M group is defining and implementing m-learning activities both in Spain and Colombia, analyzing some of the motivational and learning impacts that the use of mobile devices may have on students in contextualized learning environments.

IX. Authoring and Application of Web 2.0 and Web 3.0 Techniques to e-Learning

At the early stages of e-learning, producing content was the same as publishing a web page or a document for download in the net. With the advances on web content, learning resources are now much more complex, and therefore, much more complicated to produce. The authoring paradigm has shifted from a one-person simple resource production scenario to a variety of production scenarios. De Freitas [57] divides these emerging scenarios into four categories: learner-authored content, practitioner-authored content, commercial and public-sector commissioned content and hybrid approaches.

The trend in authoring environments could be summarized as an evolution toward highly rich, service based, collaborative approaches. The "rip, mix, and burn" paradigm popularized by Apple has an ever increasing presence in the e-learning content production landscape also due to the large number of available resources with flexible licenses such as Creative Commons (see [58] or [59] for an example of such repositories). From this trend, several research venues and results are being considered, and most of them are derived from the ideas previously described in the context of deploying e-learning experiences.

The integration of external services is perhaps one of the most challenging ones. Re-using a resource such an image, a video, an animation, or a document are fairly simple due to the editing capabilities of most learning content production platforms. The challenge now is to raise the re-use of services to the same level of simplicity. Let us illustrate this problem with an example. Let's assume that an instructional designer is creating a course and as part of its pedagogical strategy decides to use a "blog" as a reflection tool (see [60] for a discussion on how useful a blog could be in a learning experience).

How is such "resource" included in a learning activity? The first approach would be to simply explain to students how to create a blog by themselves in the ever-increasing number of platforms available in the net. But this solution has a poor performance. Students should then relay to the teaching staff the location of such blog, and they would have a wide variety of structures, policies, etc.

The important observation is that a blog is a resource that has what we call an "instantiation" phase. In other words, as opposed to an image, a document, an animation that can be used by an arbitrarily large number of users with no impact, a blog needs to be instantiated as many times as required by the number of users. Learning Management Systems tried at first to provide these services internally, but they were quickly outpaced by highly specialized platforms available in the net.

What kinds of steps are required during the authoring phase to be able to use such a service during the enactment of a learning experience? Current research ideas propose to include a generic description of the service. Such description would include very generic properties such as "blogging tool", and a set of minimum requirements. For example: authenticated, restricted access to posts, etc. This would partially solve the problem of "including" such resource at the authoring phase.

But the real challenge is to manage the "instantiation" phase, which is no longer required when the instructional designer is creating the resource, but when the experience is being deployed. In this new scenario, this resource or service needs to be instantiated as many times as the experience is enacted, and if the service is in a per-user basis, as many times as users. In [7], this research avenue is explored and demonstrated with a service to provide questionnaires using Google Spreadsheets. The objective of the presented approach is twofold. On one hand, offer the integration of highly popular services emerging in Internet at the authoring phase to truly exploit their potential. On the other hand, achieve a tight integration between the learning experience and the service execution. By "tight integration" we mean that the learning experience should be able to gain insight on what happened inside the service to potentially react to it. This paradigm would truly capitalize in the use of these resources.

There are multiple possible scenarios that can take advantage of this paradigm. The closest one to current state-of-the-art tools is the use of forms for tests or quizzes. The service can be instantiated and the obtained results used to change the structure of an experience. Forums are increasingly present in e-learning, several research initiatives have been monitoring the activities in these forums to then deduce certain conclusions (see [61] for an example). If the service is integrated as described in this paradigm, these conclusions can be used to modify the structure of the remaining activities.

A second research venue being explored is the creation of reusable e-learning content in a distributed authoring environment. The approach combines the use of markup languages (such as docBook) and distributed source code management tools (such as git). The idea is to combine a learning object creation approach with a set of rules that take those objects and create a set of learning resources. The paradigm is being used in a few courses with a high number of content creators and the initial results are promising with respect to the distributed nature of the paradigm and need further improvement to lower the learning curve to use markup languages by the lack of visual tools.

Many developments have been carried out in relation with the Semantic Web since the paper by Tim Berners-Lee, Jim Hendler and Ora Lassila [62] was published in Scientific American, and many keywords have come up since then: Semantic Web, Web 3.0 [63], Data Web, Linked Data, … Many of these developments have found application for learning. The integration of learning technologies into the Semantic Web enables interoperability not only among e-learning applications and resources, but also with other Web entities, making more powerful interactions and services possible. Service-oriented architectures have been proposed, which make available Semantic Web methods for e-learning applications, such as for adaptive hypermedia [64].

The creation of ontologies and annotations for e-learning are necessary steps to build Semantic Web applications in e-learning. In this context, ontologies represent a formal knowledge modeling of different learning aspects. The generation of such ontologies implies an extra engineering effort, but they overcome the limitations of traditional e-learning systems [65]. A classification of the different types of ontologies for education can be found in [66]. While there are several works that explain ontologies that are not based on existing e-learning specifications covering different learning issues, on the other hand there are other works that try to adapt and convert existing e-learning specifications into the Semantic Web. In this line, there are RDF Bindings for IEEE-LOM, Dublin Core, IMS QTI, IMS LD, or IMS LIP.

Several applications have been built during the last years that enable to take advantage of the Semantic Web in e-learning. This includes searching applications like Courseware-Watchdog to perform searches based on meta-data [67], or adaptive applications like [68], which personalize learning contents based on reasoning over Semantic Web resources annotated according to defined educational ontologies, or tools like SMARTIES [69] for creating instructional designs based on pedagogical models and ontologies.

Although there is a wide community supporting research on Semantic Web applications in education and ontologies, there are several and important challenges at present. Firstly, even though there are promising works for the generation of automatic annotations and ontologies from text, the provision of easy to use or/and automatic tools that generate annotations and ontologies in Semantic Web formats for all the different aspects of e-learning is a challenge. These tools should provide ideally automatic and complete modelling for the knowledge domain through the ontologies, as well as correct annotations, being aware of the changes during the time.

The distributed vision of the Semantic Web also leads to the problem of compatibility among different ontologies and annotations among different systems. Some promising ideas have been proposed, but more effort should be made regarding this issue to be able to connect the different e-learning systems.

Another important open issue is the integration of a lot of existing traditional e-learning systems into the Semantic Web, so that the advantages of the Semantic Web can be taken. This implies an effort for defining ontologies, making annotations, adaptive rules, etc. according to the specific particularities for the different applications.

The UC3M group has contributed to the integration of existing traditional e-learning systems and services in the Semantic Web. In this direction, a new architecture for combining Semantic Web techniques with Intelligent Tutoring Systems has been defined, which combines traditional e-learning formats with Semantic Web ones, and a prototype for achieving adaptive hints according to the defined architecture has been implemented [70]. This development separates the adaptive rules for execution in a Semantic Web reasoner, while keeps the non-adaptive functionality for generation of hints in a traditional e-learning tutor.

CONCLUSION

In this paper, we have presented the many research lines carried out by the UC3M group of eMadrid in the context of e-learning. The field of learning has always profited from the advances in ICT. Presently, we have a wealth of new developments that are directly applicable. At UC3M, we follow several of them that in a synergistic way enriching one another.

ACKNOWLEDGMENT

The Excellence Network eMadrid, "Investigación y Desarrollo de Tecnologías para el e-Learning en la Comunidad de Madrid" is being funded by the Madrid Regional Government under grant No. S2009/TIC-1650. Abstract—**Open Educational Resources are accessed through the web, whose real setting shows an explosion in the use and development of tools and services based on Social Software. However, the growth of this data repository makes it difficult to find information of value, and reduces the possibilities of sharing and exchanging resources. Using semantic technologies to describe educational resources enables any agent (human or software-based) to process and understand its content (applying inference rules on more structured knowledge). Metadata standards can be used to annotate educational resources; they facilitate their interoperability and discovery. In this work, we propose, OER-CC ontology, for the description of Open Educational Resources under Creative Commons Licenses. This approach is based on standard technology and metadata standards. The ontology could be utilized in higher education institutions (and organizations) to facilitate sharing and discovery of their digital content. This electronic document is a "live" template. The various components of your paper [title, text, heads, etc.] are already defined on the style sheet, as illustrated by the portions given in this document. (Abstract)**

Keywords-component; formatting; style; styling; insert (key words)

I. INTRODUCTION

Open Educational Resources (OERs) initiatives promote their global exchange with the aim of increasing the human intellectual capacity. The principal idea of the movement toward Open Educational Resources is that knowledge is a public good where technology in general, and specifically Web, provides an extraordinary opportunity for people to acquire key competences in a knowledge society while they share, use, and re-use digital contents.

OER are teaching, learning, and research digital re-sources and tools (see **Figure 1**), available on the public domain or that have been released under an intellectual property license, that is, permit their free use, re-use or re-purposing by others.

The next level of educational technology infrastructure will need to use social tools and semantic technologies applied to the Web. The application of Social Web in OER projects has demonstrated that regular users can contribute content without specialist skills; any person can participate actively as an author in the Knowledge Society. By other hand, semantic Technologies enable the power of the semantic web for easy sharing, re-using and educational resources discover.

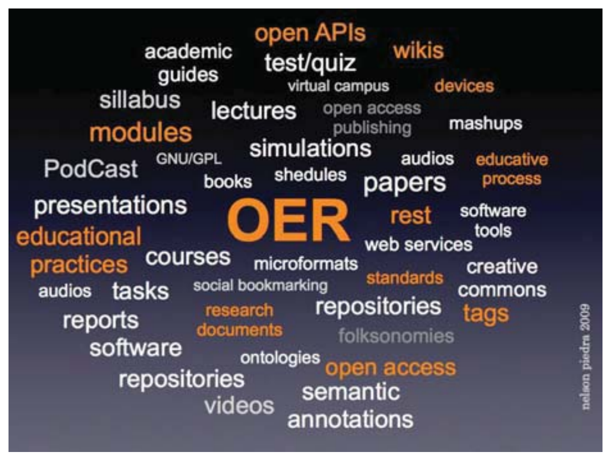

Figure 1. Open Educational Resources Map

In this paper, we propose, OER-CC ontology, for the description of Open Educational Resources under Creative Commons Licenses. This approach is based on standard technology and metadata standards. The ontology could be utilized in higher education institutions (and organizations) to facilitate sharing and discovery of their digital content.

This document is divided into 3 sections. The first section introduces the models and OER drivers and we put forward options for incorporating semantic technologies in OER description. Next, development process of OER-CC ontology is described; at each stage of ontology creation we argue the choice of each standard, tool and applied language. In the last section, we describe the recovery process of knowledge represented in ontology; several queries were designed to obtain information about the properties of the resources generated in the Computer Science School (CSS) of the

Technical University of Loja (UTPL, *Universidad Técnica Particular de Loja* - Ecuador).

II. Description of Open Educational Resources (OERs) by mean of Metadata and Ontologies

The Open Educational Resources Initiatives are based on the **Open Access (OA) movement**.

Declarations of support for OA have been developed to accelerate efforts to promote open resources, technology and teaching practices in education. The Declaration of the Budapest Open Access Initiative [1] (BOAI, 2002) was among the first to strongly promote the open and free access to academic and research contents.

In the same way, importance of OER has been promoted by international and national organizations initiatives. Some of these **initiatives** are: Massachusetts Institute of Technology (MIT) in 2001 with its project OpenCourseWare and the OCW Consortium [2], projects from OECD's Centre for Educational Research and Innovation [4], UNESCO Initiative through International Institute for Educational Planning [5], the Open University's Open Learn Project[1], Universia MIT OCW – Spain[2] and IEEE-Signal Processing Society[3] will be work with the open-access repository project Connexions. Other initiatives can be found on the Wiki of the UNESCO OER Community[4].

OER Projects can be classified according to model (funding, technical, content and staffing) used to ensure their sustainability. Downes in [3] describes each of the models.

In this paper, we focus on staffing models, that is, by the degree to which participants could actually help with resources. Considering this point of view, there are two models: producer-consumer and co-production [4] (we can find a comparison between them in the Wiki community project, WikiEducator[5]).

In **producer-consumer models** (or user-producer), an institution or consortium develop materials and release courseware under an open license, which can be reused by other providers. Within this group the MIT OpenCourseWare can be considered.

Co-production models encourage open and unrestricted participation, aimed to leverage the benefits of mass-collaboration and the principles of self-organization. This model, can promote the collaborative production of common resources.

The co-production strategies to OER production can be deployed using *Social Web* tools. The Web 2.0 or Social Web is focused in the contents, relationships and knowledge but not specifically in technology. As Will Richardson [6], [7] writes: "The good news for all of us is that today, anyone can become an all life student. (Yes, even you.) Those technologies are easy to use in a way that was not possible in the past".

[1] http://openlearn.open.ac.uk
[2] http://mit.ocw.universia.net/
[3] http://ieeecnx.org/
[4] http://oerwiki.iiep-unesco.org/
[5] http://wikieducator.org

The use of wikis is a good example of transition from static and restricted web sites to social and collaborative participation (co-authors). O'Reilly refers to Wikipedia as "a radical experience of confidence" [8]. Wikipedia, blogs and other tools allow the user to publish and then the community determines the relevance and pertinence of the content; mistakes are solved by social correction and with the support of content configuration management (version control).

The core strength of the social software is its easy use, however a OERs co-production model based on this kind of services have some weaknesses; Redecker in [13] identifies the main risks, barriers and obstacles to the implementation of Web 2.0 into teaching and learning practice. Besides those points, we also believe that one of the greatest difficulties to adopt this approach is that the use of social tools is generating an impressive growing in the quantity of contents that are available in the internet. This situation is hindering the organization, retrieval and resources interoperability and its "intelligent" processing is required. Using semantic technologies we can provide a more explicit meaning to information, so that computers can understand and generate new knowledge by applying rules of inference to a better structured knowledge

A. *Incorporating semantics in OER Production*

These days, the use of semantic technologies and applications development of the Semantic Web (SW) in the learning context, are the focus of researchers, organizations, universities and consortiums.

Semantic technologies will automate or semi-automate certain educative tasks trough "synergy between human and machines" (see **Figure 2**). Thus is explained by Gruber in [14] "Clearly, there are different roles for people and machines. People are the producers and customers: they are the source of knowledge, and they have real world problems and interests. Machines are the enablers: they store and remember data, search and combine data, and draw mathematical and logical inferences". With the incorporation of web semantic technologies in processes of creation, storage, retrieval and educational resources remix we expect a reduction in workload of those who run the learning process.

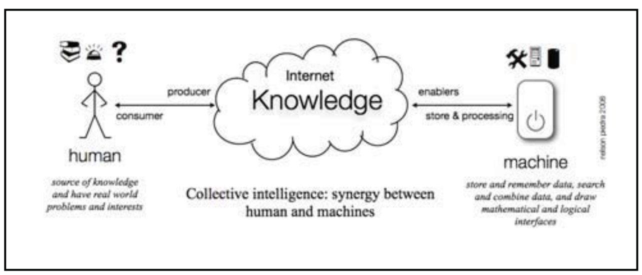

Figure 2. Synergy between human and machines

The Koper's study [15] showed application areas of the SW in education, he talk about will help to educators to perform some of their tasks such as settings, assessment and management and courses administration. We also think that the Semantic Web will enable to:

- identify more easily resources with particular properties or that have a kind of specific relationship with others;
- use of semantic rules, it can be a good support for interpretation and argumentation of several issues;
- suppliers of educational contents that use semantic technologies improve the administration, exchange and integration of resources with other information suppliers;
- bear a great potential of providing a robust and extensible base for emerging Social Web applications; interchange, distribution, and reuse of OER can be greatly facilitated by the infrastructures that the Semantic Web offers.

To achieve these objectives, educational resources should be described by a standard schema in a way that any agent (human or software-based) can understand and processing its content

1) Metadata Standards for Educational Material

Al-Khalifa and Davis as said in [24] "Metadata standards are formal specifications used to semantically annotate educational material of any king. They have been developed to support both machine interoperability (information exchange) and resource discovery by human users". Some metadata schemes allow the description of resources in XML, RDF, RDFa, or even OWL.

For the learning materials "these various standards and specifications have been developed to meet different requirements and to support the needs of different communities" [16]. Three are most recognized metadata standards:

- The IEEE LTSC (Learning Technology Standards Committee) developed IEEE LOM[6] (Learning Object Metadata).
- The IMS GLC (Global Learning Consortium) proposes IMS Learning Resource Metadata[7].
- Dublin Core Metadata Initiative[8].

The structure proposed by these standards is similar; each one has categories and each category contains a set of metadata. Depending on application, we can choose a subset or extend[9] the set with more metadata (the out-come of this adaptation process is called "*metadata application profile*"). Given the effort required to describe an educational resource using each characteristic proposed by those standards, we could create an profile for describe OERs, considering the particularities of this type of resource, such as:

- Some projects are based on social software, there-fore, metadata about the social tools, type of re-source and resource annotations (using social classification systems, such as, folksonomies) are required.
- Open educational resources are licensed under copyleft licenses such as Creative Commons (CC) or GPU/GPL, therefore, metadata about licensing is needed to determine what is permitted, required or prohibited in a work.

2) Ontologies

According to Gruber`s definition [11], an ontology specifies the conceptualization of a specific domain in terms of concepts, attributes, and relationships [12]; also it should be expressed in a *formal language* "so that a given ontology expression can be interpreted and processed" [18]. Unlike other knowledge structures (e.g. library classification or thesaurus), an ontology allows applying logic, inheritance and other issues [17].

In 1997 emerged the first **language for ontologies** SHOE[10] (Simple HTML Ontology Extensions), so far some languages have been proposed to be more complete and less complex languages than their predecessors. Nowadays the languages most used are RDF and OWL; one of limitations of RDF is that it is not expressive enough to represent complex ontologies, while that OWL extends the possibility of using logical expressions to describe complex concepts and relationships.

The **modeling of domain knowledge** can be done us-ing traditional paradigms and tools, UML (Unified Modeling Language) or database technologies. But as stated Gomez et al. [19] "…the formalisms used to model the domain knowledge and the languages that implement these techniques limit the kind of knowledge that can be modeled and implemented", i. e. "only allow the representation of lightweight ontologies". Consequently to modeling of large or complex domains have been proposed several approaches that allow us develop ontologies ("heavyweight ontologies") based on Artificial Intelligence (AI) formalisms; so we have better control over the vocabulary and the semantic. In [19] a comparative study between these three paradigms can be found.

There are several **methodologies** for building ontologies, two of them could be regarded as more mature a) METHONTOLOGY, proposed by Gómez-Pérez et al. in 1996; and b) On-To-Knowledge, proposed in 2001 by Staab et al.

Regardless of the methodology used to create the ontology, its design should be guided by the Gruber's principles: clarity, coherence, extendibility, minimal encoding bias and minimal ontological commitment; the idea is to ensure the "knowledge sharing" [21]. To fulfill these criteria, **ontology evaluation** should be performed at the same time as the development-oriented activities. Different type of evaluation could be made [23]: a) *Syntactic evaluation*, to check languages specification b) *Semantic evaluation*, focused on detecting if the ontologies have inconsistencies and redundancies c) *Lexical evaluation*, it refers to the vocabulary used to represent concepts and domain relationships. Other

/

issues related to evaluation are presented in the Brank's et al. [25] paper.

B. Related Work

We have found several works that involve the development of ontologies for a specific issue of e-learning or to modeling knowledge related to a specific problem.

1) Ontology for e-learning system

Ghaleb et al. in [12] developed an ontology for web-based e-learning system of Qatar University. End-user can annotate learning resources by means of Web form; the system converts this information to a set of RDF statements using the RAP API (Semantic Web toolkit for PHP developers). According to the authors "the ontology can be used for adaptive learning to retrieve the context of a course and to structure the contents". Their model includes a service of simple semantic search.

This work cannot be reusable in OER domain because it isn't metadata standards-based (or there isn't information) and the ontology model hasn´t been published.

2) Application ontologies for assembling learning objects

Santacruz in [26], [22] put forward *OntoGlue*, "an ontology-based mechanism for assembling learning objects". In order to assemble two learning objects, the requirements of one must be covered by the competencies of the other. The problem resolved by OntoGlue is the semantic comparison (considering that one requirement and one competence can't be syntac-tically equal, but the semantics is the same) among concepts, since mappings between ontologies are established. The standard LOM is used to describe ELOs (Electronic Learning Objects) although an extension that has been included.

3) Metadata Standards for describing Objects and Learning Resources

For semantic representation of Learning Objects. Fermoso et al. in [20] put forward the ontology LOM2OWL[11], its structure allows to describe LOs using IEEE LOM standard. Later, we will refer to this work.

For description of Learning Resources. Brown and Thomas explain in [9] metadata approach within the OER project "The Open Polytechnic of New Zealand". They created an application profile that contains necessary elements to ensure metadata interoperability "with both a national and an international audience", thus, 15 metadata was chosen of those 5 belongs to Educational Category. However, this work doesn't consider projects social software-based neither the licensing issue.

For description of works licensed under Creative Commons (CC). In 2008, CC published the metadata standard ccREL[12] (Creative Commons Rights Expression Language), it that aims to "make licensed works more reusable and easy to find". To date ccREL metadata, as encoded using RDFa or XMP.

III. DEVELOPMENT OF OER-CC ONTOLOGY

In this section, authors introduce details dealing with the implemented ontology to model the OER and CC domains. Thus, research team tried to achieve the following main goals: (i) to describe OER and CC resources using a common vocabulary by users and producers, i.e., an implemented ontology offered to students and lecturers within an educational context respectively, and (ii) to automate execution of tasks for selected domains such as information retrieval using semantic techniques.

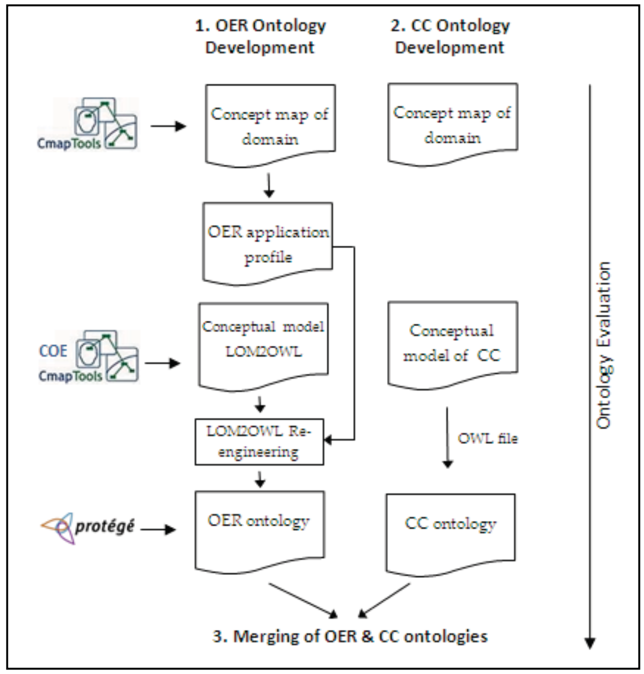

Figure 3. Process and tools for ontology development

A. Process and tools to build OER-CC ontology

Then, development process of our OER-CC ontology was divided into three general phases:

1) OER ontology development. At this point, we started with an initial ontology (LOM2OWL[13]) adapted to the metadata requirements for OERs (based on IEEE LOM).

2) CC ontology development. In this case, CC ontology was designed using METHONTOLOGY [19] guidelines.

3) Merging of CC and OER ontologies. Finally, we unified concepts, terminology, definitions and constraints from the two source ontologies.

B. Development process

As introduced before, development process was based on METHONTOLOGY [19] guidelines. This method proposes an ontology building life cycle based on evolving prototypes. That is, it allows adding, changing, and removing terms in each new version (prototype). Next, figure 3 depicts the development process and used tools through each phase respectively.

[13] http://www.cc.uah.es/ie/ontologiaLOM2OWL/LOM2OWL.owl

Therefore, we started the development process creating concept maps for both knowledge domains respectively. For this purpose, we depicted main points of OER-CC ontology with a general study of references to describe metadata of selected domains. As a consequence, we evaluated some well-known references to describe OER metadata like IEEE-LOM [30] and Dublin-Core (DC) [31]. At this point, we understand that IEEE-LOM introduces enough metadata to characterize our educational purposes for this work. In addition, IEEE-LOM was used because we think that it includes large amount of structured metadata into different categories, allowing greater semantic flexibility for our selected domains. Another important issue was that it is a leading standard within e-learning environments [16] usually.

Then, all metadata associated with CC licenses was represented considering the ccREL standard [10] which provides information related to Licenses Properties, e.g., permissions, prohibitions, requirements and general metadata. Once we had decided how to describe metadata, we selected well-referenced tools to model the OER-CC ontology successfully. Concretely, we used the following:

- **CMaptools** [28] was used to represent and intern-connect both knowledge domains, i.e., OER and CC respectively. In addition, **Cmaptools Ontology Editor** [14] (COE) was used for constructing, sharing and viewing modeled ontology based on CmapTools. Besides, this allowed preparing OER-CC ontology to be modeled using **OWL**[15] language.
- **Protégé** [29] was used to implement our ontology formally. For this purpose, all prior results were imported to this ontology editor. Then, we used **SWRL**[16] to provide deductive reasoning capabilities and **SPARQL**[17] to retrieve the educational resources metadata.

Each tool and language was applied at different stages of process.

Additionally, each prototype of OER-CC ontology was validated through evaluation items like: (*i*) Syntactic evaluation, by mean of Pellet reasoner[18] and syntax checker used for this work, (*ii*) Taxonomy evaluation, at this point we validated standard rules in taxonomies like inconsistency, incompleteness and redundancy in concepts respectively. Once we finished the development process successfully, we were ready to deploy OER-CC ontology. Therefore, next section introduces details that give preliminary evidences of our contribution in this work.

IV. OER-CC Ontology Instantiation and Retrieval

Then the formalization and implementation activities are carried out, in this last section, we attempt to provide a piece of the true potential of ontologies use to represent domains in the context of Education and particularly to describe OERs, i e.

- The machines can understand and interpret meaning of educational content, thus facilitate or automate execution of certain tasks, such as, accessibility or retrieval with the contents of both domains.
- Users and OER producers[19] can use a common vo-cabulary to describe their resources; it enables to reuse and to share application domain knowledge.
- Represent a metadata structure through ontology; it will enable interoperability among different do-mains (vocabularies). This promotes accessibility and OERs sharing between universities and organizations around the world.

One of the ways we use to demonstrate that potential is defining and executing queries and inference rules on OER-CC ontology to retrieval and to exploit its knowledge. Before discussing the results, we explain the filling the ontology with resources metadata produced in a higher institution.

A. *Instantiation process and tools*

Once the ontology is built, the process of ontology popu-lation starts, and then it allows extracting relevant information from the resources hosted by ontology. The population process "consists in creating a knowledge base containing instances of the ontology concepts and instances of the ontology relations" [19].

This process can occur in 3 ways, depending on the level of automation is required or that it can be applied. This process can occur in 3 ways, depending on the level of automation is required or that it can be applied.

1. *Manual.* This mechanism may be viable when we have a small number of instances for each concept and it can be done through ontology development tools and tool suites; they provide basic support for the ontology population so that ontology developers can create instances with their ontology editors [19].
2. *Semi-automatic*, applying automatic learning techniques on sources of unstructured or data semi-structured.
3. *Automatic*, creating specific applications (using ontology management APIs) to generate in-stances from structured data sources and directly insert them in each concept.

For the OWL ontology population, Protégé offers certain plugins.

- DataMaster[20], to import schema structure and data from relational databases into Protégé.

[14] http://coe.ihmc.us/groups/coe/
[15] http://www.w3.org/TR/owl-ref/
[16] http://www.w3.org/Submission/SWRL/
[17] http://www.w3.org/TR/rdf-sparql-query/
[18] http://clarkparsia.com/pellet/

[19] The role of users and OERs producers change depending on adopted production model. In a user-producer model, students consume re-sources and institutions generate them; while a co-production model anyone participant (including students and self-learner) can contribute to creating them
[20] http://protegewiki.stanford.edu/index.php/DataMaster

/

- XML Tab[21], to import an XML document into Protégé, creating a set of classes and instances in a knowledge base which correspond to the entries in the XML document.
- Excel Import[22], to import content and classes from Excel or CSV files, it available so far only for Protégé 4.0.

In all cases, the data source must be in a structured format and classes are created according to this structure. When the ontological model has been implemented a process is required to move instances from the new classes to existing classes.

B. *OER-CC Ontology Instantation*

To instantiate the OER-CC ontology, we considered some resources generated in the Computer Science School (CSS) of the Technical University of Loja (Universidad Técnica Particular de Loja[23], UTPL-Ecuador).

UTPL are using social software for knowledge management, learning and OER development based on a co-production model. From 2008, the School has opened completely all the training courses of Engineering free of charge; this has enabled the exchange of experiences internally and with other academic units.

A manual process has been developed to populate the OER-CC ontology with the CSS' educational resources, because Protégé plugins import schema structure and data from structured sources (unlike what is required in this work since we already have the model). Concretely, those resources are videos and keynotes authored by teachers and students basically. In addition, they are available on youtube[24] and slideshare[25] of the School's channels also. Furthermore, instantiation dealing with CC domain was considered using different types of Creative Commons Licenses with jurisdiction in Ecuador[26].

C. *Information Retrieval*

As introduced in section 3.2 we used SPARQL language to retrieve knowledge represented at our OER-CC ontology. Thus, we developed some queries to retrieve information, e.g., properties of OERs and CC licenses.

What is more, our initial results show that our OER-CC ontology has been deployed successfully, i.e., using metadata from initial instantiation of educational objects.

Some queries were designed to extract information from OER-CC ontology, geared mainly to determine its use in tasks of recovery, accessibility and OERs re-mix.

[21] http://protegewiki.stanford.edu/index.php/XML_Tab
[22] http://protegewiki.stanford.edu/index.php/Excel_Import
[23] www.utpl.edu.ec
[24] http://www.youtube.com/eccutpl
[25] http://www.slideshare.net/eccutpl
[26] http://creativecommons.ec/

/

Table I and **Table II** list some competency questions that can be answered by the ontology. SPARQL panel of Protégé was used to run queries, the next step is to develop or integrate applications (software agents or web services) that implement the above activities.

As shown in **Table I**, one of the advantages of using OER-CC ontology and the IEEE-LOM standard is that we can complete information for each resource metadata in various languages and thus facilitates multilingual search.

TABLE I. COMPETENCY QUESTIONS FOR OERS RETRIEVAL

More specific searches can be constructed by applying filters (assembling different types of combinations) on different OERs properties. Multilingual search. If multilingual descriptions of metadata were specified
Competency questions
¿What is general information of an educational resource (title, description, keywords, and other metadata)?
What educational resources are labeled with a particular word? Such questions are especially common in a co-production model in which multiple annotators can add, in a simple way, tags to each resource. The tags could be used to improve search results as proposed in [27].

TABLE II. COMPETENCY QUESTIONS FOR ACCESIBILITY AND REMIX

• We can exploit the information on licensing, contribution and attribution to facilitate accessibility and OERs re-mix
Competency questions
What are the resources created by a particular contributor and what type of contribution have done?
What are the direct contributions of a university in the OERs production and what are indirect contributions through their teachers / students?
Who should be given attribution and under what conditions we can make use of OERs?
What are all contributors (individual and organizational / institutional) of a specific OER?
What kind of licenses we use to can generate educational resources in a country and under what conditions these can be remixed?
How can access (URI or URL) to an OER and how it can display (depending on the type of resource)?
What educational use and in what context we can use an OER?

Next, we introduce a implemented query (to answer the question: what are the direct contributions of the UTPL in the OERs production and what are indirect contributions through their teachers/students, see **Figure 4**) within OER-CC ontology.

These queries results confirm that a short-term improvement in information retrieval task can be achieved considering educational resources generated at the Computer Science School of the UTPL.

Figure 4. Query for retrieval UTPL contributions

CONCLUSION

In this work, we have given initial evidences that machines could understand and interpret semantic meaning of educational contents.

As a main contribution, we have implemented OER-CC ontology to model knowledge dealing with OER and CC domains respectively. Therefore, we have been able to inference knowledge using OER-CC ontology, i.e., thorough instantiation and classification of educational objects respectively. About work in progress, research team continues working to improve OER-CC ontology deployment. Currently, we are involved with more methods to promote accessibility according to OER user requirements; e.g., the content of an educational resource could be ranked within the OER-CC ontology according to student / lecturer profile respectively.

Furthermore, this work has enabled us to implement ontologies from concept maps (process used to generate CC ontology). With the support of easy-to-use graphical tools (as Cmaptools) could massify development of ontologies, with the additional advantage it may include domain-experts.

ACKNOWLEDGMENT

Support for this work was provided by UPM under project AL09-PID-36, UTPL and scholarship provided by the *Secretaría Nacional de Ciencia y Tecnología* (SENACYT) of Ecuador.

Our thanks to eMadrid Consortium. Authors are members of GICAC-UPM that is part of eMadrid consortium.

Abstract—**Within the last years educational games have attracted some attention from the academic community. Multiple enhancements of the learning experience are usually attributed to educational games, although the most cited is their potential to improve students' motivation. In spite of these expected advantages, how to introduce video games in the learning process is an issue that is not completely clear yet, which reduces the potential impact of educational video games. Our goal at the <e-UCM> research group is to identify the barriers that are limiting the integration of games in the learning process and propose approaches to tackle them. The result of this work is the <e-Adventure> platform, an educational game authoring tool that aims to make of video games just another educational tool at the disposal of the instructors. In this paper we describe how <e-Adventure> contributes to the integration of games in the learning process through three main focuses: reduction of the high development costs of educational games, involvement of instructors in the development process to enhance the educational value, and the production of the games using a white-box model. In addition we describe the current research that we are conducting using the platform as a test-bed.**

Keywords-<e-Adventure>; educational games; authoring tool; LAMS

I. Introduction

Instructors, parents and public authorities are astonished by how dropout rates have grown in education at all levels for years. This alarming trend suggests a drastic decrease in the motivation of the students towards learning.

Several hypotheses have been formulated to explain this controversial issue. In this line, several authors like Prensky [1] argue that there is a clear disconnection between students' expectations and what they receive in the classroom. According to Prensky, current students are *digital natives*, people used to interact with rich interactive digital media such as computers, mobile devices or video game consoles; this differs from the typical pedagogical strategies in terms of content and interaction [1, 2].

To tackle this issue, a deep reform should come to the educational system, updating the content and interactivity used to support learning. One of the proposals is the use of video games and other kind of interactive technological content. Actually, the application of games in education is a trend on the rise. There is a belief that video games have potential to enhance the learning processes in multiple ways. One of the most frequently discussed is the ability that games have to increment students' motivation towards learning as they are able to capture their attention and keep them engaged and immersed [3, 4]. Other interesting traits of educational video games is that they provide immersive in-game worlds that can be explored freely by the students, promoting self-directed learning [5], their short feedback cycles with perception of progress [6], or their relation to constructivist theories and support of scaffolded learning [7].

This interest in the use of educational video games laid the basis for the <e-Adventure> project [8-10]. <e-Adventure> is a platform that has been developed by the <e-UCM> research group at the Complutense University, and its main aim is to facilitate the introduction of the games in the learning process. Nonetheless, to achieve this goal several barriers have to be tackled first. In this paper we describe the main problems that are preventing a more general adoption of educational gaming, according to our own research experience. Between the most relevant issues we find the high development cost of video games, the difficulty of involving instructors in their development, and the complexity of using the games in traditional pedagogical approaches. After that we describe how these issues have been addressed in our proposal, the <e-Adventure> platform.

All the research conducted in our group about educational games, and the effort invested in pushing the development of the <e-Adventure> platform forward has turned <e-Adventure> into a solid product that is available for download and ready to use[1]. Thus <e-Adventure> is not only the result of our past research, but also a great test-bed where we are implementing our new work on educational games. In this paper we also include a discussion about the main research lines we are working on.

Therefore this paper is structured as follows. Firstly, in section II we briefly discuss the main limiting factors for the

The Spanish Committee of Science and Technology (TIN2007-68125-C02-01) and the Ministry of Industry (grants TSI-020301-2009-9, TSI-020110-2009-170, TSI-020312-2009-27) have partially supported this work, as well as the Complutense University of Madrid and the Comunidad de Madrid (research group 921340 and project e-Madrid S2009/TIC-1650), and the PROACTIVE EU project (505469-2009-LLP-ES-KA3-KA3MP).

[1] <e-Adventure> can be downloaded from the next website: http://e-adventure.e-ucm.es

general adoption of educational games. After that, in section III we summarize the approaches that we have proposed to tackle them, and how they have been implemented in the <e-Adventure> platform. Later, in section IV, we describe the main research lines we are working on and how we are integrating them in <e-Adventure>. Finally some conclusions are presented in section V.

II. Towards the Introduction of Games In the Learning Process: Open Issues and Barriers

As stated in the introduction, video games seem to have potential as learning tools, but their use in real scenarios is limited by multiple factors that span all over the product life, affecting the design, implementation and deployment phases. In this section we discuss, according to our opinion, some of the more relevant issues that affect educational games in these three stages.

A. Issues at the Design Stage: Balancing Educational Value and Entertainment

One of the main challenges of developing an educational game is the achievement of an adequate balance between entertainment and educational value [7]. Both factors are indispensable for the success of the game. If the students do not have fun playing they will finally quit the game and all the investment would be useless. However, if all the efforts are focused on the fun-factor and the educational value is left aside, the game would have little impact on the learning outcomes of the students. Therefore the development of educational games adds, to the difficult task of designing game elements that are fun and engaging, the challenge of achieving educational value [11, 12].

To ensure that an educational game has educational value we need to effectively involve instructors in its development. On the one hand instructors are the domain experts, who can check that the accuracy of the knowledge ‘stored’ in the game is appropriate. On the other hand, instructors have the crucial responsibility of applying the games in the real learning scenario. Nevertheless current game development methodologies limit the involvement of instructors due to the technical background required. As a consequence, there is a need for the creation of specific development methodologies that take into account all these issues and propose effective mechanisms to get instructors involved in the development process.

In addition, educational games have their own needs that may differ from more traditional, entertainment-driven developments. In this sense it is very important to choose a game genre that suits these needs. There are several studies that have analyzed what are the more suitable genres for educational applications. Authors like Dickey argue that story-driven genres, like Interactive Digital Storytelling or *point-and-click* adventure games can better fit the needs of educational gaming for a broader set of domains as they promote content instead of plain action [13-16]. For instance, the presence of elements such as a slow pace, reflection, study of the environment, and problem-solving make point and click adventure games relevant from a pedagogical perspective [17].

B. Issues at the Production Stage: the Costs

One of the most drastic disadvantages of applying video games in education is their high development costs. High-profile commercial (non-educational) video games have often budgets of several million dollars. For instance, as analyzed in [18], a high percent (40% approximately) of the educational game developments active or recently finished in 2005 were expected to cost more than $100K. Arguing in the same line, the study described in [19], estimates the development costs of commercial video games in the range of $10M-$25M for 2008.

Those estimations are a barrier for the introduction of video games in the educational process, as it is almost unfeasible for most educational organizations to develop their own educational games if no external funding is available. Obviously that issue virtually narrows the applicability of educational games to pilots and research projects, impeding a general adoption.

The lack of reusability of video games is another hindering factor. Video games are usually sold and distributed as *black boxes*: self-contained, closed products that are rarely scalable to other domains and contexts. This lack of flexibility reduces the potential of video games for learning as instructors need to adapt, reuse, maintain and share their materials and those developed by others (actually these are frequent behaviors of instructors).

C. Issues at the Deployment Stage: Delivery and Assessment

Finally, some of the main barriers that hinder the adoption of educational games are related to the complexity that they introduce in the learning process from the instructors’ point of view. In this sense, the actual use of educational games is limited due to several factors.

On the one hand, there are inconveniences concerning the delivery, distribution and deployment of the games. Video games are complex pieces of software that are usually distributed in CD or DVD and that require some installation on the player’s system. In addition, while a lecture typically requires a blackboard and some pieces of chalk video games require up-to-date computers and controlled environments which are seldom present in schools [20]. Moreover, even when this kind of equipment is present in the schools, they usually lack the staff preparation and/or the time required to organize educational gaming sessions.

On the other hand, it is burdensome for the instructors to track and assess the learning experience. As games are usually *black boxes*, from which extracting information is arduous, instructors need to plan carefully how they are going to evaluate the learning outcomes and achievements of each student (usually through time-consuming debriefing sessions).

III. The <E-Adventure> Platform

The result of the research carried out in our group on educational gaming is the <e-Adventure> platform for educational game development. In this section we discuss the solutions that we have proposed for the issues discussed in section II and the more relevant features of <e-Adventure> that implement them.

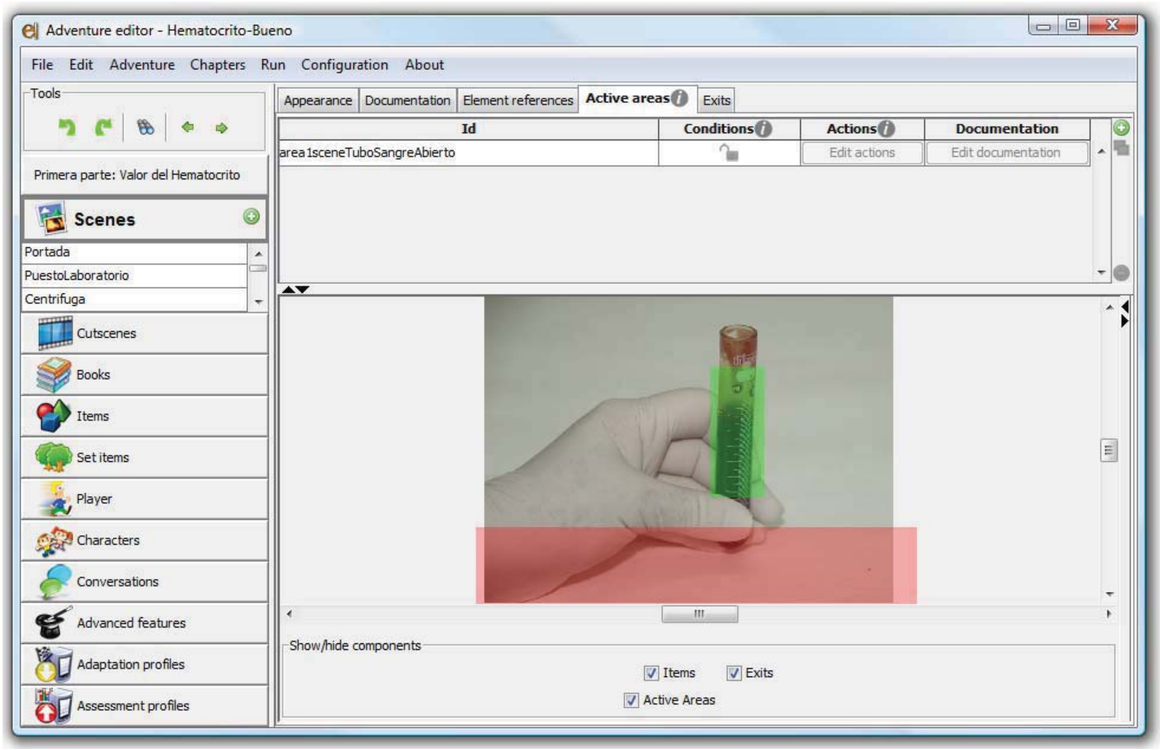

Figure 1. Screenshot of the <e-Adventure> game authoring tool.

A. Increasing the Educational Value, Decreasing the Development costs

As aforementioned, some game genres have traits that make them more suitable for educational purposes than others. In this line, story-driven games can be good educational tools as they improve the problem-solving skills and promote reflection instead of action. Thus the <e-Adventure> platform is focused on the *point-and-click* adventure game genre (in the style of games such as *Monkey Island*© or *Myst*©).

This genre is not only interesting because of its high educational value, but also because the development cost of these games is minimal. Besides, in order to broaden the potential domains of application of <e-Adventure> the platform supports the creation of two different types of games taking adventure games as a basis: *third-person* and *first-person* games. While the first type of games has been applied in concept-intensive domains like History [21], the second has been useful in the development of games for teaching procedural knowledge, for instance, in several medical applications [22, 23].

In addition, an appropriate game genre is not the only enhancement of the educational value that <e-Adventure> includes. As discussed so far, the level of instructors' involvement in the development of the games is a sound prerequisite to achieve a good educational value. <e-Adventure> aims to allow instructors to develop their own educational games, or at least contribute in their production by following two strategies.

First, along with the <e-Adventure> platform, we have proposed a development methodology for the development of story-driven educational games [24]. This model allows the cooperation of multiple roles (e.g. storywriters, programmers, artists, etc.) of different technical background in the development of the games. In this manner the methodology supports the integration of instructors in the process as non-technical staff, trying to make sure that "a good story never ends in a bad game".

Secondly, <e-Adventure> includes an instructor-oriented game authoring tool (see Figure 1.) which does not require any kind of technical background [25]. The authoring tool allows instructors to create their own games as no programming is required, and also contributes to reduce the development costs. Moreover, even if some instructors may find creating entire games from scratch too ambitious, this approach at least allows those instructors to open the games developed by others in order to review the contents, make minor modifications, adapt games for different contexts, etc., allowing them to contribute in the development process.

Furthermore, the authoring tool also promotes reuse as it has been developed in compliance with standards and specifications of the e-Learning field, allowing in this manner the exportation of the games as Learning Objects (LO) [26] that can be shared in content repositories (e.g. the AGREGA LO repository developed by the Spanish ministry of education).

B. Facilitating Deployment and Assessment: Integration with e-Learning Environments

Once the games are already created, <e-Adventure> also helps to make their use in the actual learning scenario easier. The main strategy that we have followed to address this group of issues relies on the integration of the games in e-Learning environments like *Moodle™, Sakai™* or *Blackboard™*. In our opinion this approach brings numerous benefits.

As we previously mentioned, <e-Adventure> games can be packaged as Web-based Learning Objects. This facilitates their distribution through e-Learning environments to the students' computers without requiring any installation (only a web browser is needed) [27].

Secondly, once the <e-Adventure> games are deployed on the e-Learning environment, the platform also enables a communication channel between game and server [28]. Through this channel the instructors can extract information about the progress of the student in the game, the goals that are achieved, etc., and have it submitted to the e-Learning environment to be attached to the students' profile [10, 29]. For instance, instructors could identify using the authoring tool game situations that have a relevant meaning from a pedagogical point of view (e.g. a specific puzzle is not completed and some knowledge is not unveiled), define a score for those situations and get that score sent to the e-Learning environment just as any other kind of test for the student. Hence <e-Adventure> games are not *black-boxes* but *white-boxes* where instructors are aware of what happens during the execution of the game.

IV. Open Research

As discussed so far educational gaming is a trend that has attracted the efforts of different researchers in the last few years. Nevertheless, in spite of all the work done, there are still different open issues to be solved in order to achieve the final goal of turning video games into feasible, affordable learning tools. We are thus currently exploring several lines of research and testing them within the <e-Adventure> platform, including mobile game-based learning and adaptive and accessible educational games. In this section we will focus on two specific projects: the integration of <e-Adventure> in the LAMS e-Learning environment (section IV.A) and the development of a story-driven game authoring tool (section IV.B).

A. Integration with e-Learning Environments: LAMS

As discussed previously, our approach to ease the integration of educational games in the learning process heavily relies on the integration with e-Learning environments. Although lot of research has already been conducted, resulting in the integration of <e-Adventuture> in systems like Moodle™ using standards and the Learning Object Model, we are still exploring new approaches.

As part of this research line we are working on the integration of <e-Adventure> with *LAMS* (Learning Activity Management System), an open source e-Learning environment [30]. Like other e-Learning environments, LAMS manages all the features of the online courses in a centralized way for all the roles involved. But the most interesting feature that makes LAMS different is that it also allows teachers to create *activities sequences* (that is, to model the learning flow and the activities it includes).

With the easy-to-use sequence authoring tool that LAMS includes instructors can define the learning flow by graphically combining out-of-the-box activity tools (e.g. chat, forum, question and answer activities, etc.) that LAMS integrates. Moreover, instructors can define branches in the sequence by defining conditions on the outcomes of some tools, allowing alternate paths for different students or groups and depending on their achievements. Finally, LAMS also provides a monitoring mechanism that allows modifying the flow of the sequence while it is being executed, giving the teacher more control of the educational experience.

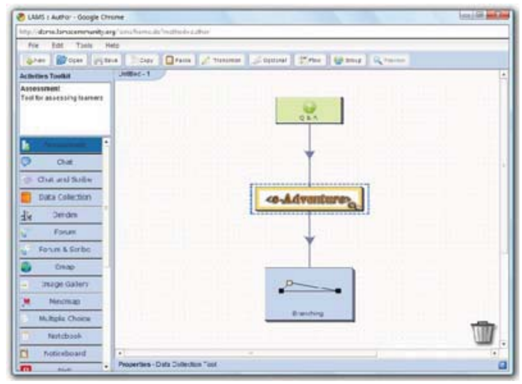

Figure 2. The activity sequences autoring tool in LAMS. A sequence of activities including an <e-Adventure> game that is used for branching.

Our aim is to make of <e-Adventure> another 'out-of-the-box' LAMS activity tool (see Figure 2.). Therefore instructors could upload their own educational games to the system and integrate them in their activity sequences. In addition, <e-Adventure> games will be able to receive the outcomes of other tools as inputs (e.g. the score) and produce their own outputs (e.g. score, time played, etc.). This opens a lot new possibilities that are interesting from a pedagogical point of view. For instance, instructors could define branches in their sequences using the outputs produced by <e-Adventure> games. In this manner instructors could provide activities to reinforce learning if the outcomes are not the expected. Moreover they will also profit from the high interactivity of the games to know more about the students and provide them more adequate activities. Finally, the inputs received from the sequence could be also used to make internal branches in the game according to the history of the student, allowing the adaptation and personalization of the game-based learning experience for the needs of each student.

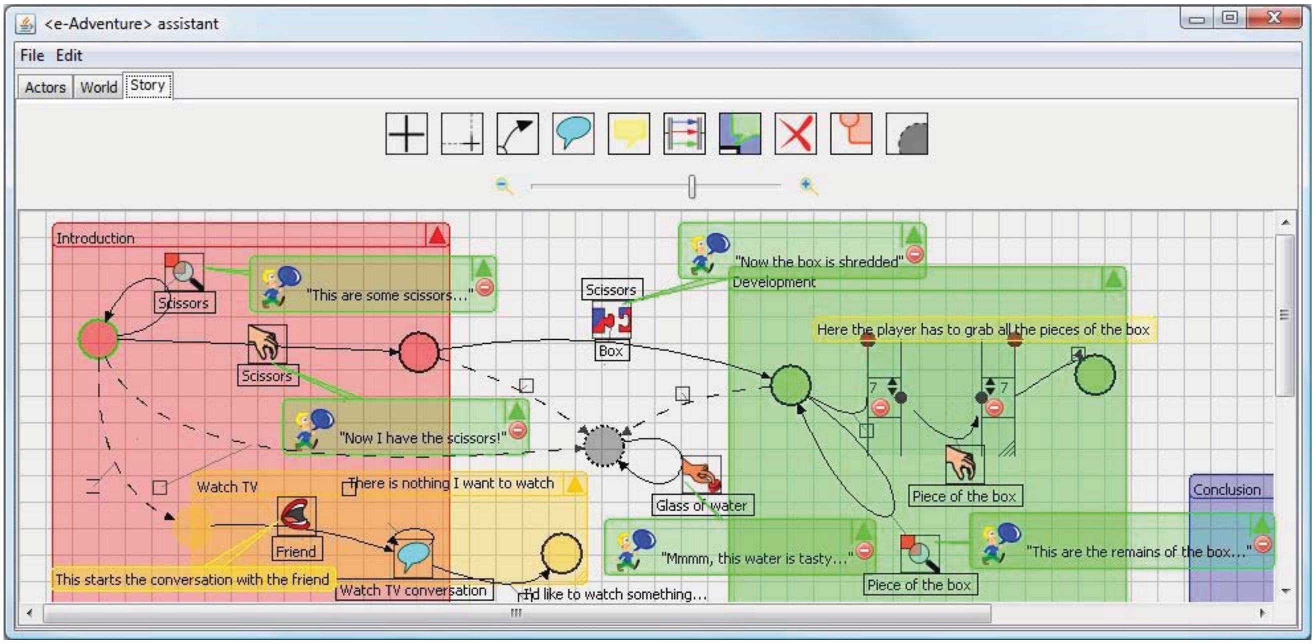

Figure 3. Screenshot of the story-driven authoring tool (prototype)

B. Easing the Authoring of the Narrative Thread: A Story-Driven Authoring Tool

One of the design issues discussed in section II refers the impact that a powerful narrative thread may have on the educational value of educational games, as discussed by other authors. Nonetheless the production of a good storyboard for an educational game is not an easy task, given that to the burdens of making the story engaging and fun we add the difficulty of achieving the adequate educational value.

That is the motivation for one of our current main research lines. Our goal is to develop a graphic authoring tool that simplifies the production of a good storyboard for an educational game in terms of engagement and educational value. Besides, we will integrate this new tool with the <e-Adventure> editor, where the description of the games and the story lays hidden behind, and intertwined with the multitude of different elements that make up the game. As a consequence of this integration, <e-Adventure> will be an innovative development framework that integrates multiple tools for each stage of the development process of the games, including not only a content-based authoring tool but also a story-driven one.

The story-driven editor will use a visual modeling language to describe the game. In this representation there are visual elements to represent the different states that the narrative thread of the game can have and the possible actions the player can take (see Figure 3.). Therefore the storywriter can visualize and edit the narrative flow and how the interactions of the player affect the course of the story.

Working over the representation of the storyline described above, the game author will be able to define automatic assessment behavior, which will ease the addition of educational value to the games.

Additionally the new authoring tool will also include a feature to model, in a separate graphic sheet, the 'virtual world' of the game. This will facilitate the establishment of a bijective relation between the story and the places where it takes place. Using these new tools the initial description of the games is streamlined, leaving details to be dealt with in a later step. This is also, in general, a good practice in game design methods [13, 31].

The design of this new authoring tool is based on ideas introduced by experts in other areas (particularly Interactive Digital Storytelling) and systems used to create interactive computer stories in the early 90s [32-34]. Besides, it introduces new elements that make it easy to guide the user in the creation of new games by reusing patterns, applying methods developed by specialists in storytelling and game-making and creating recommendations based on the structure of the story [4, 35].

V. CONCLUSIONS

In this paper we have presented the research we are conducting at the <e-UCM> group at Complutense University in educational gaming. Our aim is to identify the barriers that are preventing the generalization of educational video games and propose solutions from a technical perspective. Between the relevant issues that we have identified so far, some of the most important are the problem of balancing educational value and entertainment, the high development costs, and the complexity that games introduce in the classroom dynamics.

To address these issues we have developed the <e-Adventure> educational gaming platform, which aims to reduce the development costs while keeping high quality standards in terms of educational value and entertainment. Using <e-Adventure> it is easier for instructors to create, adapt, share and use their educational games in their courses. Thanks to all the efforts invested in developing the platform, <e-Adventure> has reached the state of 'product', going beyond a 'research prototype'. This allows us to conduct new research on educational gaming and test it within <e-Adventure>.

Abstract—**Libre (free, open source) software brings new opportunities, but also new troubles, to the education experience. It provides a great deal of new tools that can be used unexpensively and easily. On the opportunities side, it enables customization and adaptation to special needs, and full reproduction of educational experiences without depending on a budget for expensive software licenses. But it also brings the troubles of charting a new territory, maintaining applications in a demanding environment, and finding ways of adapting to specific needs.**

In this paper, we introduce these issues by analyzing a practical case study which has been run in real classes during several years: the contribution by students to a "planet" ("blog of blogs") with topics related to an educational subject.

Keywords-open source; free software; libre software, education, blogs, planets;

I. Introduction

Blogs, also known as weblogs, are websites containing notes in inverse chronological order, which are publicly accessible over the Internet. Usually, they offer visitors the possibility of commenting entries [1] [2] .

Blogs have become mainstream during the last decade, dealing with topics ranging from politics to technology. They are run with a great variety of objectives, from activists trying to publicize their opinions to corporations trying to become closer to their customers. Blogs have also been used for educational purposes, for example as a source of information for students, or as a way of presenting assignments and summaries of class work. Currently, most learning management systems include blogs as an integral subsystem.

Planets are websites which aggregate (syndicate) content from different blogs as if they were a unique blog. The name comes from Planet[1], a libre (free, open source) application that is widely used in the libre software community. Such sites are commonly found for libre software projects, aggregating contributions from developers who write in their own blogs. The way planets work is very simple. Blogs usually offer their content in some XML-based format (RSS, Atom...), known as the *feed* of the blog. Feeds can be accessed by means of a public URL. The planet software downloads feeds corresponding to the syndicated blogs and aggregates them in inverse chronological order as if all the stories would belong to a single blog. In some cases the planet only shows the title and a part of the body of the original blog entry (a small paragraph or a few lines), offering the possibility to read the rest in the original blog, thus avoiding that long stories would render the planet webpage unreadable.

To identify the authors of every single post, an avatar of the author is used, which is commonly known as a "hackergotchi". Hackergotchies help to identify the author of a contribution in the planet, since planets usually contain texts from various authors, which is much less common in regular blogs.

Planets help in the creation of a community, as the mostly personal views of contributors are grouped in a single location for each project. Informal, and sometimes personal or not-project related information is shared among the members of a project, offering new points of view and stimulating discussion and innovation.

Although planets have been used by the libre software community for some years now, there is little use of them in the educational community. However, blogs have been widely used for various educational purposes. Stephen Downes [8] has reviewed the history of weblogs in education, and has identified the five main uses of blogs in this area:

- managing classes;
- posting materials;
- holding discussions or seminars;
- publishing summaries and comments on readings;assessing tasks assigned to students who maintain their own blogs.

Downes also describes some of the problems of using this technology in education. One university setting where blogs have been used is in the lyrics. Professor Barbara Ganley has extensively documented his experience in this area for years [4].

1 http://www.planetplanet.org

In the field of Spanish-speaking education, Gewerc describes the subject "New Technologies applied to Education", parf of the degree of Master at the University of Santiago, where blogs are used [5]. This paper refers to some of the educational initiatives -written in Spanish- that use blogs, both in the field of higher education as in high school. In [7] the experience of creation and use of blogs carried out during the 2003/2004 course by teachers and students of the subject “Audiovisual Design” at the School of Communication in the University of Navarra (Spain) is documented. Within the scope of the experimental sciences, from the end of the last decade, Grupo de Sistemas y Comunicaciones (GSyC) at the Universidad Rey Juan Carlos (Spain) has been continuously using blogs in all their classes as a mean of communication among students and between students and professors, especially to assist in the development of practical subjects of Computer Engineering and Telecommunication Engineering. As an example of this experiences, [6] describes the use of Zope / Squishdot in a group of subjects.

This article presents a teaching experience of e-learning based on the use of a planet of blogs that has been augmented with functionality that allows students to evaluate the stories of their classmates. To do this, students had to create a blog for writing stories with content related to the subject. The contents of all the student blogs were linked into a planet, the central location where they can be read and commented. The experience presented refers to six subjects of non-technical degrees. Of these six subjects, one was on-site and the other five were complete distance learning experiences. All courses were related directly or indirectly to computers, information technologies, computer networks and free culture, but none of them was purely technical. The total number of students who have participated in them is around 350.

The structure of this paper is as follows: next, a methodology for the use of a planet of blogs in education is presented. Then, some hints on our experiences are pointed out. Finally, some conclusions are drawn.

II. METHODOLOGY

The procedure of this activity is as follows. Each student has to create a blog specific for the subject. All student blogs are linked from a centralized location, the planet. Students will be able to positively rate entries from blogs of their peers that they believe provide useful information for the subject.

Each student should create a blog where entries include notes related in some way with the subject (explanations, comments, anecdotes, etc.). Blogs are individual. Professors should put special emphasis on advising students that blogs should have original content, and not simply copied and pasted information from other sites. They are also instructed on how it is always good practice to reference or display external news by using links, and to comment personally the content they present. Some other hints related to writing texts for the Internet are also provided, with particular attention to how to do it for blogs. In this sense, long entries are discouraged, HTML is briefly introduced and some guidelines on the visual aspect of the blog are commented.

To create a blog, students can use one of the many free platforms that offer this service and that allow the contents of the blogs to be exported in any of the following formats: RSS 1.0, RSS 2.0 or Atom. Example of these are Blogger, WordPress, Bitacoras.com, LiveJournal or Blogia, but many other exist on the Internet. Students will then have to aggregate their blog to the planet by entering the following information:

- The URL of the blog
- The name or pseudonym of the student
- The e-mail address of the student

The resulting form can be seen in Fig. 1:

Fig. 1.- Registration form.

Once properly registered, the blog will automatically appear on the planet.

Every blog must have a minimum number of entries at the end of the semester. That number of entries has to be calculated according to the number of students, because if the required frequency is very high the total number may be too big to be followed properly by students. In the learning experiences, weekly and biweekly frequencies have been tested, so that at the end of the semester there are at least a dozen (or half a dozen) news per student.

The votes received by the blog of a student, coming from peers will be considered for the evaluation of the activity.

In addition, and to foster that students rate their peers on a regular basis, voting entries from other blogs will also be taken into account. In this way, both writing in their blog as well as reading the planet accounts for the final mark. Teachers can assess additional items positively, in general, once the activity is finished. This may include aesthetic considerations (configuration of the blog, proper use of a blog-suitable style, etc.) in addition to the quality of the content.

Each student will have a number of points each week that can be distributed among the entries of blogs of his peers. To do so, at the bottom of each entry on the planet there is a link "Vote me!" through which you can rate that specific entry. The votes of peers and teachers will be taken into account when assessing the subject.

From the experience in several subjects, we have noted that the number of votes per student and per week should be at most a quarter of the total number of blogs syndicated in the planet. The rationale for this lies in the fact that if students have too many votes, discriminating between good and bad entries is not possible. Giving students a number too small, on the other hand, discourages reading the planet as once they have given out all votes, they may stop reading more stories. For the usual class of 40 to 50 students, five to ten votes per week is in general an acceptable number. Teachers may vote the entries they like, although in their case they have an unlimited number of points.

Fig. 2 shows how the planet is structured. On the right, after a brief introduction and some links to the page with the registration form and the page with the rules of the activity, the stories authored by students are listed in reverse chronological order. Each story has its own box, which shows the name of the author, the text of the post and two end links. The first link, "Vote me!", allow students to vote the story, while the second, "Read the full entry", leads to the website blog, since for space reasons entries on the planet are shown only partially (only the first 250 characters are displayed in this example).

Meanwhile, on the left side of the window there is some information about when the planet was last updated, and the list of syndicated blogs. The planet is automatically updated every hour, which means that every hour the software of the planet takes the feeds of the syndicated blogs and generates the list of stories in reverse chronological order that can be seen on the right.

If a student decides that a story of a colleague on the planet is worth one point, clicking on the link "Vote me!" takes him to a page where you are asked to fill out the form shown in Fig. 3.

Fig. 3.- Voting form.

III. Teaching Experience

The authors have been able to test the methodology in several university courses and postgraduate degree subjects. The problem areas found were as follows:

- Creating the blog. As the subjects involved in this experience were mainly targeted to students of non-technical degrees, this was for many of them the first time they faced the world of blogs. To mitigate the problem, we encouraged their peers with advanced technical knowledge or who were more familiar with technology to devote their first entries to how to set-up and manage a blog.

- Identification of the feed and registration at the planet. Once the blog has been created, the identification of the feed, including its URL, is a problem for many students. This may become a main blocker, since that information is necessary for registration. The greatest difficulty is in fact the concept of feed itself, which is not easy to understand at first for many students. Therefore, teachers are encouraged to show the difference between the feed (intended for machines) and the main blog page (intended for humans) and to show some examples.Avoiding impersonation when voting. To prevent anyone from voting on behalf of a peer, we had to think of a way of avoiding it. The mechanism we finally implemented was very simple: when you vote, you must indicate your e-mail address. With every vote a voucher of the vote is sent by email, stating that the vote has been stored and urging the receiver to contact the teachers in the case that the vote was not given by him.

- Detection of deceptive voting. The fact that students themselves can assess their peers can lead to situations where two or more students may use fraudulently the voting system, voting indiscriminately. It may happen that a student randomly distributes votes without reading the entries, thus obtaining a good assessment in reading. To avoid these situations, we have designed and implemented a voting analysis software that using data mining techniques and social network analysis identifies "abnormal" situations.

IV. Conclusions

This article has presented a teaching experience of blogging by students of non-technical degrees in which they participate in the evaluation of the contents provided by their peers. We have seen the procedure followed in this activity and have highlighted the experience of deploying it in several universities for several subjects.

Acknowledgments

The authors of this article want to show their appreciation to R. Plaza by the completion of voting analysis software, as well as GSyC professors, who helped with the set-up and monitoring this activity: E. Soriano, A. Santos, K. Leal and L. Rodero.

This work has been funded in part by the Comunidad de Madrid, under the E-Madrid Excellence Network.

Automatic Guidance Tools for Enhancing the Educative Experience in Non-Immersive Virtual Worlds

Preliminary results from project V-LeaF

Mariano Rico, David Camacho, Estrella Pulido

{mariano.rico, david.camacho, estrella.pulido}@uam.es

Abstract— **The interest of the Education community for Virtual Reality (VR) technologies has increased in the last few years due to their attractive 3D immersive worlds and facilities to provide a good environment to develop educational and collaborative tasks. However, these technologies present three main drawbacks: (1) a high cost in terms of hardware and infrastructure, (2) a high level of technology knowledge, and usually programming skills, is required to build up an educational and functional platform, and (3) once the educational platform is available for use, the educators are limited to the functionalities provided by the platform used. Our previous experience, designing and deploying a VR educational platform, named V-LeaF, showed that non immersive platforms (close to the gaming 3D platforms) provide High School educators and students with an attractive environment in which many features of the teaching/learning experience can be explored. However, this technological strength appears as a potential weakness feature of our platform when is used by high school students. Serious problems to maintain the student attention in this kind of domains have been detected, so the educators must employ time and dedication to ensure that students are really attending and acquiring the educational concepts scheduled. In this paper we describe an initial set of software tools developed (for both teachers and students) to solve the previous problem. An eye-gaze monitorization device allows teachers to focus the students' attention. A forms-based recommender system allows students to guide teacher's activity.**

Keywords: Virtual worlds; Virtual reality; Education; Recommender systems; Opensim

I. INTRODUCTION

The application of Virtual Reality to education requires a specific infrastructure, such as hardware in the classroom, or wearable devices, and its economic cost can be high as it is the case for immersive technologies. In this paper we show a software infrastructure capable of emulating hardware devices and communication between these devices. Specifically, we have created virtual versions of immersive virtual reality teaching-oriented devices, most of them based on monitoring the activity of students and teachers.

For example, students' eye-gaze monitoring allows us to provide teachers with a virtual device capable of displaying the "attention-level" of students. Eye-gaze is a key factor to check the comprehension level of students in immersive virtual environments [1] [2], but the effects of this factor in non-immersive environments (such as V-LeaF) has not been checked yet.

From our previous experience using Virtual Worlds environments with High School students, under the project V-LeaF[1] , we detected problems to maintain reasonable attention levels in the students. To monitor students by using immersive devices does not look to be an operative and scalable solution. For this reason a new system has been designed in a particular VR educational platform that allows in a non-intrusive way to monitor the attention of the student. The non-intrusive characteristic is essential if the educators need to provide a free environment for the student, improving their cooperation and collaborative skills. On the other hand, automatic recommendations and information about the attention level of the students must be provided dynamically to educators.

The paper is structured as follows: section II provides a brief description about our VR educational platform and other related work. Section III describes the automatic monitoring system. Section IV gives details about the scheduled experiments to be carried out by using the proposed system and, finally, Section V shows conclusions and future work.

II. VIRTUAL REALITY EDUCATIONAL TECHNOLOGIES

A. Underlying technology

The proposed monitoring and recommender system has been created by using the V-LeaF platform [3] [4], an infrastructure initially oriented to high school teachers and students, aimed at enhancing the teaching and learning experience respectively.

This work has been funded by the Spanish Ministry of Science and Innovation under the projects V-LeaF (TIN2008 - 02729 - E/TIN) , METEORIC (TIN2008-02081) and e-Madrid(S2009/TIC-1650).

[1] See http://this.ii.uam.es/vleaf

V-LeaF uses the infrastructure provided by OpenSimulator [2], an open source project which allows **developers** to extend the base functionality by means of pluggable software artifacts named *modules*, such as RealXtend[3]. An in-world programming language oriented to **users** is provided, aimed at providing functionality to in-world objects. In such a way, V-LeaF extends functionality by allowing teachers to use (and, eventually create) in-world objects with a given functionality. By using this approach the adoption barrier is lowered, by allowing teachers to create teaching devices for the V-LeaF community. Objects created under this contributory philosophy can be modified and extended by other teachers, evolving according to the users (teachers) needs.

The V-LeaF project site provides teachers with manuals and tutorials in two levels: basic and advanced. The basic level provides information about how to use the teaching devices, not requiring technical skills at all. The advanced level provides material about the in-world programming language (Linden Script Language, or simply LSL), the development of teaching-devices such as the ones described in the basic level, and the V-LeaF installation guides to allow teachers to create their own V-LeaF virtual worlds. The skills required for the advanced level have been minimized. Most of this material was requested and supervised by high school teachers participating in the first V-LeaF experiments carried out during the 2008-09 course.

B. *Related Work*

Second Life (SL) raised the educators' interest towards virtual worlds due to its high power/easy-of-use ratio. For the first time, the application of virtual worlds to education is in teachers' hands, and many studies involving high school teachers have been carried out [5-8]. Some of the authors participated in the creation in SL of a virtual version of our academic institution (EPS-UAM) [4] in 2008. Although we realized the possibilities of this environment, we noticed that this virtual world could be improved in several aspects:

- To create objects in SL requires renting a parcel. This is an administrative task with an economic cost.
- The parcel is not isolated of the rest of the SL world. While students attend a course, other users can get in this parcel and interact with the students, which may interfere in the lessons course.
- The lack of parental control (as a "black" list of locations not recommended) discourages this world for under-18 students.

Although the SL parcel's access-control policy can be customized, the skills required to achieve this task are high for average users (teachers). V-LeaF provides teachers with a web application to organize students in groups, thus simplifying this management task (see Fig. 1). V-LeaF students belonging to a given group are bounded to a specific "island", and the access policy prevents students from leaving the island and prevents students in other groups from getting into the island.

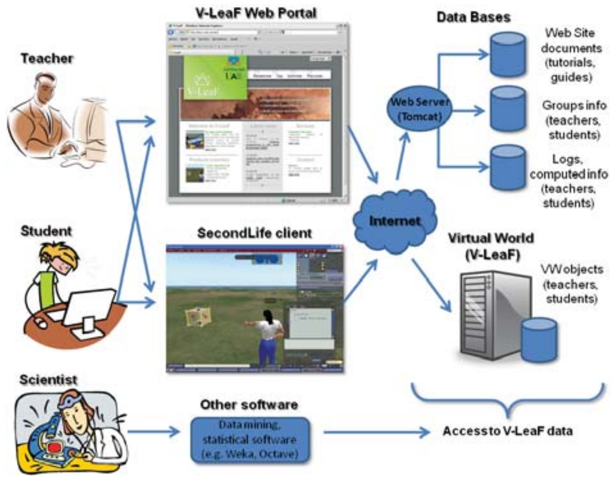

Figure 1. The V-LeaF infrastructure.

OpenSim can be regarded as a non-commercial version of SL. OpenSim is free source, and can be downloaded and installed for free. The compatibility with SL is almost complete: the in-world programming language (LSL) is portable, objects are interchangeable between these worlds and even the communication protocol between clients and servers are compatible. An enthusiastic community of developers provides new software modules to extend the basic functionality (e.g. to allow new in-world programming languages). Our aim is to create a similar community but oriented to teachers, not to professional software developers, focused on teaching devices and teaching techniques.

An additional benefit of using open software is that the functionality of the platforms can be modified. This task requires advanced skills (e.g. management and development of C# software projects), and is not intended for teachers, but it is the added value of V-LeaF. For example, V-LeaF can monitor students and teachers silently. However, SL or the "non-hacked" OpenSim (on which V-LeaF is based), warn users when they are going to be monitored.

III. V-LeaF Virtual devices in action

There is a need for evaluative systems to measure the success of virtual environments by monitoring students, teachers, contents an technologies [9]. Having this objective in mind, the following is a list of relevant virtual devices developed by our team. The selection of these devices was the result of a requirement analysis made by high school teachers that attended the first V-LeaF experiments carried out during the academic course 2008-09.

A. *Monitoring the students eye-gaze*

As we pointed out previously, the importance of eye-gaze in learning is well known. For example, there is a relation between teacher's eye gaze and student's attention and contents comprehension [1]. Another interesting experiment from this

[2] See http://opensimulator.org

[3] See http://www.realxtend.org

[4] See http://www.ii.uam.es/esp/sl/index.html

study states that the location of the student in the virtual classroom has a direct effect in the student results. These experiments were carried out in immersive environments in which each location changed the student view of the teacher, privileging locations close to the teacher and with a direct vision (face to face).

3-D multiuser virtual environments (3-D MUVEs) [10] such as V-LeaF, are found familiar to students due to its similarity to modern 3D games. Although these environments do not provide students with the realism of immersive technologies, both approaches share the importance of social aspects of digital learning environments [11]. For example, the theory of Transformed Social Interaction (TSI) [12] divides the potential of real-time transformations during interaction in three groups:

- *Social-Sensory abilities*. These transformations complement human perceptual capacities. For example, virtual devices can monitor student's activity to be reported to the teacher in real time. This is the most relevant aspect exploited in V-LeaF.
- *Self-representation*. A given avatar can be rendered (transformed) in different ways. For example, it could be the case that some students learn better with smiling teachers, while others improve their learning with serious teacher faces. Although the virtual world provided by V-LeaF is the same for all participants, there is an exception: student's view point. Unlike immersive environments, in MUVEs it is important to distinguish between the avatar's view point and the user's view point. For example, although the student's avatar is quiet facing to a given object, the student can observe this scene from any direction by moving his/her own "camera". This fact can be exploited to suggest users to move their cameras to a privileged position, without having to move their avatars.
- *Social environment*. The perception of the rest of participants can be modulated to filter, for example, distracting gestures of participants. This aspect cannot be modified in V-LeaF.

The virtual device named "Students Monitor" (SM) comprises the teacher monitor and a bracelet that each student must wear on his/her wrist. Each wrist monitors the student eye-gaze (indeed the position and direction of his/her camera) sending the information to the teacher monitor. This monitor shows a graphical representation of the location of each camera (see Fig. 2), in which color and blink are visual indicators of the student visual focus. The monitor has a default configuration, but this can be configured by the teacher, with parameters for (only the most significant are shown):

- *List of relevant objects.* By default it comprises only the teacher, but this list can include other objects relevant for the students learning process, such as blackboards or workbenches.
- *Maximum gaze inattention time.* Number of seconds that the student can lose visual attention. When this limit is exceeded, the student blinks in the teacher's monitor.
- *Refresh frequency.* Number of times per second that the teacher's monitor request data to each student's bracelet.

All the information managed by the Students Monitor is available for researchers and teachers through a web application in which raw data are provided as CSV files. Some basic analysis is shown in the web application pages.

The teacher's monitor can be attached to the user's view to avoid indiscreet students' views. This mechanism, provided by OpenSim is also used by the virtual device shown in the next subsection.

Figure 2. Teacher's monitor of the "Students Monitor" virtual device. This monitor is a virtual object that can be attached to the user's view (usually the teacher's view). In this example it is attached to the upper left corner.

B. *Evaluating the teacher activity*

One of the student demands is a mechanism to anonymously evaluate the teacher activity. To this end, a virtual device named "Teacher Evaluator" was developed by our team. This device comprises a Questioning Object attached to each student's view (see Fig. 3) and an Evaluator Object attached to the teacher's view (see Fig. 4). As all the objects are attached to the participants' views, the anonymity is guaranteed for students and teachers.

The Questioning Object prompts students with questions one at a time and it is configured externally through a web application. These are the most relevant parameters:

- *Evaluation frequency*. Number of minutes between questions. There is a random delay to avoid the synchronization of the students' responses.
- *Questions*. This is the list of questions that will be presented to the students during the teacher's activity. Although there is a default set of generic questions, these questions can be adapted to the subject domain to provide a more precise result. The current implementation only considers mono-answer questions in order to simplify and minimize the student's response time.
- *Answer tolerances*. Each answer has a tolerance associated. This tolerance is the percentage of students that can answer this question. When this tolerance is

exceeded, the Evaluator Object warns the teacher, who will reformulate or retell the conflictive topic.

The Evaluator Object can be configured to relax the warning conditions for different situations. The conditions in a 10 min. talk may be different to the conditions for a 50 min. talk.

As for the Students Monitor, the information recorded by this virtual device is exported as a CSV file for additional analysis and a basic summary is displayed in the web application pages.

Figure 3. Questioning Object (upper left corner) in action. A question with 5 possible answers is prompted to the student. The student can provide an answer or cancel the request.

Figure 4. Teachers' Recommender system in action. The Evaluator Object displays the recommendation in the teacher's view centre. Information collected from the students' questioning objects is used by the recommender to guide teacher's activity in real-time.

IV. Scheduled Experiments

This section shows a set of scheduled experiments to be carried out by high school students during the course 2009-2010. These experiments exploit the virtual devices described in the previous section.

A. *Related to monitoring students' eye-gaze*

By using the Students Monitor, we have designed the following experiments:

1) Test the Bailenson results. Bailenson reported the existence of privileged positions (close and facing to the teacher). These results were obtained in immersive environments, and we should check that this effect is observable in 3D-MUVEs such as V-LeaF. If this effect was observed the utility of an automatic recommendation system for students could be evaluated. This system could suggest the better user's view (camera position) to attend a teacher's lecture.

2) Evaluate the utility of the Students' Monitor. Two groups of students are required. Both are evaluated after a teacher's lecture by means of a contents questionnaire. One of the groups will have a teacher assisted by the Students' Monitor. Significant deviations should be identified to show the effectiveness of this virtual device.

a) The effect of being monitored. The behavior of students can change when they know that they are monitored. This should be researched. V-LeaF allows both policies: silent and classical monitoring.

3) Evaluate the efectiveness of the Teacher Evaluator. In a similar way to the evaluation of the Student's Monitor, the efectiveness of the Teacher Evaluator module should be tested with two sets of users.

B. *Evaluations wars*

Let us image a classroom in which students evaluate the teaching quality (perceived quality) and teachers pay attention to students' gaze inattention. It could be the case that students with low gaze attention became stressed by the teacher, resulting in a negative feedback for both students and teachers. This kind of destructive effect between virtual devices could be an interesting matter for research.

V. Conclusions and Future Work

For many years, immersive environments have shown that teaching can be improved in different ways. For the last years, the fast development of personal computing has resulted in powerful computers with graphical features capable of providing users with rich 3D virtual worlds. Many of the lessons learned in immersive environments can be applied to these new low-cost environments.

Our team has built, on top of the OpenSim platform, a software infrastructure, named V-LeaF, initially oriented to high school students and teachers but with a wider application scope. Any social task involving avatars can benefit from this platform.

One of the results of the application of V-LeaF to real high schools was a list of "useful" teaching virtual devices, identified by both teachers and students. The most relevant virtual devices created are shown in this paper, as well as the experiments that can be carried out. As we have described in section IV, next steps will include several experiments with educators and students from high schools to obtain analytical measures of the results by using our new monitoring device.

Acknowledgment

We would like to thank the V-LeaF development team (Víctor Cabezas, Daniel Gómez, Elena Vargas, and Daniel Bravo) and the Madrid High Schools Institutions (I.E.S. Antonio de Nebrija and Virgen de la Paloma) for their work in this project.

***Abstract*— In the last years, authoring based on e-learning standards has been consolidated as a core factor of industry and development of interoperable and effective virtual learning environments. However, there is a need for further research on abstraction to provide a more instructional view in the context of authoring tools in a variety of ways, in order to avoid being driven by Learning Technology (LT) specifications, facilitate instructional knowledge aggregation, and to provide an appropriate level of clarity and semantics in the design of collaborative activities. We propose a combination of techniques to provide this instructional abstraction in the context of the new European educational model, combining instructional layers and collaborative scripts in authoring tools, and semantic web techniques for extending e-learning material in order to harness the wealth of existing web content and semantically labeled repositories.**

Keywords: E-learning content modeling, Educational authoring, collaborative learning, e-learning standards, Semantic web

I. INTRODUCTION

The generation of educational content and design of collaborative activities has always been a big effort, especially because in many occasions the objective of the author or group of authors is to reuse existing resources and develop a complete course, including complex activities with content and user interactions. If the main goal of a learning object (LO) is to be used for teaching and learning, the second one in importance should be its reuse. To this end, extensive research has been carried out in the last years to standardize learning content components and collaborative interactions [14], to make them usable in interoperable and maintainable content repositories. To organize and help in the retrieval of the right LOs, metadata labels have been defined and standardized. But this has introduced an additional burden, namely that of annotating LOs appropriately following these metadata.

In this context, gathering educational content is a matter of two factors (a) reusability, which implies to have the resource at the appropriate level of granularity, and (b) availability, which tackles the idea of actually finding the most appropriate resource using a variety of techniques. The fact is that authoring tools usually do not implement features for these two factors and generally also lack of the appropriate abstraction level to provide an efficient way to search and retrieve content and on the other hand, a suitable way to describe learning courses at an instructional level of abstraction.

To overcome these problems in authoring of educational material we propose a combination of techniques to provide instructional abstraction by means of instructional layers, collaborative scripts in authoring tools and semantic web techniques for extending e-learning material in order to harness the wealth of existing web content and semantically labeled repositories.

II. INSTRUCTIONAL LAYERS, KNOWLEDGE MODELLING AND COLLABORATION

From the instructional point of view, the notion of Learning Object has been extrapolated from a variety of computational paradigms like *reusable component* as a software engineering concept, providing structured reusable elements labeled with metadata, and also from knowledge engineering, allowing content organization using knowledge-based structures like ontologies or semantic web development. On the other hand, from the cognitive sciences perspective, the adoption during the 50s and 60s of some instructional theories based on cognition have obtained useful abstractions to specify appropriate methods and situations in which those are to be applied during learning process [7].

In this scenario, very rich tools are available to tackle with the problem of providing flexibility in the creation of courses based in the aggregation of LOs [1][2]. However, this authoring tools have not evolved in a parallel way to be instructional aware, and still focus strongly on LT specifications and implement a LT specifications' syntax driven approach to implement the process of authoring [15]. The authoring of learning content has similarities with the COTS software building model, as it combines creation from scratch and reuse and modification of existing content, freely available on the network or stored in repositories. In this case, the reusing process needs some meaningful way to search and retrieve the appropriate content shaped as learning objects (LOs). Current research agrees that approaches based on a plain classification of LOs by means of a metadata labels lack a meaningful way to search, retrieve and reuse LOs from an instructional perspective. The reason for this drawback is based on the fact that (1) from an instructional perspective, retrieval of a collection of LOs by matching metadata attributes does not replicate the way a teacher operates when creating its own material, and (2) from the authoring perspective, the construction of metadata instances is very costly and not as precise and consistent as desirable.

A. Using knowledge modeling to improve authoring, collaboration and virtual learning communities

It has been mentioned that people is actually a killer application of the Internet, and it is with people and some organization that impressive results are achieved at low cost (for instance, del.icio.us, Wikipedia, Twitter, or the syndication of blogs) [31]. In this sense creating educational content can also be done by users providing the appropriate environment. Several repository efforts have been launched but they have not yet taken off.

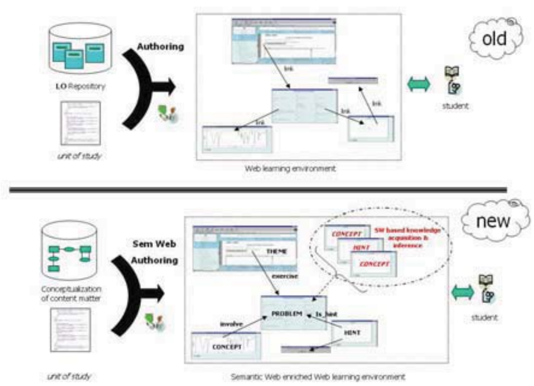

Figure 1: Semantic annotation of educational content

Sometimes the problem is one of granularity: the presentation of the learning resources is too broad as to ease the reuse of specific content. But if the granularity is too small, it is more difficult to have a good overview. Concerning this point, we agree with the approach proposed by [19] of using Topic Maps. Actually, we have already explored that from the teachers' point of view, authoring of educational content is easier to create if it is previously instructionally structured based on a pedagogical ontology (See Figure 1). This way teachers can refer to LOs like i.e. '*I would show here examples to illustrate this concept*' or '*exercise this concept solving this problem*' or '*give me a hint*'. We can be even more precise by saying *'insert here some easy examples to illustrate this concept'* and so on [2].

In the current way of retrieving LOs, we look for terms that match the metadata attributes, but without asking for a precise instructional relationship. So, the retrieved elements will have to be filtered one by one. We proposed to embed a semantic query language in LT specifications and the creation of a semantic layer based on the conceptualization of a subject domain. We think educational content authoring is a 2-step process. Firstly, there is a need to create an instructional view of the learning content at a low level of granularity. In this sense, some works suggest the use of semantic layers to organize information in the repositories [19]. Our approach also proposes using a semantic layer, except that we use RDF/OWL [24] [23]. There is a very strong relationship between RDF and Topic Maps. Simply stated, one could say that RDF provides a simpler and less specific model, based on more fundamental concepts. It is thus more flexible. Moreover, the possibility of reasoning with tools such as CWM or Pychinko, provides us with a tremendous power, allowing the inference of new information from existing metadata by the use of rules [18].

Some ideas are possible in this respect. As we have already evaluated authoring can be combined with topic maps as a way to link LT-based specifications to a cognitive-based framework [8], where LOs no longer remain as isolated components and act as a part of instructional ontologies. One way for improving LT-based specifications could be using embedded languages for allowing the creation of semantic instructional queries and referring instructional content at a higher level of abstraction [15] [6]. This authoring model would allow also the creation of dynamic links in the educational content, creating on the fly content in the case the reference had been updated, obtained by a direct reference or by means of inference of semantically labeled resources using reasoning link CWM and that is partially developed in [18] and [31]. The objective in this sense is not so much the development of new content specifications based on learning technologies or e-learning standards, but to use consolidated specifications such as IMS stack to integrate on them some mechanisms that allow the use of the described techniques with the objective to validate them in a real context of virtual campus. Going beyond reasoning, semantic web techniques have also a huge potential for enhancing eLearning search and retrieval, such as selecting, recommending, repurposing and reusing learning resources or tailoring learning activities to a given social or working context. Ontologies lie in the core of these techniques as they are able to provide a formal and shared conceptualization for every aspect within a learning set-up and scenario and to infer new and unforeseen facts implied by the available knowledge. Hence, we propose using ontologies as the foundation for the aforementioned semantic layer. Besides, using ontologies could help characterizing LOs in terms of semantic entities instead of the traditional syntactic approach. It has been signaled that retrieving LOs from a repository by searching field contents fails to catch the user's intentions, which tends to make its results either inaccurate or inadequate for the user [25]. Furthermore, as metadata standards impose a number of constraints on the possible values, learners and educational authors are supposed to know the right searching terms for a given query beforehand in order to get a good precision and recall. Ontologies allow turning syntactic metadata into semantic annotations as well as enabling searching for resources in a way far richer and closer to the users' needs than a mere keyword search. In this sense, instructional uses of the LOs are a distinctive trait, which could be used to drive the searching process, thus allowing a new kind of meaningful, *usage-directed* semantic query.

A number of techniques are going to be used to achieve this goal:

- Ontological Engineering, including locating candidate ontologies to reuse, aligning and merging them and building the lacking parts by using ontology design patterns such as those described by [26] for obtaining or building set of ontologies gathering all the necessary knowledge and representing every relevant instructional entities and relationships, making it explicit and easier to (re)use as well as binding the instructional ontologies to existing educational standards (such as SCORM, LOM or IMS-LD) for enabling the interpretation of existing metadata to bootstrap the semantic annotation process.
- Inference techniques, based on Description Logics [23] [28] and rule-based engines[30].
- Semantic annotation based on the representation and efficient retrieval of terms related to the aforementioned ontologies [29] [24]. As a result, it will be facilitated the reuse and repurposing of available Learning Objects (or their meaningful components) both in an Learning Object Repository and on the web.
- Clustering techniques for discovering new knowledge gathered from the web, such as FCA [27].

All these techniques are to be applied bearing in mind the pedagogical objective of designing a recommendation mechanism based on semantic search and able to cope with the actual needs of instructional designers and learners that would create a new kind of LO, which could be named *recommendation* LOs. Such a LO, would consist of contents collected from the web as the result of an *usage-directed* query as described before.

B. *Modeling collaboration*

The field of e-learning, collaborative learning is a pedagogical paradigm that is getting a growing acceptance. It is articulated by arranging a set of students into a number of small groups to carry out several learning activities together. Within these settings, learning objects, rather than being provided by teachers and instructional designers, arise as a consequence of the joint work of the groups supported by collaborative tools. These new kinds of objects have been coined as ELOs (Emergent Learning Objects).

The paradigmatic shift consists in moving from the teacher-centered perspective, where the instructor delivers the appropriate contents to the students, to the learner-centered one, where students take a more active role while teachers mediate and moderate the learning process. Articulating its instructional workflow requires storing and later retrieving ELOs. These objects have to be characterized with respect to a new dimension, that of the collaborative context whence the ELOs arise. And furthermore, the collaborative context where ELOs emerge can help automating their characterization in terms of context-dependent metadata. It is quite important to determine the elements to take into account to populate the context for facing these requirements. Examples of such elements would be the collaborative activity being developed, the group or the involved tools.

Socio-collaborative context elements are fed from the collaboration-oriented virtual learning environments (VLE), and particularly, from the use students make of them and their integrated tools. Hence, VLE must be built taking into account four main requirements:

- Defining the social structure for the underlying virtual learning community (VLC) where the learning scenarios are to be unfolded and particularly, the set of groups and types of users required for this development.
- Designing the collaborative work that learners will be involved in, including defining activities according to a pedagogical method, describing their sequencing along an instructional workflow, defining the roles suiting an appropriate division of labor, etc.
- Supporting the collaborative interaction by integrating an open set of external mediating tools within a VLE. The integration mechanism must provide a sufficient interoperability level for the users to perceive a smooth sense of continuity in their learning experiences. ELOs are, in this sense, a main resource as a vehicle to provide functional connection between tools an so achieving the desired interoperability level.
- Catching all the dynamical aspects inherently bound to the collaborative learning scenarios specification, such as, creating informal learning groups within the experiences lifespan, supporting activity monitoring and control or assisting the evaluation and grading tasks.

To face these requirements, we have developed the PELICAN e-learning platform [20] [21] [22]. Different users can perceive this tool from several complementary perspectives:

- PELICAN as a design tool. PELICAN is used by instructional designers as a design tool to define collaborative learning scenarios. The platform provides a simple and flexible modeling language to allow the definition of all the aspects related with collaborative experiences (social arrangements, collaborative work, monitoring rules, collaborative evaluation strategies, etc.) Notice that these specifications could be reified as LOs to foster their reusability along different pedagogical contexts and reduce the design efforts.

- PELICAN as a VLE environment. From the students' point of view, PELICAN is perceived as a collaboration-oriented VLE. Hence, it provides the required technological infrastructure to support the previously designed learning scenario development such as shared virtual workspaces, access to web references, interaction services and so on.
- PELICAN as an integration platform. PELICAN can also be considered an integration platform as it provides several mechanisms to incorporate external tools supplying interaction services to virtual workspaces at various integration levels.

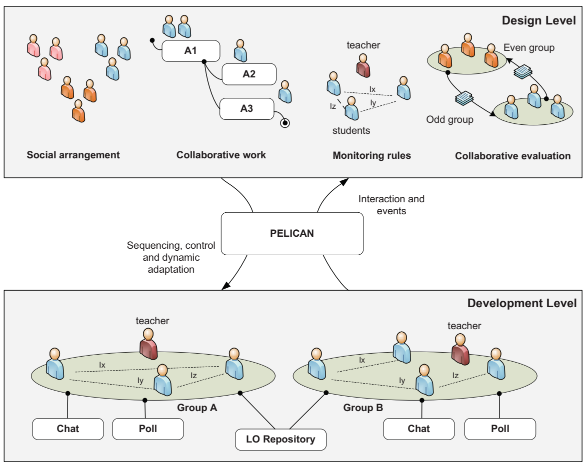

Figure 2: Two working levels within PELICAN

According to these three perspectives the instructional workflow in PELICAN is stated at two working levels. As it can be seen in figure 2, within the design level instructional designers specify in a formal and computational way all the aspects related with the learning scenario being undertaken. At development level, teachers deploy the design of a learning scenario along one or several workspaces bound to different socio-collaborative contexts. Between these two layers PELICAN is located as an orchestration mechanism to synchronize instructional workflows within each workspace with the prescriptions expressed in the scenario specification at design level.

III. INSTITUTIONAL POLICIES: E-LEARNING STANDARDS AND EDUCATIONAL METHODOLOGIES IN THE CONTEXT OF EUROPEAN EDUCATIONAL SPACE

In the current arena of educational standards, the development of ad-hoc standards leads to a large extent forced the re-use of existing ones. Given the new production framework being proposed here, where educational institutions need to adapt the content life cycle towards a sustainable model, they have to combine their own research and development in the area of educational standards. Given this approach it would be possible to integrate lecturers into the authoring of standardized content via a strategy of institutional production using tools that implement instructional design in the abstract sense reflected in their VLEs, and thereby avoiding the use of syntax driven tools. The UNED has since 2006 being generating open content, specifically Open Educational Resources (or OERs), marked up using various educational standards. Specifically, given the accessibility needs of an important part of our students, these resources needed to include meta data not only on the type of content but also its structure and the way in which it can be adapted and presented to students with special needs.

A. *Deploying e-learning standards policies*

Distance learning in virtual environments allows intensive use of new technologies, especially in the field of creating and managing multimedia content. The use of multimedia resources, either as asynchronous or synchronous learning tool in virtual environments can improve content learning with a high visual and interactive effect. But multimedia source material is diverse, ranging from video lectures to radio broadcasting, videoconferencing and slide presentations developed in many different formats.

This availability of this highly heterogenous bunch of educational objects implies that a single standardized metadata schema does not conform, as a rule, the definition of an educational repository metadata architecture, as in the case of an organization like UNED. In this context, the development of an application profile specifically designed for a LO repository with large multimedia component is highly important, being necessary to correctly define a set of metadata associated with the nature of the object which will structure and identify all elements and relations between them. In this sense and, overall, the use of standards-based content description XML allows to describe completely and extending all the elements that are part of a course.

Using XML as a standard basic language for describing content is widespread used in e-learning standards based on LOM, DublinCore and others, as well as schemas for description of multimedia (MPEG-7 is an example) or the packaging of objects (eg, SCORM). Therefore, it is perfectly feasible to full integrate the profile as a standard inside an environment that fully uses the other, providing they have a common language and a consistent set of metadata.

This new application profile will result from the integration of different standardized metadata schemas (generic, such as Dublin Core, educational like LOM, and multimedia such as MPEG-7) and represents the first step of a long process to ensure consistency and reuse of these contents in the future. Taking LOM as a starting point it may be a good choice, or at least an appropriate option but will implya greater effort (as far as labeling is concerned) in relation to other alternatives such as DublinCore. Moreover, at present, there are many more application profiles based on DublinCore than in LOM. This does not mean in any way, that the use of DublinCore is most appropriate. The reason is based mainly on one side in the simplicity of the Dublin Core metadata (as opposed to a larger number in LOM). For another, the more "generalist" DublinCore pursued against a better "educational" search with

LOM. In any case, as shown in this document and the referenced literature, it would be more difficult making the transition from a profile based on Dublin Core to a profile based on LOM than viceversa.

The subset of LOM metadata related to technique or technology will be somehow redefine to accommodate the huge volume and type of learning objects along with a set of other standard schemes which will define more precisely the audio and visual properties of the objects. In the case, the metadata that are commonly used in the LOM standard will be integrated in the data flow described by the MPEG-7, so that the latter becomes a comprehensive description of the reusable learning objects [32].

B. Software and content accessibility conformity

ICT technologies led each student to fulfill their learning process at their time, place, pace and capacities, but if the methodology is non-accessible for people with disabilities it is completely useless. Attention to diversity must be paid continuously, as the learning process is a continuous mode.

A critical issue to improve drastically the quality of the educational process is the development of high quality on-line learning resources and educational software [33] and the accessibility level of these materials will make a difference. A precise control must be taken into account over the creation process, analyzing the existing standards for learning resources, their level of accessibility, developing new laws, directives, standards, specific guidelines and new authoring tools. The appearance of Open Source development tools for SCORM compatible materials has achieved a great goal [34].

Non-accessible web interfaces prevents and hinder right access to information and services for Internet users. Even W3C (World Wide Web Consortium) promotes since many years accessibility standards and guidelines for both content development and authoring tools, reality is highly disappointing. The problem of accessibility is not yet understood by developers and producers and also there is still a lack of development frameworks covering the whole software development life-cycle that include accessibility checkpoints.

Lecturers and learners should be provided with specific means so that they can interact with learning material regardless of disability, benefits of accessibility compliance are not only for people with disabilities, but also for elderly people, all users in general. Learning environments will be Web based in most situations [35], therefore Web materials displayed into LCMS must be available for all users. The materials will run with the same behavior in all environments, have a consistent user interface and be easily navigated so that the content can easily be accessed and understood. IMS GDALA (Guidelines for Developing Accessible Learning Applications) offers specific guidelines for design and development of e-Learning applications in all the lifecycle and W3C/WAI WCAG (Web Content Accessibility Guidelines) give general guidelines to achieve accessible content.

Lecturers create learning content using above standards. Courses will be delivered and display through an e-Learning platform - that is in fact a Web based application - therefore greater flexibility and automatic processes are desirable from the point of view of the creator, commonly the lecturer. Authoring tools are the main point in the stages in the creation of educational content. The most widely used technical development so far is based on the use of validation and verification tools for web content after development. This validation cycle model is close related to the methodology called software prototyping based on the creation of prototypes, i.e., incomplete versions of the software program being developed. A prototype typically simulates only a few aspects of the features of the eventual program, and may be completely different from the eventual implementation.

The chances of the result of the validation process vary depending on the project and the available resources, in most cases it is reduced to the validation of the use of standards and accessibility and omitting the rest of the characteristics involved. Some authors propose methodologies based with an expanded user-centered development. In this type of solutions, starting from a simple design and considering all users, accessibility requirements are considered at first, before the initial prototype is developed, along with the rest of software requirements. Therefore in this model, the prototype is evaluated in the most possible ways obtaining then the most complete error report.

In another category are those solutions based on the development of web content using authoring tools that include accessibility standards like (X)HTML and CSS. At first they represent a guarantee of compliance with W3C standards and other requirements of accessibility and usability. Often these authoring tools also include validation tools or links to them, being designed to operate in a similar way as the validation cycle model. Such tools (as the ones that comply with W3C ATAG guidelines) are one of the best alternatives. In practice, it is a limited solution, having trouble with dynamic web pages or parts that are not included in the set of standards. As in the previous case, there is an intermediate solution being used only for the development of specific content based on (X) HTML or CSS.

In a new category one could gather all those new technologies arising from technical innovation around the Web 2.0 [36]: developments that use sets of Web 2.0 standards, Rich Internet Applications (RIA), Semantic Web or Micro formats. Actually, the application of these techniques usually takes place as a whole in the project so that it is analyzed through a unique hybrid model that represent simplified solutions. The use of Web 2.0 elements benefits accessibility:

- they are standardized elements already,
- there is the possibility of reutilization of models with RIA Mashup components,
- many metadata information exists to provide Semantic Web functionality.

Regardless of the use of RIA technologies, other authors defend in any context the use of semantic information in addition to accessibility aiming the usage of standards (X)HTML, CSS, XML for data and SOAP and DOM for data exchange and interaction. This concept is at the heart of Web 2.0, and thus is implicit in the use of these technologies. Alongside, he believes that Semantic Web complies accessibility conformity of software components because of the metadata information also easier from RIA technologies because it has been taken into account almost since its inception. Finally, the semantic information is supplemented with the use of Microforms or metadata patterns that complement those elements likely to present accessibility problems.

Regarding the scope of this solution, it is beneficial because it provides innovative technologies for web development. RIA technologies certainly give greater power and functionality to the web, besides being really closed to accessibility conformity because of the use of web-based standards and reutilization of components. Still in the area, Mashup development ensures separation of structure and content, facilitating the publication of content with a minimum and accessible version from any application or Web service. On the other hand, the semantic information through metadata is a very valuable partner to enriched components, so that that they can be interpreted by assistive technology tools and accessibility APIs for platforms.

C. *The European Educational Area*

In a broader context, the new European Area [9] and its convergence in education designed a model closer to what today is conducted in North America and Japan. In such systems is given greater importance to the practice load during the conduct of a subject. By providing an orientation toward more experimental tasks, and a clear direction to the working world, students develop a range of skills than in degrees with less experimentation do not have. This is an excellent testbed to carry out institutional standardization policies.

The most visible set of changes involves the abovementioned adoption of a US-like unified cycle structure involving graduate-master-doctoral cycles, as well as the adoption of a single unit of measurement, the ECTS (European Credit Transfer Systems) credit (which refers to 25-30 student hours of total effort, rather than being measured in hours of face-to-face lessons as before). In many countries (such as Spain), this involves the re-design and thus the (re)accreditation of all the degrees, under the quality certification system required by the EHEA. This massive, simultaneous redesign of all degrees presents daunting challenges but also offers unprecedented opportunities. On the one hand, since all degrees must be simultaneously redesigned, synergies among them can be effectively exploited, thus encouraging the re-utilization oriented approaches discussed in this paper (LCMS, standards like LOM, Dublin Corem QTI, IMS, SCORM, etc.). On the other hand, shifting the unit of academic measurement to student hours (through the ECTS) facilitates the seamless combination of face-to-face, distance and blended learning in academic degrees.

The other, maybe even more significant but more subtle set of changes are those aimed at shifting the focus from instructor-centered “teaching” to student-centered “active learning”. It involves methodological changes such as continuous evaluation, de-emphasizing theoretical lectures to focus more on assignments and projects, higher practical focus, allowing students higher flexibility to design their own curricula. When combined with budget limitations, this methodological shift strongly supports the introduction of effective IT based approaches to alleviate the burden on the instructor’s resources. These should facilitate the educational equivalent of the current manufacturing trend towards “mass-customization”, thus allowing individually tailored learning paths with a level of resources similar to that required by standardized education. In addition, several countries are taking this opportunity to introduce far-reaching modifications in their educational systems, which further strengthen the case for the introduction of IT based educational innovation. For example, in Spain, until now, all “official” degrees were listed in a catalogue compiled by the Education ministry (universities could also grant their own degrees on whatever they wanted, but those did not have official recognition). This catalogue included the name and the degree curriculum (structure), up to certain level of detail. The new system, however, breaks away from that closed catalogue approach and just issues some very generic guidelines to which new degrees should conform. Within this framework, universities (both private and public) are free to propose whichever degree titles and supporting curricula they want. Once the proposal is cleared from a quality criteria point of view (general quality criteria, such as the faculty CVs, cohesiveness of the proposed degree curriculum and appropriateness of the supporting IT infrastructure) the new degree is inscribed in a national registry, and the university is free to offer it (subject, again, to periodic quality evaluations).

One last aspect worth highlighting regarding the EHEA is its emphasis on promoting mobility and the international dimension in education (through joint international degrees or through mobility in selected subjects of end term Thesis). Again, achieving this objective would be assisted by the adoption of standards-based, location independent IT-based educational solutions. These should support both distributed provision of learning services (e.g. in degrees offered by consortia of universities) and their consumption by distributed student groups, facilitating not just the interaction between students and instructors, but also the increasingly critical interaction among participants in distributed teams.

IV. BACKGROUND OF UNED RESEARCH GROUPS

Researchers in the UNED belong to LTCS[1] (LSI Dept.), G-Elios (DIEEC[2] Dept.) or ATLAS[6] (Modern Languages Dept.) groups. Some of their members also belong to the CINDETEC unit, a Vice-chancellorship that coordinates the university's e-learning infrastructure.

The LTCS Group is made up of researchers from the LSI Department at UNED and external collaborators that work developing projects which apply learning and collaborative technologies to the support of human activity in distance learning scenarios. The research is based upon:

- Knowledge-based Authoring
- Collaborative modeling in educational contexts
- E-learning standards
- Software and Content Accessibility conformity

The group's research lines can be situated within the area of educational technologies, specifically learning, both individual and collaborative. The first relates to different aspects of instructional knowledge representation and its normalization. The second is centered in the problems associated with collaborative learning and the mechanisms that sustain and define the activities that configure it. The third goes from the description of the collaborative workspaces or mediational tools that facilitate the communication between distinct agents in the process, to the analysis of the process based upon records of the activities undertaken. The latter reinforces accessibility issues while delivering eLearning services.

The group has participated in the following project in the last years: ENLACE[1] 2005-2007 / COLDEX[2] IST 2001-32327 (IST program)/ EA2C2 [3] (TIC 2001 -00007) and CELEBRATE [4] (2002-2004) IST-35188 / e-XCELLENCE 2004-3536/001-001 EDU-ELEARN and eXcellence+ action 2007 – 1999/001-001 TRA-MULPRO[5] and EduTubePlus 2007 EDU 427003[6].

As well as working in different research projects, the group participates in other activities that promote investigation and its diffusion, taking part in summer courses, doctoral courses, and specialised seminars and congresses at both national and international levels.

The G-Elios group belongs to the Department of Electrical Engineering, Electronics and Control (DIEEC[7]) of the School of Industrial Engineering at the UNED has a major focus on research in the Advanced Educational Technologies Applied to Engineering, with special emphasis on e-learning, due to the model of teaching in UNED (which is distance education). This characteristic makes that communication between teachers and students is especially in a virtual way, ie through some form of electronic means, primarily through e-learning platforms. This means that individual departments and research groups from the University are working on this route in order to improve the attention offered to its more than 200,000 students.

7 http://ww.ieec.uned.es

In this sense, the DIEEC, has over 10 years working in the area of e-learning, with 14 national and international projects. Worth quoting some of the most recent international projects such as “PED -CARE (Pedagogical Distributed Group Care)”, “Elearning Thematic Network”, “Internet-based Performance Support System with Educational Elements”, “IPLECS – Internet-based Performance-centered Learning Environment for Curricula Support”, “mPSS – móbile Performance Support for Vocational Education and Training”, “SOLITE SOFTWARE LIBRE EN TELEFORMACIÓN”. And in the national scope, "s-Labs –Integración de Servicios Abiertos para Laboratorios Remotos y Virtuales Distribuidos”, “MOSAICLEARNING: Aprendizaje Electrónico Móvil, de Código Abierto, basado en Estándares, Seguro, Contextual, Personalizado y Colaborativo” o“Comunidades Virtuales de Alumnos” as an example. The G-elios research group (Grupo de Investigación en Ingeniería Eléctrica y Tecnologías Avanzadas en Educación, Electrónica, Control, Computadores, Energías Renovables, Sostenibilidad, Movilidad y Comunicaciones) meets 22 researchers (the mayority of them with PhD degree) within the department.

Finally the ATLAS[8] group has been working in the area of intelligent language learning systems for several years and has been involved in a series of funded research projects: The Virtual Verb Trainer (VVT), The Virtual Authoring Tool (VAT), I-Peter I, I-Peter II, COPPER and I-AGENT, the latest and currently ongoing project with a Ministry of Education grant, number: FFI2008-06030.

***Abstract*— This paper presents a technology platform as a resource for the teaching of control engineering. The platform in question combines the educational potential of software of design and simulation of control systems - MATLAB ® - and the connection between this software and a pilot distillation column. The research hypothesis is that the use of technology platforms such as this helps to develop aspects not only stimulated with simulation. Therefore, an experiment based on the constructivist and social-interactionist theory has been designed to detect student development and to capture their impressions of the platform. The results are presented as graphs and impression reports of the teacher.**

Keywords-technological platform, control systems, constructivist theory.

I. Introduction

Emphasis on the teaching of techniques instead of concepts results in a fast forgetfulness by students. The teaching of theory detached from practical aspects does not properly prepare the student for his professional life [12].

Nowadays, the teaching of engineering and the methods used by teachers do not significantly contribute to the development of skills and competences needed by professionals, especially in a control engineering and automation course.

The theories selected for didactical and pedagogical conception of this platform have as their main argument the attempt to approach teaching of engineering – typically instructionist – to the most adequate paradigm for building knowledge and inherent competences to this professional, opposed to the positivistic and behaviorist theories that prevail in this segment of higher education. Such platform, which has a system and control project and simulation software and integration between the simulation software and a real scaled system, provides students with a favorable environment to the development of competences and skills required to their jobs.

According to [11] recommendations by the Accreditation Board for Engineering and Technology (ABET), an American institution that aims at establishing specific quality criteria for each major, undergraduate courses should encourage the ability to apply knowledge of mathematics, science and engineering; design and conduct experiments; analyze and interpret data; design a system, component or process to meet desired needs; function on multi-disciplinary teams; identify, formulate and solve engineering problems; understanding of professional and ethical responsibility; communicate effectively (written and orally); understand the impact of engineering solutions in a global and societal context; engage in life-long learning; use the techniques, skills and modern engineering tools necessary for engineering practice.

Through an appropriate computational support, this professional in formation has access to common problem situations in their professional environment, as long as a didactical and pedagogical strategy by the teacher favoring the student's production/authorship and development is used in association. To do so, certain aspects must be outlined, such as the evaluation process.

In engineering courses, teachers, who are excellent conveyors of knowledge – as if knowledge could be conveyed and not built – usually regard evaluation as a confrontation process between the teacher's questions and the student's answers, searching for an approximation measure between both to generate a likely grade or concept that represents the entire individual learning throughout the term.

Following the knowledge building process implies favoring student's development, guiding them in tasks, offering new references or explanations, suggesting investigations, providing enlightening experiences to foster knowledge expansion [6].

Within the context of a formation based on paradigms that originate from constructivism, critical-dialogical and social-interactionist pedagogies, educational evaluation is not something detached from the large procedural set that configures formal school and college education. It is intrinsic to educational practice, teaching and learning [1].

However, a learning evaluation process should be continuous and present throughout the entire teaching-learning process, a limited evaluation such as a test is not able to represent all the knowledge built in the student's cognitive structures.

This study is structured as follows: the second section presents a brief state of the art of using similar technological platforms; the proposed technological platform is presented in the third section, stressing its main constituent components. The fourth section presents the proposal of a didactical-pedagogical experiment, and the fifth section brings the results of the case study. Final considerations are discussed in the sixth section.

II. A BRIEF STATE OF THE ART

The state of the art that congregates several studies related to the proposed platform can be quite briefly approached in the following paragraphs. It is important to stress that, in spite of the similarity of the proposed platform with varied remote laboratories mentioned in the studies below, this work aims at using the technological resource as a facilitator for a didactical-pedagogical experiment to investigate the importance of this platform for the teaching of control engineering and automation.

Aktan et al. [2] use the paradigm of distance learning, in which students, teachers and equipment are geographically separated, to develop a remote access real-time laboratory to teach control engineering. The entire apparatus enables students to develop and depurate distance programs and then carry out online experiments to control a robotic manipulator.

Liou et al. [7] used the Labview software to control electrical systems, such as RLC circuits and electric engines. Users use the Internet to access Labview parameters and are able to interact with the systems simulated by it.

Schmid and Ali [10] developed an Internet-based system to teach control engineering. This system enables a more comprehensive visualization and simulation of dynamic systems due to use of a standard web browser. Virtual Reality Modelling Language (VRML) is used to animate dynamic systems. In addition to these resources, the virtual course is composed of tutorials, exercises and virtual experiments.

Clume and Gomes [4] presented a system for remote control of real-time processes using the Internet, following a client-server architecture. A project interface and fuzzy controller tuning is made available for the user. The remotely accessed equipment is a pendulum. Tests were performed at Universidade Federal de Juiz de Fora (UFJF) and at Universidade Federal de Santa Catarina (UFSC) to validate the capacity of system remote access.

Zeilmann [13] presented a proposal of control, supervision and monitoring of industrial processes by the Internet. He presented the study under the perspective of three contexts: industrial plant, server and client. Through integration of web technologies and fieldbus networks, it provides remote access for users to the devices communicating via Foundation Fieldbus protocol. It is an advancement in relation to other remote laboratories due to the proximity between the pilot plant and those found in the industry.

Casini et al. [3] developed a laboratory for the remote teaching of process control techniques. Control modules available at the laboratory are position control, speed control, both of a DC engine, tank level, and helicopter simulator.

It focuses on competition between users and their control algorithms, creating a ranking for those who develop algorithms with better performance.

Dormido et al. [5] presented an online laboratory for experiments in a non-linear, multivariable system, three attached tanks, enabling students to learn in practice essential aspects of process control. Through the integration of EJS (Easy Java Simulations) and eMersion – collaborative tool for online experiments – people involved can have greater flexibility to perform experiments.

Based on this scenario, it is possible to observe a main focus on verification of tool quality only quantitatively and in the process of building such technological platforms. This study aims at observing the student's evolution during use of the tool, which basically takes an entire term, using two verification tools: a questionnaire for students and the records of a teacher's impressions.

III. THE PROPOSED TECHNOLOGICAL PLATFORM

Development of a technological platform for the teaching of control engineering and automation must pass through use of existing and available computational and technological resources at the laboratory of industrial automation of Instituto Federal Fluminense. These resources, commonly explored separately, now start to integrate an environment of project, simulation, implementation and tests for advanced control strategies.

Differently from many laboratories with remote access available in teaching institutions around the world, this laboratory aims to serve as foundation for studies by students enrolled in a regular and in-person course, making clear that the intention, at least not initial, of this study is not to investigate the advantages of these laboratories for distance learning.

The platform has three basic constituent elements:

- Real system, represented in the form of a pilot distillation column.
- MATLAB/SIMULINK®, control system project and simulation software.
- Integration of the above software with the real system through a mediation and acquisition system of industrial data – Foundation Fieldbus (SYSCON®) and the OPC servers that integrate Smar® SYSTEM302 package.

The choice for proprietary software is due to the fact that there is no equivalent software for function inherent to application, stressing that all software used is properly licensed. Figure 1 presents the constituent elements of the platform in the form of a diagram.

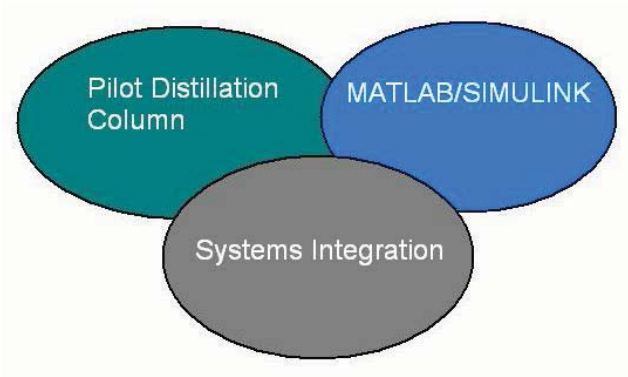

Figure 1. Components of the technological platform.

A. The Distillation Column

In many laboratories of the automation course of Instituto Federal Fluminense, there are prototypes of industrial plants and processes. Through systems of data measurement and acquisition similar to those used in industrial environments, these prototypes allow students to interact with the equipment and learn techniques of process control identification, which are used by control and automation engineers. Among existing laboratories, the pilot distillation column is closest to an industrial process in terms of instrumentation system and productive capacity. A picture of the distillation column can be seen in Figure 2.

Figure 2. Pilot distillation column.

B. Integration of Communication Software

This column has a supervision and control system quite close to the reality found in transformation industries, which base their processes in distillation, such as sugar mills and oil refineries.

Integration between SYSCON® and its installed OPC servers enables access to parameters of the instruments connected to the plant, which allows measurement of variables and acting in final control elements, such as flow control valves. Such availability of data will be used by MATLAB® for the last integration level, enabling control of the distillation column.

C. Project and Simulation Software

MATLAB® has great acceptance by engineers because it has toolboxes for many areas of scientific knowledge, especially engineering courses. In terms of control engineering, it has a graphic environment that works with the concept of block diagram and signal flow for the project and simulation of control systems known as SIMULINK®. After version 7, MATLAB® gained a specific toolbox for OPC communication, which is the most widely used dynamic transference protocol in the industry. This allowed the integration between a software program used at the university and industrial equipment, such as distillation column instruments.

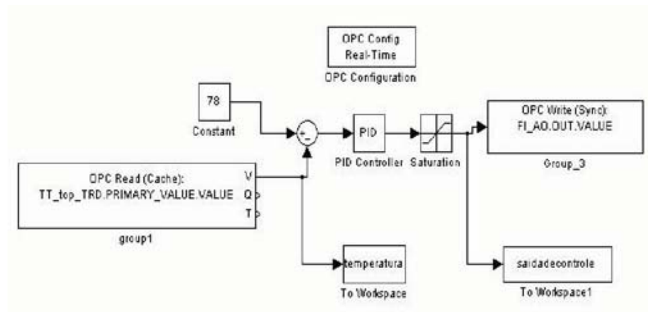

Figure 3. Control system with OPC communication.

Figure 3 shows a SIMULINK® screen with an implemented control system accessing instrument parameters from OPC communication blocks. Projected and simulated control systems by students can then be tested in the real system.

IV. EXPERIMENT CHARACTERIZATION

The didactical-pedagogical experiment was performed at Instituto Federal Fluminense and used as empirical field 8th-period students of the Control Engineering and Automation Superior Course, more specifically students enrolled in the advanced control course.

Certain aspects should be observed throughout the term so that, by the end of the course, it is possible to collect data and analyze results under the light of involved theories.

Taking such aspects into consideration, constituent steps are presented in the characterization of the didactical-pedagogical experiment.

Among these steps, the following stand out:

- Laboratory physical structure. Students use desktop computers with 2.4 GHz Core 2 Duo, 2MB cache, 2GB RAM, 120GB hard disk SATA, 19” Widescreen TFT LCD monitor in conformance with ABNT norms, ABNT2 keyboard. These PCs are connected to a Hub along with the Device Fieldbus Interface

(DFI), allowing access to the plant by all computers. License for MATLAB® version R2006a for up to 20 network machines.

- Verification of impressions relative to students' progress in the form of daily records made by the teacher. Excerpts of these records are shown in section 5.
- Record of students' impressions in relation to the platform. A modified version of the SERVQUAL tool – applied in verification of service quality – was used; further information will be presented in section 5.

This experiment proposes that during classes the teacher should provide idealization and problems for the student and play the role of a possible partner in the teaching-learning process either as a student helper or as an encourager of new investigations.

The steps of the suggested methodology to define and execute the experiment are based on the premise that it is not correct to see teaching-learning processes as a paralyzed process starting at a given point and ending at another with an evaluation of concepts. It should be regarded as a continuous process fostering daily progress and requiring periods of reflection between sequence processes of assimilation and accommodation and resulting in the much outlined reflexive abstraction [9] originating not only from the individual's actions, but also from action coordination.

Within such reality the proposed technological platform is inserted as an environment in which students are able to design, simulate and implement advanced control systems and test their performance on the pilot distillation column.

V. RESULTS

Results were divided into two parts; one concerns the reports of teacher's impressions in the classroom, and the other is relative to verification of an existing gap between students' expectation and perception when using the proposed computational platform.

Parasuraman et al. [8] presented the methodology used to create the SERVQUAL scale. It is an interactive process of quality assessment of five companies in the segment of services in the 1980's in the USA and subsequent verification of internal consistency of the questionnaires using Cronbach's alpha coefficient1. The authors reduced 150 original items to a questionnaire with only 22 items, which can also be reduced. This study only used ten items to be included in the questionnaire applied to students.

Choice for the SERVQUAL scale in this study was motivated by the facility to quantify subjective values and impressions of clients (students), and its important capacity to demonstrate the gap between expectation and perception by making verified aspects a little more tanglible.

Students evaluated each of the ten items in relation to expectation and perception. To do so, they had to sort the items into one position in the numeric scale composed of seven positions known as Likert scale2 because of its level of agreement with the presented statement. According to the excerpt taken from the questionnaire:

The technological platform helped performing the tasks.

1	2	3	4	5	6	7

Other examples of statements include the following: The technological platform is essential to perform the tasks; The platform was relevant to consolidate the concepts learned in the classroom; The technological platform helps us develop competences required to our professional formation. Ten statements were used. Based on the collected data by the questionnaire, it was possible to graphically establish the difference between expectation and perception in terms of response frequency, resulting in the chart shown in Figure 4.

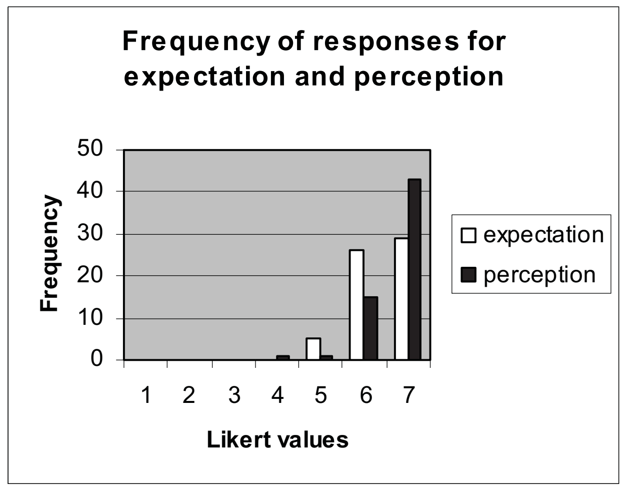

Figure 4. Response frequency chart for expectation and perception.

The chart in Figure 4 shows a quite high frequency for number 7 in terms of perception. It can be concluded that for most questionnaire items the students strongly agree with the proposed statement. The high frequency for numbers 6 and 7 in terms of expectation suggests that students had a good expectation toward the tool, which is positively confirmed in perception.

Students' follow-up throughout the term was performed on a daily basis by the teacher of advanced control. Only a summary of his impressions will be included in this paper, focusing on the most relevant impressions. The group is composed of eight students in the eighth period of Control Engineering and Automation. All the excerpts below refer to the teacher's statements.

> *In general, students had an excellent performance in this course. Such performance was seen by the*

[1] Cronbach's alpha is a coefficient used to measure the internal consistency of questionnaires.

[2] Likert scale is a five- to seven-point scale used to quantify subjective aspects.

> *end of the term, but knowledge was built at each interaction in class.*

Based on the teacher's comments, it is possible to note that students' progress during the term was evident, reflecting in performance results by the end of the term.

> *First students had expository classes of theoretical background about the main techniques of advanced control.*
>
> *At a given point, students were explained about use of the technological platform proposed for development and application of advanced control systems.*

Theoretical background was necessary to make students more able to achieve the objectives proposed in subsequent stages.

> *From then on, students were encouraged to work on projects and solve specific control problems using the platform. In many classes students had initiative and helped each other, showing ability for team work.*

By working with a new class model that favored participation and production, and encouraged to work on projects, there was an adequate environment for the development of highly valued competences, such as team work.

> *An assignment by the end of the term in which students had to design, implement and test an advanced control system using the proposed platform, showed they were already able to manipulate the tool. By the end of the term, students presented their projects and control systems, which were working according to specifications.*

It is possible to observe that they developed the main competence required to a control and automation engineer, that is, development and application of a control strategy for industrial processes.

VI. FINAL CONSIDERATIONS

The proposed environment aims at providing students with a favorable environment for the development of competences and skills required to a control and automation engineer, such as those presented in [11]. It was able to achieve the objective based on analysis of results.

The didactical-pedagogical conception of the experiment and analysis of results were developed to approximate constructivist theories, especially in aspects regarding proposal framework and tools used to obtain the results. Results achieved by application of tools were considered satisfactory for a pilot study. Such statement can be confirmed by presentation of results as a chart, showing acceptance of the platform by students, and also by the teacher's reports.

Further studies include application in other advanced control groups and development/use of new tools to follow the students' progress throughout the term, such as a daily report.

Abstract—**This paper addresses a way to motivate freshmen students benefiting from the work of term students in graduation projects. The application of concepts from digital electronics and analog telecommunications systems can reinforce cooperation of students at different levels on a positive way and strength skills. This can also be used as demonstrative experiences to attract prospective students to electrical engineering courses. The experience of a cooperative work with graduation projects is presented and how it can facilitate younger students work and thus contribute for their motivation and skills. The graduation projects used are briefly presented and some results are shown and discussed.**

Keywords- Antenna measurements; computer aided instruction; cooperative work; graduation projects; electrical enginnering education

I. Introduction

Younger engineering students often face some difficulties with working methodologies, namely on how to take the maximum from individual and team work within the time slot available to accomplish the tasks. This is more noticeable at laboratory classes when a plan of sequential actions needs to be designed, discussed and performed within the group. Besides social and personal relationship factors – students often do not know each other very deeply at early stages – this is also due to a natural lack on basic technical background, skills and confidence, regarding their freshmen status. Although collaborative work and project groups are good learning methodologies [1], usually there is a diverse function within the team. Some students tend to assume a passive attitude while others, probably facing the same difficulties, try harder and focus on the main objectives. However, without a proper guidance and clear focus, both tend to become unmotivated, either by the apparent increase on workload due to the sense of missing results, or by the non-perception of what is really important, which is typical at early stages, as a consequence of a lack on non critical analysis and non critical thinking.

To keep or improve motivation, the idea of very difficult piece of work to accomplish or repetitive and useless tasks should be avoided, especially in cases that require a large amount of measures as is the case in antenna measurements. Rather, the adoption of a systematic approach and a focus on the meaning and importance of each step are of great importance. Some key factors that contribute to student's motivation are: a clear idea on the applicability of the concepts and a focus on "how and why it happens" or "how it works". Simple examples are computer internal architecture, the use of software to control the hardware, namely on using the computer peripherals (e.g. signal generation). Another key factor to increase motivation is the knowledge and the applicability of some graduation projects made by senior colleagues. Regardless its complexity, it may give to younger students the sense that they are also capable of doing the same or even better and in that way increase self-esteem.

The main objective of this paper is to describe a collaborative work experience with engineering graduation projects and how it is useful for freshmen students. These can serve as aiding tools on facilitating their work at laboratory classes, and enrich their skills on using a multidisciplinary approach. The paper is organized as follows: section II presents the motivations of this work, the graduation projects are described in section III, the collaborative experience in section IV and in section V we present a summary with the main contributions.

II. Motivation

The motivation for this collaborative work started in two main branches: one in the field of telecommunications and the other one in digital electronics. Two years ago (approximately) the authors decided to take advantage from the work of senior students on graduation projects to facilitate the performance of freshmen. Thinking on its use for didactic purposes on laboratories it was also decided to introduce some new features and increase their motivation with specific applications. Both were first proposed carried and supervised separately by the authors and at a later phase improved and connected in order to enrich multidisciplinary application of concepts.

A. Antenna Measurements

The Telecommunications Laboratory (Lab-T) at the Superior School of Technology of the Polytechnic Institute of Castelo Branco (EST-IPCB) supports the Telecommunications courses of the bachelor degree (3-year) on Electrical and Telecommunications Engineering. The Lab-T is equipped with several didactic kits and test equipment and supports, among others, the practical and laboratory classes of Electromagnetic Waves, Propagation and Antennas. The later is a second year, second semester course, studying subjects related to antennas

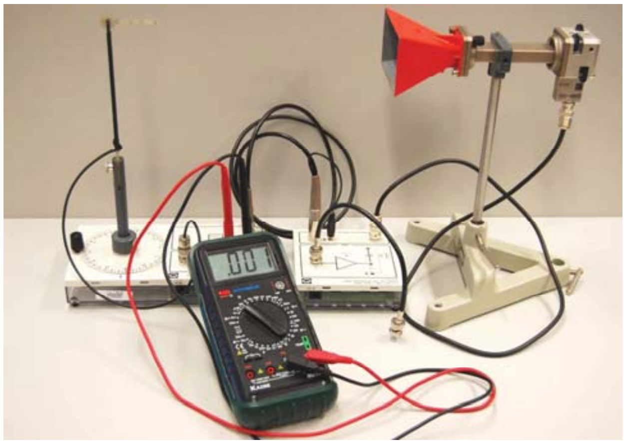

Fig.1. View of the main components of the MTS 7.6.5 antenna measurements station: TX antenna (right) supply and amplifier (middle) and RX antenna (left) with a Yagi structure.

in several different types and configurations [2]. One of the most common experiments carried at the Antennas course is the evaluation of the radiation pattern of linear antennas. For that purpose students use a Leybold–Didactic MTS 7.6.5 kit (the older version) shown in Fig. 1. The complete measurement station consists of emitting and reception terminals and a set of absorbing mats (not shown in figure). The emitting terminal comprises a horn antenna fed by a Gunn oscillator, which operates at 9.4 GHz, whose power supply is modulated, that is to say that the emitting electromagnetic power is modulated, by a 1 kHz square wave. The reception terminal consists in a small $\lambda/2$ dipole test antenna mounted in a rotating plate, with a 360º degrees scale graduated in 5º degree steps, where λ is the wavelength. The $\lambda/2$ dipole reception antenna can be augmented to form a dipole with λ , $3\lambda/4$ and 2λ and the influence of reflector and/or director parasitic elements of antenna arrays with different configurations can also be studied.

The MTS 7.6.5 station supports the study of the radiation pattern of antennas, both on the plane of electrical field or the magnetic field (i.e. horizontal or vertical polarization) or the free space attenuation tests. The first is performed putting the reception antenna at one fixed distance from the emitter and collect data of the voltage (rms value) for several angular orientations within 0º and 360º. The attenuation test consists on collecting data of the voltage values for several distances of the receiving antenna from the emitter. In both tests, the all process was originally operated manually, i.e., the positioning of the reception antenna, the adjustment of its orientation on the rotating plate, the measures, etc. To complete the experiment students had to introduce all data in a spreadsheet software application (e.g. Microsoft Office Excel or Open Office Calc).

Under these conditions, the average amount of time spent to perform a complete radiation pattern experiment is around 30 minutes per group of students, thus allowing up to 6 groups to take measures in a 3-hour session in laboratory. Even for groups of 4 students this represents significant restrictions if one considers the average number of students per class which is around forty, each semester. With these factors in mind, it became clear the need for some significant improvements and for a system for the automation of the MTS 7.6.5 measurement station, capable of collecting data and perform measures from a test setup. Moreover, the objectives and technical requirements were suitable for a 3-year graduation project.

B. Instrumentation Electronics and Computer Organization

The study of computer based instrumentation requires knowledge of computer architecture and organization, its peripherals, I/O addressing and programming skills, besides the knowledge on the operation of the devices. One can study each subject in a separate way and use specific didactic kits for each subject: the operation of Analog to Digital Converters (ADC) and Digital to Analog Converters (DAC) devices, PC internal buses, peripherals and I/O ports, etc.

The major advantage of this approach is the management of the laboratory due to the use the didactic modules in a complementary way by splitting the class in two turns. When the first half uses the ADCs module, the other half uses DAC, and so on. This way only the half of equipments are needed to accomplish with required tasks at laboratory classes. Although the Electronics Lab at EST-IPCB has several didactic modules to help teaching these subjects, they are in general poor in modularity and flexibility, not easy to interconnect and some require an external control unit.

As there were some obsolete PCs with Windows®98 operating system it was decided to use them for supporting units at laboratory classes in an integrated environment as

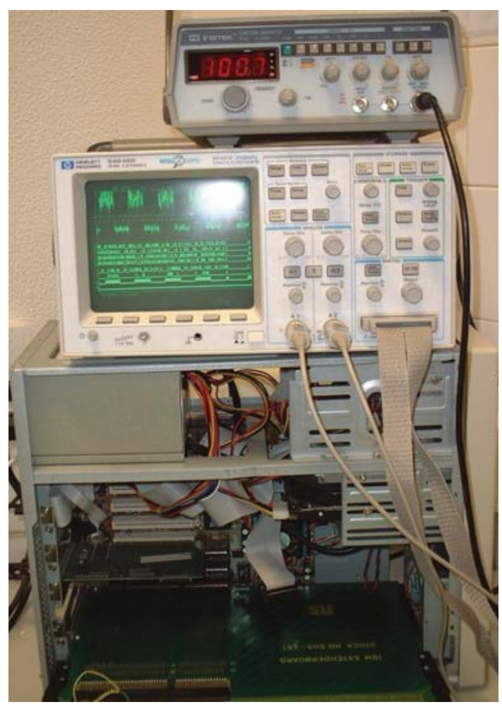

Fig. 2. The integrated environment station: a PC (Windows 98®) with an extender board on the bus (E-ISA), a data analyzer and a frequency counter.

shown in Fig.2, and considered a good alternative solution for the students work and for future expansion on functionalities.

III. Graduation Projects as Aiding Tools

Based on the motivations described above, and pursuing previous work on trans-disciplinary projects [3], the authors proposed and supervised two separate graduation projects to help students at laboratory classes, both requiring hardware/software skills. One project aimed the automation of the antenna measurement station. The other project aimed to help the study of computer architecture and organization, also the practical demonstration of some electronic devices commonly used on instrumentation electronics, using simple and typical applications such as signal generation and data acquisition on a PC via the parallel port.

A. Graduation Project I: Automation of the MTS 7.6.5

The tasks involved in this project include the design of the interface electronic circuits, motor driving, signal conditioning and the assembly and testing of a prototype [4]. The automation system for the MTS 7.6.5 antenna measurement consists of a PC acting as central and control unit, and other functional blocks as depicted in Fig. 3 a). The software application running at the PC controls the stepper motors on the receiver platform, acquires data from the conditioning envelope of the receiver signals through a parallel port and controls all the processes.

The emitter block consists on a power supply of the Gunn oscillator that allows to varying, the -9 V_{dc} medium supply voltage, between -7.5 V_{dc} and -10.5 V_{dc}. This variation can be obtained by a 1 kHz internal square wave oscillator or by external signals (e.g. voice) as depicted in Fig. 3 b), and the radiated power varies proportionally to these. The receiver block consists in a test antenna with a rectifying diode connected for envelop detection (amplitude demodulation), an amplifier with a gain of 1000, and two distinct circuits: one for radiation pattern measurement and the other one for the external signals transmitted by emitter. Finally, an interface circuit samples the signal and converts it to digital with 8-bit words (sample and hold device - S/H and analog to digital converter - ADC) as shown in Fig. 3 c). There is also a circuit for amplifier and loudspeaker to listen the recovered signal when one uses a voice signal at the emitter. The test antenna is mounted in a small platform with wheels, able for translational and rotational movements, actuated by stepper motors for positioning: displacement and rotation. It is possible to place absorbent mats to mitigate any interference due to reflections when measuring the radiation pattern, or to study the influence of these interferences.

Fig. 4 presents a detail of the receiver antenna mounted on the mobile platform and the electronics card for interface and drives for the motors and Fig. 5 shows a snapshot of the software application where it is noticeable an example of antenna radiation pattern and on the left, the values of the voltage measured and acquired for that test. The remaining buttons are for configuration and for test setup. The application also has the possibility to export data in Microsoft Excel (or compatible) files format for further processing.

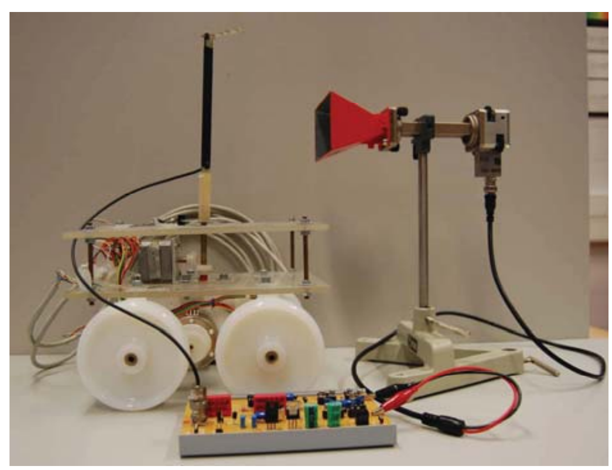

Fig.4. Final assembly: mobile platform with receiver antenna mounted and electronics circuits for motor drives and signal conditioning.

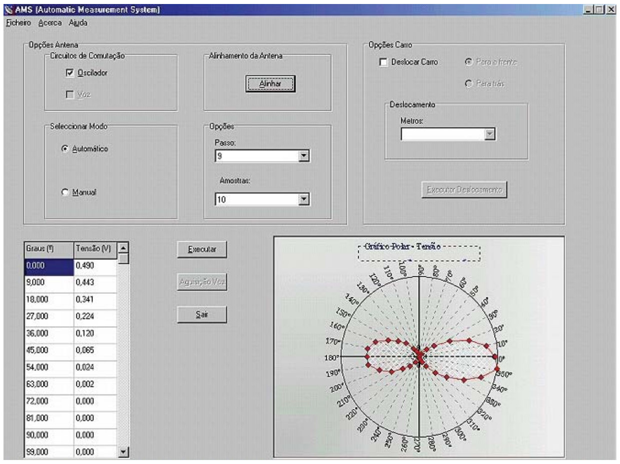

Fig.5. Snapshot of software application: A^2MS (Automatic Antenna Measurement System).

B. *Graduation Project II: PC Based Signal Generation*

This project aimed to help students to study computer architecture and organization, namely for subjects on the operation of internal buses, peripherals, I/O ports, and computer instrumentation electronics devices such as ADC and DAC and also how software interconnects with hardware. For didactic purposes the E-ISA 32-bit [5] bus was chosen and some obsolete PCs with Intel Pentium IV processor and Windows® 98 operating system were used. On the other hand, the signals generators available at the laboratories had mainly a bandwidth up to 2 MHz which was one additional objective: the possibility for low cost signal generators for frequencies above 5 MHz for the three standard signals: sinusoidal, square and triangular waves. The block diagram of the signal generator card is depicted in Fig. 6. The core of the system is the MAX038 Signal Generator IC (manufactured by Maxim Integrated Products, Inc), associated to a DAC IC to control digitally the frequency of oscillation and the duty-cycle. The output frequency is determined by a reference current injected in pin I_{IN} (using a DAC device) and one external capacitor C_{OSC}. For a given current and capacitor it is possible to have an additional adjust on the output frequency within a 70% span through a voltage signal provided by another DAC output. The duty-cycle is also programmable from a voltage, the output amplifiers gains are defined by digitally controlled potentiometers and even the waveform selection is made by changing two bits.

The tasks related to the graduation project consisted on the design of a prototype card to fit into the E-ISA bus whose final prototype assembly is shown in Fig. 7 a) [6]. The hardware module is 16-bit addressable within the range 0300h and 031Fh and fully controlled by a software application with windows-like interface. The software controls two fully independent channels and generates two separate signals, as shown in Fig 7 b) and c). The results obtained exceeded the initial specifications for each channel, allowing the generation of signal within a frequency range from 1 Hz up to 10 MHz, a variation on duty-cycle from 10 to 90%, linear variation on amplitude from 1 to 13 V_{pp}, and the possibility to add a DC component to the signal.

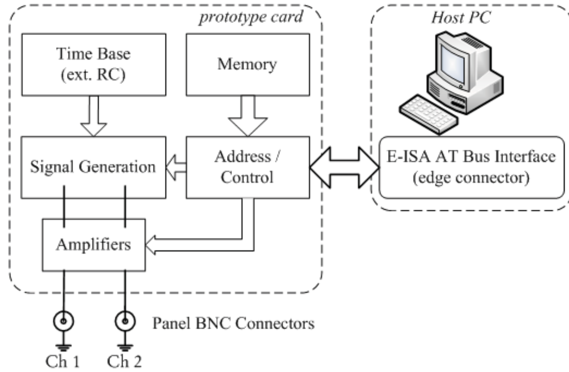

Fig. 6. Conceptual block diagram of the signal generation system.

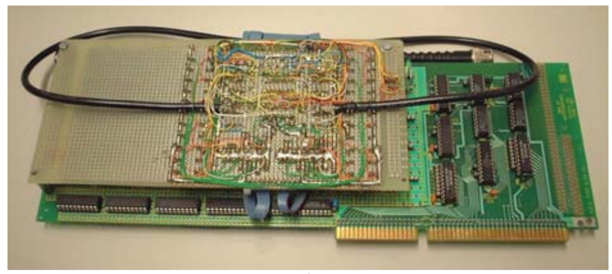

a)

b)

Fig. 7. The PC based signal generator: a) prototype of the hardware assembly to fit into the E-ISA PC bus and b) snapshot of the application that controls both channels.

Besides its use as signal generator, this prototype help students to study all the steps involved on signal generation process, the organization of the memory spaces on the PC, and the functioning blocks of the hardware prototype card. In order to accomplish with the didactic purposes and facilitate the study of computer architecture, the hardware card can be fitted on an E-ISA bus extender board, in a similar way as that presented in Fig 2. With this solution it is possible to analyze signal activity and data on the computer bus while signals are being generated.

IV. Collaborative Work Experience and Results

The results when carrying both graduation projects were very good as there was a great commitment from the term year students on finding solutions and testing different approaches. One should also point the enthusiasm and good expectations from freshmen students, especially on how it facilitates their work on measuring antennas; also the perception of digital systems, memory spaces, I/O addressing and instrumentation devices, from the practical point of view. Moreover, the PC based Signal Generator can be connected to the Automated Antenna kit system as external signal source thus forming a fully automated test station using a single computer to control all the processes. Although there are commercial solutions available, we preferred this approach not only because of economical reasons, but also due to technical and pedagogical aspects. We consider it as an added value as we gain flexibility on introducing test points on significant stages of the measurement chain; also because we have deep knowledge of the systems and so forth have conditions to improve its functionalities.

The automated antenna measurement system allows a significant cut on time spent with manipulation and repetitive tasks thus avoiding the sense of boring or false useless procedures. As the sequential tests are previously defined and performed automatically, it also avoids errors on measures of voltage signals. With this system the time spent on performing tests was reduced around ~50% thus achieving a significant speed up gain in laboratory classes making possible up at least 10 groups per 3 –hour session. Is also allows an easy way to produce reports on the experiments, namely on graphics, since data is automatically stored in spreadsheet type files. Thus, it is possible to test the behavior of a microwave link under different conditions, and various types of modulating signals and frequencies.

The gain on time to perform these measures and the improvements on accuracy are reflected in a better quality of the radiation pattern. Also provides extra spare time to further analyze the results and interconnect practical results and theoretical concepts, thus leading to better reports on the subject. Besides the use as supporting units to laboratory classes the system is also used for experimental presentations to prospective students at secondary level, in order to attract them to electrical engineering field. Some basic experiences on computer organization and I/O and also on the fundamentals of analog telecommunications are presented and discussed with attendees. The one that most frequently get attention and interest involves a voice signal that modulates a carrier generated by the PC signal generator and transmitted through the microwave link and hear it at the loudspeaker.

The opinion of the students is important in the context of any process within the learning process, so we evaluated their opinions on the degree of satisfaction with the proposed approach. We conducted a brief enquiry with five simple question in what students have to give a rank to its significance within the range from 1 to 5: 1 (very poor), 2 (poor), 3 (fair), 4 (strong) and 5 (very strong). We collected anonymously the answers of twenty (20) freshmen students to the following questions:

Q1 – “Contribution of this approach to enlarge the scope of the learning in general in a multidisciplinary way”;

Q2 – “Importance to the laboratory class with the speed up and improve of the accuracy of the measurements”;

Q3 – “Significance to the laboratory work by the ease of use while avoiding the sense of repetitive and boring tasks”;

Q4 – “Importance of computer based measurement systems and its concepts in the course”;

Q5 – “Contribution to the particular and specific objectives of the course and to the overall skills”.

The results shown in table 1 indicate that the majority of students consider this approach significant in terms of benefits both, to facilitate their work and to strengthening their specific and overall skills. The results in cases of “no opinion” or “no answer” were considered not significant.

At the present there is some work in progress with the objective to upgrade the interconnection of the systems and to add new functionalities, namely the use of USB for communication between the mobile platform and the host PC and the possibility to convert it in a remote lab experience. This way some new subject will be included in the multidisciplinary approach, namely the TCP/IP protocols and services supported on the Web. Students are also being asked to contribute with their ideas, as privileged users, about current functionalities, new aspects and new features that they think are important to include in future releases.

V. Summary

This paper describes an interconnected work experience with two engineering graduation projects and how it can benefit freshmen students as demonstrative of theoretical concepts and also on facilitating their work at laboratory. Both projects form a fully PC based automated test station, namely an Automated Antenna measurement KIT as well a signal generated system.

The experience was very positive as students felt involved with solutions and improvements to the learning process. It also contributes to their skills and expertise on strengthening its concepts in telecommunications and digital electronics. The results obtained are much better compared to the original measurement system and procedures, because it saved time and improved accuracy of the radiation pattern. Another point that deserves to be mentioned is the enthusiasm and expectations from freshmen students, especially on how it could facilitate their work on measuring antennas; also the perception of

Table 1. Results of the enquiry concerning the importance of this collaborative work to the role of the students.

	1	2	3	4	5	No Opin.	No Ans

FPGA/Embedded System Training Kit Targeted to Graduate Students Towards Industry Level Short Training

Syed Zahidul Islam, Razali bin Jidin, Syed Zahurul Islam and Fazrena Azlee binti Hamid
Centre for Communication service Convergence Technologies
College of Engineering, Universiti Tenaga Nasional, Putrajaya, Malaysia

Abstract— **The wide application of embedded systems become a trend in the post-PC era. In the College of Engineering, Universiti Tenaga Nasional (UNITEN), embedded system education is one of the characteristic subjects, so "practical training" is the brand new characters as the most important process in the embedded system education towards industry-geared training. The training is an on-campus process toward gaining the practical experiences which are suitable for the real engineering design or IT related companies, especially so for the students without past work experiences. Practical training using single industrial grade kits on embedded system has expanded to most Electrical and Electronic Engineering for both undergraduate and graduate students. The course has been updated towards industry employees training especially to meet their design aspects. Embedded systems course have been deployed in numerous fields which have different requirements of embedded systems architecture. In this paper, a project-based learning strategy using single training kit is proposed as a pedagogical tool for embedded system education. The proposed project-based learning can motivate students to integrate and formulate the multi-disciplinary knowledge previous learned into a real-world embedded system project development. The course development focused on lecture–lab integration and laboratory learning. Course and lab activities were designed using a learning model that captures lower-order and higher-order cognition levels of Bloom's taxonomy.**

Keywords-Embedded Systems, FPGA, Training KIT, and Graduate education.

I. INTRODUCTION

Many universities offer introductory courses that focus on microcontroller-based systems and embedded programming using different training kits. Advanced courses often do not have a common focus and are not available until the graduate level, leaving a gap in training undergraduates. The courses are integrated through a coordinated set of learning outcomes and the use of related tools and technologies. In addition, the courses are designed with special attention to integrating the lecture and laboratory experiences, making explicit the relationships between lecture topics and laboratory exercises.

A single kit can provide training for various domains such as programming language, digital system (hardware descriptive language) and basic image processing. It comes with an option for future updates. Since the training modules are designed with the objectives to reduce learning efforts and industry relevant, it will benefit many students.

II. COURSE OVERVIEW

The embedded system is a science of the theory and practice regarding as equally important. Figure 1 shows the overview of the course materials related to the training courses. A tutorial course will introduce the domain knowledge and common research issues to students. Programming skills training is necessary when learning embedded systems. It is a good method to practice programming skills through the laboratory (*Lab*). To practice Labs needs an auxiliary tool, *target platform*, a prototype of the hardware of embedded systems. ARM architecture [6] is very popular for embedded system products. The programming skills are necessary skills for advanced research in the future.

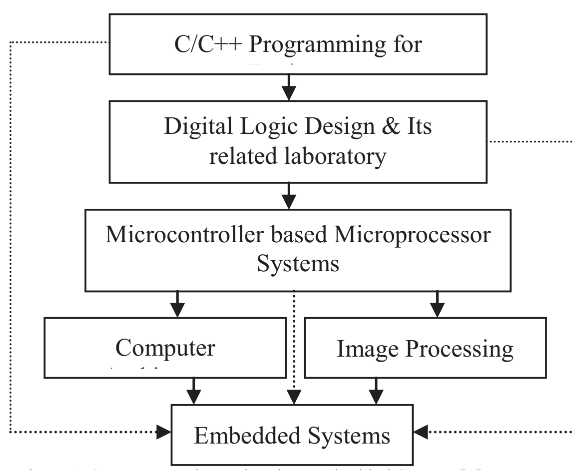

Figure1. Course overview related to Embedded System [1]

Full training course is divided into few sections. Table1 shows the overall structure of the training materials. In embedded C programming, pointers technique, serial communication implementation (UART), interrupt handlers, and image processing is covered. In HDL, combinational logic design, synchronous and asynchronous state machine design, RISC processor design, and custom IP design is included. In SW/HW design, architecture of the soft core and its buses, interfacing with timers IP, UART IP, configurable parallel port, interrupt controller are covered.

TABLE1. CONTAIN OF THE TRAINING COURSES

Embedded "C" Programming	a. Pointers (Accessing content of memory locations) b. Serial communication + Byte Transfer + Array-type Variable c. Ethernet: Send/Receive Data Byte to an IP node d. Interrupt handlers e. Image Processing (algorithms such as depicted in Figure 5)
HDL	a. Combinational logic (examples: decoder, mux, DFF) b. Synchronous state machine / State machine c. Embedded Processor & Hierarchical Buses d. Custom IP cores & Bus Interfaces e. Image Processing (Implementation of algorithms on hardware such as on PLD or FPGA)
HW/SW Co-design	a. Architecture b. Processor Buses & Busses Protocols c. IP cores: 1. Timers 2. Serial Communication 3. Configurable Parallel Port 4. Interrupt Controllers d. Interrupt Handlers/ Processor context switch
System Software	a. Script Linker file, make file b. System timer c. Multitasking & multithreading d. Device Drivers (Device interface, polling/ interrupt driven)

III. PROFESSIONAL ENGINEERING PRACTICE BASED ON PROBLEM SOLVING

Student survey shows that development of student design skill, engineering practice quality, self learning ability, and communication and team work skills, course assignment is not sufficient. Hence, a series of progressive engineering learning skill is necessary. Three stages learning are focused to fulfill all skills. At the first stage, examples based design, which in some extent of a cognitive leaning process is covered. In this stage, students can be experience and have a better knowledge about general hardware design using VHDL, embedded system concepts, design components, design IP, subsystems and design procedures. The aim of the second stage targeted to prepare students with effective use of existing workbench, platform and tools for embedded system design, development and research, and students can grasp how to design, build and troubleshoot an embedded system by existing tools or components based on progressive design and development specification. Student involved in experiential learning emphasized on two section: "simulated" and "authentic" [5]. Simulated experiential learning contains carefully guided learning activities in order to create a specific learning outcome. Authentic experiential learning often made the student engaged in completely open-ended learning and sometimes with limited guidance. Since Engineering practice play important role in embedded system, high level synthesis engineering experiential learning is necessary for students, and the students complete designs within strict hardware design and embedded software programming conventions which are similar to those on which industry engineers are currently working on. In this respects, comprehensive integration design projects is chosen from industry, university-sponsored research, or other practical application environment. Sufficient number of students is made a group so that Working in teams is helpful for building cooperation, leadership, and communication skills which is necessary in student's future work. A cooperative, practical and structured embedded systems design experience was needed in embedded system education. The design experience is based on a problem-based learning approach that motivates student learning and develops skills required by the student in a future professional capacity. Engineering practice should play a more important role in embedded system education. Design software included in training courses included "industrial-strength" features such as real-time, in-circuit debugging and field programmability, and students should be trained to conform to corporate design practices, such as design and coding conventions. The experience can be created, in part, to give students exposure to strict design specifications and the need to follow them faithfully, which is one of the most popular request for an engineering project development.

IV. PRACTICAL TRAINING

The act of rehearsing a behavior over and over, or engaging in an activity again and again, for the purpose of improving or mastering it, as in the phrase "practice makes perfect"[2]. Practical training on embedded system is an on-campus process to gain the practical experiences which are suitable for the real design companies. The propose training interacted between the theoretical courses and the real company practices. Generally, in the design companies, practice means work for the real projects [3]. Even if the work is quite simple, to implement the basic functions or to write the documents, the results will be used into the software products finally. The term training refers to the acquisition of knowledge, skills, and competencies as a result of the teaching of vocational or practical skills and knowledge that relate to specific useful competencies [4]. So, people within many professions and occupations may refer to this sort of training as professional development. The offered embedded system training can be on-the-job or off the-job as the focus on jobs [5]. On-the-job training takes place in a normal working situation, using the actual tools, equipment, documents or materials that trainees will use when fully trained. On-the-job training has a general reputation as most effective for vocational work. Off-the-job training takes place away from normal work situations, implying that the employee does not count as a directly productive worker while such training takes place. Off-the-job training has the advantage that it allows people to get away from work and concentrate more thoroughly on the training itself. This type of training has proven more effective in inculcating concepts and ideas.

To give the clear concepts and the feasible analysis, the relative definitions, such as practice and training, are discussed carefully, and the advantages are carried out.

In Practical Training, the educational philosophy is based on "learning by doing", which means that the practical training heavily focuses on the students actually performing the tasks. Software engineering is a fundamentally practical activity and students find it difficult to see the value of activities without them being placed in a realistic context. The attempt at providing an assignment that has significant similarities to a real-world project.

For the practical training, the courseware has much difference with the common textbooks. The use of courseware according to its design intent: stated learning objectives and audiences, would by definition be the only use the developer can evaluate and assess. The instructors should plan on providing appropriate documentation and understanding of how to evaluate the use of the courseware.

V. Design Examples

Embedded System based practical training to the graduate students towards industry level is focused on Xilinx Microblaze and PowerPC platform integrated system [6]. Figure 2 shows the XILINX hardware architecture to design embedded system. Most of the practical embedded system design for this training materials are used this architecture.

In training materials, few issues are covered which are significant affects on industrial design. At initial stage for beginners trainee, hardware design using FPGAs is covered so that at any stage in peripheral hardware can be designed and interface with processor to achieve expected embedded system. Next stages, standard peripheral hardware available as a Intellectual property (IP) such as USART, BRAM, SRAM and its controller interfacing techniques are trained. In addition, on-chip processor software design using C/C+ for Microblaze soft core processor is covered so that HW/SW design experience can be applicable to the any embedded design company.

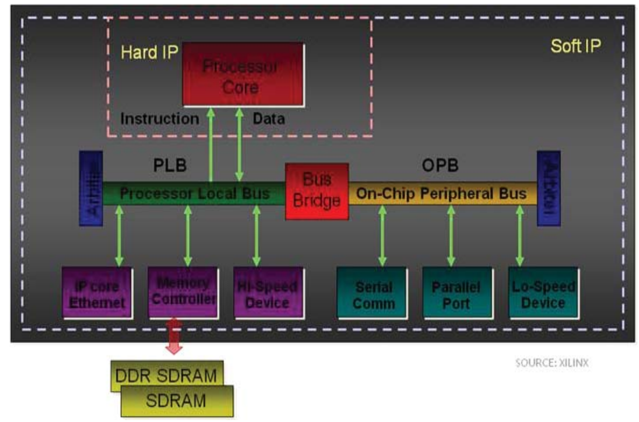

Figure 2. Xilinx embedded system hardware architecture [6]

A. Experimental Setup: On-Chip Game Design

This experimental setup is intended to cover full hardware design using VHDL in FPGA platform. Trainee is given required schematic diagram for the game design. Figure shows the given hardware setup for the light chasing game design. Figure 3 shows the hardware setup using VHDL.

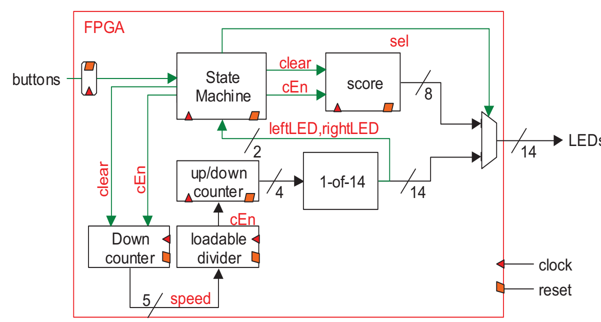

Figure 3. On-chip hardware setup for simple Game design

Trainee will design individual module using VHDL including state machine. After complete all modules, they need to design top-level module to interconnect all modules as required. After complete this module, they will be able to know how to design HW module and controlled by state machine.

B. Experimental setup: Transceiver via Serial Port

This experimental setup is to expose students to interfacing of Universal Asynchronous Receiver Transmitter (UART) to XILINX soft core Microblaze processor. Data transferring over the bus is between two UARTs and saved in pointer variables. The C programming was emphasized for processor.

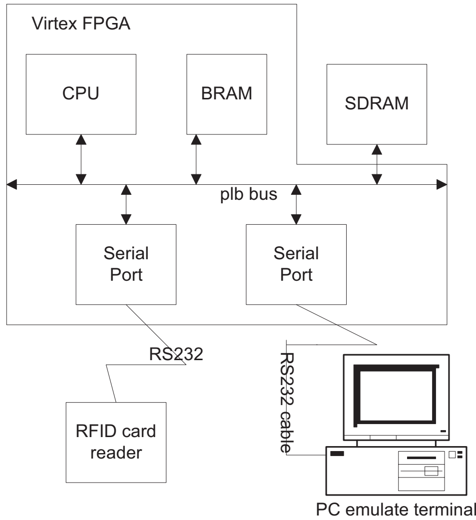

Figure4. Example design of UART interfacing with PLB bus

C. EXPERIMENTAL SETUP: IMAGE PROCESSING

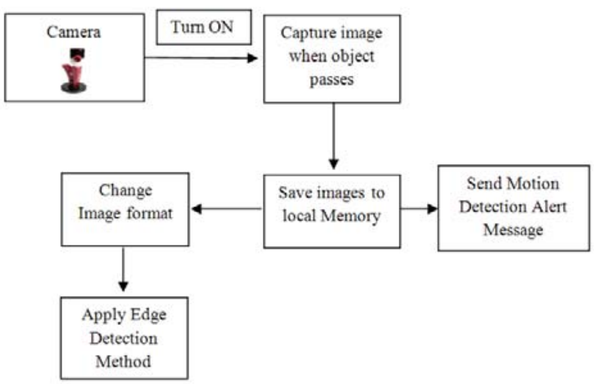

Figure5. Example design of interfacing camera for capturing images and detecting edge

Figure 5 is on the image processing module. The experimental setup is to make camera turn on and capture images when there is a motion. After taking pictures, it is saved on local memory and also sent to alert messaging system through internet and Application Programming Interface (API). The images are needed to convert to portable network graphics format. Then enhanced Sobel edge detection method is applied to detect edges of the images.

VI. STUDENTS RESULTS ON WORKS

Figure 6 shows the students examination results on the course for previous semester. Over three semester evaluation period, most students have able to enhance their understanding, consistent with the excellence examination results and project presentations.

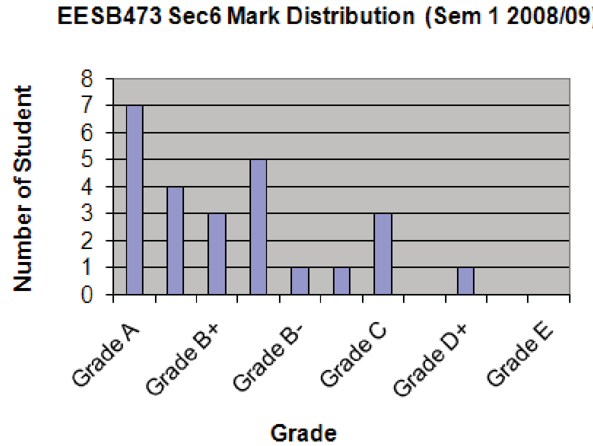

Figure6. Student result on embedded system design course

Figure 7 shows the snap shots of the student project on embedded system. In the picture, students are testing there projects on RFID projects.

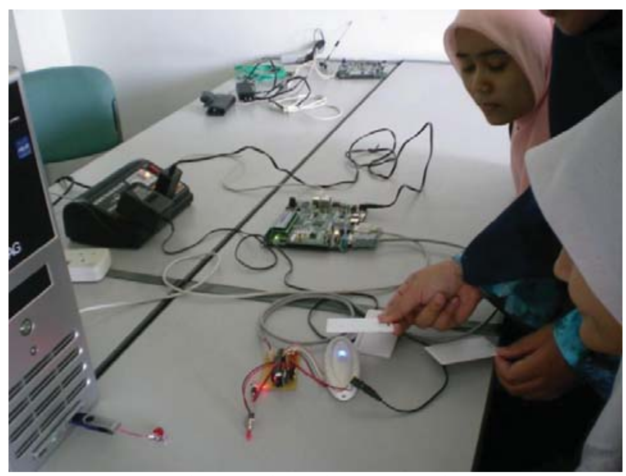

Figure7. Snap shot of student's design project during testing

VII. CONCLUSION

An integrated kit for both hardware and software lesson modules can assist student to grasp difficult abstract concept, thereby improve learning outcomes especially on programming language, microprocessor, digital system. The hardware and software modules include several level of Bloom taxonomy especially to help students to learn difficult concepts toward achieving the synthesis level learning outcome and at the same time expose them to in industrial-grade design environment.

***Abstract*—The design of friendly user tools for power electronics applications is a hot topic among the researchers all over the world. In fact, the digital signal processors programming is a hard task which requires a deep knowledge of the specific hardware platform where the user control program is implemented. In this paper, a user interface for programming digital signal processors (DSP) to control a power electronic converter is presented. The proposed program, called $jscomm$, is currently used as a useful tool to understand how the DSP is programmed, to control a power converter safely and to monitor all the interesting variables of the power converter operation.**

I. Introduction

The simulation and experimental testing of power systems is a fundamental topic of electrical and electronic engineers all over the world [1]–[8]. In this way, different simulation softwares for understanding power electronics have been developed in order to facilitate the teaching in such a difficult topic for new or non-expert students and researchers. As one of the most interesting current simulation tools, the interactive power electronics seminar (IPES) software is a simple educational module dedicated to basic power electronics circuits [9]. Using this tool or other similar, the students can learn the basic operation of many power converter topologies, signal theory in power electronics, pulse width modulation and space vector modulation, etcetera.

On the other hand, recently the e-learning concept has been also successfully applied to the power electronics teaching achieving good results [10], [11]. Using e-learning platforms, the student/researcher can operate a hardware system usually via web. In this way, the user is working with a distant real prototype and is operating it online. The e-learning concept is very useful where a high number of users have to actuate with a single hardware prototype. However, only by simulations or using the e-learning, the students and/or researchers do not actually work with real prototypes and they do not notice the hardware/software problems related with real applications of power converters. They do not see with their own eyes the converter operating, hear the switching noise or work with real power active and passive devices.

In this way, the use of laboratory prototypes especially designed and built for educational purposes is very useful. Using this kind of prototypes, the users are closer to the real power system design dealing with problems such as the power devices sizing, the measuring errors effects, the switching noise, etcetera. Several user tools are required in order to facilitate the interface between novel users and a complex power system formed by the power converter experimental setup, the measuring system and the control hardware (usually a digital signal processor (DSP)). These user tools can be developed by an unique software which implements an interface carrying out all the necessary operations under safe conditions.

II. The proposed user interface ($jscomm$)

In this paper, a friendly user interface for DSP programming and control of power electronic converters is presented. The software, called $jscomm$ has been developed in the Power Electronics Research Group at the University of Seville. The $jscomm$ software is currently being used for post-graduate students in order to develop, test and adjust control techniques for power electronic converters as a part of the required knowledge to get the PhD degree. It is being applied to medium-high power systems but it can be also used for low power applications.

The $jscomm$ software objectives are:

- The $jscomm$ can operate independently of the specific DSP platform by Texas Instruments. In this way, the user can carry out the tests avoiding a deep knowledge of the hardware.
- Using the $jscomm$, the necessary state machine to control a power converter can be easily developed and monitored during its operation.
- The controller of the power converter can be tuned and tested observing the influence of the controller constants on the power converter operation.
- Using the oscilloscope tool present in the $jscomm$, it is also possible to monitor any control or measured variable. This facilitates the user C code debugging finding possible errors in the implemented control techniques.

A. The oscilloscope tool

The $jscomm$ provides an oscilloscope plotting any variable of the power system (the number of channels is configurable). In this way, the operation of the power converter can be monitored online and the implemented control technique can be tested safely. A snapshot of the oscilloscope present in the $jscomm$ is represented in Fig. 1. It is important to notice that not only the physical variables of the prototype can be

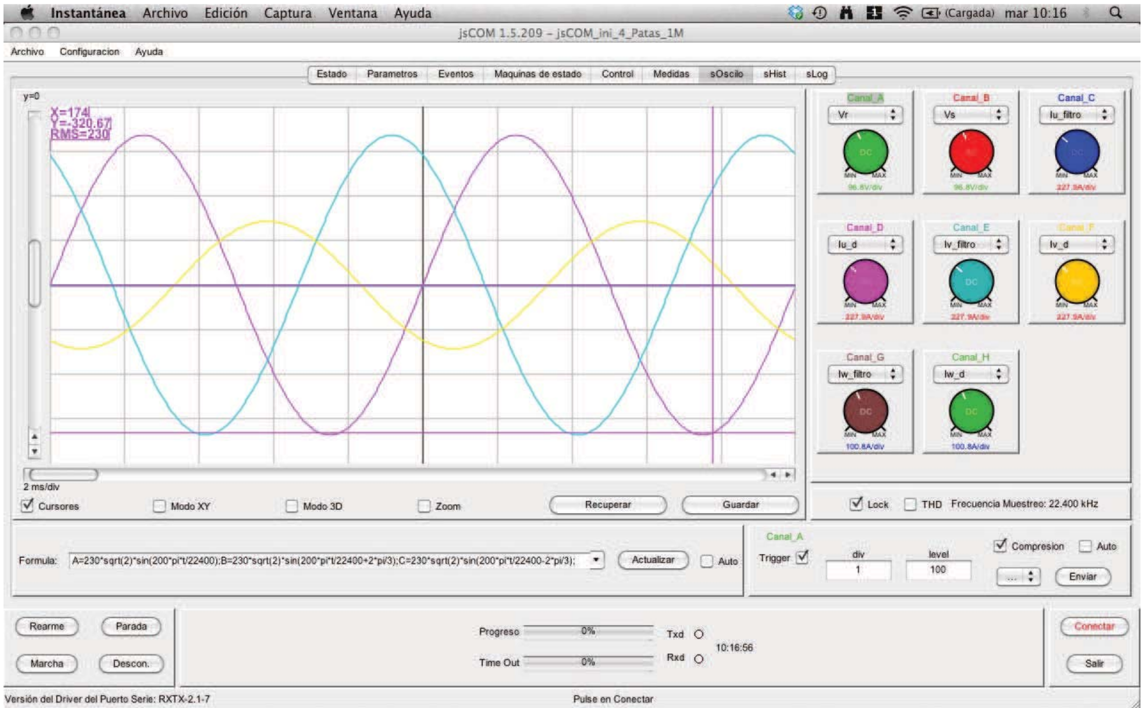

Fig. 1. Eight channels oscilloscope where control or measured variables can be plotted online.

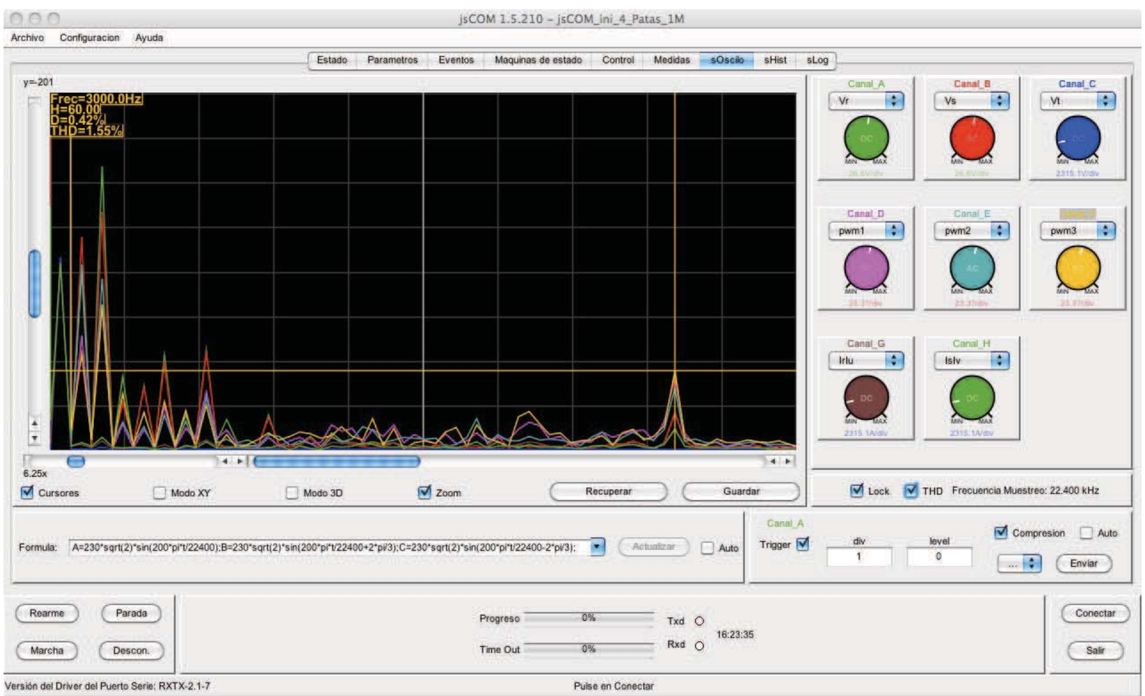

Fig. 2. Oscilloscope tool representing the harmonic spectrum of a measured variable.

represented but also the auxiliary programming parameters. This capability for tracing any DSP control program internal variable facilitates the debugging procedure and the understanding of the power converter behavior. The oscilloscope tool provides important information such as the RMS value and the average value of each channel. As usual oscilloscopes,

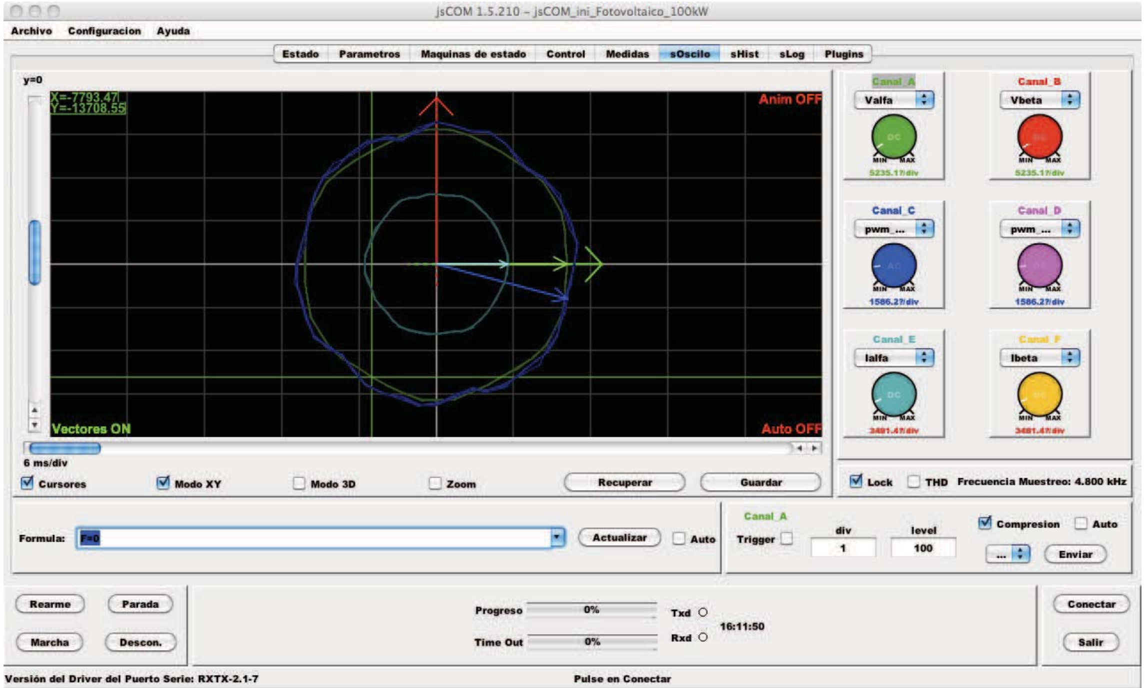

Fig. 3. Oscilloscope tool configured in the XY representation mode.

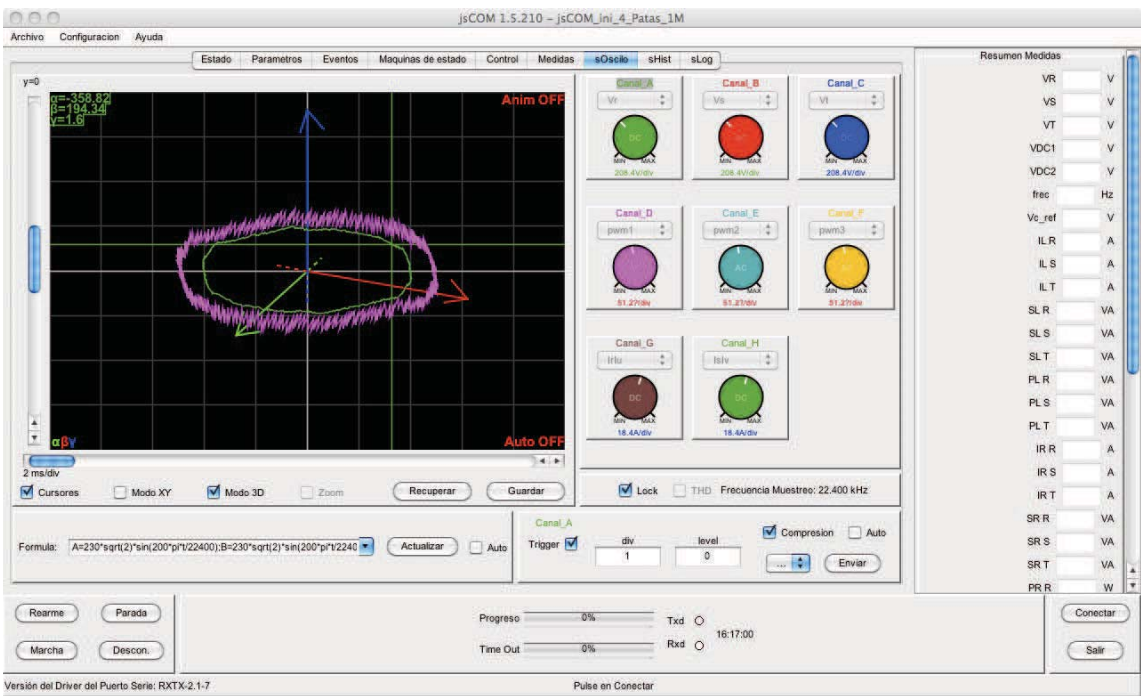

Fig. 4. Oscilloscope tool configured in the three-dimensional representation mode.

it provides the trigger function which is useful to capture the waveforms when a condition is fulfilled. In addition, the volts/div, amp/div and time/div in the $jscomm$ oscilloscope have exactly the same functionality compared with real oscilloscopes. As an additional function, it is possible to carry out mathematical operations using the oscilloscope channels as a sum, subtraction, multiplications, etcetera. In this way, it is possible to calculate operations such as A=A+B-C+3*D for instance (where A, B, C and D are the four first oscilloscope channels). Besides, as an additional functionality, the harmonic spectrum can be also plotted providing important information for power systems and this is shown in Fig. 2.

Finally, two representation options can be defined in the $jscomm$ oscilloscope tool. Firstly, the XY representation mode can be defined representing channel A versus channel B. The XY representation mode is useful in power electronics system to represent variables in alfa-beta coordinates. A representation of the $jscomm$ oscilloscope working in XY mode is shown in Fig. 3 where a phase current of a power converter is represented in the alfa-beta plane representing the beta current versus the alfa current. Secondly, a three-dimensional representation mode can be also chosen. In this way, three different channels can be represented and it is useful to represent for instance the phase currents of the power converter in in a cartesian coordinates frame. The three-dimensional representation mode is shown in Fig. 4 where the phase currents of a three-phase power converter are plotted. These two representation modes help to the user to understand how the power converter is operating and the influence of the controller on the power converter operation. Finally, it has to be noticed that these representations are plotting information continuously using a trail to represent past samplings as can be observed in Fig. 3 and Fig. 4.

B. The states diagram tool

One of the most interesting characteristics of the $jscomm$ is that it includes a tool for developing a states machine to control the power system. The states machine is plotted using a classical diagram where the states are represented using balls and the conditions to carry out the transitions between the states are defined using arrows. As a Moore machine is implemented, each state has defined outputs and the transitions are combinations of the inputs or other conditions written on each arrow. The transitions can be defined as:

- User commands such as $stop$ or $connect$ related to buttons present in the $jscomm$ user screen.
- Measurements such as the dc voltage, excessive phase currents, emergencies, etcetera.
- A time condition defining therefore transitory states.
- A combination of the previous ones.

An example of the generation of the states machine for a conventional three-phase power converter rectifier is represented in Fig. 5.

It is very important to notice that the states machine diagram, developed by the user with a very friendly software interface, directly generates the corresponding C code to be implemented in the DSP. In this way, the generation of the states machine, needed in most of the power system applications, is simplified. In fact, the use of the states machine diagram avoids design errors and, during the converter operation, the state where the converter is working each moment is highlighted.

C. The calibration tool

An important topic of the power conversion is the calibration of the voltage and current sensors. This issue has to be carried out minimizing the possible measuring errors and the

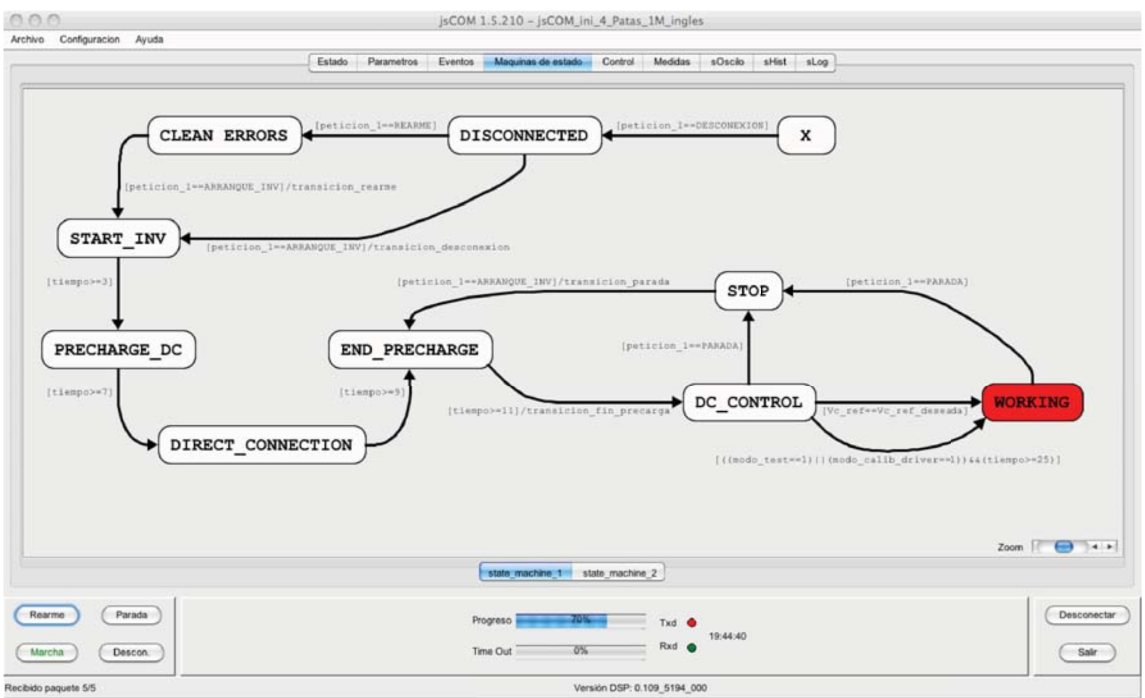

Fig. 5. States machine screen where the possible states and the transitions are defined.

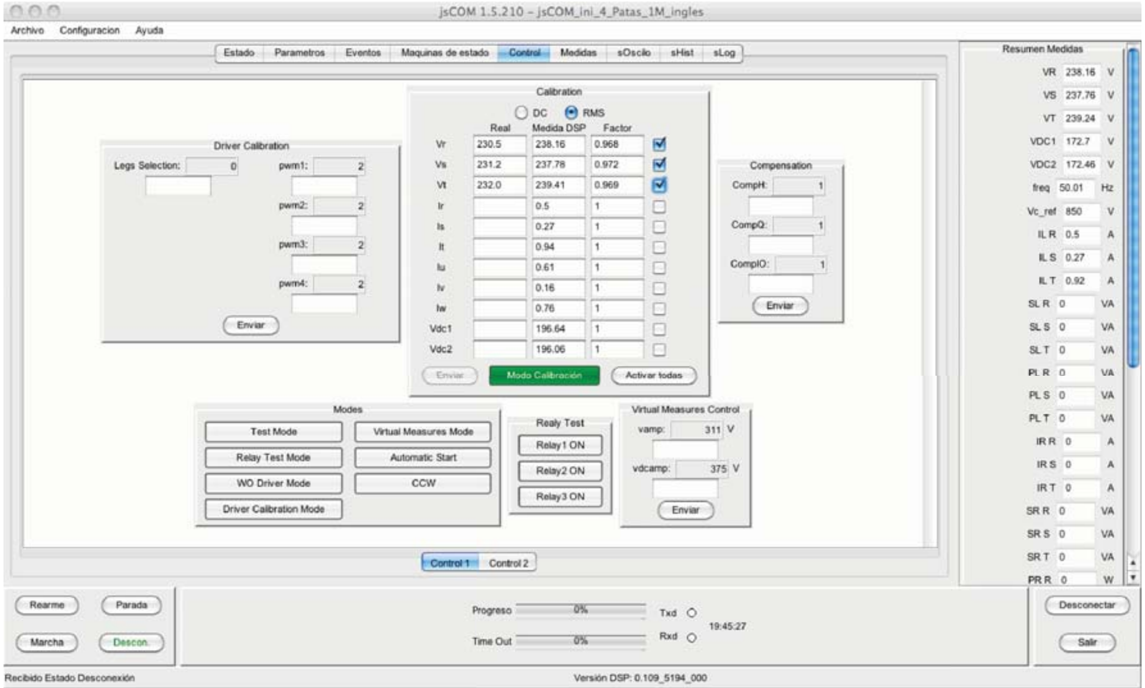

Fig. 6. Calibration tool where the measurement adaptation parameters are determined to reduce the calibration errors.

Fig. 7. Controller screen where the tuning of the controller constants can be done.

$jscomm$ software provides an automatic calibration tool to solve it. All the measurements of the power system can be calibrated online. The user has to introduce in the $jscomm$ calibration screen the actual value of the measurement and execute the automatic self-calibration tool. The self-calibration procedure calculates the measurement adaptation parameters to reduce the measurement errors. Finally, once the power converter sensors have been calibrated, the measurement adaptation parameters can be saved in a file for next experiments. In this way, the calibration procedure has to be executed only the first time and it is not necessary to repeat all the process. The $jscomm$ calibration tool is represented in Fig. 6.

D. The controller adjustment tool

The design of high performance controllers for power converters is a hard task for non expert students/researchers. A lot of efforts are usually spend on the adjustment of the controller parameters and the determination of the dynamic and steady-state behavior of the power system. Typically the optimal controller parameters do not coincide with those optimal for the real prototype due to small differences such as voltage drops, losses, passive device tolerances, noise, calibration errors, etcetera. In this way, it is always necessary a tuning procedure to obtain the best possible performance of the power converter.

The $jscomm$ users can design any control technique to be implemented in the power converter. The $jscomm$ permits to change the values of the controller constants during the operation of the converter making easier the controller constants tuning process. This fact can show the impact of any term of the controller on the performance of the control variables. For instance, considering a classical controller where an external voltage control loop and an internal current control loop are used, the influence of the proportional, integral and derivative PID controllers on the dc voltage or the phase currents can be measured. This can help to novel power control researchers to understand the operation of the power converter and the controllers design. A snapshot of the controller adjustment tool present in the $jscomm$ software is presented in Fig. 7.

E. The emergency management tool

An special attention has to be paid on the emergencies management. The main concern in a educational power system is the safety and all the possible emergencies have to be taken into account. This emergency could be an overvoltage, overcurrent, minimum voltages in the dc side, driver errors, communication errors, etcetera. If an emergency happens, the $jscomm$ software stops the power system operation and shows the emergency cause to the user highlighting the corresponding flag in the emergency tool. This tool is shown in Fig. 8.

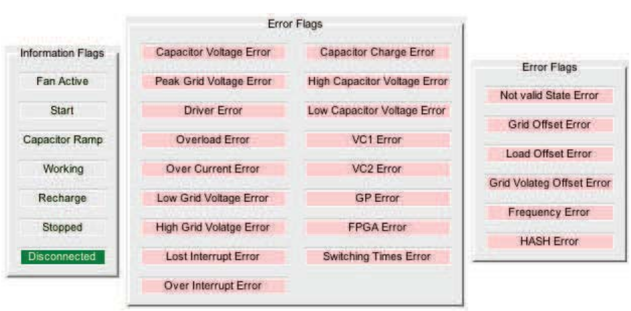

Fig. 8. Emergency tool showing the possible emergencies in the power system.

F. Auxiliary $jscomm$ tools

Some extra functionalities have been added to the $jscomm$ program. These auxiliary tools are:

- FFT calculation.
- Data compression in the communication between the DSP and the $jscomm$.
- Log file generation including a historical information about all the operations carried out in a $jscomm$ session.
- Flash memory programming.

III. Conclusions

In this paper, a user interface, called $jscomm$, for programming digital signal processors (DSP) to control a power electronic converter is presented. The $jscomm$ software is currently being used for post-graduate students in order to develop, test and adjust control techniques for power electronic converters as a part of the required knowledge to get the PhD degree. All the tools provided by the $jscomm$ program have been introduced during the manuscript.

Abstract—**This paper shows the activities of the Technical Committee of the CESEI (Spanish Chapter of the IEEE Education Society). The CESEI is focused on the development of the education in engineering, mainly Electric and Computer Engineering, and the Technical Committee is devoted to contribute to its awareness and dissemination. As in other interdisciplinary fields, the engineering education field involves several sources of information and different stakeholders, each one with its own focus and purpose. As a result, sometimes it may be complex for practitioners and researchers to identify the more appropriate entities for their interests. The CESEI Technical Committee tries to solve this difficulty by providing updated information about the main publications (journals), events (conferences), organizations and other elements of interest.**

Keywords- e-learning publications, e-learning research

I. INTRODUCTION

Engineering education has risen as a global discipline during the last decades [1]. As a discipline it is usually considered multidisciplinary, involving particular topics of the engineering domains (electrical, computer, civil), social, legal and business issues, in addition to general education concerns. At this point, a common criticism to the consideration of engineering education as a discipline is that education researchers could better solve engineering education problems. Anyway, the teaching and learning of engineering has captured so much attention that it is a discipline on its own.

Nowadays there exists a large scientific community supporting the engineering education discipline. At engineering universities and schools it is very common to find researchers and research groups working on engineering education problems. Many engineering companies also have created groups to work on these topics in the context of life-long learning or career development programs. At a higher level, persons, groups and companies are joined into national and international associations whose main purpose is to work towards the development and empowering of this discipline. These organizations sponsor a large number of events and publish journals and books focused exclusively on engineering education problems. Some of these events and journals have been assessed as very relevant by main research indexes.

This interest on engineering education is also present in one of the most important engineering associations: the IEEE. The IEEE is the world's leading professional association for the advancement of technology. The IEEE name was originally an acronym for the Institute of Electrical and Electronics Engineers, Inc. Today, the organization's scope of interest has expanded into so many related fields, that it is simply referred to by the letters I-E-E-E (pronounced Eye-triple-E) [2]. IEEE includes many unique technical organizations, active in the areas or publications, conferences and building technical communities. Among these organizations, the Education Society (EdSoc) was created with the main aim of "*shall be scientific, literary, and educational in character. The Society shall strive for the advancement of the theory and practice of electrical and computer engineering and of the allied arts and sciences, and the maintenance of a high professional standing among its members and affiliates, all in consonance with the Constitution and Bylaws of the IEEE and with special attention to such aims within the field of interest of the Society*" [2]. His fields of interest are: "*Educational Methods, Educational Technology, Instructional Materials, History of Science and Technology, and Educational and Professional Development Programs within Electrical Engineering, Computer Engineering, and allied disciplines*" [2].

In 2004, it was created the Spanish Chapter of the Education Society of the IEEE (from now on CESEI). The CESEI has the same fields of interest and aims that the IEEE EdSoc has. Nevertheless, the CESEI is focused in Spain and in the Spanish tongue area [3]. Inside the CESEI several Technical Committees were created CESEI [4], one of them devoted to the dissemination and awareness of the engineering education field.

The final goal of the CESEI is to promote the development of this discipline supporting practitioners and researchers. To contribute to this goal the Technical Committee provides updated information about relevant conferences, journals and organizations. We consider this information very useful for professionals and researchers, because it is offered a clear picture of the main actors involved and the key sources of information. This paper is produced as a contribution to this effort, including an updated and complete compilation of engineering education associations, conferences and journals at world and Spanish levels.

II. Practice in Engineering Education

Typically, engineering education is organized along disciplinary lines. In the US and Western Europe one often finds engineering departments with titles such as Civil Engineering, Chemical Engineering, Computer Engineering, Electrical Engineering, Industrial Engineering, etc. The curriculum on these departments is usually made up by two years of education in fundamentals (mostly mathematics and physics), followed by disciplinary education within the confines of their specialized faculty and facilities. In some cases, students are offered with additional courses in social, business and legal sciences. These, however, are seldom integrated with the engineering curriculum in a manner that enhances the disciplinary knowledge or the practice of engineering techniques.

The specialized nature of engineering education runs contrary to the increasing need to prepare engineers for multidisciplinary and interdisciplinary work. In the real world, engineers often work in teams with other engineers and non-engineers with a wide range of specializations. The engineering process thus almost always transcends the particular engineering discipline and requires a much broader ”holistic” view. Moreover, the engineering workplace has undergone significant changes in the last decades. Nowadays, almost all engineers depend on networking and computing tools. In this way, engineering education needs to extend beyond technical and scientific aspects, involving the master of issues such as:

- The ability to effectively communicate in written and oral forms.
- A set of business capabilities, practices and awareness. This includes understanding of marketing, economics and organizational management, their interplay among themselves and with the engineering process.
- An understanding for and work ethic for leadership in the workplace, individual and team contributions, sensitivity to customer needs, their incorporation into the engineering and engineering management process, and commitment to the concepts of total quality management.
- A sense of professional, ethical and legal responsibilities.
- An appreciation of the joy of learning and of the need for lifelong learning.
- An appreciation for intellectual breadth to be not only an engineering leader but a well versed and updated participant in societal activities. To reach this requires an appreciation for the humanities, arts, politics, law and business beyond that which is technically or scientifically targeted.

As the engineering curriculum is altered, it must be also addressed how we teach and learn it. In Europe, the Bologna Declaration signed in 1999 has accelerated these changes and new degrees have appeared. On the other hand, those changes have promoted a deeper interest on methodology, considering issues such as: how faculty interact with students, how students learn, and how emerging technologies are embedded into the educational environment making it more exciting and more effective.

III. Research in Engineering Education

Engineering education has become field of scholarly research in its own right. The past engineering education practices based on the transfer of knowledge, experiences and beliefs are no longer sufficient. Globally, engineering education is on the agenda for solving important issues for the future of engineering education, such as recruitment of students to engineering programs, the need for new competences and the ability to deal with new types of interdisciplinary and complex knowledge. More over, these changes have to be performed in accordance with sound research. This turn towards a more research-based approach is sustained by the growth in conferences, journals and publications dedicated to engineering education. The problem at this point is to get a clear picture of the main actors involved in this discipline: who are the more important associations? What are the best journals? Which is the most appropriate conference to publish a kind of research? These are some of the questions that users in the engineering education domain could be asking themselves. This section provides an excerpt of the main actors on this domain to solve them.

A. Engineering Education Associations

Associations focused on engineering education are spread worldwide. In this section we show the more important ones, taking into account their dimension, research relevance and international dimension. Table I includes key data together with the main conferences and journals supported by them. These conferences and journals are introduced in the following sections. Next it is provided a brief comment about the goals and scope of each of one of these associations:

- AACE is “*an international, not-for-profit, educational organization with the mission of advancing Information Technology in Education and E-Learning research, development, learning, and its practical application*”.
- ACM SGICSE mission statement is “*to provide a forum for educators to discuss issues related to the development, implementation, and/or evaluation of computing programs, curricula, and courses, as well as syllabi, laboratories, and other elements of teaching and pedagogy*”.
- AIED is “*an interdisciplinary community at the frontiers of the fields of computer science, education and psychology*”. It promotes research and development of interactive and adaptive learning environments for learners of all ages, across all domains. Its goal is “*to advance knowledge and promote research and development in the field of artificial intelligence in Education*”.

- APSCE objective is "*to promote the conduct and communication of scientific research related to all aspects of the use of computers in education, especially within the Asia-Pacific*".
- ASEE is "*a nonprofit organization of individuals and institutions committed to furthering education in engineering and engineering technology*".
- The IEEE CS is "*the world's leading organization of computing professionals and the largest of the 38 societies of the IEEE*". This society is dedicated "*to advancing the theory and application of computer and information-processing technology*".
- The IEEE ES fields of interest are "*the theory and practice of education and educational technology involved in the effective delivery of domain knowledge of all fields within the scope of interest of IEEE*".
- The IEEE LT is a technical committee of the IEEE CS. It has as a purpose "*to contribute to the field of advanced learning technologies*".
- The IFEES is and international society that groups to 48 member societies and companies. This association is working to establish effective engineering education processes of high quality around the world. Its final goal is "*to assure a global supply of well-prepared engineering graduates*".
- IGIP is working in cooperation with other associates dedicated to engineering education, such as SEFI and IFEES, "*to support the development of engineering education*". It has working groups in curriculum development, international aspects of engineering education, knowledge management and computer-aided technologies, languages and humanities in engineering education, mathematics and natural sciences in engineering education, people and technology, postgraduate education and qualifications framework, technical teacher training, women in technical careers, and working with projects.
- SEFI is the largest network of higher engineering institutions and of individuals involved in engineering Education in Europe. SEFI aims are "*to develop information about engineering education, to improve communication and exchange between professors, researchers and students and to promote cooperation between the various institutions concerned with engineering Education*". It maintains WGs on the following issues: Curriculum Development, Continuing Engineering Education, Mathematics, Information and Communication Technologies, Gender and Diversity, Physics and Engineering Education, Ethics in Engineering Education, and Engineering Education Research.

B. Engineering Education Conferences

As other research disciplines, there exists a plethora of events (conferences, symposiums, workshops) where it is feasible to publish research works about engineering education. Moreover, many times the research works in engineering education are multi-disciplinary and in this way it is possible to publish them in several scopes. Anyway, there are also specific conferences more specially focused on engineering education.

Table III includes a list of the main events related with engineering education. The data provided for each event is the acronym, full name, involved associations, (geographical) area, first year edition, scheduled (annual or bi-annual character and months of the year in which it is celebrated), and classification in accordance with the CORE index. The first issue to notice is that there are some conferences with a history of near 40 years. Meanwhile, there are other conferences much more recent, some of them with an existence of 5 or 6 years. In relation with the geographical area there are localized conferences in the main continents except in Africa. The other conferences usually vary their localization from continent to continent.

To classify these events one of the more important research indexes is used. The Computer Research and Education of Australasia (CORE [1]) is an association of university departments of computer science in Australia and New Zealand to assist and advance research in computer science and information technology. In January 2008 this association published a ranking of ICT conferences classifying them in accordance to the quality of the papers into five tiers:

- Tier A+. Typically, a tier A+ conference would be one of the very best in its field or subfield in which to publish and would typically cover the entire field/subfield. These are conferences where most of the work is important (it will really shape the field), where researchers boast about being accepted, and where attendees would gain value from attending.
- Tier A. Publishing in a Tier A conference would add to the author's respect, showing they have real engagement with the global research community and

[1] http://www.core.edu.au Last access on November 2009.

that they have something to say about problems of some significance. Attending a Tier A conference would be worth travelling to if a paper was accepted.

- Tier B. This covers conferences where one has some confidence that research was done, so publishing there is evidence of research-active status (that is, there is some research contribution claimed, and a program committee that takes its job seriously enough to remove anything ridiculous or ignorant of the state of the art), but it's not particularly significant.
- Tier L. These are local conferences, which may be important for the social cohesion of the local community and for networking.
- Tier C. All the rest.

In this section we have just shown conferences in the tiers A+, A and B. There exist much more conferences related with engineering education in tiers L and C. Anyway, as it has been described, the relevance of these conferences from a research point of view is smaller.

TABLE III. MAIN ENGINEERING EDUCATION CONFERENCES

c. Classification in the Australian Ranking of ICT Conferences

d. *Informing Science Institute* (informingscience.org)

C. *Engineering Education Journals*

This section includes some journals publishing papers about engineering education. Table IV includes the main journals in the engineering education discipline. The data provided for each journal is: name, URL, first year of publication, number of articles published the last year (2008), number of issues per year, the involved associations, the impact factor and the ranking. These last two items have been taken from the research indexes published by Thomson Reuters: the Journal Citation Reports (JCR) Science Citation Index (SCI) and Social Science Citation Index (SSCI).

In the SCI and SSCI the research relevance of a journal is given by its impact factor. Nevertheless, the impact factor is usually not taken into account as an absolute number, but in the context of the category in which the journal is included. In this way, these indexes arrange journals in several categories and the relevance of each journal is considered in accordance with its relative impact factor position regarding all the journals in the same category. Usually, the categories are arranged in four quartiles and the journals in the firsts quartiles are the more important ones. As the reader can see, some journals are included in several categories and in this case it is usually taken the more favorable classification.

1) Journals in the JCR Science Edition

There exist several journals related with engineering education in 6 areas. The aims and purposes of the main journals are the following ones:

- *Computers and Education*. It is a technically-based, interdisciplinary forum for communication in the use of all forms of computing in the use of computing and Communications technology to contribute to all aspects of cognition, education and training, from primary to tertiary and in growing open and distance learning environments.
- *IEEE Transactions on Education*. The scope of this journal covers "educational methods, educational technology, instructional materials, history of science and technology, and educational and professional development, as well as programs within electrical engineering, computer engineering, and allied disciplines".
- *Journal of Engineering Education* focuses exclusively on scholarly educational research in engineering education.
- *Science and Engineering Ethics*. This journal explores ethical issues confronting scientists and engineers. "*Coverage encompasses professional education, standards and ethics in research and practice, extending to the effects of innovation on society at large*".
- *International Journal of Engineering Education.* This is an interdisciplinary journal, which tries to provide a balance between papers on developments in educational methods technology, case studies, laboratory applications, new theoretical approaches, educational policy and survey papers.
- *IEEE Technology and Society Magazine* covers a vast area of topics, including engineering ethics and professional responsibility, engineering education and technical expertise.
- *International Journal of Technology and Design Education "encourages research and scholarly writing covering all aspects of technology and design education. The journal features critical, review, and comparative studies. In addition, it includes contributions that draw upon other fields such as historical, philosophical, sociological, or psychological studies that address issues of concern to technology and design education*".
- *Computer Applications in Engineering Education* focuses "*on the innovative uses of computers and software tools in education and for accelerating the integration of computers into the engineering curriculum*".
- *International Journal of Electrical Engineering Education* "*features articles and book reviews which highlight aspects of the teaching of current topics in electrical and electronic engineering. Within an engineering educational context, these can range from specific projects, case studies and reports of laboratory practice to broader developments such as new teaching methods, curriculum design, assessment, validation and the impact of new Technologies*".

a. Thomson Scientific 2008 Journal Citations Report (JCR). SCI: Science Citation Index. SSCI: Social Science Citation Index

b. Position in the subject category and quartile of the JCR. Subject categories: [1] Computer Science, Interdisciplinary Applications; [2] Education, Scientific Disciplines; [3] Engineering, Electrical & Electronic; [4] Engineering, Multidisciplinary; [5] History & Philosophy of Science; [6] Multidisciplinary Sciences; [7] Education & Educational Research

c. *IEEE Society on Social Implications of Technology* (www.ieeessit.org)

2) Journals in the Social Science Citation Index

In addition to the JCR SCI there are other publications in the JCR SSCI. One of the more important is the Journal of Educational Technology & Society. This journal "*seeks academic articles on the issues affecting the developers of educational systems and educators who implement and manage such systems". The articles should discuss the perspectives of educators and (educational system) developers' communities and their relation to each other*".

Among the areas of the SSCI there is one named Education and Educational Research. This area includes 113 journals. It is important to notice that some journals are listed both in the SCI and in the SSCI, for example the *Journal of Engineering Education* and *Computers and Education*. Not all the journals in this category accept papers about engineering education, but some of them have as scope evaluation methods, case studies, innovative pedagogical methods, curriculum organization, etc.

3) Other Journals

There are several journals not indexed in the JCR but it is quite feasible that they will be indexed in the near future. These journals have not been included in the JCR because they have been initiated in recent years (it is needed some years to enable the calculation of the impact factor) or because they are just published on-line (up to date, just paper journals are considered in this index). Anyway, the following journals are very interesting and they use to include valuable articles:

- *ACM Transactions on Computing Education* (toce.acm.org). This journal was named as *Journal on Educational Resources in Computing* (JERIC) until January 2009. Endorsed among other ACM groups by the SIGCSE, it is intended to support all aspects of computing education. The intention of its editors and directors is "*that TOCE become the most prestigious and influential publication in computing education*".
- *Engineering Education: Journal of the Higher Education Academic Engineering Subject Centre* (www.engsc.ac.uk/journal/index.php/ee/about/editorial Policies#focusAndScope). Published twice a year since 2006 including two types of articles: (i) papers on any topic relevant to engineering education as pedagogic research papers, case studies, critical reviews and evaluations; and (ii) comments with scholarly responses to previously published articles from the journal.
- *European Journal of Engineering Education* (www.tandf.co.uk/journals/tf/03043797.html). It is published six times a year since January 2006 by the SEFI to provide a forum for dialogue between researchers and specialists in the field of engineering education mainly at European levels.
- *IEEE Multidisciplinary Engineering Education Magazine* (www.ewh.ieee.org/soc/e/sac/meem/index.php/meem). It is the official publication of the IEEE ES Student Activities Committee since 2005. This journal is run for and by students. It focuses on "*education, bearing in mind that the expected readers are the students/teachers/facilitators who will be responsible for designing educational programs*".
- *IEEE Transactions on Learning Technologies* (www.computer.org/portal/web/tlt). It is a joint publication of the IEEE CS and IEEE ES initiated in 2008 and with 4 numbers per year. This journal covers research on such topics as: innovative online learning systems, intelligent tutors, educational software applications and games, and simulation systems for education and training.
- *Inroads – SIGCSE Bulletin* (jinfo.lub.lu.se/jinfo?func=fullRecord&jId=14692&issn=10963936). Published since 1969 twice a year by the ACM SIGCSE it provides "*a forum for university educators to discuss concerns about development, implementation, and evaluation of computer science programs and courses, as well as syllabi and problem sets*".
- *International Journal of Artificial Intelligence in Education* (ihelp.usask.ca/iaied/ijaied/). This is the official journal of the AIED Society. It was initiated in 1989 and publishes 4 numbers per year with papers and other items (e.g. workshop proceedings, conference reports, invited powerpoint presentations, news items, etc.) concerned with the application of artificial intelligence techniques and concepts to the design of systems to support learning.
- *International Journal of Computer-Supported Collaborative Learning* (ijcscl.org). Its publication was initiated in 2006 by the ISLS to promote a deeper understanding of the nature, theory and practice of the uses of computer-supported collaborative learning. A main focus is how people learning in the context of collaborative activity and how to design the technological settings for collaboration.
- *Learning Technology Newsletter* (www.ieeetclt.org/content/newsletter). It is published 4 times per year since 1999 to report the activities of the IEEE LT.

IV. ENGINEERING EDUCATION IN SPAIN

Similarly to the worldwide level, engineering education in Spain has been developed as a proper discipline. This can be supported by the existence of several associations, conferences and journals. Next sections provide an outlook to the more important ones.

A. Associations

During the last years the CESEI has been a main actor in the promotion of engineering education as a main practice and research disciplines. A main proof of its activities has been the organization of awards to the best final studies project and PhD thesis during the last four years [6].

In addition to the Spanish chapter of the IEEE Education Society, there exist the following associations related with the engineering education:

- ADIE: *Asociación para el Desarrollo de la Informática Educativa* (www.adie.es/webadie/).
- AENUI: *Asociación de Enseñantes Universitarios de la Informática*.
- GEIDI: *Grupo de Estudio e Innovaciones Docentes de la Informática*.
- *Ibero-american association of institutes of engineering education.*
- Spain SIGCSE Chapter (www.sigcse.es).

B. Conferences

The following conferences accept contributions about engineering education:

- *Jornadas de Enseñanza Universitaria de la Informática* organized by the AENUI.
- CITA: *Congreso Iberoamericano de Telemática.*
- CUIEET: *Congreso Universitario de Innovación Educativa en las Enseñanzas Técnicas.*
- SIIE: *International Symposium on Computers in Education*.
- FINTDI: *Fomento e Innovación con Nuevas Tecnologías en la Docencia de la Ingeniería.*
- TAEE: *Tecnologías Aplicadas a la Enseñanza de la Electrónica*.

C. Journals

There are several journals in Spain or in the Latin-America area that publish papers about engineering education:

- IEEE RITA: *Revista Iberoamericana de Tecnologías del Aprendizaje* (webs.uvigo.es/cesei/RITA).
- *Novática* (www.ati.es/novatica) is not focused on education, but it publishes papers on this topic.
- *Revista de Educación* (www.revistaeducacion.mec.es) from the *Instituto Nacional de Evaluación y Calidad del Sistema Educativo*.
- *ReVisión* (ww.aenui.net/ReVision) published by the AENUI.
- CIEET: Cuadernos de Innovación Educativa en las Enseñanzas Técnicas published by the Board of Directors of Schools of Technical Engineering
- RIE: *Revista de Investigación Educativa* (www.um.es/depmide/RIE).
- RIED: *Revista Iberoamericana de Educación a Distancia* (www.utpl.edu.ec/ried).

V. Conclusion

Engineering education has flourished as a great discipline during the last years. In this way, there are a large number of associations involved organizing conferences and publishing journals on several topics of this area. At this point, it is usually a problem to identify the key actors and sources of information. The Technical Committee of the CESEI is trying to support this discipline. Particularly, it tries to identify the main actors involved, their goals and main activities. This paper includes a compilation of some of this data. We hope it can be valuable for novice and common users that at some point need precise information about this domain.

In any case, this cannot be considered as a finished work and we will continue updating it. Similarly, any contribution or comment is welcomed.

A PRACTICAL ELECTRONIC INSTRUMENTATION COURSE FOR ENGINEERING STUDENTS

Daniel Ramos and Fernando Alonso-Fernandez

ATVS - Biometric Recognition Group, Escuela Politecnica Superior
Universidad Autonoma de Madrid, Avda. Francisco Tomas y Valiente, 11
Campus de Cantoblanco, 28049 Madrid, Spain
email: {daniel.ramos, fernando.alonso}@uam.es

ABSTRACT

A course on Electronic Instrumentation has recently been developed at the Universidad Autonoma de Madrid (Spain), which specifically emphasizes practical aspects. The objective of the course is to link theoretical principles with practical issues of electronic instrumentation through the development of a final project. First, students take practical work in several different scenarios, which are the basis for the design of an engineering project aimed to solve an electronic instrumentation problem which is set by the students. Students are exposed to a set of multidisciplinary aspects, both theoretical and practical, providing them with the ability of integrating blocks in which they have practically worked into a full instrumentation project. The course provides not only enhanced academic training but also increased student motivation, as students are encouraged to propose their own projects.

Key-words: electronic instrumentation, practical approach, correlation theory-practice, student evaluation.

1. INTRODUCTION

One of the fundamentals of the technological progress in the field of electronic instrumentation is the need for practical training as an essential part of the learning activity. The process of engineering generally consist of the following sequential activities [1]: i) conceive, ii) experiment, iii) design, iv) build, v) test, and vi) improve. In most of these activities, practical aspects are crucial. It is therefore necessary an exposure to these aspects, in order to make electrical and electronic engineering graduates more employable and productive when they enter industry. However, although the resources present in a typical engineering laboratory usually cover isolated blocks of a whole project, it is desirable that the students develop the abilities to integrate blocks of a project in which they have practically worked. This interest is motivated by many aspects and manifests at many levels, from the technical structure of the final product to as an element of the development scheme. Unfortunately, resources present in an electronic instrumentation laboratory are not always enough to guarantee the acquisition of the abilities to accomplish such integration process, especially aimed at industry engineering work.

With these ideas in mind, a course on Electronic Instrumentation has been developed at the Universidad Autonoma de Madrid, which is a mandatory subject of the last course of the M.Sc. in Telecommunication Engineering. The goal of the course is not only to provide students with the theoretical principles, but also to link them with the practical aspects of electronic instrumentation. First, the students take practical work in the technical abilities of the electronic instrumentation course in several different scenarios, using the available hardware at the laboratory. The objective of yielding awareness about the whole project is achieved by means of simulated case studies, which are designed by the students, and which include the hardware used in the laboratory as a critical part.

In this paper we describe the particulars of this course, highlighting his objectives and contributions, and we will analyze whether the practical implementation proposed indicates a successful achievement of the proposed objectives. The course has been successfully developed and taught to 40 students from February to May 2009. Results presented in the paper illustrate the relationship about the scores obtained by the students in theoretical and practical work, and also presents experiments comparing the scores in each of the modules of the proposed practical methodology proposed. There are also included the results of the final student official opinion polls that are conducted at Universidad Autonoma de Madrid every academic year. Outcomes have been satisfactory, showing that students are satisfied with the course, and more motivated since they are allowed to take active role in the design and experimentation of an electronic instrumentation system.

This paper is organized as follows. In Section 2, we highlight the motivation, objectives and contributions of the proposed methodology. The organization of the course is described in Section 3, including details of the practical sessions and of the evaluation methodology. Results of the course implementation are included in Section 4, giving details of the marks obtained by the students and the results of the student opinion polls. Conclusions are finally given in Section 5.

2. MOTIVATION, OBJECTIVES AND CONTRIBUTIONS OF THE PROPOSED METHODOLOGY

Modern electronic instrumentation requires broad knowledge of a multidisciplinary approach [2]. It is therefore fundamental that the students face problems not only related to the implementation of electronic instrumentation systems, but also to the integration of such implemented modules among an industrial development chain. The objectives of the course are therefore adequate to this principles. After completing the course, the students should be able to do the following:

- Understand the principles of electronic instrumentation.
- Understand the main specification of a measuring system.
- Utilize a PC-based hardware that provides interaction with external signals, sensors and devices.
- Design simple measuring systems and micro-controller-based applications.
- Learn to integrate hardware instrumentation modules into a full instrumentation project.

The resources needed to accomplish the first four objectives can be provided by the typically available resources in a laboratory at the university, and at a reasonable cost. However, the last objective is costly, since it implies the availability of a full industrial system in which the modules developed at the laboratory should be integrated. This exceeds the budget that many universities dedicate to teaching laboratories.

The accomplishment of all the objectives described, including the last one, motivates the organization of practical work proposed in this paper, which constitutes the main contribution of the proposed methodology. The idea is to divide the practical working time (15 hours) into four different sessions. The first three sessions consider the implementation of several hardware modules which can be developed with the available equipment at the laboratory. The last session is a case study proposed by the students under determined guidelines, where an engineering project is proposed considering the hardware modules developed. This last session will not be finally implemented, since it consists of a full engineering problem, but their specification must be detailed and all the proposed blocks of the project have to be described with the required level of an engineering project. Figure 1 summarizes the proposed methodology.

With the proposed course, students not only supplement their academic training in electronics, but also gain experience in applying theoretical knowledge to the resolution of practical problems.

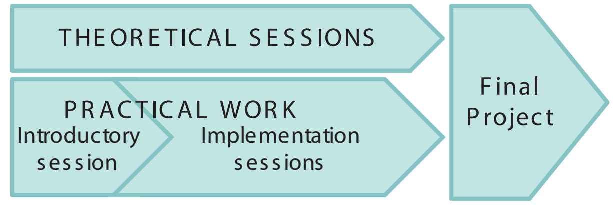

Fig. 1. Proposed practical methodology, which is the main contribution of the course.

Theoretical topics

1. General Principles of Instrumentation.
2. Statistical Error Analysis.
3. Electronic Instrumentation Amplifiers.
4. Analog-Digital Conversion.
5. Measurement of Physical Magnitudes.

Laboratory sessions

1. Introduction to Laboratory Hardware.
2. Thermometer Using the Analog-to-Digital Converter.
3. Dusk Indicator Using the Voltage Comparator.
4. Brushed DC Speed Control with Optical Encoder Feedback.
5. Engineering Project.

Table 1. Syllabus of our Electronic Instrumentation course.

3. ORGANIZATION OF THE COURSE

The organization of the course is summarized in the Syllabus presented in Table 1. The four-month course provides 4.5 lecture credits (45 hours in the current Spanish system) and 1.5 laboratory credits (15 hours in the current Spanish system). A set of laboratory sessions complement the theoretical training and a final design project is used to assess the practical knowledge acquired by students.

The required skills the students may have to take advantage of the course and achieve its objectives are as follows. It is recommended that students have passed previously other subjects on Circuits and Electronics, Circuit Analysis and Design, Signal Processing, Digital Systems and Programming (including assembly code). Therefore, it is intended for students with a previous background and skills in electronics.

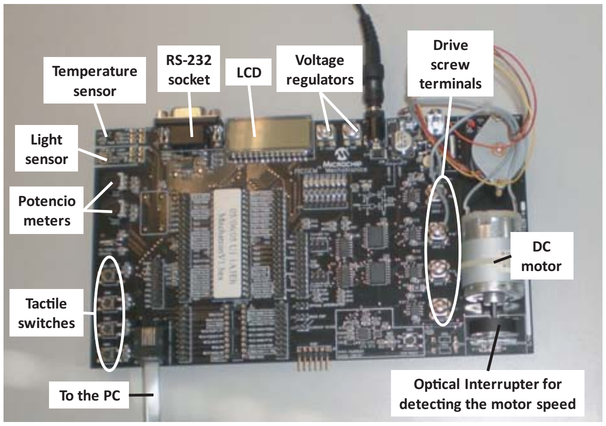

Fig. 2. Photograph of the PicDem development board from Microchip (TM) used in the laboratory practicals.

3.1. Theoretical Sessions

Theoretical sessions are mainly based on lectures which cover the topics included in Table 1 (top). These topics are typical in modern electronic instrumentation, and there is plenty of bibliography available. We have used mainly [3], which has proven to be an extremely useful resource for the course. Other useful references, recommended for the students were [4, 5].

3.2. Practical Sessions

Methodology

The practical methodology sketched in Figure 1 is developed as follows. The first introductory session and the subsequent three units in Table 1 are small projects where the students have to implement several functionalities using the available hardware of the lab.

The hardware used in the whole course is the so-called PicDem development board from Microchip (TM) (Figure 2), which is a platform to handle several electronic sensors (including a temperature, light and optical encoder sensor) and other devices (engines, light emitting diodes, etc.) using a PIC microcontroller. The software used to control the board is the MPLAB (TM) IDE [6], which runs on a Personal Computer (PC). Since it is running as software on the PC, it has complete information about the internal state of the microcontroller at each instruction (memory areas, register, peripherals, etc.), allowing real time monitoring.

The software includes several demonstration programs covering basic tasks such as reading a sensor, interfacing to a LCD and driving a motor. These projects also provide examples of how to use the various peripherals of the card. We have organized the laboratory sessions so that they are based on the use of these projects. The projects are of increasing difficulty, allowing to build knowledge as students progress from one project to the next. The assembly source code has comments with allow to identify relevant steps, so students are able to monitor the execution although they are not familiar with the specific programming language. This avoids tieing students to a manufacturer-dependent solution, which is quire important in such a changing technological field [2]. At the same time, students do not have to invest time on learning specificities of the particular micro-controller which, in all probability, will be different to those that they will find in their respective job positions.

Sessions Organization

The students are organized in teams of a maximum of 2 members, and they work together to accomplish the objectives in each of the laboratory sessions. Each session lasts 2 hours and the sessions are organized considering that the amount of work needed exceeds the 2 hours available, therefore a substantial amount of work should be performed by the student outside the session. The sessions and the main expected results are described as follows (see Table 1, bottom):

1. Introduction to Laboratory Hardware. The hardware used in the laboratory (PicDem board) and the PC-based interface (MPLAB (TM) IDE) is described, with the aim of serving as an interface for the students to start interacting the system.

2. Thermometer Using the Analog-to-Digital Converter. A thermometer is implemented using the temperature sensor in the PicDem. Then, the static transfer function of the thermometer is measured, taking different references of various reliability. The aim is to highlight the importance of a proper calibration process, as well as to let the students learning to work with analog-to-digital converters (ADC) and conditioning circuits. This covers several of the theoretical aspects of the course (theoretical topics 1, 4 and 5 in Table 1).

3. Dusk Indicator Using the Voltage Comparator. A dusk indicator is implemented using the light sensor of the PicDem. Using the PC-based interface, the charactersitics of the components are measured (sensor, comparator). The need of hysteresis in the whole process is analyzed and a hardware alternative for its implementation is theoretically derived. This session covers part of theoretical topics 1, 2 and 5 in Table 1.

4. Brushed DC Speed Control with Optical Encoder Feedback. A DC motor is controlled by the use of the optical encoder present in the PicDem board. The characteristics of the motor and the PicDem are measured and documented using the PC-based interface. Moreover, the circuit used to feed the motor (Pulse Width Modulation circuit included in the PIC of the board) is also characterized. Finally, the static transfer function

relating speed to input voltage is estimated under several situations, leading to a complete understanding of the system under analysis. This sesison covers part of theoretical topics 1, 2, 4 and 5 in Table 1.

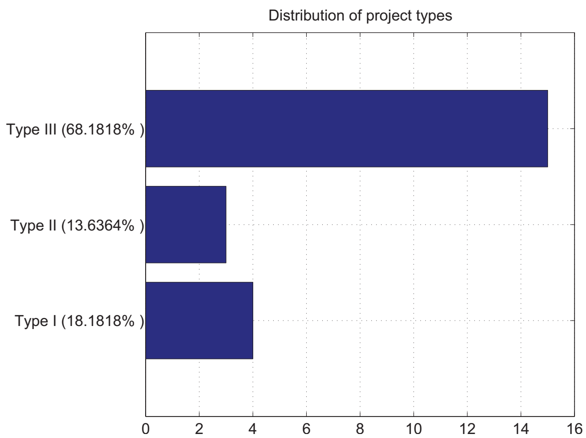

Fig. 3. Distribution of project types (I, II and III with increasing difficulty) among different teams of students for the laboratory session 5 of the proposed practical methodology.

Engineering Project

The main contribution of the proposed methodology is the existence of a final project (lab session 5 in Table 1) whose aim is to integrate part of the developed modules in previous sessions into a full engineering project. Thus, in this last session students are asked to design an engineering project to solve an electronic instrumentation problem which is set by themselves. The main condition of the project is the use of the laboratory hardware as a critical component. The proposed work methodology considers the following steps:

- **Identification of an engineering problem** where electronic instrumentation will play a fundamental role. For this section, the students must be creative in applying all the concepts acquired in the theoretical sessions, also considering the modules implemented in previous practical sessions. Aspects to evaluate are the potential difficulty and the originality of the problem.

- **Identification of the components** needed to solve the instrumentation problem in the form of an engineering project. In this section, not only the components have to be specified, but also their relationship with the available hardware, namely PicDem (Figure 2). The level of detail to be specified is maximum, with the requirement of finding technical sheets for each component, and also to explain it deeply in order to integrate it in the whole project. The components may be PicDem components (either used in previous sessions or not previously explored at all) or other external components. The evaluation of this step will be based on the difficulty to find the specified components, the technical adequacy of them to the problem, the performance with respect to other options in the market and the level of detail of their description (technical sheets and additional information).

- **Engineering project.** Here the student should give a solution to the proposed problem in the form of an engineering project. It is not a requirement to make the programming routines for PicDem operation in assembly code, but the pseudo-code of its operation should be included. Schematics, diagrams and detailed descriptions of the solution adopted with a clear explanation of the relationship among components and with the problem to solve are also required. In this section the evaluation will be based on the quality of the schematics and diagrams, the adequacy of the project to the problem to solve, the quality of the explanations and the implementability of the designs and solutions adopted.

Several types of possible projects are proposed to the students, which serve as guidelines to their development. Each type of project presents an increasing difficulty which allows students to quantify the relevance of the problem presented and the solution adopted. The proposed project types and their characteristics are specified here:

1. **Type I Project.** This project basically consists of improving one of the modules implemented in previous sessions in order to give solution to the problem proposed by the students. No internal or external component is required. This project is the easiest of all, which is considered in the evaluation (see Section 3.3).

2. **Type II Project.** This project considers two alternatives: i) the project includes other components of the PicDem not used in previous sessions; or ii) the project includes other components external to the PicDem. Given the difficulty of searching, analyzing and specifying components not seen before, the evaluation of this project is more favorable than in the Type I (but less than the Type III, see next).

3. **Type III Project.** In this project, both components of the PicDem not used in previous sessions and other components external to the PicDem are used. Given the difficulty of searching, analyzing and specifying components not seen before, the evaluation of this project is the most favorable of all the proposed Types.

3.3. Evaluation

As it happens in the Spanish education system, the evaluation of a course is given in a $[0, 10]$ interval, being 0 the minimum

Type I

- Measurement of Light Time.
- Motor Control by Temperature Sensor.
- Motor Control by Temperature Sensor.
- Motor Control by Temperature Sensor and Speed Measurement.

Type II

- Control of a Window Blind by Light Sensor.
- Domotic Control of a House.
- Motor Control by Temperature and Light sensors, and Switches.

Type III

- Automation of a Lighthouse.
- Control of a Canopy by Humidity and Light Sensors.
- Hold-on Time Control for a Bus Line.
- Measurement of Glucose Level.
- Motor Control by Strain Gauges.
- Obstacle Map Design.
- Simulation of Inhabited House.
- Smoke Detector.
- Stability Control of a Car.
- Temperature and Humidity Measurement and Registry.
- Temperature Controller.
- Temperature Measurement and Registry.
- Turbo-Engine Pressure Control by Solenoid Valve.

Table 2. Project titles grouped by project type.

score and 10 the maximum score, and considering that a student passes an exam when his/her score is greater or equal than 5. The evaluation of the whole Electronic Instrumentation course was given by the following formula, derived from the current rules at Escuela Politecnica Superior at Universidad Autonoma de Madrid:

$$FS = 0.25 \times PS + 0.75 \times TS \qquad (1)$$

where FS is the final score of the course, TS represents the score obtained in the evaluation of the theoretical work and PS is the score of the practical work. As additional constrains, it must happen that both $TS \geq 5$ and $PS \geq 5$, meaning that the student has to demonstrate his attitudes both for theoretical and practical work.

The theoretical score TS is obtained from an exam where the knowledge acquired in theoretical sessions is evaluated. The exam encompasses a closed-answer test (30% of TS) and some design problems to solve (70% of TS). For this exam, according to the Spanish law, a student can attend two times per year. If they do not pass the first call (in June) they can attend to the second call.

The criteria for evaluation of all the practical part of the course has been transparent in all moment, with the students being informed of it conveniently from the beginning. The score PS is computed as follows:

$$PS = 0.20 \times S_2 + 0.20 \times S_3 + 0.20 \times S_4 + 0.40 \times S_5 \qquad (2)$$

where S_i is the score obtained in laboratory session i as it is enumerated in Table 1 (bottom). It can be noticed that laboratory session 1 is not evaluated, because it is an introductory session. Moreover, the project represent almost half of TS, representing the emphasis that the practical methodology of the course presented in this paper puts in the integration of modules into a full engineering project.

For the evaluation of the engineering project (laboratory session 5 in Table 1) the project types (Type I, II and III, see Section 3.2) has an influence in the final qualification. The idea followed is that the more difficult the project, the more difficult will be to achieve a higher score. However, there is the opportunity of achieving the highest score with all the project types if the quality is sufficiently high. Thus, a correction factor has been imposed to the score obtained in laboratory session 5 depending of the project type that the students have selected. In this way, Type III projects would tend to obtain the highest scores, whereas Type 1 projects will tend to obtain the lowest scores.

4. RESULTS

The results presented here are interpreted over a sample of 40 students of the last course of Telecommunication Engineering at Universidad Autonoma de Madrid. Since the students are

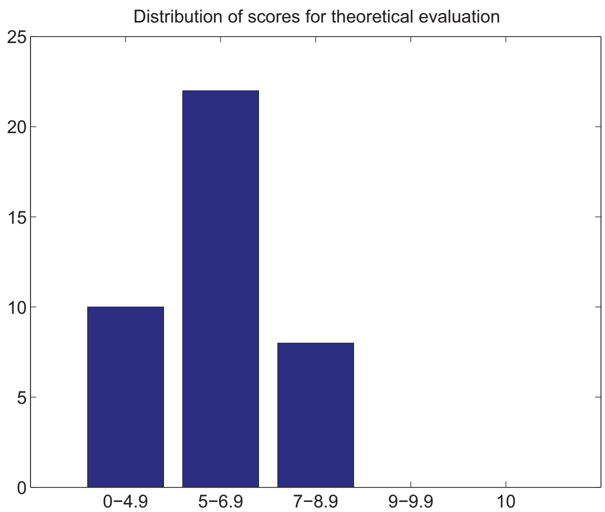

Fig. 4. Histogram of theoretical scores TS following the Spanish evaluation system (from 0 to 10). 40 students analyzed.

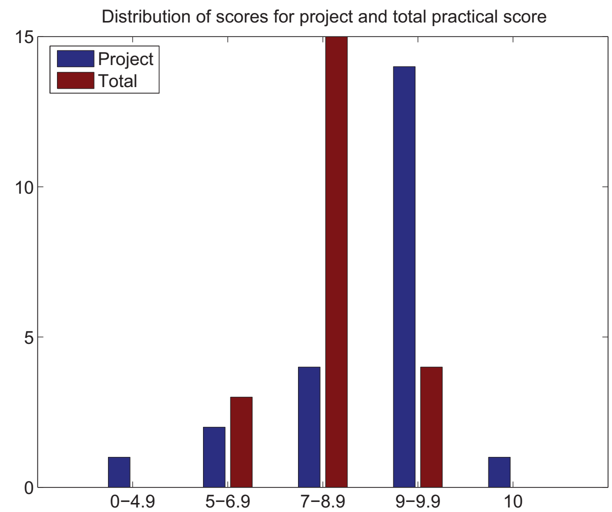

Fig. 5. Histogram of practical scores PS and scores for the proposed project S_5 following the Spanish evaluation system (from 0 to 10). 22 teams analyzed.

organized into teams of maximum 2 people for practical laboratory work, the sample reduces to 22 teams for the analysis of the outcomes from the practical part of the subject. Also, since 2009 was the first year in which the proposed methodology is implemented, the sample cannot be compared in time. This is proposed as future work of this contribution.

4.1. Project type distribution

Distribution of project types among teams in the selected sample is shown in Figure 3. It is shown that the students have mainly selected Type III projects, which are much more difficult to develop. This is an indication of the degree of motivation of the students with respect to the proposed methodology. Moreover, given the transparency in the evaluation methodology followed, such distribution means that the students are ready and willing to explore and deeply specify components not seen before, and to integrate it into an engineering process. This is an indicator that the knowledge acquired in the theoretical-practical methodology followed seems sufficient for them in order to accomplish the objectives of the project.

Table 2 lists all the titles of the projects, classified by project type. It is observed that the originality of the project title depends on the type of project, being Type I projects much more typically seen than Type III projects.

4.2. Scores

The scores obtained in the theoretical subject (TS scores) are represented in Figure 4. it is observed that the scores concentrate in the 5 to 8 region, not being higher than 9 in any case. This is an indicative that, although the vast majority of the students pass the exam ($TS \geq 5$), obtaining the maximum score (10) is extremely difficult. This has been the trend in Spanish evaluation methodologies over decades.

Figure 5 shows histograms with the distribution of the scores obtained in the practical part of the course, compared to the score obtained in the proposed project (laboratory session 5). It is observed that, in general, the scores in the practical part of the course are significantly higher than in the theoretical part of the course (compare with Figure 4). This was a design requirement, since the challenge of practical sessions should be kept while fostering the student's motivation. Moreover, in general it is observed that the trend of the scores in the proposed project is much higher than the total score. That means that, despite the intrinsic difficulty of an engineering project, the students have taken the initiative to accomplish it in a successful way. Figure 6 shows the distribution of scores for each of the sessions in the practical part of the course, namely S_2, S_3, S_4 and S_5. These results confirm this trend, showing a remarkable improvement in the score obtained by the students with the number of laboratory session.

Correlation between theoretical knowledge acquired and practical competencies is shown in Figure 7. It is observed that the correlation coefficient among the theoretical score (TS) and the practical score (PS) is positive, and having a non-negligible value of 0.32 from a maximum of one. That indicates that the theoretical knowledge gained by the students is in relation to the practical abilities achieved, which fulfills part of the objectives of the course. This is also seen in Figure 8. if we obtain the correlation between the theoretical score and the proposed project (laboratory session 5).

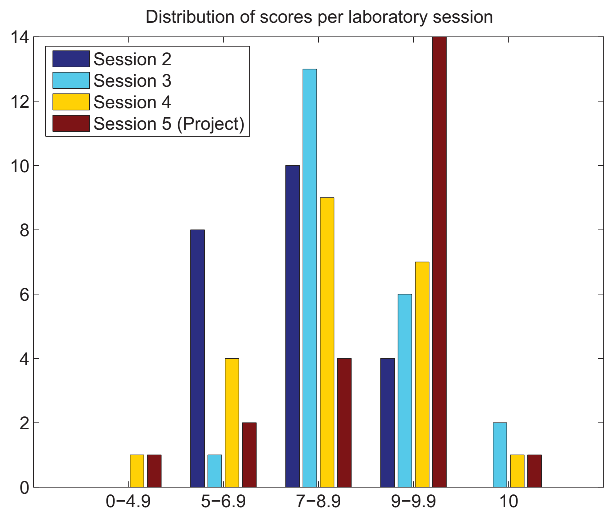

Fig. 6. Histogram of practical scores for all the laboratory sessions following the Spanish evaluation system (from 0 to 10). 22 teams analyzed.

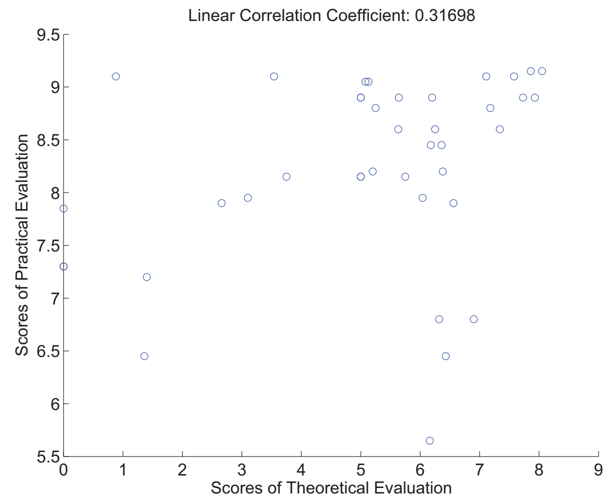

Fig. 7. Scatter plots showing correlation between theoretical scores (TS) and practical scores (PS). Correlation coefficient is also shown. 40 students analyzed.

Again, the correlation is positive, and the coefficient has also a non-negligible value, in this case of 0.25, indicating that the objective of the proposed project of yielding practical and theoretical abilities to students to solve electronic instrumentation problems has been achieved.

4.3. Official student opinion polls

Figure 9 shows the results of the official polls conducted by Universidad Autonoma de Madrid, illustrating the opinion of the students about their work in the laboratory. The aspects evaluated are the following:

1. Clarity of concepts.
2. Organization.
3. The teacher dominates the subject.
4. Availability of the teacher in case of doubt.
5. Receptive and friendly attitude of the teacher.
6. Regularity of assistance.
7. Punctuality.
8. **General opinion about the laboratory.**

The results of such polls are extremely satisfactory, over the mean value of the same school and university. That indicates that, although such results do not refer strictly to technical topics, the laboratory has been worthy for the students, and their degree of satisfaction is excellent.

5. CONCLUSIONS

The design of modern electronic instrumentation requires broad knowledge and a multidisciplinary approach, as reflected in the structure of this course. A final design project is used to link theoretical principles with practical issues of electronic instrumentation, so that they acquire the ability of integrating blocks in which they have practically worked into a full instrumentation project.

Outcomes have been extremely satisfactory. Students enhance their academic education, are more motivated, play an active role in project design and receive crucial pre-career exposure to practical aspects. Among the different types of possible projects, students go for the more difficult to develop, which is an indication of the degree of motivation of the students with the proposed methodology. Distribution of marks show an increasing tendency with the number of laboratory session, indicating a correct progress of the students throughout the course. Finally, results of the opinion polls carried out at the University show an excellent degree of satisfaction by the students.

Teaching Microprocessors Design Using FPGAs

Joaquín Olivares, José Manuel Palomares, José Manuel Soto, Juan Carlos Gámez
Dept. of Computer Architecture, Electronics, and Electronics Technology
University of Córdoba
Córdoba, Spain
olivares@uco.es

Abstract— **Microprocessors is a typical subject within the Computer Architecture field of scope. It is quite common to use simulators in practical sessions, due to the complexity of its contents. In this paper a new methodology based on practical sessions with real devices and chips is proposed. Simple designs of microprocessors are exposed to the students at the beginning, rising the complexity gradually toward a final design with a multiprocessor integrated in a single FPGA chip. Finally, assessment results are shown.**

Keywords: Learning Experiences; Laboratory Experiences; Teaching Engineering; Computer Architecture

I. INTRODUCTION

Traditional laboratory practical sessions to teach microprocessors are based on simulators, in this paper an experience implementing real microprocessors is shown. The main purpose is to encourage the student interest and to improve the assessment. This proposal is useful for many subjects within several engineering degrees. This activity was carried out in particular in the Microprocessors subject, in the degree in Computer Sciences at the University of Córdoba.

In most cases, computer architecture has been taught with software simulators [1], [2]. These simulators are useful to show: internal values in registers, memory accesses, cache fails, etc. However, the structure of the microprocessor is not visible, and students are not aware learning a real processor. Recently [3], [4], digital design is being teaching using real Programmable Logic Devices (PLD), showing it attractiveness for the students. Also recent works shown how the learning throw projects and games based on FPGAs are very useful [5].

In this work, a methodology for easy design and real implementation of microprocessors is proposed, in order to provide students with a user-friendly tool. Simple designs of microprocessors are exposed to the students at the beginning, rising the complexity gradually toward a final design with two processors integrated in an FPGA; each of which has an independent memory system, and are intercommunicated with a unidirectional serial channel. Furthermore, an introduction to the architecture of a T1 SUN OpenSparc system with 8 processors, 4 thread/processor plus one MicroBlaze is introduced at the end of the semester while students are working on their projects, this final seminar is useful because students are encouraged when see that a high performance parallel architecture is suitable of being implemented on a single FPGA Virtex5 [6].

In this paper the methodology to design and implement a microprocessor or multiprocesors is presented. To illustrate it with high detail and in a useful way, how to design the most complex practical session is shown. In section I, other methodologies based on simulators are referenced. The software platform used to implement real processors is presented in section II. Features of MicroBlaze processor are introduced in section III. The course practical content is described in section IV. To illustrate how a processor is designed and implemented, section V presents a brief guide of how to build a biprocessor, this is the most complex practical session. Finally, conclusions are presented in section VI.

II. SOFTWARE TOOL

The Xilinx Platform Studio (XPS) is used to design MicroBlaze processors. XPS is a graphical IDE for developing and debugging hardware and software. XPS simplifies the procedure to the users, allowing them to select, interconnect, and configure components of the final system. Dealing with this activity, the student learns to add processors and peripherals, to connect them through buses, to determine the processor memory extension and allocation, to define and connect internal and external ports, and to customize the configuration parameters of the components. Once the hardware platform is built, the students learn many concepts about the software layer, such as: assigning drivers to peripherals, including libraries, selecting the operative system (OS), defining processor and drivers parameters, assigning interruption drivers, establishing OS and libraries parameters.

Students have deeper documentation available in [7], [8], and other useful resources recommended are [9], and, [10].

An embedded system performed with XPS can be summarized as a conjunction of a Hardware Platform (HWP) and a Software Platform (SWP), each defined separately.

A. The Hardware Platform

The HWP is described in the Microprocessor Hardware Specification (MHS) file; it contains the description of the system architecture, the memory map and the configuration parameters. HWP can be defined as one or more processors connected to one or more peripherals through one or more buses. The definition of the activity follows this sequence:

- To add processors and peripherals.
- To connect them through buses.

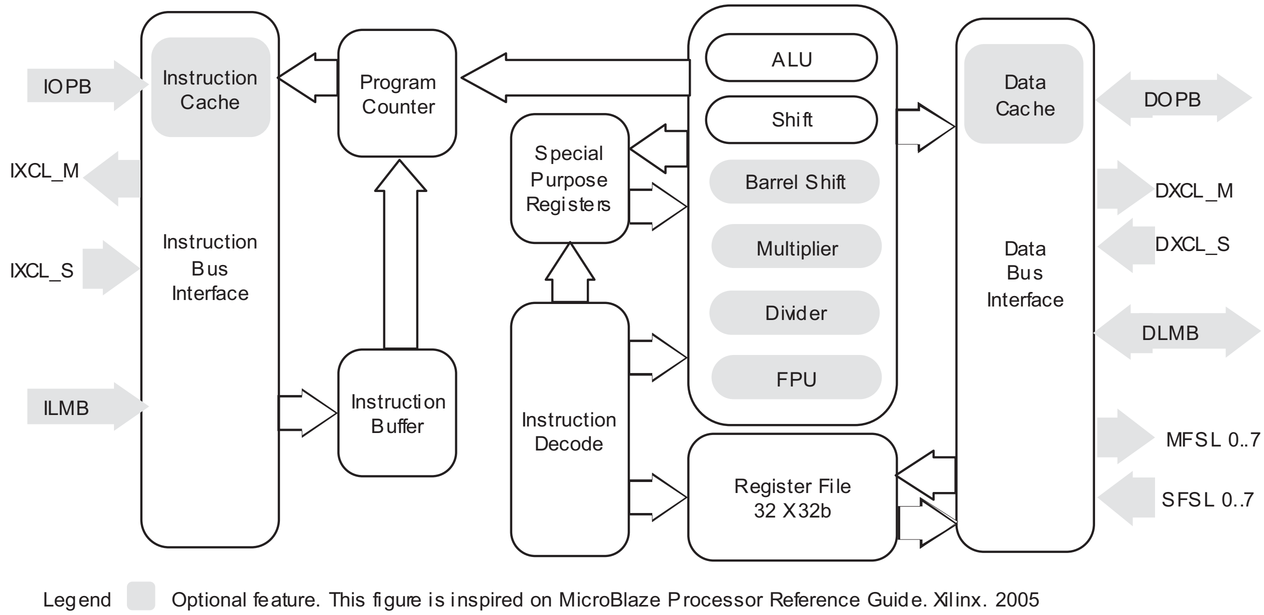

Figure 1. MicroBlaze architecture. In gray, reconfigurable components

- To determine the processor memory allocation.
- To define and connect internal and external ports.
- To customize the configuration parameters of the components.

B. The Software Platform

The SWP is described in the Microprocessor Software Specification (MSS) file; it contains the description of drivers, component libraries, configuration parameters, standard input/output devices, interruption routines and other software features. The sequence of activities needed to define the SWP is the following:

- To assign drivers to peripherals.
- To assign interruption drivers.
- To establish OS and libraries' parameters.

III. The MicroBlaze Processor

MicroBlaze is a 32-bit specific purpose processor developed by Xilinx in VHDL. It can be parameterized using XPS to obtain an *à-la-carte* processor. It is a RISC processor, structured as a Harvard architecture with separated data and instruction interfaces.

MicroBlaze components are divided into two main groups depending on their configurability as shown in Fig.1.

Some fixed feature components are:

- 32 general purpose registers sized 32-bit each.
- Instructions with 32 bits word-sized, with 3 operands and 2 addressing modes.
- 32 bits address bus.
- 3-stage Pipeline.

Some of the most important configurable options are:

- An interface with OPB (On-chip Peripheral Bus) data bus.
- An interface with OPB instruction bus.
- An interface with LMB (Local Memory Bus) data bus.
- An interface with LMB instruction bus.
- Instruction cache.
- To include EDK libraries.
- To select the operative system (OS).
- To define processor and drivers' parameters.
- Data cache.
- 8 Fast Simplex Link (FSL bus) Interfaces.
- CacheLink bus support.
- Hardware exception support.
- Floating Point Unit (FPU).

IV. Practical Designs

Practical sessions introduce gradual learning, allowing the fast design based on previous sessions. Essential problems in hardware programming will be raised:

- Hyperterminal serial communication.
- Using IO ports.
- Memory controller.
- Interruption routines and priority.

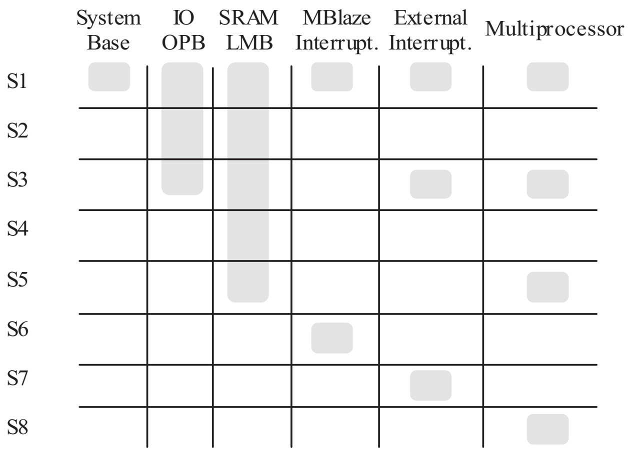

Figure 2. Sessions and contents.

- Message passing in multiprocessors communication.

The practical content of the subject is composed of 8 projects. In the first session, students make a basic system which will be used in following sessions as the base core system. Second and third sessions are used to introduce the input/output flow and the communication with external peripheral through the On-chip Peripheral Bus, for general purpose. SRAM external memory is added to the system at fourth session. Next session is dedicated to the External Memory Controller and how to split the bus. MicroBlaze interruptions are added in the sixth session, and external interruptions using the interruption controller are included in the seventh session. Finally, students build a biprocessor, using the Fast Simple Link channel at session eight. In fig. 2 the relation between practices is shown. For instance, 5th session is based on all previous sessions, 7th session is based on 3rd and 1st session.

V. Biprocessor System Design

The last and most complex practical session is the design and implementation of a biprocessor. A computational system composed of two MicroBlazes will be designed. Both MicroBlazes will be interconnected using message-passing protocol. Each MicroBlaze has its own non-shared memory for instructions and data.

In the Fig. 3 a diagram with the structure of the design is shown. In it, the buses and components used have been detailed. It also includes how they are interconnected

At first, following the logical sequence exposed previously, a HWP will be created. This HWP will include the configuration of the components and buses, their interconnection, the memory map, ports and other parameters.

In the following subsection, the steps needed to configure the system will be described. Trivial stages, such as the creation of the project, will not be included in this paper. The parameters shown in this section depends on the FPGA chip, in this case the Spartan 3 board [11].

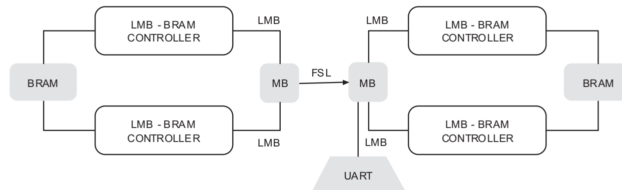

Figure 3. Biprocessor system diagram.

A. Hardware Platform Specifications

This stage is described in the MHS file. Following, the components specified in the structure of the system are enumerated:

- Two MicroBlaze processors.
- Two on-chip RAM memory blocks (BRAM), one for each processor.
- One UART.
- One OPB bus, to connect the UART with the slave processor.
- Two LMB buses to communicate each processor with their respective data memory controller; and another two LMB buses to interconnect the processors with their instruction memory controller.
- One FSL channel to intercommunicate each processor with the other.

After that, the interconnection of buses and components is defined. The connection of the memory ports are also set at this point. The student has to specify in the connection matrix which components are linked to which buses and with which kind of connection.

In the exposed case, four LMB buses are needed to access local memory, two for each MicroBlaze, because each processor has its own memory subsystem.

Also, one FSL channel which connects both processors.

Each BRAM has been designed with 4 different ports. Each MicroBlaze reaches its memory block through two different interfaces (instructions and data).

After that, it is necessary to map the components inside the configuration memory of the processors. XPS provides a functionality which is able to compute automatically a valid configuration memory map for a monoprocessor system structure. However, as the system proposed is a biprocessor one, this functionality cannot be used.

Each MicroBlaze looks for the first instruction in its program at memory address 0x0.

The next step is to define the internal and external ports. Most of the internal ones are configured by XPS with default settings. It is also necessary to define and to connect some of the internal ports to make the system works: those ports related to the reset and clock signals must be forwarded to all of the subsystems and components. Four external ports are mandatory: clock, reset, UART in and UART out. With these ports, the student sends commands and synchronization information to the system. Finally, the components are configured. The parameters for each component and their meaning are described thoroughly in the documentation included in the XPS platform.

Particularly, MicroBlaze includes a parameter which selects the amount of FSL interfaces used. Thus, both processors have to set this configuration value to one to allow the communication between them. The configuration of this parameter is done by changing C_FSL_LINKS. This parameter has to be set to a numerical value, representing the amount of FSL interfaces to be included in the core.

Another interesting configuration to be mentioned is the UART operational configuration. The student has to determine the operational frequency, the application of the parity bit checking, working bauds, etc. A valid set of parameters for the UART and MicroBlaze are the following:

1) *UART parameters.*

a) C_CLK_FREQ = 50_000_000. Set the frequency of the OPB bus, connected to the UART. It has to coincide with the operational system speed.

b) C_BAUDRATE = 19200. Set the bauds for the UART. The terminal used to receive characters has to be configured at the same baud rate.

c) C_USE_PARITY = 0. Set whether the UART should work with parity bit or not.

2) *MicroBlaze parameters.*

a) C_FSL_LINKS = 1. In order to communicate between the two processors, at least, one FSL channel has to be defined.

After the HWP is defined, the netlist files and the support files can be generated.

B. Constraints File

The constraints file specifies how external ports from the designed system correspond with the Spartan-3 Board [ ] pins:

```
# Clock signal.
Net sys_clk LOC=T9;
Net sys_clk TNM_NET = sys_clk;
TIMESPEC TS_sys_clk = PERIOD
sys_clk 20000 ps;
# Reset button
Net sys_reset LOC=l14;
Net sys_reset TIG;
# UART
NET TX LOC = R13;
NET RX LOC = T13;
```

Once the constraint file and the HWP are ready, XPS has enough information to create the internal bitstream file.

C. Software Platform Specification

The SWP corresponds with the Microprocessor Software Specification (MSS). The first step is to select the drivers for the components, the SWP libraries and the OS for each processor. In this project, the standalone OS is selected, no libraries are used and the drivers for the components are established by default.

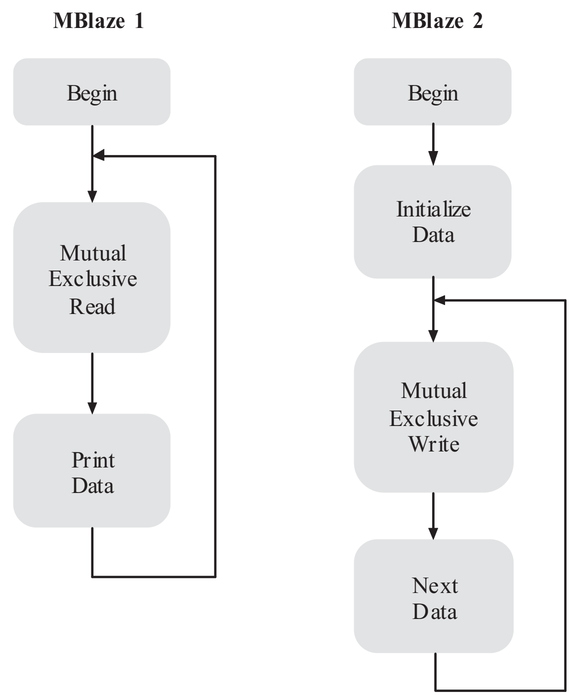

Figure 4. Software application flowchart.

In the following step, the configurable parameters from processors and drivers must be edited; also the interruption routines must be assigned if needed; for instance, in the system under explanation, the interruption routines are not used. In this case, all fields are configured by default except for the processors, which must be configured to work at 100 MHz.

In the final step, the OS libraries configuration parameters are edited and configured. The standalone OS has a minimum size software layer with some primitives for input/output, control, memory allocation, etc.

In the proposed system, the student must specify the UART as the input/output standard peripheral. This is established by assigning the UART to the OPB master MicroBlaze.

Once SWP is configured, it is possible to program the processors software code. However, it is necessary to generate previously the libraries and the Board Support Package (BSP).

D. Software Application

To carry out the goals of this work it is necessary to create two SW projects, one for each MicroBlaze. With these, each Microblaze will execute its own program.

Some primitives are used to allow a fluid message passing between both processors through the FSL channel.

The writer processor generates the data that will be sent to the reader processor through the FSL channel using mutual exclusion primitives for message passing. The OPB bus master sends the data received by the reader processor to the UART.

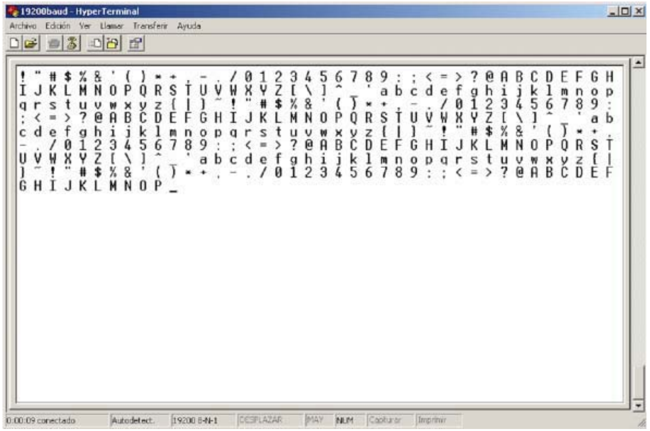

Figure 5. Hyperterminal capture while the both processors are i

After the compilation of the software application, the FPGA configuration file is generated.

Finally, the configuration file is loaded into the FPGA. After all these steps, the students execute the global system and they verify that both processors work properly: The reader processor reads data generated from the writer processor, and the writer processor generates successive data. This process is shown in Fig. 4.

Following the code based on C language for both MicroBlaze processors is shown. Some Xilinx libraries are required to optimize the code and to use some resources:

MicroBlaze 1 Code. Reading data from MicroBlaze 2 and showing them in the UART

```
#include <mb_interface.h>
int main( )
{
  int i;
  while(1) {
    microblaze_bread_datafsl(i,0);
    xil_printf("%c ",i); }
  return;
}
```

MicroBlaze 2 Code. Generating consecutive ascii characters and sending them to MicroBlaze 1 through FSL

```
#include <mb_interface.h>
int main()
{
  int i = 33;
  int c;
  while(1) {
    for(c=0;c<10000000;c++);
    for(c=0;c<10000000;c++);
    icroblaze_bwrite_datafsl(i,0);
    i++;
    if(i>126) i=33; }
  return;
}
```

Hyperterminal screen was captured and is shown in Fig. 5 to show the results when the both processors are running.

VI. Conclusions

XPS can be used as an excellent tool for the students to design and build complex architectures avoiding implementation details. Otherwise, they would spend a lot of time until they master concepts and techniques to develop those systems. Students understand the functionality and the structure of the different components, in order to interconnect all of them to build either a monoprocessor or a biprocessor.

A notable improvement of the qualifications compared to the average of the previous five years was obtained. In particular, in 2008 an improvement of 21% was obtained in front of the mean of the assessment for 2005-07 period. In 2009 the improvement in the assessment was 22%.

As a result of a survey, students are more motivated using real devices than using just simulators.

Furthermore, the configuration of each of the component parameters contributes to a better understanding of the developed architecture. And they are able to test how different values for those parameters influence the performance of the whole system. Finally, a guide on how to implement several processors systems on a single FPGA chip has been provided.

Acknowledgment

Authors wish to remark the great task carried out by the Xilinx University Program, XUP; and the Sun Microsystems OpenSPARC University Program, which have donated software and materials which have been very useful to partially finance this work.

Development of a Small Radio Telescope at the Technical University of Cartagena

A duty with our students and society

José Luis Gómez-Tornero*, David Cañete-Rebenaque, Fernando D. Quesada-Pereira and Alejandro Álvarez-Melcón
Dept. of Information and Communication Technologies, Technical University of Cartagena (UPCT), 30202 Cartagena, Spain
email: *josel.gomez@upct.es*

Abstract—**An initiative carried out at the Technical University of Cartagena (UPCT, Spain) to encourage students and promote the interest for Scientific and Engineering Culture between society is presented in this contribution. For this purpose, a medium-term (4 years) project based on the design, fabrication, testing and set-up of a small Radio Telescope system has been carried out. The main novelty is that this project is entirely being done by students of last courses of our Telecommunication Engineering Faculty, under the supervision of four lecturers.**

Keywords- Electrical engineering education; Electromagnetic engineering education; Systems engineering education.

I. INTRODUCTION

As we are immersed in the "Bologna process" to reach the EEES (European Space for Higher Education) [1], academic and government regulators request for innovate experiences to improve the learning process, highlighting the necessity of development of more practical, less theoretical, teamwork, interdisciplinary competencies. Very worrying is the reality detected in the last decade that shows that young people around Europe are losing their interest in Science and Engineering culture (see, for instance the objectives and effort made in Spain by FECYT [2]). Being aware of these facts and feeling responsible as part of a public University, some lecturers of the Telecommunication Engineering Faculty at the Technical University of Cartagena (UPCT) decided to undergo the experience of involving our last course students in the development of a Small Radio Telescope (SRT).

These lecturers coordinate some telecommunications related syllabus like Electromagnetism [3,4], Antenna Engineering [5,6] Microwave Engineering [7-8], or Radio Communication Systems [10]. We thought that Radio Astronomy [11-14], and particularly Amateur Radio Astronomy [15-17] is an interesting application of Microwave Engineering that might motivate students to put effort in these courses [18]. Moreover we though that involving the students in the setting-up, operation, maintenance and enhancement of a SRT system (see Figs.1-2) could be a good idea to have a permanent practical laboratory where they could feel free to improve their knowledge and skills related with these technologies. Besides, this Radio Telescope can serve as tool to attract future students to our Faculty, and also very useful to disseminate Radio Astronomy between non-specialized individuals, local amateur astronomers [19,20], and society in general.

Figure 1. Students and lecturers at work mounting the SRT antenna

The main novelty of this activity is that the entire Radio Telescope system (see scheme in Fig.2) is being entirely developed, manufactured, tested and set-up by the students, using the facilities available in our modest laboratories. To our knowledge, this is the first proposal in Spain to promote Radio Astronomy with these particular characteristics. Other public Spanish Universities proposals, such as the ones from the University of Valencia [21] or the University of Cantabria [22] have also made use of a SRT to introduce their students of Physics and Astronomy to this fascinating world. However, in these cases, the entire SRT was designed, manufactured and sold by external Engineering companies [23-26]. Another well-known example is the Spanish-NASA project known as PARTNeR [27] started in 2004, and which involves the use of the 34m diameter NASA Radio Telescope at Robledo de Chavela (Madrid, Spain) to disseminate Radio Astronomy among high-school and University students [28]. Like other Spanish professional Astronomy institutions such as IAA [29] or IAC [30], these initiatives make use of professional and large Radio Telescopes with the aim to make public their facilities and divulgate Radio Astronomy to society. On the contrary, the initiative proposed and carried out at the UPCT

This work has been partially supported by Regional Séneca Foundation under project 02972/PI/05 during 2006-2008, and partially by the Technical University of Cartagena (UPCT) during 2009 and 2010.

has an academic origin, with the main objective to stimulate the potential and improve the learning process of our graduate and postgraduate students in the fields of Electromagnetism, Antenna and Microwave Engineering, and Signal Processing. In the international picture, similar university projects can be found at MIT Haystack Observatory (Boston, MA) [31], Cardiff University (UK) [32], or Saint Mary's University (Canada) [33]. Nevertheless, a secondary objective and interesting consequence is the application of this project to share this amateur SRT between high-school students, local Astronomy associations and society in general, trying to attract new students to our faculties and improve the interest of young people for Science and Engineering. A similar task in an international level can be attributed to the SETI (Search for Extra Terrestrial Intelligence) team [34], in his aim to let individuals collaborate in this search, with projects as the SETI@home [35] or the development of amateur SRTs for SETI Argus Project [36-37].

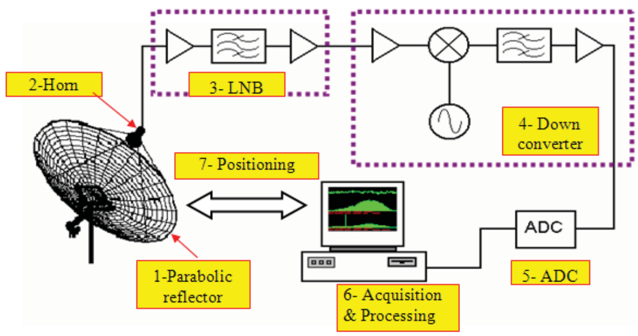

Figure 2. Scheme of the Radio Telescope subsystems

In this paper, the particular objectives of the SRT project undergone at the UPCT will be described, illustrating the methodology used to improve the learning process of the aforementioned undergraduate and postgraduate courses. Also, the response of the students and the results obtained will be addressed, together with the main future lines.

II. Objectives and Benefits

The main objectives of this initiative, and the associated benefits for the students, can be summarized as follows:

1- **Development of a small radio telescope (SRT)** capable of detecting the **L-band emissions of atomic hydrogen** (1.42 GHz). This frequency was chosen since the hydrogen line emissions from our Galaxy are quite abundant and relatively strong [11]. Moreover, this microwave range provides understanding of high-frequency related phenomena studied in Antenna [5-6] and Microwave [7-10] Engineering without overcoming the 6GHz band, in which the manufacturing and testing of circuits and antennas becomes much more expensive and difficult. Therefore, the microwave receivers working at this frequency are *relatively easier and cheaper to design and manufacture*, if compared with higher frequencies or more sensitive receivers, which might be impractical for modest tools and laboratories like the ones that our graduate students can use.

2- The system (see Fig.2) must be entirely designed, manufactured, tested, set-up and maintained by our students. In this way, the students face a complex project, in which ***practical, interdisciplinary, teamwork competences*** must be developed with a concrete target. In this way, we try to *make **the students realize of their actual developed abilities as future engineers***. It has been found that many students have the feeling of having developed too theoretical, poor practical skills in our Engineer faculties, feeling unprepared for real practical works [1,2]. Even if the lectures do not believe that this feeling corresponds to reality, it is good to make the students realize from and early stage about their actual abilities to face real, practical, complex, interesting engineering projects, so they feel more *motivated and confident*.

3- The SRT system involves different theoretical concepts which the students are supposed to have gained during their graduate and undergraduate courses (mechanics, physics, astronomy, electronics, electromagnetism, microwave circuits, antennas, signal processing, instrumentation…). In this way, we make the students develop ***interdisciplinary skills***, gathering the knowledge of all these courses together to face this work. We believe that this is a more realistic and practical position for them to face the real world, opposed to the academic perspective of “unconnected courses” so often addressed by graduate students.

4- Apart from being multidisciplinary, we also look for development of ***teamwork competences***, needed for practical big projects which cannot be faced by a single person.

5- Once the initial SRT has been set-up and installed at UPCT, it is intended to be a ***constant tool for teaching and upgrading***. The basic system provides an *excellent laboratory* to make *permanent improvements* and *develop future projects* in any of the associate disciplines and technologies. The idea is that the ***students of UPCT must feel fry to conceive and propose new project*** which might upgrade the performance of the SRT, working out their ***creativity and research abilities***.

6- A more *wide objective* is to use this SRT to ***attract young people and increase their interest in Sciences and Technology***[1]. Particularly, the SRT is intended to help in the recruitment of new students to our Engineering Faculties [2].

7- Radio Astronomy is not as spread and known in society as its optical counterpart, probably due to the complexity associated to microwave circuits and antennas. The SRT has also the *social objective* of **introducing *students and amateur astronomers to Radio Astronomy and linked technologies***.

III. Methodology

To face objectives 1-5, some UPCT lecturers started by the end of 2004 a set of BsC and MsC final projects, which were supported from 2006 to 2008 by a Regional Foundation project [38]. The methodology was based on the division of the whole SRT system in several subsystems, as illustrated in

Fig.2. In this way, each student could choose the SRT subsystem he or she wanted to work at, either in the initial design or in the continued upgrading. Obviously, the student and the supervisor should be aware of the state of other SRT projects, improving the result of previous projects and responding to the necessities of current works undergone by other colleagues. A total of **4 lecturers and 32 students** got involved from 2005 to 2009 in the development of the different subsystems of the SRT, with an **average extent of 9 months** (one course) per project.

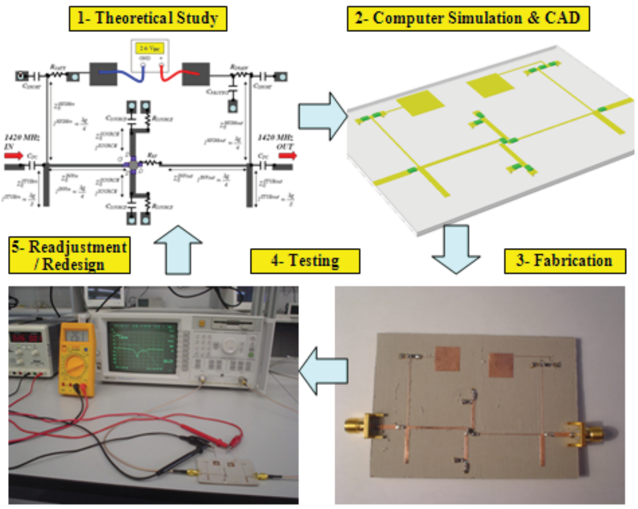

Figure 3. Scheme illustrating the methodology used in each subsystem project for the particular case of the SRT Low Noise Amplifiers (LNAs)

As it is shown in Fig.2, the SRT system is divided in the following comprehensive subsystems:

1- Parabolic Reflector

2- Horn

3- Low Noise Block comprised of:

- 3.1- RF Band Pass Filters
- 3.2- Low Noise Amplifiers (LNAs)

4- Down Converter comprised of:

- 3.1- Low Noise Amplifiers (LNAs)
- 3.2- Local Oscillator (LO)
- 3.3- Mixer
- 3.4- Intermediate Frequency (IF) Filters

5- Analog to Digital Converter (ADC)

6- Acquisition & Signal Processing

7- Control of Motors for Positioning and Tracking

It must be noted that each of this subsystems, although connected and dependent each other, have an individual particular function, which corresponds to a type of hardware signal processing. Moreover, these subsystems practically cover most of the type of circuits used in analog microwave systems [10], so that the SRT receiver scheme in Fig.2 can be **generalized to many other applications concerning Telecommunication Engineering** and Microwaves for Industrial, Scientific and Medical Applications [7,8]. All the students must have, therefore, a broad perspective of the overall receiver system, and at the same time a more meticulous standpoint of the subsystem they are in charge of. In this way, it is promoted the ***interdisciplinary and teamwork competencies***, and a broader knowledge of radio communication systems. The basic methodology of each subsystem project is illustrated in Fig.3, consisting of several steps:

a) **Theoretical study** of subsystem, using the associated disciplines textbooks [3-10], and particularly one text book developed by the supervising lecturers [39].

b) **Computer aided design** (CAD) and simulations using commercial software, such as *Ansoft High-Frequency Structure Simulator* HFSS [40] for linear electromagnetic three dimensional simulations, *Agilent Advance Design System* ADS [41] for linear electromagnetic planar circuit simulations, *Applied Wave Research Microwave Office*-MWO [42] for microwave circuit linear and non-linear frequency analysis, and *Orcad PSPICE* [43] for microwave circuit non-linear transient time-domain analysis. Depending on the type of subsystem, the student might have to use one of these packages (or a combination of them), so that the her or she must learn the main differences, similarities and applications of each one of these **commercial microwave CAD tools**.

As descriptive examples, Figs.3, and 4 illustrate the microwave circuit CAD with MWO for the LNAs and the mixers, respectively. Figure 5 shows an example of microwave transient analysis of the microwave local oscillator (LO) using PSPICE. Finally, Fig.6 depicts the electromagnetic CAD of planar microstrip RF filters, while Fig.7 illustrates three dimensional electromagnetic CAD of the horn of the SRT employing HFSS CAD.

c) **Physical design** of actual prototypes using the more convenient technology. Particularly, planar microstrip PCB (Printed Circuit Boar) technology [9] has been used for most of the microwave circuits (LNAs, RF filters, LO, mixers, IF filters), while waveguide technology has been used for some of the RF filters [4] and the horn antenna [6]. In this way, the students have to face different **practical microwave technologies**, understanding their advantages and drawbacks.

d) **Fabrication of the prototypes** in the corresponding technology using the more appropriate processes, such as photolithography for printed circuits or drilling and mechanization for waveguides and horn antennas. The students gain at this stage a novel **practical perspective about manufacturing processes** (possibilities, limitations, applications), which usually have not been gained in previous courses.

e) **Testing of the circuits**, using the RF instrumentation available in the laboratories. Again, depending of the particular subsystem and technology, different types of measurements and instruments might be used, such as DC voltage supplies, RF generators, spectrum analyzers, network analyzers, RF probes and oscilloscopes. This part is also very interesting for the students, since they **deal with real instrumentation** which is not used in many theoretical courses.

f) After comparing the results of their experiments with the theoretical design and CAD simulations, it is quite common that the student must make some **readjustments and even redesign the circuits** to improve the performance of the actual designs. In this stage, the students learn the difference between the world of CAD model and the real world, understanding also the **importance of using accurate and efficient electromagnetic/electronic simulation tools**.

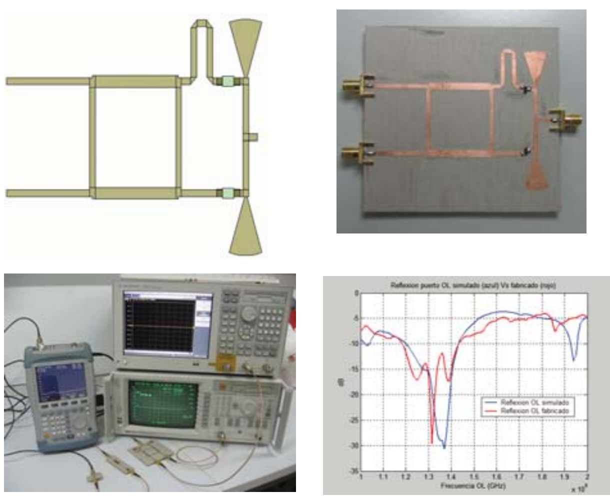

Figure 4. Development of the SRT microstrip mixers

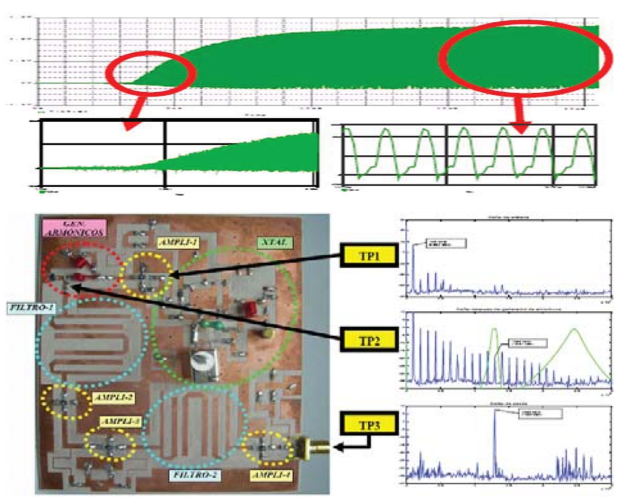

Figure 5. Development of the SRT microwave local oscillator.

Figures 3-9 schematically show some examples of this methodology applied to several of the subsystems of the SRT (LNAs, mixer, local oscillator, RF filters, horn, parabolic reflector and positioning subsystem). Moreover, it must be said that in these four years of work, several improved versions of each subsystem have been designed, so that the students collected the work done in previous years by older colleagues, and worked hard to progress for the better performance of the whole SRT. We believe that this method is very instructive and encouraging for students, since they feel that they are part of a big project in which many people are involved in **teamwork** trying to design the complex system.

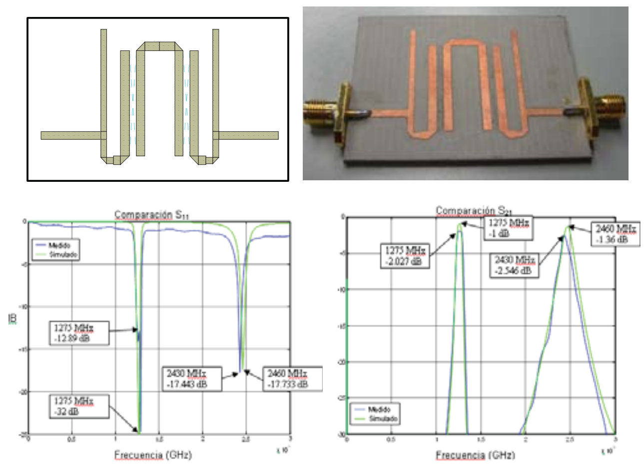

Figure 6. Development of the SRT microstrip band pass filter

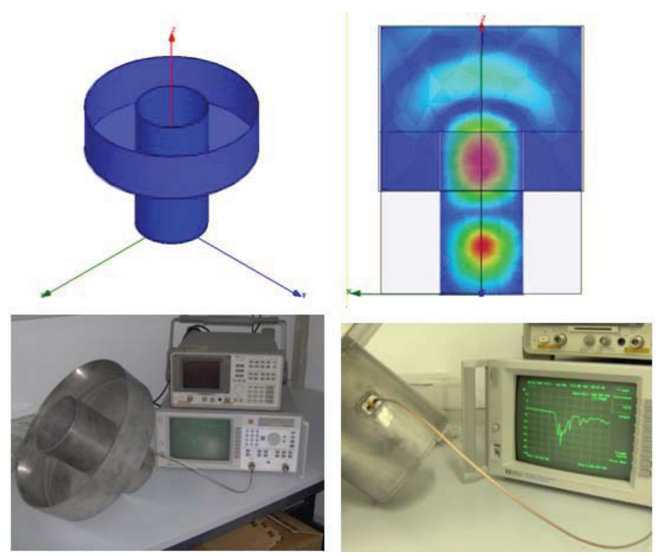

Figure 7. Development of the SRT horn feeding the parabolic reflector

Particularly interesting was the design of the parabolic reflector and the positioning system, shown in Figs.8-9, since they mixed up **interdisciplinary work** involving mechanics and high-power engineering. Another interesting part for the students is the assembly of the different subsystems to conceive the **whole RF receiver** (Fig.2 and Fig.10). For this purpose, especial RF system analysis CAD (*Applied Wave*

Research Visual System Simulator VSS [44]) was used, as illustrated in Fig.10. The same aforementioned methodology is applied for the development of the whole RF receiver, with the particularity that the student must have a deep knowledge of all the RF subsystems involved, which where designed in previous projects. Also, the fabrication and testing of the entire RF receiver is more complicated, since the students must deal with a more complex board and several RF subsytems.

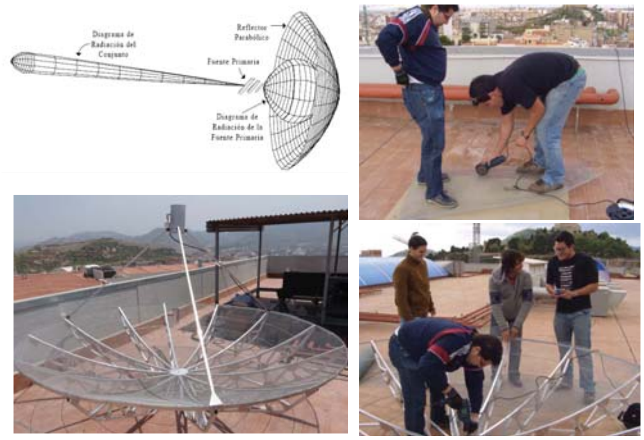

Figure 8 Development of the SRT parabolic reflector

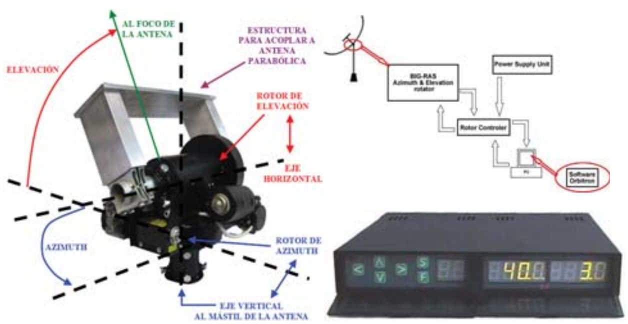

Figure 9. Development of the SRT positioning subsystem

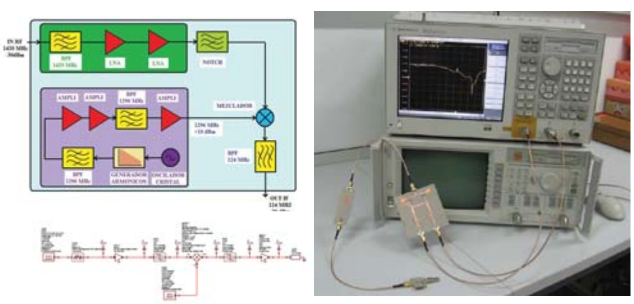

Figure 10. Development and assembly of the whole SRT RF receiver.

The emplacement of the engines and antenna was also very instructive and entertaining for the students, as shown in Fig.11. All participants were very excited to see the SRT located at the final position. For this stage, a solid and stable post was designed, fabricated and sited in the roof of one of the buildings of the University [45]. Finally, the engines were placed on top of the post, and the reflector together with the horn and some LNAs were assembled to it. The students made careful experiments at this stage, in order to properly place the horn at the focal point of the reflector, as shown in Fig.12. A final picture of the SRT from the outside of the building at UPCT is shown in Fig,13.

Figure 11. Emplacement of the engines and antenna at post.

Finally, a web-page has been created to hold and share updated information of this project [46], including general information about Radio Astronomy and Microwave and Antenna Engineering. Particularly, this web page holds all the technical reports derived from the students' MSc projects, including powerpoint presentations and some interactive applets, which might be useful for other people interested in amateur Radio Astronomy.

IV. RESULTS AMONG THE STUDENTS

To evaluate the degree of success of this initiative, with respect to some of the objectives described in Section II, several questions were addressed to the students (a total of 32), once they had finalized their project for the SRT. The questions are summarized below:

1- Do you think working in this project has made you improve your practical abilities? *(Not at all, Not sure, Sure)*

2- Do you think this project has been relevant in your formation as a future Engineer? *(Not at all, Not sure, Sure)*

3- Do you think that this project has been relevant to better understand the associated disciplines that you studied in previous courses (microwaves and antennas)? *(Not at all, Not sure, Sure)*

4- Do you think that this project has improved your teamwork skills? *(Not at all, Not sure, Sure)*

5- Do you think that this project has improved your motivation and interest about the degree you studied? *(Not at all, Not sure, Sure)*

6- Do you think that this type of projects could substitute the associated theoretical courses? *(Not at all, Not sure, Sure)*

All the students responded to questions 1-5 with the "*Sure*" answer, showing an **excellent degree of success among the students** with respect to objectives 2-4 of Section II. It is interesting to note that 53% of the students answered "*Not at all*" to the last question, a 31% answered "*Not sure*" and the remaining 16% answered "*Sure*". Obviously, this project is not intended to replace the theoretical courses, which in opinion of this lecturers are indispensable for the students in order to face the more practical projects proposed in this SRT initiative (as 53% of the students addressed).

From the lecturers' point of view, it is being a satisfying experience (despite the big effort and time of dedication needed to supervise these projects), since the students showed high degree of interest and satisfaction, presenting own judgement and clever ideas, and yielding fruitful discussions and enhancement. Therefore, we really believe that this initiative strongly improve the learning process of the associated Microwave and Antenna Engineering courses, and it is extensible to any other Engineering course. The main condition is to find a practical and interesting application (in this case Radio Astronomy), making the students face an appealing Engineering task to develop their highest potential.

V. CONCLUSIONS AND FUTURE LINES

Objectives 6-7 of Section II can only be achieved after the SRT is used for **dissemination between high-school students and astronomy amateurs in the future**. Particularly, the first future line is to calibrate the SRT to be able to map our Galaxy, so that appealing results as the hydrogen line map shown in Fig.14 can be obtained and shared with visitors.

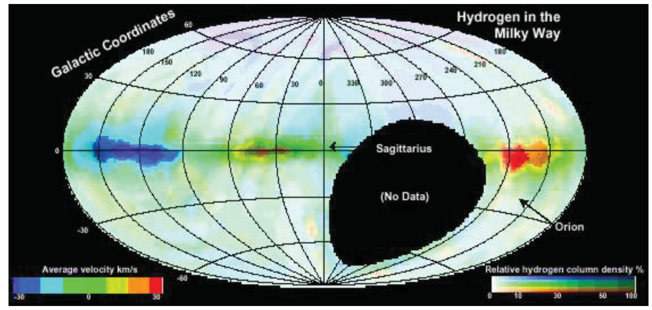

Figure 14. Hydrogen line map of our Galaxy.

Objective 5 is a consequence of the success of the development of the SRT initial system and the good response of the students, so that **this SRT will be used by the students to upgrade its performance and propose new applications**. One of these future upgrades might be the design of an interferometer radio telescope (Fig.15), or the development of receivers and antennas working at other frequencies to detect other interesting signals from our Solar System and Universe. Moreover, the SRT is intended to participate in the SETI project [34,36], which can be another attractive application to increase the interest among the young students and future graduates.

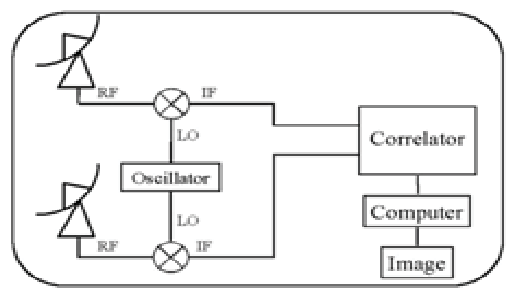

Figure 15. Scheme of a basic linked radio interferometer.

Nevertheless, the authors of this work believe that this type of initiatives are not given enough importance by the actual academic system, which mainly score the lectures by their research results. This fact makes that the endeavor of University lecturers is set on pure research, not being worthy to waste time and energies carrying out dissemination projects like this one which might not be valued in accordance to the effort needed. However, the authors of this paper believe that these enterprises are of key importance to the future of Science and University, and moreover they are a duty with our students and society.

ACKNOWLEDGMENT

This work has been partially supported by Regional Séneca Foundation under project 02972/PI/05 during 2006-2008 [38], and partially by Technical University of Cartagena (UPCT) during 2009 and 2010. This project would have not been possible without the excellent response and enthusiasm of our students, which are named in chronological order (indicating the course years and the subsystem in which they worked as part of this project): Ricardo Alarcón Llamas (design of LNAs, 2005-2006), Pedro Enrique Ros Avilés (mixer, 2005-2006), Joaquín López Castaño (RF filters, 2005-2006), Mónica Martínez Mendoza (RF filters, 2005-2006), Anna Kamasheva (LNAs, 2006-2007), Gonzalo Peñafiel Beltrán (LNAs, 2006-2007), Mónica Moragón Serano (oscillator, 2006-2007), Adrián Juan Heredia (horn, 2006-2007), Francisco Javier Sandoval Piqueras (mixer, 2006-2007), Ramón Angosto Sánchez (parabolic dish, 2006-2007), Juan Antonio Rosell Franco (RF filters, 2007-2008), Javier Molero Madrid (down converter, 2007-2008), Jesús Mora Rodríguez (parabolic dish and down converter, 2008-2009), Marta Rodríguez García (parabolic dish and down converter, 2008-2009), Cynthia Cerezo (microwave detectors, 2008-2009), Miguel Damián Truque (parabolic dish and positioning system, 2009-2010), Pedro Bermejo (oscillators, 2009-2010) and Javier Jimenez (positioning system and final down converter demonstrator board, 2009-2010). The authors want to acknowledge the support of Dr. Isidro Villó, Dr. Isidro Ibarra and Dr. Rafael Vilar from the UPCT, who made possible the final set-up of the parabolic dish and motors in the buildings of the UPCT, and also the scientific and technical wise advices of Dr. Isidro Villó (UPCT), Dr. José Carlos Guirado Puerta (University of Valencia, Spain), and Dr. José Ignacio González Serrano (University of Cantabria, Spain).

***Abstract*— Collaborative evaluation is still a less explored subject within the collaboration field. This paper proposes a methodology to collaborative evaluation based on the 3C collaboration model, which can be applied both in learning or working groups. This paper also presents two case studies run on graduate courses of the Computer Science Department of Catholic University of Rio de Janeiro for collaborative evaluation of the students work. The case studies suggest that the methodology is appropriate for this type of assessment. In addition, students participating in the experiment rated the experience as positive, confirming the premise that students value and miss the collaborative evaluation.**

Keywords- Collaboration, Groupware, Collaborative Evaluation, Assessment

I. INTRODUCTION

Collaboration is a process by which individuals negotiate and share relevant insights to solve a problem. It is a coordinated and synchronous activity, result of a continuous attempt to construct and maintain a shared understanding of a problem [9].

In collaborative learning, the student is responsible for his/her own learning, and collaborates with the other group members' learning, constructing knowledge through reflection on group discussion [5]. The active information exchange instigates interest and critical thinking, allowing learners to reach better results than by studying alone. In collaborative learning, the teacher shifts his/her role from authority to supervisor.

Computer Supported Collaborative Learning (CSCL) studies how people can learn in groups using computers. This approach proposes the development of new software that allows group learning and offer creative activities of intellectual exploration and social interaction. CSCL is often combined with e-learning, which can be defined as organizing instruction using computer networks, like the Internet [10].

Due to the collaboration between participants, the traditional assessment methods-- in which the teacher prepares a written test and the student must answer the questions correctly-- are insufficient to measure the results of collaborative learning. Much like the learning process, the assessment should itself be collaborative, thus allowing the evaluated student and their colleagues to contribute to the assessment process, which is no longer the sole responsibility of the teacher.

The research presented in [3] illustrates how the students consider and miss collaborative assessment when it is not used. In the words of the learner of an online course that suggested the proposal:

"Evaluating is a very interesting activity. We can reflect, analyze, consider… a lot of other reasons could be listed to justify this activity; to assess the other and yourself. I don't understand why this deliciously cognitive activity – to evaluate – is an aspect restricted to teachers (…) See how simple it would be if, at the end of each message, a field were available at the same site for you (the learner) to evaluate by giving a grade and commenting."

[8] points out that, for teachers, student evaluation has always been challenging, and it is difficult to understand the real level of conjecture of the student learning. In addition, states that the evaluation is still a cause of anxiety in both teachers - because there is a concern about quality, loyalty, fairness, integrity, trustworthiness, privacy, efficiency and honesty of the evaluation - and in students - due to fear, insecurity, humiliation, distrust, anger, rage and tumult of the evaluation.

When students share the responsibility of evaluation, the comprehension and the utility of evaluation increase [7][6]. To the evaluated ones, having several assessments of their work increases confidence on the results of the evaluation. Additionally, the evaluators better understand the process and the objectives of the assessment, thus increasing their critical sense and ability to improve on their own work.

Despite the evidence of the benefits of collaborative evaluation, the literature still suffers from the lack of a methodology for conducting such assessment. To fill this gap, this paper proposes a methodology based on the 3C Collaboration Model. Section 2 presents a summary of the 3C model and section 3, the steps of the proposed methodology. Section 4 describes the application of the methodology in two case studies and Section 5 provides a analysis of the participants. Section 6 assesses the proposed methodology based on the results of case studies and finally section 7 presents the conclusions of the paper.

II. THE 3C COLLABORATION MODEL

To collaborate, individuals should exchange information (communication), organize themselves (coordination) and operate together on a shared space (cooperation). The exchanges that occur during communication generate commitments that are managed through coordination, which organizes and disposes of tasks that are executed in cooperation. When cooperating, individuals need to communicate in order to negotiate and decide about unexpected situations. Finally, through perception, the individual is informed about what is happening and obtains information necessary to his/her work. The diagram in Figure 1 summarizes the main concepts discussed. This diagram, proposed in [4], is a refinement of the 3C model originally presented in [1].

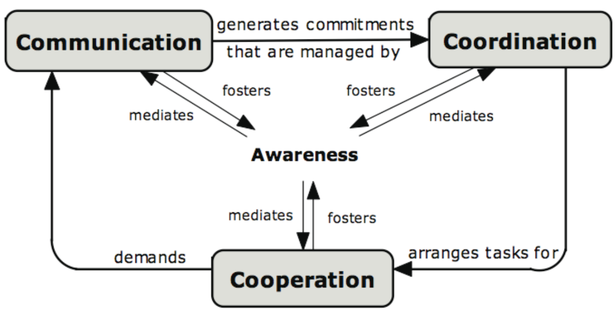

Figure 1. The 3C Collaboration Model

This section presented the theoretical concepts that were the basis for this research. The next section presents the proposed methodology for supporting collaborative evaluation in learning or working groups.

III. THE METHODOLOGY FOR COLLABORATIVE EVALUATION

The methodology for collaborative evaluation proposed as follows defines the necessary steps for the preparation, implementation and dissemination of evaluation results. It is important to emphasize that its use is not restricted only to the educational field. It can also be applied, for example, to evaluate scientific papers for publication at conferences or in the evaluation of corporate projects by coordinators, clients or stakeholders. The following are the steps of the methodology.

1. Definition of assessment sources

At this stage, should be defined according to the application scenario, what are going to be the sources of evaluation, i.e., which actors will effectively play the role of evaluators. These actors should be grouped according to their profile, for example, teachers and students, in the case of an assessment of scholar work in the classroom; or coordinators, peer developers and customers, in the case of an assessment of a corporative project to develop a system. At this stage, it should be determined if the self-evaluation is going to be included or not.

2. Defining the type of evaluation: Qualitative, Quantitative

In this step, we must determine whether the assessment will be qualitative (assessment through comments), Quantitative (assessment by assigning concepts or notes) or mixed.

3. Analyzing the domain for developing the evaluation criteria

The domain in which assessment will be applied needs to be analyzed to define the appropriate evaluation criteria. For example, should be considered if the assessment is in academic or corporate environment. When in an academic environment, for example, it should be considered the course level (undergraduate or graduate), the objective of the work to assess, if it is individual or in groups, and other factors. For each criterion must be chosen a type of evaluation among those defined in step 2.

4. Grouping the evaluation criteria in templates and associating evaluation sources

Defined the evaluation criteria, we must group them into templates that are associated with the assessment sources defined in step 1. A template is a set of criteria that can be represented by an evaluation form. Each source must have an evaluation template associated to assess a work, but the same template can be shared between more than one source of evaluation.

5. Defining the composition of the final grade

The next step is to define how the final grade is calculated: which criteria will be considered, and the weight of each one. We can also define weights for each of the sources of evaluation, according to the analysis of the field. This step is optional because in some cases a final grade is not the purpose of the evaluation.

6. Defining the mechanisms for conflict resolution

This step is focused on analyzing the assessments to check for possible conflicts, which means differences between assessments that may indicate that some of the two assessments was not done properly. The aim of this step is not necessarily reach a common assessment, but do evaluators consider the arguments of the conflicting evaluations to confirm that the reviews are really different or if there was any error in the judgment. This procedure aims that the final evaluations are most appropriate and consistent with reality. Thus, it should be set for each domain what characterizes a conflict, and how it will be resolved.

7. Defining the format of the final evaluation report

It must then be defined how the results of the evaluation will be presented to the assessed ones. It is recommended the use of a consolidated report showing the evaluation by criteria (you can choose to display all the evaluations received for each criterion, or just the average received on each criterion) and the final grade, if applicable. In this stage, the planning stage of the activity of collaborative evaluation is closed.

8. Presenting the work to be assessed

In this step, the implementation phase of the collaborative evaluation starts, according to the steps 1 through 7. According to the case, the work to be evaluated can be made both synchronously (e.g. oral presentation with PowerPoint slides) or asynchronously (e.g. work submission via e-mail to the evaluators).

9. Assessment

After presenting the work to be evaluated, the evaluators should use the appropriate template to perform the evaluations. This step can be done through a paper or electronic, form or with the support of a system.

10. Disseminating Results

Then, the evaluation results should be disseminated as appropriate for each area. The evaluation report defined in step 7 should be submitted to the evaluated ones, and depending on the case also for evaluators too (for example, in the academic environment, for teachers and in the case of the corporate environment for leaders or coordinators).

For the conception of this methodology, it was considered as the theoretical basis the 3C model presented in section 2 of this article. The model shows the importance of communication, cooperation and coordination for effective collaboration. Next, we show how each element was considered in developing the methodology proposed in this paper:

Communication: should occur in the presentation of the work to be evaluated (step 8). It is also very important in the step of conflict resolution of the evaluation (step 6).

Cooperation: it is present in the process of collaborative evaluation in itself, in which a group of evaluators using a shared model assess the same work. Evaluators cooperate participating in the evaluation process, in order to reach a common goal - the end result of the evaluation.

Coordination: the whole process of collaborative evaluation can only occur if there is coordination between all parties. You must dictate the rules of the process for the assessed to present the work to be evaluated and for the evaluators to assess it properly. All participants must have a clear understanding of its role in the process. It is desirable to have a central figure in coordinating the process for best results.

IV. Case Studies

To validate the application of the methodology proposed in this work in collaborative evaluation of academic work, 2 case studies were performed in graduate classes of the Pontifical Catholic University of Rio de Janeiro (PUC-Rio). For each case study, we used an instance of the framework IssueNet, described in detail in [2]. The main module of the system is a task manager that implements a workflow for creation, assignment and assessment of tasks. Thus, the system calculates the final grade of an activity from the tasks related to it, using specific criteria reported by the user. In the following subsections will present the case studies.

A. Case Study 1

The course "Project of Software Systems (PSS)" is offered by the Computer Science Department of PUC-Rio in the area of Software Engineering, and is attended by students in undergraduate and graduate levels. This case study was conducted during the final work, in which students should develop a framework and implement an instance on an issue of free choice. The theoretical concepts learned in the course must be correctly applied to the work. Weekly, each student must present to the class the progress of his/her work. The presentation is in Power Point format and should address the scope defined by the teacher in the course schedule. The other students have only to attend to the presentation whereas the teachers have to evaluate it. At the end of the semester when each student presents the complete work, the grades of the weekly presentations are taken into account in calculating the student's final grade.

The case study was to examine the application of the methodology proposed in this paper to conduct collaborative evaluation with participation of students, and was used in a class of 11 graduate students. In subsection C, will detail how the methodology has been applied to this case study in particular.

B. Case Study 2

To confirm the results obtained in the case presented in subsection A, the methodology proposed in this paper was also applied in a case study conducted with 43 students and two teachers in a different graduate course in PUC-Rio.

Among the activities of the course, students must present orally and in groups of up to 5 members, a work about design patterns. The works are presented to the teacher and the whole class. In previous classes, the evaluation of the work was done exclusively by the teacher using her own criteria. In this case study, this assessment was made collaboratively, and more than one teacher participated in the evaluation.

C. Applying the Methodology

The methodology proposed in section 3 was used for the elaboration of the assessment activity of the two case studies. The following are detailed how each step of the methodology was applied to each case study.

1. Definition of assessment sources

For both case studies was determined the use of 2 sources of evaluation: evaluation of the professors and students (peer review). Specifically in the case study 2, one work was evaluated both by members of the group (self-evaluation) and by the other students in the class.

2. Defining the type of evaluation: Qualitative, Quantitative

In both case studies were used both qualitative and quantitative evaluation. In case study 1, for each criterion should be assigned a grade from 1 to 5 (quantitative assessment) and a comment (qualitative assessment). In the case study 2, it was determined that the evaluation would be primarily quantitative. For each criterion of quantitative evaluation, should be assigned one of the following concepts: Poor, Weak, Fair, Good, Excellent. These concepts have been mapped in grades from 1 to 5 to facilitate the calculation of the final grade. To complement and enrich the evaluation, a field of general comments would be available with optional padding, representing the qualitative assessment.

3. Analyzing the domain for developing the evaluation criteria

In case study 1, the purpose of the work was to develop a complete framework, from modeling to programming. Each student presented his work in three phases of an hour each. In the first week (phase 1) should be presented the definition and application requirements. In the second week (phase 2), the goal was to present the computer modeling work. The third and last week (phase 3), the goal was to present the complete system, running. To this end, 5 criteria were developed for each phase such as Definition of the use case requirements (Stage 1) Formulation of Diagram of Classes and Sequence (Stage 2) and Integrated presentation of the various aspects of solving the problem (Phase 3).

In the case study 2, the purpose of the work was the creation, modeling and presentation of a social networking site using 3 design patterns seen in class, chosen by the group. The duration of the presentation should be a maximum of fifteen minutes. Five evaluation criteria have been developed: Adequacy of the presentation on the time available, Quality of slides and oral presentation, Creativity of the system and of the chosen patterns, Appropriateness of the patterns to the system and Correct application of the concepts.

It is important to say that in both case studies, it was established the criterion General Score, which represented the final evaluation of a work. This criterion will be further detailed in step 5.

4. Grouping the evaluation criteria in templates and associating evaluation sources

In case study 1, we decided to create a single template containing all the assessment criteria, and assign it to both students and teachers. In case study 2, were created 2 templates: one for teachers and one for students, the latter also used in self-evaluation. For the template of the students, we chose to use the criteria more focused on the presentation itself, and not in evaluating the theoretical knowledge presented. For the template of the teachers were used both criteria for evaluating the presentation and criteria for evaluating the application of theoretical concepts.

5. Defining the composition of the final grade

In both case studies, all the evaluators were asked to evaluate the criterion General Score with the grade that would effectively be taken into account in the calculation of the final evaluation of students. This value should not necessarily be the average of the grades awarded in other criteria (whose function is to enrich and detail evaluation), but the general score that the work should receive, in the opinion of the evaluator. The composition of the final grade of each job was also the same for the two case studies. It was calculated as 0.7 * average of teachers grades + 0.3 * average of students' grades. We decided to use this formula because of the limited experience of evaluation that, in general, the students have.

6. Defining the mechanisms for conflict resolution

In both case studies, it was decided that a conflict would be characterized by a difference of 3 or more points in the evaluation of certain criteria. For example, if on the criterion C1 the Assessor A1 has assigned “Weak” (or grade 2) and the Assessor A2 has assigned “Excellent” (or grade 5), it would be characterized as a conflict. In case study 1, it was decided that the conflict would be resolved through tasks designed for conflicting evaluators inside the IssueNet. In the case study 2, it was decided that the conflicting evaluators would be called by e-mail to clarify their evaluations.

7. Defining the format of the final evaluation report

In case study 1, the final evaluation report of a work could be consulted through the system IssueNet. This report showed in detail all the grades and comments received at each stage of evaluation, and the final grade of the work. In the case study 2, because it had simpler templates, we chose to send a spreadsheet showing all the concepts, comments and the final grade of the work.

8. Presenting the work to be assessed

In both case studies, the work was presented orally and was used PowerPoint to present it. In case study 1, the work is individual and only one student made a presentation, while in case study 2, each group decided if would be one or more presenters.

9. Assessment

In case study 1, the evaluators conducted the evaluations directly in the IssueNet system. In case study 2, due to limitations in the classroom in which there were presentations, the evaluators conducted assessments on paper forms and then the teacher recorded the evaluation forms on the IssueNet system.

10. Disseminating Results

In case study 1, the final evaluation report was published on the IssueNet environment for consultation by both evaluated and evaluators. In the case study 2, the evaluated students received by e-mail the same report generated by IssueNet.

V. ANALYSIS OF PARTICIPANTS

In case study 1, when asked about the collaborative process of assessment, most students approved the experience. Most students (85%) said that compared with traditional evaluation, in which only the teacher evaluates, the collaborative evaluation is good or excellent, and they also agreed that to evaluate their colleagues helps to hold attention in class and learn the theoretical concepts of the discipline. While 70% of the evaluators agreed that the peer evaluation helps improve their work, 15% expressed as neutral. When asked whether to evaluate their colleagues causes the evaluator feels playing a more important role, 57% agreed, 15% were neutral and 28% disagreed. Students also pointed out that the collaborative evaluation facilitates interaction between students and allows direction of efforts in light of the weaknesses of each.

In case study 2, the majority of students also approved the experience of collaborative evaluation: 81% enjoyed the experience. When asked to compare this practice with the traditional evaluation, 86% rated collaborative evaluation as good or excellent and 72% said that the evaluation of their colleagues helps to hold attention in class and learn the theoretical concepts of the discipline. When asked if to evaluate their colleagues causes the evaluator feels playing a larger role, 78% agreed, 6% were neutral and 16% disagreed. As in this case study only 45% of students enriched the assessment of colleagues with comments beyond the simple allocation of concepts, they were asked why, and most (75%) claimed that the evaluation criteria used were already sufficient for a proper evaluation.

VI. Methodology Assessment

After completion of two case studies, it was found that the collaborative assessment methodology was well accepted in both groups. Below some important points extracted from the evaluation of case studies are highlighted.

In case study 1, students said that by having to evaluate their colleagues they pay more attention to the presentations, what helps to identify improvements and best practices that can be applied to their own work. They also stressed that the collaborative evaluation facilitates interaction between students and allows the direction of efforts in the light of the weaknesses of each. Thus, the collaborative evaluation allowed students to add value to the work of colleagues, and in fact the progress of work using the contributions received during the ratings it was actually perceived. However, students stressed that they would like to have discussed the assessments more in order to share opinions, to understand better the rating received by colleagues, to establish better theoretical concepts of discipline and to enrich the learning of the group with the exchanged ideas. Thus, there are indications that a stage of discussion of the assessments should be included in the methodology to achieve greater use of collaborative evaluation.

In the case study 2, the collaborative evaluation was seen by students as a way to better understand the assessment process and thereby enable a self-assessment in order to improve their own work. They also stressed the advantages of being able to exercise the critical thinking of each one playing the role of assessors, increased interaction between students and an evaluation with different points of view and more complete than the traditionally received only from the teacher. In addition the students absorb better the concepts of discipline paying more attention to the presentations of the work. Although the students felt motivated by the responsibility to assess their colleagues in a fair, impartial and serious way, they were concerned in making sure that all colleagues would have this right feeling. Thus, strategies should be investigated to incorporate into the work a change in attitude on the part of evaluators, emphasizing their responsibility to contribute to the grade of a task.

VII. Conclusion

This paper presented a methodology for collaborative assessment based on the 3C Collaboration model that can be applied both in working or learning groups. Two case studies taken in graduate courses of the Informatics Department of PUC-Rio for collaborative evaluation of academic works suggests that the methodology is appropriate for this type of assessment. In addition, students participating in the experiment rated the experience as positive, confirming the premise that students value and miss the collaborative evaluation. In future work, we intend to evaluate the application of this methodology in different scenarios, for example, in evaluating corporate projects, and investigate solutions to fill the gaps identified by case studies.

Abstract— **The paper proposes a conceptual model for designing a people-finding system in a Learning Network. The system is intended to help a learner in getting recommendation about suitable people who are interested on a similar topic and share common learning goal with the current learner. We propose that by using the user-generated (text) content, social-bookmarking and social-tagging, driven by Web 2.0 approaches, we can implicitly profile people and find people's interests on a given topic. We also like to use their existing social connections as an evidence to select suitable people in recommending a learner.**

Keywords-recommendation systems; web 2.0; social matching; learning technology; social support system; people-finding systems; learning network; informal learning

I. Introduction

Paul is a student of education sciences, he needs to write a project paper on the topic of "education and technology". Suppose he wants to draft a report on the uses, benefits, roles and implications of the Information and Communication Technologies (ICT) in education. He can start his search on internet and find a plethora of websites, research papers, blog-posts, bookmarks and other electronic resources that could help him to achieve his learning goals. The search will give him enough information, hard enough to decide himself their relevance. On the other hand, he is also interested to connect to people having experiences, interests as well as expertise in the area of "Educational Sciences and Technologies", he can ask for their help, suggestions, build up social connection and share knowledge. In this paper we are interested to bring in attention of a specific class of people-finding systems which are meant to recommend people who are associated, have specific knowledge or interests in a given domain. The problem which motivates this research is inspired by the following comment:

"When I have a question or a problem, I want to be able to immediately figure out who is willing, qualified, and able to help me solve it. Since the problems and questions come in every shape and size, some sublime, some ridiculous, I want my Instant Knowledge System to help me distinguish and locate an appropriate trusted source – an expert"

Dennis D. McDonald, excerpt from "Bringing Knowledge, Relationships and Experts Together"

What is referred here as an Instant Knowledge System, generally means a type of system to find people having knowledge in a problem domain. The problem of identifying people "who know something relevant" to the needs of information seeker is very relevant in an online Learning Network. Formally, a Learning Network is defined as an online network to support the learning needs of lifelong learners in a particular knowledge domain [1]. A Learning Network supports heterogeneous people of different age groups, expertise-levels and interest, to fulfill their learning goals. Learning Networks are meant for self-directed learners [2] who make their own learning plans, according to their learning needs, irrespective of place, time and pace of learning [3]. In such a Learning Network, very likely a learner would remain hidden from others even though s/he matches with others in common interests or knowledge. In particular, while performing a learning activity s/he needs to know about other learners who may provide her/him with support, advice or help. Research has shown that, learners' success or failure on a learning activity also depends on how well they are connected to other learners [4, 3]. In a situation where a learner searches for people, s/he needs to manually browse through the profiles or websites of individuals to get to know about others. It is a time taking and tedious job to manually browse through peoples profiles, especially in a large network of people. This also leads to increase the extraneous cognitive load [5], the efforts required by learner to gather information relevant for learning from disparate sources. A people-finding system in Learning Network would help to automatically search and suggest learners whom they match. Thus, we initiated research for designing and developing to find suitable others for a learner: a people-finding system, we call it as Social Support System (SoSuSy) in Learning Networks. In this paper we want to report about the approach we want to take, methods we want to use and the current state of work to develop a first prototype of SoSuSy.

II. PEOPLE FINDING AND RELATED SYSTEMS

People finding systems are a class of recommendation system meant to find a person who has knowledge on a specific problem domain [6]. There have been many efforts till date to realize such systems in locating people or expert [7, 8, 9, 10,

This paper is (partly) sponsored by the TENCompetence Integrated Project that is funded by the European Commission's 6th Framework Programme, priority IST/Technology Enhanced Learning. Contract 027087 (www.tencompetence.org).

11, 12, 13]. These systems use different techniques and have addressed different scenarios like answering a specific question, expert location for sharing advice, visualizing the competence of organizational groups etc. Typically, these systems use information from different range of sources like centrally held database of personnel skills [14], to systems that use real-time information held within the corporate system [15]. There has been development of people-finding systems that use an organization's common set of resources, including e-mails, phone books and peer-reviewed technical report repositories to identify the required expert [16]. Most of the expertise finding systems are system-centered since they use specially created data-bases containing people's profiles, maintained by the organizations. The problem associated with these profiles is that they are not updated regularly and people do not have a control on the content. With the advent of Web 2.0 and Social Software, people can bring in their content to the web using services like Blogs, social bookmarks, and social-tags (tag clouds) and they are able to build social ties globally with ease using social software (facebook, linkedIn, myspace etc.). Recent studies on the existing expertise finding systems have identified the need to focus attention on the user-generated content [17] and their social connections [18] to find experts. These information sources are publicly available and can help making open profile of people, showing their knowledge, expertise and interests. To address the limitations of previous studies and the avenues from the emerging web. We describe the basic conceptual model of our proposed system in the next section and suggest that by using the user-generated content (blog-posts, social-bookmarking and social-tagging), we can find people's interests on a given topic. We also like to analyze their existing social connections as an evidence to select suitable people in recommending a learner. With such recommendation service our intention remains in connecting people in a Learning Network to increase social capital, thereby increasing the productivity of learners by supporting interaction with others.

III. BASIC CONCEPTUAL MODEL

A. *Main Idea*

We attempt to design, develop and test a software prototype called Social Support System (SoSuSy) for the lifelong learners in the Learning Networks, (for general overviews please refer to our previous published work [19]). A system to find suitable people when the questions like "Who should I ask?" arises in a learner's mind. This research is an extension to the research efforts of providing a generic social help in an online community, similar to the expert finding systems in an organization, multi-agents learning support or virtual help assistants as reported in previous section.

B. *Social Support System (SoSuSy)*

In the current work, we are not only interested in experts search but also in any learner who is knowledgeable enough to help another learner on a particular question. We assume as a pre-condition, that people maintain their web presence by write about their interests (blogging), sharing bookmarks (tagging) and having social contacts (social network). They maintain the information online and let it accessible publicly. The advantage of open information is that anyone can reflect his interests (by using tags to associate with a concept, or social book-marking) and knowledge (blogging about a certain topic). By taking this information into account, search can be made to show fellow learners who might be suitable for giving a help request. A SoSuSy in Learning Networks would be an added value for a learner to know about people and decide whom to and how to interact with them. It will provide several benefits to a learner:

- A learner could connect and make social ties with other learners either for question in hand or for future contact in similar context.
- It is possible that in connecting people to other people, one can share and exchange expertise about the information which is not documented like people's experiences (tacit knowledge) and interests. A learner could share with others different perspectives on a topic, comparing and constructing meaning, which would lead to effective learning for her/him.
- A learner would not only depend on experts but s/he can seek help from any suitable person available in the Learning Network, where people with different levels of expertise exist.

C. *Web 2.0 content as a source for finding people*

The current internet provides several tools and applications (Web 2.0 applications), that make it easier for people to bring in their content to the internet. People in a Learning Network may already have online public information about their interests, skills, competence or knowledge, such information can be written as a free-text description on their web page, they might also write blog-posts which are then tagged to particular concepts and can be viewed as tag-clouds that indicate their interests. For example, people can write about their experience on "Scuba diving" and tag it with "diving" "underwater" etc, they can bookmark all the resources related to "diving". Such sources of information like bookmarks of interest, writings in the form of blog-posts, shows interests in the particular knowledge domain.

The user-generated content can be created in different forms like texts, videos, audios, pictures, documents. These are dynamic content (regularly updated) and provide latest information about people, like their working context, interests, knowledge, expertise and ideas. This information about people is relevant to suggest who is associated with which topic. The Social Support System will use the user-generated content which is a bottom-up information source about people, facilitated by Web 2.0 applications like web-logs (Blogs), wikis and social book-marking tags etc. There are several reasons to consider the user-generated content. First, as the use Web 2.0 applications are getting popular, it has become easier for people to maintain online information. People can write what they think about particular issues using Blog services (wordpress, blogger etc.) and categorize (by tagging) the Blog posts using keywords, bookmark their interests using social bookmarking services (furl, delicious etc.) and manage their social contacts (friends or colleagues) using social networking sites (facebook, linkedIn etc.). These sources of information are useful to make an open profile about people based on their interests, knowledge and competence on a particular topic. This information is valuable in addition to the evidence of people's competence formally stored in ePortfolios or in organizational records. Second, people need not be enforced by organization to follow strict structure to organize their personal profile, cases where information about people is maintained as log data in organizational repositories. Third, profiles maintained within organizational repositories do not always reflect people's knowledge and current interests, they become obsolete with time. Fourth, even when a new learner enters a Learning Network, s/he may already have existing information (blogs, bookmarks and social contacts). So we do not only depend on learner's information maintained during learning (e.g. completion of learning activities in a Learning Network) but we can make use of personally generated information (blogs, bookmarks and social contacts) about learners that reflect their learning achievements, knowledge, competence and interests performed before even joining a Learning Network. The challenge is how we can use the information from Blogs and tags to prototype a system for recommending suitable people to a learner in a Learning Network. We detail the process involved in identifying people to recommend to a learner. The process consists of three inter-related sub-process as follows:

For a given question of a learner to find people on a given topic:

1. We need to find the sources of information, which are relevant to the question. We call them key-concepts, represented by a set C.

2. We need to find people who use tags to associate with these key-concepts. This can be known by analyzing contents, namely; (a) People create their own content, e.g., by blogging. (b) People show interests in others content, e.g., by bookmarking.

3. We need to rank each person based on their association with key-concepts and social connection. We could then modify the results based on the social distance between the learners.

Each of the aforementioned points can be further elaborated. First, key-concepts may be represented informally as tags, blogs tagged with keywords, and bookmarks tagged with keywords. Second, there are people who are associated with these key-concepts, because they frequently use tags or keywords. The association means that they may have interests, knowledge, or skills about such a key-concept. People can either create their own content by writing about it (blogging, publishing etc.), or show interests in others content by book-marking with social tagging (e.g, del.icio.us). Third, social connection between people could provide information about people's network. Social connection could be based on friendship, co-working, partnership etc. Therefore, people who are socially connected and also working on a common topic may be recommended to a learner who are new to a topic. This description is illustrated in figure 1.

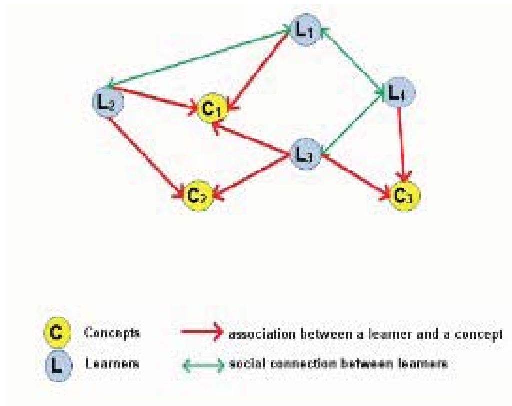

Figure 1. Associations between learners and concepts

In Fig. 1, learner L_1 is associated with the concept C_1 and has social ties with learners L_2 and L_4.

The bold (uni-directional) arrow indicates learners association with a given concept. They mean that the learners themselves make association (e.g. by using tags) with this particular concept. The bi-directional arrows indicate the social connections between the learners. A bi-directional arrow indicates that both learners are involved in getting in contact with each other by having common interests on a given topic (concept). Combining the three, namely; (a) key-concepts, (b) people's associated with key-concepts, and (c) social connections between them as depicted in Fig. 1, we could derive a model in terms of a simple equation to recommend a suitable person in a Learning Network. The rank of each person could be then based on their association with a key-concept and their social ties with fellows on similar key-concepts. We can also assign weights to the association to determine to what extent people are interested in a given concept. This will also reflect their expertise on that particular concept. The following equation shows the dimension to consider for implementing Social Support System.

*Rank of person = key-concepts * people associated with key-concepts * peoples' social connection*

D. Method used for requirements analysis

As the current state of work, we are doing requirements analysis using the process of Concept Mapping [20]. Concept mapping is a process to describe ideas of an expert group of people on a given topic. Concept mapping process consists of: generation of statements by the experts (brainstorming); rating and sorting of statements; and interpretation of the concept map (data analysis). While all three stages may be done in face-to-face sessions, in this study the first two stages were done by mail due to participants' busy schedules and different locations. All concept mapping analyses were accomplished using The Concept System© (Version 4.0.147, Concept Systems Incorporated, Ithaca, NY). The results are represented as concept in a visual form that represents the focus of experts (see Fig. 2). We considered it a useful method for requirements analysis for developing a conceptual framework of Social Support System. By using the Concept Mapping process we intend to get group opinion of experts on the distinct features of SoSuSy.

On the basis of research problem we selected a total of 11 different participants from 7 different countries across different continents. Each participant came from a variety of educational backgrounds, namely: computer sciences, business management, human resources, education sciences and journalism. The idea was to gather varied expert opinion on the topic of Social Support System, from a diverse group of people. An email invite was sent to each of the participants with the brief description of the requirements of social support systems in Learning Network. They were asked to think-aloud about the need for such a system in Learning Network that searches for people. They were given a trigger statement: "*What defines a good Social Support System in Learning Network*". The trigger statement helped them to generate statements about the features or characteristics, that they thought are necessary to develop such a system in Learning Network. After each participant has completed the task of sorting, the results of all the participants are combined. First, a similarity matrix was constructed that represented the relative similarity of participants' sorting statements, i.e the results of the sort for each person are put into a square matrix which has as many rows and columns as there are statements. The values of this matrix is either '1' or '0'. The value '1' indicates that the statements for that row and column were placed by that person together in a pile while a '0' indicates that they were not. Second, the individual sort matrices were added together to obtain a combined group similarity matrix which is considered as the relational structure of the conceptual domain because it provides information about how the participants grouped the statements. A high value in group matrix indicates that many of the participants put that pair of statements together and implies that the statements are conceptually similar in some way. This group similarity matrix was analyzed using non-metric multidimensional scaling analysis with a two-dimensional solution, which generated x and y coordinates in a two-dimensional space for each statement based on its mathematical similarity to other statements. Third, statements were combined into clusters using a hierarchical cluster analysis. The results of the hierarchical cluster analysis were superimposed on the multidimensional scaling results to create a map displaying the points graphically within each group, with polygonal boundaries surrounding the points in each cluster group. A hierarchical cluster analysis yields all possible cluster solutions, from each statement in its own cluster to all statements in one cluster.

E. Results

In Fig. 2, there are 10 different clusters shown, which depicts how they were grouped together by hierarchical cluster analysis [20]. The main point of interpretation of the cluster map is that all participants come to figure out well the interrelationships among the clustered statements. It is aimed that everyone in the group has a clear picture of the project through the concept map. The clusters shown are depicting the expert opinion on various features that a Social Support System should have with varied degree of importance (shown as multiple layers on each cluster).

We briefly list and explain the meaning of each of the 10 clusters as depicted in Fig. 2.

1. Technical features: Focusing the state-of-art technologies for development like web 2.0 applications and Social apps.

2. Showing search similarity: The feature focuses on the search options where people would like to know the search results similar to what they are looking for.

3. Visibility: The feature focuses on the how social help system provides visibility of learners in the Learning Network.

4. Business application: The social help system as a tool for collaboration for further interests and commercial interests among people.

5. Communication among learners: The tool supports effective sharing of knowledge among learners facilitating communication via email, instant messengers or phones.

6. Learning community and connection among varied people: The tool supports forming learning communities and enhancing communication among the participants.

7. Facilitating learning and engagement: The tool provides support for bringing people to engage on a learning task and enhance learning by social engagement.

8. Interface design: Easy to use features and user-interface to search for suitable people in a network of learners.

9. Effects on society: The overall effects on society as a useful feature for supporting learning by socialization.

10. Output and Solution execution: The feature focusing on additional support like finding not only people but also relevant learning resources, supporting external collaboration, other embedded support.

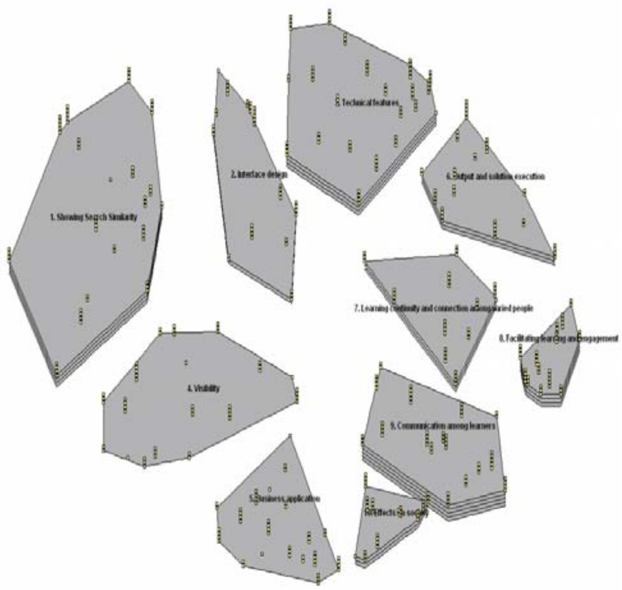

Figure 2. Cluster Map eliciting the focus on different required features of a social help system

IV. Discussion

Web 2.0 and Social Web provide the possibilities of exploiting the web to develop services for people recommendation in a Learning Network. The Social Support System plays the role of ‘knowledge broker’ to effectively moderate knowledge sharing between the members of a Learning Network. Social-support in the Learning Networks would give many benefits to a learner. First, the problem of isolation of learner in online Learning Network could be addressed by bringing a learner in contact with other learners. Second, a learner would not only depend on experts but s/he can seek help from any suitable person available in the heterogeneous Learning Networks. Third, it is possible that connecting people to other people, one can share and exchange expertise about the information which is not explicitly documented rather held by individuals, like peoples’ experiences, interests and also tacit knowledge. To the best of our knowledge we claim that the use of expert Concept Mapping method is a novel approach in needs analysis of Social Support System. We will report on further results in consecutive papers.

Abstract—**This paper describes an experience that has been carried out by several professors in different subjects. Our experience is framed within the First Plan in Teaching of the University of Seville. All involved subjects belong to the electronic technology area and from three Computer Science degrees. We propose to use, in a combined way, some learning techniques: cooperative learning as complement to traditional learning, role-playing technique and jigsaw technique. We have considered a base methodology but in each subject a variant of it has been accomplished. We have used several evaluation techniques, such as reciprocal evaluation, electronic portfolio and check lists. Applying our methodology helps us to detect learning problems before the term ends. Also, in tune with the framework of the European Higher Education Area (EHEA), our methology gives a boost to develop transversal competences as important as work (or study) management, empathy and understanding of other members in a workgroup, conflict resolution, capacity to make decisions as well as coordinate and communicate with other members in a workgroup and also with the professor.**

Keywords-component; Innovative education, evaluation techniques, cooperative learning, role-playing, reciprocal evaluation, electronic portfolio.

I. INTRODUCTION. BACKGROUND

The experience described in this article is part of a project granted by the University of Seville's First Self-funded Teaching Scheme. This project focuses on aspects related to the implementation of the role-playing technique combined with cooperative work. The tasks carried out under this project seek improvement in the learning process of students.

The project has been implemented in all three Computer degrees at the University of Seville:

- Engineering in Computer Science (ECS, 5 years)
- Technical Engineering in Computer Systems (TECS, 3 years)
- Technical Engineering in Computer Management (TECM, 3 years)

The experience described in this article is a summary of what was implemented during the academic year 2008 / 2009 in classroom groups listed in TABLE I. The First-year courses are all compulsory, while the third and fifth-year subjects of study are optional.

TABLE I. SUBJECTS OF STUDY INVOLVED IN THE PROJECT

Subjects of study	Degree	Year	Class-room group	Nº of students	Teacher
Computer Structure and Technology II	TECM	*1º*	2	*87*	*M.C. Romero*
Computer Structure	TECS	*1º*	1, 2 and 3	*240*	*I.M. Gómez & M.P. Parra*
Computer Structure	ECS	*1º*	1 and 2	*150*	*C. Baena & M. Valencia*
Peripheral and Interfaces	TECS	*3º*	All	*120*	*F. Sivianes*
Advanced Digital Systems	ECS	*5º*	All	*20*	*M. Valencia*

The content of this paper is arranged as follows. In the next section we outline the motivations of our work. In section III we identify our main goals and, in section IV, the methodology followed for the execution of the work, which presents variations in the different subjects of study. In Section V, we discuss briefly some of the results obtained and, in section VI, we finish by stating the main conclusions.

II. MOTIVATIONS

Traditionally, expositive lectures have been the most common in university classrooms promoting, in most cases, individual student learning. With the implementation of the EHEA [4], the Technical College of Engineering and Computer Science at University of Seville joined in 2003 a pilot adaptation project, which, over time, has incorporated most of the subjects taught at the Technical College. Our department has actively participated in this pilot experience from the beginning and during subsequent courses, incorporating into their courses different ongoing evaluation mechanisms in line with the new European framework ([7], [8], [9] and [10]).

In our effort to improve student learning, during the last academic year (2007/2008) we started an isolated experience in group work and in the current academic year (2008/2009) we have implemented the project entitled "Implementation of the role-playing learning technique in groups from different computer science degrees and courses". Furthermore, in some of the groups, the role-playing technique was combined with cooperative learning activities.

In the role-playing technique or role exchange [7] students adopt a role and are encouraged to think, act and make decisions as their characters would. This technique promotes creativity, teamwork, reading and oral and written communication. This is a very versatile technique that can be applied in virtually all areas of knowledge and enables the simulation of real-life situations.

Moreover, as J. B. Cuseo noted in [3], cooperative work provides some advantages compared with traditional learning, such as:

- Promoting the active involvement of students during the learning process,
- Giving importance to the interaction of group members as a tool to increase the level of learning (group and individual),
- Reducing dropout rates in classrooms,
- Promoting critical thinking,
- Increasing student satisfaction in what they learn and how they learn it and promoting more positive attitudes towards the subject of study,
- Achieving better academic performance in science and technical areas, and
- Preparing students for the workplace.

In our project we propose to combine both techniques taking the best of each approach.

III. OBJETIVES

Our work focuses on improving the learning process of students studying subjects related to Electronic Technology within Computer Science, although what is described in this article could be applicable to any other matter. In this paper we propose its application to five subjects of study including:

- Computer Structure and Technology II (TECM), Computer Structure (TECS) and Computer Structure (ECS): all three are compulsory subjects for first year students and have very similar content. They are courses on computer design and applications –of Digital Systems in general– at RT (Register Transfer) level, and by creating a bridge between hardware and software, they develop programs at the machine-instruction level (assembly).
- Peripherals and Interfaces (TECS) is a third-year elective subject that aims to provide students with knowledge about specifications and technical literature on peripherals provided by manufacturers of equipment and programs; to solve problems with peripherals and interfaces found in an information system, application or network and to design and implement a control software or driver to control peripherals.
- Advanced Digital Systems (ECS) is a fifth-grade subject also optional that deals with the realization of digital systems with high speed and power consumption performance using advanced integration technologies and high-density programmable circuits (FPGA: Field Programmable Gate Arrays).

As mentioned before, in order to achieve this improvement in the learning process two different techniques have been jointly applied: role-playing and cooperative learning. They have not been applied exactly in the same way in all groups, as we will explain below.

On the one hand, by applying the role-playing technique we attempt to promote empathy and understanding for others, since all students perform all defined roles and are able to put themselves in their peers' shoes. Putting it into practice continuously during the academic year, students will be able to recognize, in themselves and in their peers, their capabilities, attitudes, values, and in some cases, to characterize their conduct and that of their classmates. In addition, it encourages students to accept others, resolving conflicts and developing responsible decision-making skills.

Furthermore, when combined with collaborative work, the development of abilities related to the five ingredients of cooperative learning is encourage [6]: positive interdependence, individual accountability, face to-face interaction among the peer group, interpersonal and group skills (such as coordination and communication) and group reflection.

All these abilities can be considered within the transversal skills put forth by the EHEA and its practice enables students to enter the workforce with some background in these skills.

As we will see below, in some classroom groups the ultimate goal has been for each cooperative group to develop, by the end of the teaching period, an electronic portfolio that showcases the work developed by that group during the entire course and, moreover, it has proved a useful tool for evaluating the work of the group.

IV. Methodology

First of all, it must be noted that the activities developed for this project were proposed to students as elective tasks as part of continuous assessment. Then, at the beginning of the term, students will decide whether or not they want to perform them. At this point an immediate question arises: what do students who choose not to perform these tasks do when group sharing takes place in the classroom? In our case, that time may be used to study the subject or resolve any question that the teacher can propose.

If the student chooses to perform these activities, we ask them to make certain commitments, such as continuing with the activities throughout the semester, otherwise he or she would leave the group stranded, and attending classroom lessons, at least on the days scheduled for group sharing (they are provided with a calendar).

To carry out this project each teacher divided the subject to teach in as many sections as the different tasks programmed in the course. Obviously, the division of the subject depends on the subject syllabus and how the teacher wants to schedule each activity during the semester. In our case, although the basis of the methodology was common, each teacher applied it slightly differently in each subject, which shows that, albeit general, this methodology can be tailored in multiple cases. A detailed explanation on what has been applied in each course will be provided in the next sections.

A. Methodology basis

Students are assigned to three- or four-member base groups[1], ensuring that the number of students matches the number of roles defined. The number of roles should match the number of sections in which the teacher has decided to divide the subject syllabus for the continuous assessment. Thus, each student performs all the roles on a rotating basis and the total number of activities carried out by the group also matches that number.

Several strategies are possible for the selection of base groups. For example, in one of the strategies applied in our case students can choose a partner and the teacher is the one who arranges the entire group in pairs. In this way, the formation of groups of friends is avoided and it promotes students to strive to work with peers whom they do not know, which is a situation similar to the one they will most likely face as they enter the workplace.

Each group should do as many activities as the number of sections in which the teacher has divided the subject syllabus and each student has a different role in each task.

The activity statement of each cooperative task performed by the groups is made public through the e-learning platform (WebCT in our case) or in the classroom. It includes all the roles and their descriptions. Each group member may decide the initial role assignment.

[1] Base groups last for the entire course.

In some courses, each group should develop an electronic portfolio which will include the work of each section, both the individual work of each group member and that of the group. Portfolios are handed in upon completion of each section of a task, so that teachers can analyze learning trends and detect any anomalies, which is what teachers usually call “concept failures”. Error explanations are provided to the group, not to individual students, so if it is a common error, not only will the student who made the mistake learn, but also the rest of his or her teammates.

In the prototype project each task is also divided into four parts:

- Part I: Work Planning. Each group should come to an agreement and establish a task calendar. When the activity is finished, each group should hand in a document showing the originally planned programming and the real one, with a brief analysis explaining the difference between them, either in a paper document or uploading the document to the electronic portfolio.
- Part II: Assimilation of fundamental concepts. For this part the following must be programmed:
  - Individual reading of the relevant subject outside the classroom and each group member will independently develop:
    - Student 1: a concept map relating the key concept of the relevant subject to all areas studied in this subject.
    - Student 2: ten three-choice, multiple-choice questions (a, b and c) on the appropriate topic.
    - Student 3: a glossary of the fifteen key terms of the relevant subject.
    - Student 4: A two-page (maximum) summary of the most important aspects of the topic.
  - Experts meeting to discuss the documentation produced using the puzzle technique (or jigsaw) [5].
  - Base group meeting so each student can explain his/her assignment to their classmates.
  - Homework: corrections, amendments and assignments should be included in the portfolio or paper document.
  - Submission of portfolio or paper document to the teacher.

  The idea is that students learn to solve any problems and questions proposed by the teacher on the subject to study, using the puzzle method, and that any group member understands how the concept map is constructed, is capable of solving the multiple choice questions, defines any glossary term and considers whether the summary of the subject prepared by their colleague is adequate or not.
- Part III: Practical applications of concepts. Learning to select the most important aspects of the subject, to write a statement correctly and to solve it in the most appropriate way.

TABLE II. *ROLE ASSIGNMENT*

Student	Role	Developed Skills
Student 1	PROPOSER Teacher that proposes a test statement on the relevant matter.	The ability to analyze what information is the most important of the subject taught; the ability to effectively search for information to prepare the statement; implementation of the knowledge acquired in Part II, since the statement should be feasible for the Student; self-assessment capability; and motivation to propose innovative and challenging statements.
Student 2	REVISER and EDITOR Teacher that: • reviews the proposed statement • corrects the exams • reviews exams with students once they are corrected	Critical ability, and putting into practice the knowledge acquired in Part II. The ability to assess the work done by someone else and to take responsibility for that assessment. The ability to set objective correctness criteria. Developing communication skills when justifying grades to students during the review period with the marking criteria set in advance.
Student 3 (*)	STUDENT Student tested on solving this statement in the time specified by the proposer.	The ability to cope with a problem on your own in a bounded time and the motivation to reinforce the knowledge acquired in class and the work of Part II.
Student 4 (*) (**)	STUDENT Student tested on solving this statement in the time specified by the proposer.	The ability to cope with a problem on your own in a bounded time and the motivation to reinforce the knowledge acquired in class and the work of Part II.

(*) Students 3 and 4 should resolve the problem individually.
(**) When four-member groups are not feasible, the Student 4 role disappears.

Table II shows the initial role assignment, taking turns with each activity, and the various skills that are developed for each one.

After this phase, each student must prepare the documentation for the group work associated with their role. The documentation of the entire group is included in the portfolio or in a paper document and delivered to the teacher for review.

- Part IV - Mini-conference: Learning to apply the skill of synthesis, to perform oral presentations and prepare visual documentation in the shape of a poster.

The group should prepare a poster on the practical application of Part III and give a five-minute oral presentation using the poster. The teacher in-situ will choose who will perform the presentation, thereby evaluating the whole group. When using the electronic portfolio for assessment, the poster will be included in the same electronic format.

B. Variations in the different subjects

The information related to the implementation of the project to each of the subjects involved is shown in TABLE III and TABLE IV.

TABLE III. *SUMMARY OF THE METHODOLOGY APPLIED IN ALL THE SUBJECTS INVOLVED IN THE PROJECT (I)*

Subject to study	**Total no. of tasks during the course (***)**	**Topics addressed**	**Pedagogical techniques applied**	**Evaluation**
CST2(TECM) – Group 2	4	– Analysis and Design of Digital Systems – Design of a simple computer – Semiconductor memory – Case study: the MC68000 microprocessor	– Role-playing – Cooperative Work – Puzzle Technique (jigsaw) Parts of the base project: All	Two individual partial tests, with two parts each, corresponding to the division of the syllabus, scored from 0 to 10. In addition, students can earn up to 1 extra point for the cooperative work by applying: - the self/peer evaluation using rubrics, - the concept map evaluation - the evaluation the poster oral presentation, - The portfolio evaluation. This additional point is added to the average score of the partial-test.
CS (TECS) – Group 1	3	– Analysis and Design – of Digital Systems – Design of a simple computer – Case study: the MC68000 microprocessor	Role-playing Parts of the base project: - Part III	1 extra-point maximum will be added to the final score of the partial test.
CS (TECS) – Group 2	3	– Analysis and Design of Digital Systems – Design of a simple computer – Case study: the MC68000 microprocessor	Role-playing Parts of the base project: - Part III	A total of one extra point will be added to the final score of the partial test.
CS (TECS) – Group 3	4	– Analysis and Design of Digital Systems – Design of a simple computer – Case study: the MC68000 microprocessor	Role-playing Parts of the base project: - Part III	A total of one extra point will be added to the score obtained in continuous assessment, which consists of two tests: **Test 1:** the SD-DC assignments score will be added. **Test 2:** the 68000 assignments score will be added.
CS (II) – Group 1	1	– Design of a simple computer	Role-playing Parts of the base project: – Part I – Part II – Part III	A total of two extra points will be added to the (CS) test score. This test will carry 33% weightage on the final score, so this assignment is worth 0.67 points.
CS (II) – Group 2	1	– Design of a simple computer	Role-playing Parts of the base project: – Part I – Part II – Part III	A total of two extra points will be added to the (CS) test score. This test will carry 33% weightage on the final score, so this assignment is worth 0.67 points.

TABLE IV. *SUMMARY OF THE METHODOLOGY APPLIED IN ALL THE SUBJECTS INVOLVED IN THE PROJECT (II)*

Subject to study	Total no. of tasks during the course (***)	Topics addressed	Pedagogical techniques applied	Evaluation
PI	3	– Characterization of peripherals and interfaces – Starting the development environment. – Driver implementation for peripheral control through its interface	Role-playing	Two individual partial tests, with two parts each, corresponding to the division of the syllabus, scored from 0 to 10. The work group students who, after the individualized assessment of the assignments, pass the tests, need not sit the partial tests to pass the course.
			Parts of the base project: – Part I – Part II – Part III – Personalized assessment on the work done	
ADS	3	– Temporal characterization – Arithmetic circuits – Synchronization	– Role-playing – Debates	It will account for 25% of the final mark of the continuous assessment. 25% for theoretical tests, and 50% lab project assignment.
			Parts of the base project: – Part I – Part II – Part III	

TABLE V. *QUANTITATIVE RESULTS FOR THE INVOLVED SUBJECTS*

(1) Number of students enrolled
(2) Number of students per workgroup
(3) Number of students who did assignments
(4) Number of students who took a test and did their assignments
(5) Number of students who took a test and did NOT do their assignments
(6) Number of students who passed and did their assignments
(7) Number of students who passed and did NOT do their assignments
(8) Number of students who failed and did their assignments
(9) Number of students who failed and did NOT do their assignments

V. RESULTS

By analyzing the number of students who took a test and did their assignments (column 4 at TABLE V) and the number of students who passed and did their assignments (column 6 at TABLE V), we can get that, on average, 80% of students who use this methodology pass the subject in continuous assessment or in term-end examinations.

On the contrary, if we analyze the number of students who took a test and did NOT do their assignments (column 5 at TABLE V) and the number of students who passed and did NOT do their assignments (column 7 at TABLE V) we observe that, on average, among the students who took the test but did not use this methodology, 54% failed.

We see that there is a significant deviation in the number of students who use this methodology in the different subjects and groups. We believe that this difference may be due to several reasons:

- In some subjects the methodology has not been implemented from the beginning of the semester, therefore there is no continuity in the implementation of these methods and their execution is late, when the student has already lost motivation in the subject.
- In some subjects a partial application of the methodology has been carried out (only Role-playing - Part III - is applied, but not the rest) and, curiously enough, the "passed" percentages obtained are lower (67%, 40 % and 67% for TECS groups 1, 2 and 3, respectively, and 86%, 100%, 93%, 93%, 100% for CST group 2, CS groups 1 and 2, the IP group and ADS group, respectively).

We must also take into account some peculiarities:

- In CS (II), each base group faced all three roles simultaneously: each group with respect to their peers had to assume the role of the teacher, reviser-editor and student.
- In CS (II), participation was planned for the third lesson of the term, which is evaluated in Test 2 of the three the subject has. At this stage of the term, dropping the course reached the usual high percentage in the last four academic years.
- In CS (II) group 1, the apparent "complete success" in terms of participants is due, at least in part, to the fact that the percentage of volunteers was low and the participants were the best students (those who excel in any system).
- In ADS the 3 participating students represented the total number of students in the course. The other 9 enrolled students never attended class or submitted any assignment.

VI. Conclusions

From an educational point of view, the implementation of this educational initiative has entailed:

- The study and experimentation with methodologies whose application is not usual in the courses taught.
- The carrying out of a methodological change aimed at learning and assessing the transversal skills that complement the assimilation of course content. The methodology allows to further assess subject-specific skills.
- Promoting the use of active learning methodologies.
- The analysis and promotion of different ways of group work.
- The design of practical teaching activities.
- The design and implementation of new assessment systems.

Having implemented this methodology, we can state that:

- It is undeniable that in carrying out this experience time and effort was spent to organize the activities, coordinate the work groups and review the students' ongoing assignments, which is added to the regular teaching activity. However, the following positive aspects can be noted:
  - Easy and quick detection of weaknesses in the (individual or collective) learning of subjects so that special attention can be paid to them in classroom lessons.
  - Students become more involved in the subject, know and treat their classmates with more familiarity, and classes are more interactive, which will have positive implications in the learning experience.
  - In general, by using these techniques, students' grades are higher than they usually are, provided they are applied throughout the course and in a continuous fashion. For example, for CST(2) group 2 the percentage of students who passed the course in the first-term exam for the academic year 2007/2008 was 33%, while that of the academic year 2008/2009 was 70%.
- The main difficulties encountered were:
  - The high number of students. The courses involved in the project have an average of 77 officially enrolled students per class. Although the dropout rate is high, even from the beginning of the course, an average of 55 students often remain in class. So, in some cases, as we have seen, it involves a large number of working groups per teacher. With such a number of students / groups, we find that:
    - Group management is complex, especially during the first three weeks of the course. It is understood that it is just a matter of experience in the application of these techniques.
    - The application of the puzzle technique in the classroom is difficult for two reasons: first, the teacher cannot cope with the monitoring of the progress of the expert meetings and, secondly, the activity is very noisy. The first problem could be solved through the collaboration of student interns to assist in managing the work of groups during the group sharing sessions, and the second disadvantage begins to disappear as students become accustomed to this way of working.
    - Narrowing which parts of the syllabus can be set aside for cooperative activities and which parts are not is a complex task. The content of these courses is dense and it is not trivial to discern what is accessory.
- Explaining the new method. The teacher must devote classroom time to explain how the new method works and what the procedure to be followed by students is. That time is subtracted from the teaching of the subject,

but we think it is not wasted time because the student's achieved understanding of the material is deeper.

- First-year students are more confused by the many changes, so we consider it more appropriate to apply these techniques in second term subjects.

Finally, note that some of the factors used for assessment (and rating) of each student in each base group were:

- Rule compliance: deadlines, submission of reports and maintaining base group meetings.
- The information provided by students: time spent, resources used, interaction with other group members, group self-assessment and co-assessment among members of the same base group (through the use of headings, for example).
- The teacher's grade on the assignments produced and students' tasks directly supervised by the teacher.

ACKNOWLEDGMENT

We would like to thank the University of Seville for providing the financial means to launch this project, within the Teaching Methodologies Renewal Plan of the University's First Self-funded Teaching Scheme, and the Technical College of Engineering and Computer Science for their support in its diffusion.

***Abstract* — A lot of training time is devoted to help teachers arrange appropriate interactions between students and materials, and to how teachers should interact with students. However, how students should interact with each other is relatively ignored. It is a good idea that students learn within a supportive community in order to feel safe enough to take risks. Cooperative Learning (CL) is a successful teaching strategy in which small teams, composed by students with different skills, use a variety of learning activities to improve their understanding of a subject [1]. Each member of a team is responsible not only for learning what is taught but also for helping his or her teammates learn, thus creating an atmosphere of achievement. In this paper an experience in CL with a group of students with different skills and ages developing the harness subsystem of the first lunar spacecraft built and operated by students across European Space Agency (ESA) Member States and ESA Cooperating States is described.**

Keywords- Cooperative Learning, aeorospace project, European Space Agency.

I. INTRODUCTION

The European Student Moon Orbiter (ESMO) is planned to be the first European student mission to fly to the Moon [2]. ESMO represents a unique and inspirational opportunity for university students. ESMO provides students with valuable and challenging hands-on space project experience in order to fully prepare a well qualified workforce for future ESA missions, particularly those planned by the Exploration and Science programmes in the next decades.

In addition, ESMO has a powerful education outreach aspect and a strong attraction for younger students studying in universities across Europe. It also represents an opportunity to contribute to the scientific knowledge and future exploration of the Moon by returning new data and testing new technologies.

More than 300 students from 29 Universities in 12 countries are participating in the project, which has successfully completed its *"Phase A: Feasibility Study"* and it is proceeding into preliminary design activities *(Phase B)*. The ESMO spacecraft is designed to be launched into Geostationary Transfer Orbit (GTO) as a secondary payload in the 2013/2014 timeframe. The student teams are expected to provide most of the spacecraft subsystems, payload and ground support systems in coordination with their universities and through sponsorship by the European space industry.

The Power Supply Systems group, which is part of the Electronic Technology Division of the University of Oviedo (Spain), submitted a letter of interest to the ESA for participating in the selection process to find a university team to develop the harness subsystem. The proposal of this group was selected, after being evaluated for experts, and now the Power Supply Systems group is the responsible team of the harness subsystem of the satellite.

The Power Supply Systems group is formed by eight researchers, four of whom are PhD Electrical Engineers and professors, and the rest are PhD students. To develop the harness subsystem of the spacecraft, the group considered to form a team with engineering students and to implement some CL strategies. This kind of learning is still uncommon in technical areas of knowledge, but it is considered a key element for improving the capabilities of students [3]-[7]. Some university students with different skills were interested in ESMO and the team was composed in February 2008.

II. METHOD

A. ESMO groups and tools for cooperative working

The ESMO project is divided by the ESA in more than twenty subsystems, which include the whole spacecraft, and other necessary tasks as the ground segment or the mission analysis. Each subsystem is developed by a group of students who belong to a European University. These groups must interact with each other so that they know about the evolution of the project. To facilitate this interaction, the ESA encourages the use of some interactive tools. The most interesting ones are:

- A Google group, in which all subsystems are signed up, to discuss and comment about critical questions. Thanks to this tool all the members of the ESMO can know each other.

- A weekly chat, in which some questions are solved talking with experts and another problems are discovered thanks to the interaction between subsystems. It is a direct way to solve problems quickly in a real time conversation with the members of the rest of subsystems.

- A biweekly work report to evaluate the progress of each subsystem. It is a good way to teach students how to write and read technical documents.

- A FTP site for each subsystem to share some of their work with the other subsystems. This is a very useful tool to be updated of all the progress of the different subsystems.

- On-line interactive programs to develop some of the work using dedicated software provided by the ESA. Students have to adapt themselves to use dedicated programs for each activity.

- Four workshops per year at European Space Research and Technology Centre (ESTEC), where one representative from each team is invited. This is the moment when all the students can talk together. They have to present their works in public, ask other members some questions, speak with experts of the ESA, etc. Usually in these workshops there are also some activities to have fun all together.

Thanks to all this tools the members of each subsystem have a global view of the evolution of the project. The interaction between students from different countries, cultures, universities, and degrees also help them to develop communication and social skills.

B. Structure of the Harness team.

The actual structure of the Harness team, defined by the Power Supply Systems group, can be seen in Figure 1 and it is described as follows.

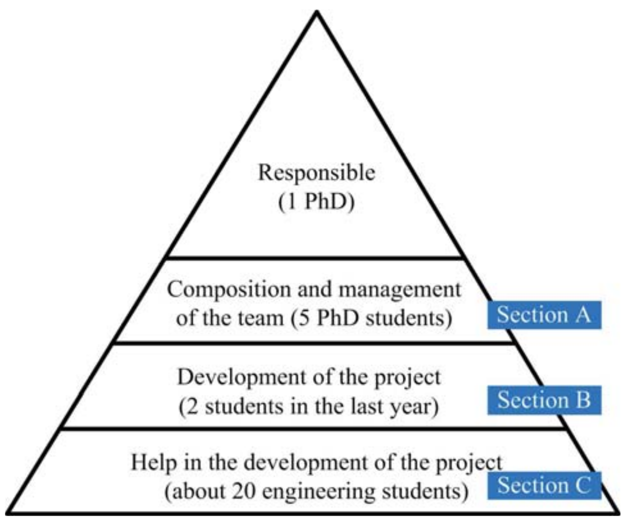

Figure 1. Structure of the Harness team

The responsible of the Harness team is the responsible of the Power Supply Systems group, an expert Electrical Engineer PhD professor, who can help the rest of the team to solve important problems. He is not the responsible of the organization of the Harness team, he only advise the other components of the Power Supply Systems group if they have great troubles.

The rest of the components of the Power Supply Systems group, particularly five of them (all of them are PhD students), have composed the Harness team and must manage and organize its work. They have to evaluate all the advances made by the students, solve the questions they could have, distribute and organize the work, etc. These members of the Harness team are expected to participate in the project till the launching of the spacecraft. We are going to call them, section A students.

Regarding the development of the harness of the ESMO project two engineering students are making their Master thesis. They are working together, making reports, schemes of all the system and the connections needed, revising the electrical requirements of the rest of the subsystems, etc. These two students are making most of the jobs required in the design of the harness, supervised initially by section A students and latter by experts from the ESA. We are going to call them, section B students.

The Harness team is completed with a group of engineering students (about twenty) with different ages, skills and knowledge. These students do not have any benefits for participating in this project (such as money, increase in their marks, etc) except for their own learning about aerospacial projects. These students are divided in small groups to analyze each subsystem. They help students section B, and at the same time they are learning about the global system and the harness subsystem. We are going to call them, section C students.

The different degrees of students forming the Harness team are specified in Table I. As can be seen, most of the students are telecommunications engineers, simply because some members of the Power Supply Systems group are teachers in this degree and they are very well know by the students.

TABLE I. DEGREES OF THE MEMBERS OF THE HARNESS TEAM.

	Number	Electrical Engineer	Telecommunications Engineer
Responsible	1	1	
Management	5	2	3
Development	2		2
Help and assistance	20	2	18

Until this moment, we have been working with this structure for approximately seventeen months with very good results. Nevertheless, variations on the student number and possible evolutions between different student sections are expected.

After being working with this structure for a time, we can recommend a range of students in each section: section A students must be between 3 and 6 to properly manage all the rest of students. Section B students must be between 1 and 3 to carry out most of the required jobs. Finally, section C students must be between 15 and 30 students to help students B. We are very proud of the great number of students who want to participate in the project and their motivation, and so we can choose the number of students in each section.

C. Cooperative tools and work

About thirty students from different degrees and obviously with different skills, as it has been mentioned before, compose the Harness team. This is a very important advantage to develop an interdisciplinary topic as the harness of a satellite.

Nevertheless, it is difficult to coordinate so many students. Several cooperative tools have been used to make easier the interaction between all the members of the team. The most important ones are:

- Biweekly meetings: these meetings are being mostly carried out by section B students, with oral presentations supported with PowerPoint slides, in which their advances are presented and discussed with the rest of students. Occasionally, section C students make some oral presentation presenting important changes in other subsystems.

- A Google group: section C students have created a Google group (different from the one of the ESA), as can be seen in Figure 2, in which all the members of the team are signed up. We can interact and express our opinions about each subsystem of the satellite and the questions discussed during the biweekly meetings.

- An electronic calendar: thanks to this tool, integrated in the Google group, the meetings can be programmed in an adequate date for most of the members of the team. It is difficult to find a satisfactory date for all the students, due to their different timetables. Usually, meetings are programmed in some particular hours in the week, that are specially good for the students, then the members of the team can confirm their attendance, and after evaluating the number of confirmed members, the date is postponed or fixed. This can be easily done using the Google group.

Figure 2. Google Group of the Harness team

- Webpage: A couple of section C students have elaborated a webpage of the team. This webpage is updated monthly with the most important advances made by the team. Thanks to this tool other students can know about this project and can be interested in participating. On the other hand, this webpage adds our sponsorships and publishes the help of some people and institutions. You can see this webpage in the following address http://pels.edv.uniovi.es/ESMO/

Figure 3. Presentation of the webpage

III. Results and discussion. Meeting of goals

A. General learning of different section of students.

Most of the members of the Power Supply Systems group, whose structure has been mentioned before, besides working as teachers in a university are investigating in several projects. The available amount of time to carry out the ESMO project was very little. Nevertheless, the project seemed so interesting that they wanted to participate developing one of the free subsystem, in particular the harness subsystem. As they could not leave their projects, they thought about forming a group of students, with a particular structure, to carry out this new and interesting project. Initially, section A students (PhD students) were very pessimistic about the participation and collaboration of the rest of degree students, but when the announcement of the project was published a lot of students were interested and so, the Harness team was created.

Using the mentioned CL tools, the needed jobs for the harness subsystem in the ESMO project has been properly performed till this moment without too much time expended by section A students. Moreover, these members have put into practice their knowledge about CL, and have learnt about the interaction between students and between teachers and students. Their principle objective was to motivate the rest of students and give them enough tools to work together. They have not developed the harness of the ESMO but they have helped the degree students (especially from section B) to do it.

The two current section B students have carried out an excellent work which can be enough to present as a Master thesis, however they will continue working in the team (their Master thesis will be presented in December 2009). They have elaborated most of the documents needed, asking some questions to the rest of the students about the rest of the subsystems in the biweekly meetings. These two students have developed three different possible solutions for the harness of the satellite, which were presented in the last workshop in the ESA with a lot of success.

Section C Students have helped these two colleagues and have improved their knowledge about global and interdisciplinary projects in general and the ESMO project in particular. Most of these students have an important global knowledge of the whole spacecraft, which few of the rest of the participants in the ESMO project have.

In the following months section B students are going to present their Master thesis, and as they are going to finish their degree, a section C student is going to start elaborating another different Master thesis. All the students of the team have been assisting to most of the meetings, so they are well updated about the progress of the project (also thanks to the news in the Google group). As all of them have a lot of knowledge about the project, they can progress forming part of a higher section of students in the proposed structure of the team.

B. Technical proposal to the harness subsystem.

It is nearly impossible to sum up in this paper all the details of the technical solutions provided by the two section B students to the harness subsystem. However, an introduction to the solutions provided by the team for the harness of the ESMO will be given.

The most important requirements for all the components of the harness (cables, connectors, couplers, etc.) are:

- All cables shall be insulated with modified radiation cross-linked PTFE.

- All connectors contacts shall be Gold-Plated (Be-Cu) and crimpable.

- All components shall have Space Qualification

It is also very important the distribution of the harness in the spacecraft, taking into account the allocation of the rest of the subsystems (Figure 4).

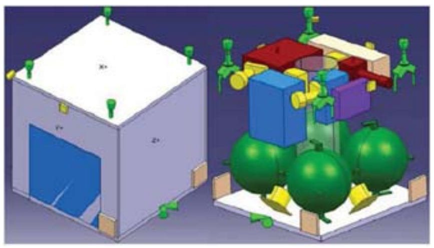

Figure 4. General structure of the ESMO

In ESMO satellite it can be differentiated the following four types of harness:

1. Harness of Power: The Electrical Power Subsystem (EPS) provides a 28V unregulated bus. The connectors considered are rectangular. In the EPS box there will be 4 connectors with 37-pin and in the rest of subsystems a 9-pin connector is enough, except in critical subsystems where redundant connectors are needed (Figure 5). The cable shall be twisted pair and is estimated to be 24AWG for most subsystems.

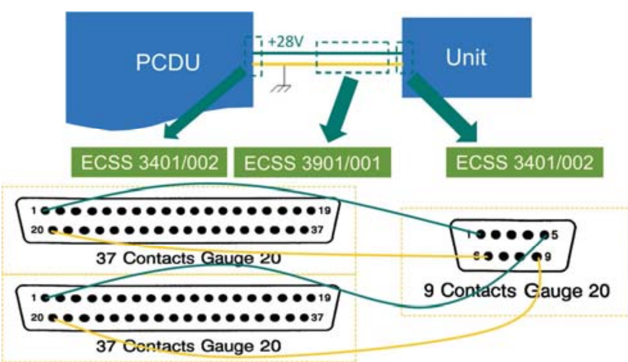

Figure 5. Distribution of the pins of the harness of power

2. Harness of CAN: The design of the CAN network is about to be defined by a proposal from ESA-ECSS (European Cooperation on Space Standardization). The connectors shall be compliant to specification: MIL-C D38999 and shall be a 9-pin micro-miniature D-type. The cable is recommended to be Electromagnetic Pulse (EMP) shielded. This option uses only two connectors per CAN node, both with the following pin-assignment (Table II):

TABLE II. DISTRIBUTION OF THE PINS OF CONNECTORS IN CAN BUS.

Pin	Function	Pin	Function
1	CAN_H (PRIMARY)	6	CAN_L (PRIMARY)
2	Reserved	7	CAN Ground (Required)
3	CAN_SHLD	8	CAN Ground (Optional)
4	Reserved	9	CAN_L (REDUNDANT)
5	CAN_H (REDUNDANT)		

3. Harness of RF: The RF connection works at 2.3GHz. There are four connections between the transceiver and the antennas. The considered cable is Coaxial with less than *0.5dB/m* losses. For this purpose, SMA connectors (Military Qualified) are required in order to satisfy the requirements of total transmission losses.

4. Harness of RS-232 & RS-422: These connections are conceived as dedicated lines between the most critical subsystems of the spacecraft. Both protocols have a common physical layer and use the same connector and cable type. These connections will be designed in accordance with the respective standard, but taking into account the general requirements written above.

C. Learning of the members of the team.

Obviously, all the members of the team have obtained some technical knowledge about the project (depending on its section and the participation in the team) which is considered very important. This learning has been demonstrated by all the students in the meetings of the team with oral presentations, clever questions, great suggested ideas, etc. Most of them have learnt some of the following topics:

- Selection of components (connectors, cables, couplers, etc) following the requirements for aerospacial missions.

- Knowledge about the different kind of electromagnetic interferences that can affect the components in the space and some ways to avoid this effect.

- CAN bus networks specially develop to use in the space.

- Different kinds of redundancy used in the harness for aerospacial validation of the system.

- Use of dedicated software (DOORS) to learn how to analyze electrical requirements taking into account the specifications of the system.

- Use of dedicated software (CATIA) to develop the 3-D design of the harness of the system

- Different solutions to manufacture an electrical ground to use as the reference (this is not so obvious in a spacecraft).

They have also improved some transversals competencies such as search of information, capacity of synthesis, critical thinking, decision-making and read and write technical documents in a different language.

Also, in order to analyze other general benefits of the participation in the Harness team, we have evaluated most of the students making oral presentations. We have compared the results of the evaluation of the students participating in the

ESMO project with other students making their Master thesis in different topics, not related with the ESMO.

In Figure 6 some results are showed, where we can see that students participating in the ESMO project obtained slightly better results than the other students. We should take into account that students making their Master thesis are in their last year, next to finish their degrees, while most of the students of the Harness team are in the third or fourth course of their degrees. These results demonstrate that students participating in the ESMO project have a great level of motivation and participation, working very hard in their oral presentations without any reward.

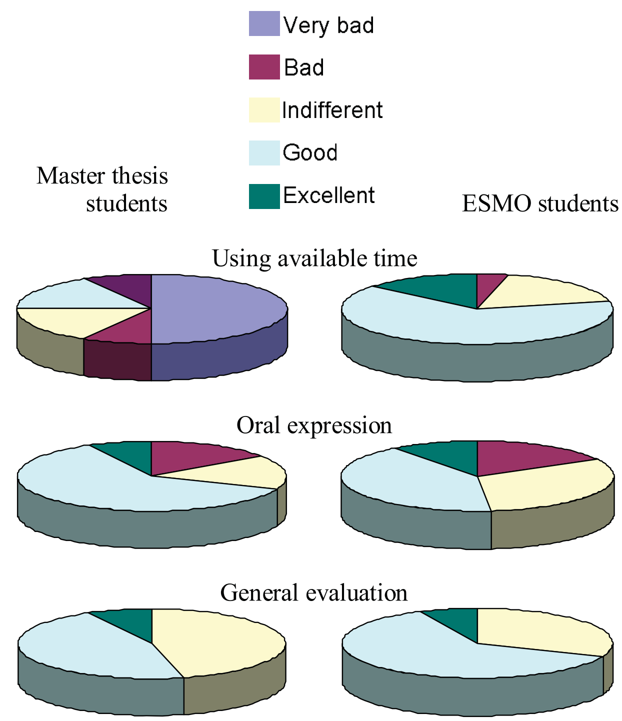

Figure 6. Evaluation of the oral presentation of the team

D. Evaluation of the progress of the team.

To evaluate the progress of the project a little opinion poll was developed to all the members of the Harness team (section A, B and C students). All of them estimate their activity in the team and the benefits in their learning of the participation in the project. The answers of different sections of students are significantly different, due to their different task developed in the team, however all the responses have been put together to evaluate the progress of the team in global.

In Figure 7, the results of the survey are showed. The project is well valued for almost all the members of the team. However some members feel that their activity in the team is very poor, especially section C students. To solve this problem we are right now carrying out different free task for this kind of students, such as oral presentations, search for sponsors, etc.

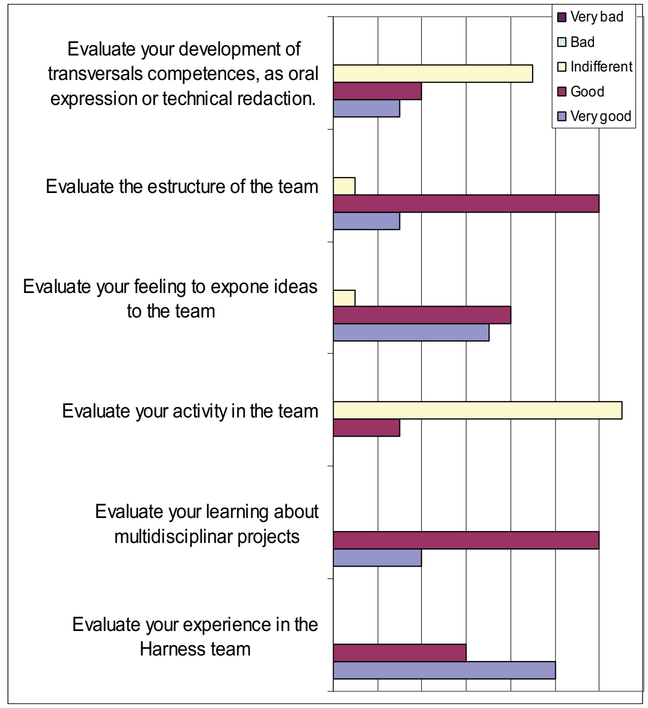

Figure 7. Evaluation of the project by the Harness team

IV. CONCLUSIONS

The possibility of being involved in a very interesting project working in aerospace topics in the ESA, like the ESMO project, was proposed to a group of researchers with very little time to work on it. In spite of this constraint, the project was so attractive that they considered trying to develop it with the help of some students. The interest of so many students for this project was surprising and aims the researchers to form a team to carry out the harness subsystem of the ESMO project.

Thanks to the help of the students the time expended by the researchers would be less, but the main problem would be how to organize and manage so many different kinds of students.

The researchers of the Power Supply Systems group decided that the project should not be developed by them and then explain the work made to the rest of students. This could be similar to the traditional way of teaching, which can be compared to a train that will go on, with or without their wagons.

On the other hand, the proposed methodology was to let the students make all the work required to carry out the project. The task of section A students would be the distribution of the work between the different kinds of students and provide suggestions, revisions and help in certain mishaps. This method is similar to the proposed way of learning by the European Higher Education Area (EHEA), which can be compared to a racing shell that will only go on if everyone row, and so the working rate will be specified by the own students [8].

Figure 8. Metaphor between teaching (train) and learning (racing shell).

Putting into practice the CL tools and methodologies that have been described in this article, some very interesting solutions have been proposed to develop the harness of the ESMO. The learning of all the members of the Harness team has been very successful without having to expend a lot of time. Different students have learnt different concepts about harness, the other subsystems (communications, propulsions, power conversion …), interdisciplinary projects, cooperative and collaborative working, and besides that, they have shared with each other the different knowledge they have. Moreover, they have improved a great number of transversals skills.

All the members of the Power Supply Systems group have been pleasantly surprised with the collaboration of so many students in the described project without any reward except from the learning of new topics. Moreover, the structure of students proposed and the collaboration between all of them using the CL tools detailed in this article, are considered to give very good results when developing a complex system as the harness of a satellite.

Abstract— **Student assessment plays a fundamental part in every e-learning process, where it can serve to check whether the learner has achieved the intended learning outcomes (summative assessment), but also as a means to aid in the learning itself (formative assessment). Nevertheless, there exist no formal standards to cover this type of content, just some specifications, such as IMS QTI. In this article, we present a study of formats for assessment and their usage in Europe. We also present a reference metamodel for assessment that covers the needs of all stakeholders in relation to this topic.**

Keywords - assessment formats, IMS QTI, reference metamodel, ICOPER.

I. Introduction

ICOPER [1] is a Best Practice Network that started in September 2008, funded by eContentPlus programme of the European Comission. As part of the ICOPER objectives, a reference model (ICOPER Reference Model) will be provided and some mechanisms to ensure involvement, cooperation and adoption of standards in the European educational framework. To accomplish this goal, the project will systematically analyse the specifications and standards available and in use, to draw conclusions on their validity.

In the context of the ICOPER project, an effort is under way to analyse assessment standards and specifications. This work has been carried out by the work package "Assessment and evaluation testbed", led by Carlos III University of Madrid. The analysis has focused on IMS Question and Test Interoperability (QTI) [2] because it is considered as *de facto* standard. Besides, this work package has other responsibilities like proposing a set of best practices in the scope of learning assessment, detecting and solving QTI interoperability problems by helping to complete the available tools to guarantee a robust exchange of assessment material [3].

This paper presents the results of the analysis of assessment formats and specifications, from the technical point of view, and their actual usage in Europe. As a result of this analysis, a reference metamodel for assessment content is proposed as a best practice in the assessment domain.

II. Assessment formats and specifications

A. Methodology

The Model Driven Architecture (MDA) standard [4] has been used in order to analyse assessment specifications. Concretely, UML diagrams (what henceforth are called metamodels) have been used because they provide us with the following advantages as stated in [5]:

- Abstraction from secondary aspects such as syntax and concrete XML bindings.
- Better understanding of the format management.
- Development of systems easy to maintain and re-use (and therefore interoperable).

The criteria applied for the selection of the formats and specifications to be analysed are based on their relevance in the e-learning environment. Some additional formats used by ICOPER partners have also been included in the analysis due to their widespread deployment and experience as well as the possibility of an in-depth analysis of them granted by the consortium. The chosen specifications can be classified in two categories:

- **Assessment purpose formats**, whose main objective is the authoring of assessment resources. In this category, the studied formats are: IMS QTI (versions 1.2.1 and 2.1); formats belonging to Learning Management Systems (LMS), either open source systems like Moodle XML or commercial like Blackboard; and application specific like Hot Potatoes or OpenMark, an ad hoc format developed by the Open University of United Kingdom (OUUK).
- **General purpose formats**, whose original purpose is not learning assessment but can nevertheless be applied to it. The chosen formats belonging to this group are DocBook, used to write book and technical articles, FML, for describing Frequently Asked Questions, QAML, specification for question and answers, and SuML, used for writing surveys.

B. Comparative analysis of assessment formats

Once the assessment format metamodels were developed, a series of qualitative comparisons between them were carried out.

First, a set of key features was defined for assessment formats. The selection of features was based on the IMS QTI specification and the conceptual model that will be presented in Section IV:

- **Response and outcomes processing**: the possibility of processing the response given by the student in order to determine if it is correct or not; the processing of several question responses in order to get a global result of the assessment. Response processing can be defined as an external process.

- **Metadata** capabilities: the possibility of storing the metadata of assessment items, sections and tests.
- **Hybrid question** management: the possibility of defining a hybrid question as a combination of a set of simple ones.
- **Correct response** indication: the possibility of indicating the correct response given a concrete question.
- **Multiple responses** related to one question: the possibility of defining more than one response to a given question (one correct and the others incorrect).

Table I summarizes the comparison of the analysed formats regarding the characterising features discussed above. The only common one is the use of metadata, but it is limited to a series of predefined fields like author or date in some formats. Most of them permit multiple responses to one question (only SuML and FML cannot represent it). The remaining features such as establishing the correct response, response processing or using a hybrid question are only supported by the assessment-purposed formats, that is, IMS QTI, Moodle, Hot Potatoes, OpenMark and Blackboard

TABLE I. KEY FEATURES IN ASSESSMENT FORMATS

Formats	*Meta*	*Proc*	*M.R.*	*C.R.*	*Hybrid*
IMS QTI	X	X	X	X	X
Hot Potatoes	X	X	X	X	X
MoodleXML	X	X	X	X	X
OpenMark	X	X	X	X	X
Blackboard	X	X	X	X	X
DocBook	X		X		
FML	X				
QAML	X		X		
SuML	X				

On the other hand, a series of question types have been selected in order to support the comparison between assessment formats. The selected question types have been classified according to the FREMA model [5] into the following sets:

- **Constrained response**: a question whose response is constrained to a space of solutions. That is, the student does not need to write any words, just to select an option from a set. Examples of this type of question are multiple choice questions (MCQ), multiple response questions (MRQ), true/false (TF) and matching.
- **Constructed response**: a question whose response is open, that is, it is constructed by the student. Examples of this type of questions are short-answer questions, essays, fill in the blanks (FIB), crosswords, etc.
- **Miscellaneous/mixed**: questions that do not fit in the previous categories, like practice sessions, simulations, etc.

Taking into account this classification of question types, a set of them has been selected in order to make up a representative sample. The selected questions types, which have been collected from the assessment formats studied in the previous section, are as follows:

- Short answers: a textual answer consisting of a few words.
- Essay: a textual answer with unlimited or limited number of words that is not corrected automatically.
- Multiple choice question (MCQ): choose one option out of a list of possible answers. This type includes True/False (TF) questions.
- Multiple response question (MRQ): choose one, more or no option out of a list of possible answers.
- Fill in the blanks (FIB): complete missing words in a sentence or paragraph.
- Match: given two lists of terms, match each term on one list with one term on the other.
- Crossword: fill out a crossword using definitions of words in horizontal and vertical positions.

TABLE II. QUESTION TYPES IN ASSESSMENT FORMATS

Formats	*Short*	*Essay*	*MCQ*	*MRQ*	*FIB*	*Match*	*Cross*
IMS QTI	X	X	X	X	X	X	X
Hot Potatoes	X	X	X	X	X	X	X
MoodleXML	X	X	X	X	X	X	
OpenMark	X	X	X	X	X	X	
Blackboard	X	X	X	X	X	X	
DocBook	X	X					
FML	X	X					
QAML	X	X					
SuML	X	X					

Table II summarized the comparison of the formats regarding the types of questions supported. Short answer and essays are supported by all formats. Only formats developed for assessment purpose, however, allow multiple choice, multiple response, fill in the blanks or match questions. Crossword is a complex question type that Hot Potatoes supports and that can also be implemented in IMS QTI though in a more challenging way.

III. ASSESSMENT FORMATS USAGE IN EUROPE

As part of the analysis of assessment formats, a study of the usage of standards and specifications for assessments in Europe has been carried out. In order to accomplish this task, two different methodologies could have been followed:

- A quantitative analysis of a larger number of institutions using a statistical study
- An in depth analysis of a representative sample of institutions using both quantitative and qualitative methods.

The second methodology fits the objectives of the ICOPER project and can take advantage of the possibility of analysing, in depth, the institutions inside the consortium. Even more importantly, it is more appropriate for determining, analysing and understanding the underlying causes supporting the evidences found.

Figure 1 shows the distribution of use of the diferenent assessment formats, being the most spread ones IMS QTI, Blackboard and MoodleXML. The IMS QTI specification is considered as a *de facto* standard thus it is not unexpected to see its usage in several cases. Conversely the use of Blackboard can be justified because it is considered as one of the first e-learning tools. With respect to Moodle, (the most used e-learning tool currently) it also appears in the first position of this list. In the studied sample, it can be stated that the IMS QTI specification is used at least as frequently as proprietary formats that belong to two important tools in the e-learning scenario: Blackboard and Moodle. But considering all proprietary and ad-hoc formats as a single set, the ratio of usage of IMS QTI is rather low revealing a lack of acceptance of the specification. This statement is confirmed in [6].

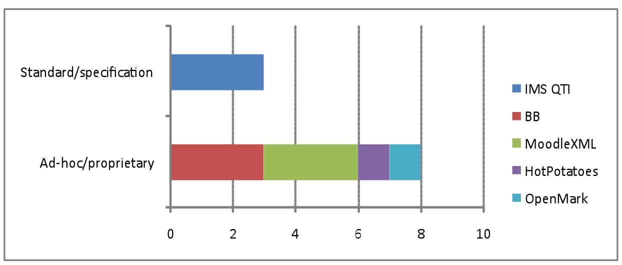

Figure 1. Usage of assessment formats

IV. REFERENCE METAMODEL FOR ASSESSMENT CONTENT

A. Proposal of a reference metamodel for learning assessment content

Due to the deficiencies detected during the metamodels analysis described in Section II and the analysis of required concepts in the assessment environment that will be presented in other paper of this special session, it has been considered necessary to propose a reference metamodel for assessment content.

Three parts have been identified in the assessment formats: presentation, processing and content. This model is focused on assessment content (it is intended to keep it simple to facilitate its adoption). It covers the assessment resources (content) and results (feedback and grade) from the assessment conceptual map. It is designed to provide assessment interoperability, so it avoids ambiguous definitions and duplication of information (such as some of the deficiencies found in QTI, as explained in the paper about interoperability in this special session).

The proposed reference metamodel accomplishes all key features discussed previously except processing, because this service can be externalised. In the same way, the proposed metamodel covers all questions types considered in the qualitative assessment formats comparison. Thus, the reference metamodel can be regarded as a minimum set of entities that accomplish the key features of existing assessment formats. This set is minimum in order to foster simplicity and ease of implementation, which are interesting features from the point of view of interoperability.

The reference metamodel for assessment content comprises all features required for completeness and interoperability in the learning assessment process. The basis of this metamodel is the IMS QTI metamodel and the generalized model created by Zuzana Bizonova in her PhD thesis [7] that is a study of a set of tools that have an assessment module, i.e., Claroline, Moodle and OLAT.

The initial version of the reference metamodel presented some deficiencies, the main one being the lack of support for learning outcomes different of knowledge, i.e., skills and competences. As competence-based learning is one of the ICOPER main objectives, it is necessary that the proposed metamodel cover these types of learning outcomes too. A new version of the model has thus been developed to fix such deficiencies.

The main concept of the reference metamodel, shown in Figure 2, is the assessment item. It represents an assessment entity that makes sense isolated. It is an abstract concept (like an abstract class in a object oriented programming language) that has three types of concrete realizations: question, task and assignment. Assessment items are composed of a definition, that is the wording of the question, and other metadata, like estimated duration of the assessment item or the author of this item.

Questions are used for assessing knowledge (like all the assessment formats studied previously) and they contain some entities related with this task: set of possible responses, correct response declaration and grading/feedback assigned to every possible response (in the case of constrained response questions).

Tasks target the assessment of skills, besides the knowledge that is implicitly used in such skills. They may make use of a series of hardware and/or software tools in order to perform the assessment. For example, ad-hoc software would be required for a simulation of the specific subject being assessed. Thus, tasks cover FREMA question type miscellaneous/mixed that were not covered by questions, although some constructed questions can be also considered as tasks, e.g., essay assesses writing skills.

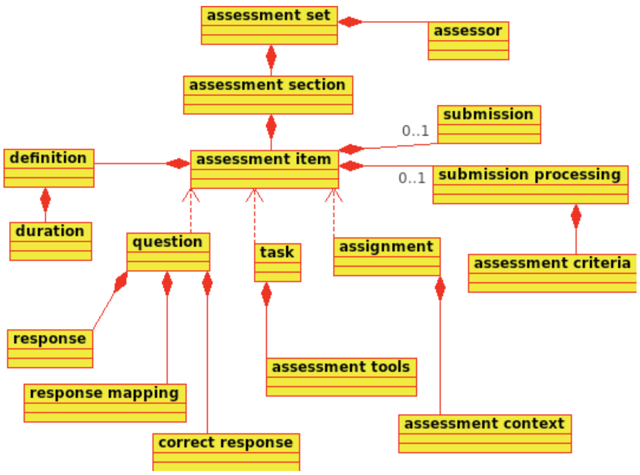

Figure 2. Reference metamodel for assessment content

Finally, assignments are defined to evaluate competences (besides skills and knowledge) and require an assessment context. For example, work in groups can be assessed using a group of students that participate in the assessment process; this group of students is the context when a particular student is assessed.

On the other hand, student response (submission) is associated to assessment item, but this response can be or not be processed. It is also possible that this processing was defined as an external process. This processing is executed following a certain assessment criteria.

Finally, assessment items can be grouped in assessment sections, and sections in assessment sets that would correspond to complete exams. Given a complete example, it could be useful to define the evaluator in charge of this process, that is who assesses the student. The information of the assessor of an assessment set can be used to define the assessment method of this set, what is an important characteristic of this resource. For example, it can be useful as metadata of assessment resources in a repository in order to search automatic assessments (whose assessor is a computer).

B. Validation of a reference metamodel for learning assessment content

In order to validate the proposed reference model, model comparisons between the reference metamodel and the metamodels studied in Section II have been performed. A series of model transformations have been defined ad-hoc for this purpose. Thus, an algorithm has also been defined, which consists of an ordered set of transformation steps. After the executions of these steps, one model should be transformed into the other one; if so, it is demonstrated that they accomplish the same features.

The model transformations that have been defined to compare metamodels are as follows:

- **α-conversion**: an entity or attribute changes its name
- **attribute2entity**: an attribute changes its role to play like an entity
- **extension**: the addition of an entity or an attribute
- **relocation**: the change an entity or attribute position in the model

Once defined the basic transformations, an algorithm is executed consisting on a set of ordered steps. These steps are basic transformations, from a chunk of one model that accomplish a key functionality to a equivalent section in the metamodel that is being compared to.

This methodology has been used to compare the first version of the reference metamodel for assessment content to IMS QTI (version 1.2.1 and 2.1). The comparison results is that the proposed metamodel accomplishes the key features defined before, that QTI was supposed to accomplish based on its analysis. Thus, this reference metamodel was a simplification of QTI model maintaining the defined key features. It is assumed that these conclusions can be extended to the second version of the reference model because it has been built following the same premises of the first one.

V. CONCLUSIONS

In this paper, a study of the most relevant assessment formats and specifications in present day e-learning systems is presented. A qualitative comparison has been performed among the studied assessment formats, following a list of defined key features and questions types. As a result of this analysis, a series of deficiencies have been detected in the studied formats, like the range of supported learning outcomes (limited to knowledge) and the lack of content interoperability. A study of specifications usage has been also presented, concluding that IMS QTI is not used as frequently as expected due to the detected problems [3].

Besides, a study of the concepts of learning assessment has been performed and, as a result of it, a concept map of this domain has been developed. This tool will allow us to know exactly the concepts used in learning assessment and the relationships between them.

Finally a reference metamodel for assessment content has been proposed, which solves the problems found in the specifications study. This metamodel is based on the comparison of assessment formats and the concept map developed previously. It should be also mentioned that the metamodel was defined having in mind assessment content interoperability.

As future work, it is planned the refining of the reference metamodel for assessment content in order to cover all necessary aspects in assessment domain. On the other hand, a data model is also planned to be created, based on the concept map and the reference metamodel, which will allow to carry out an actual implementation of this proposal.

A proof of concept will be executed in the Open ICOPER Content Space (OICS), a federated repository of assessment content, consisting on integrating and managing assessment material. This implementation will be used as validation of the reference model presented in this article.

Abstract— **In outcome based learning, learning outcomes (knowledge, skills and competences) to be achieved by learners are in the focal point of the learning process. All educational activities and resources need to be related to the intended learning outcomes of a learning module or course, in order to assist the learners in successfully achieving the intended learning outcomes at the end of the learning experience.**

Outcome based assessment means that the assessment process must be aligned with the learning outcomes. This means that it should support the learners in their progress (formative assessment) and validate the achievement of the intended learning outcomes at the end of the process (summative assessment). It also means that the assessment process should be adapted depending on the kind of outcomes that it is aimed to appraise.

This paper presents an insight into the current state of outcome based learning within Europe and proposes a unified conceptual model for outcome based assessment, shaping a theoretical framework for the integration of learning outcomes, assessment and units of learning as key concepts. An application scenario is finally described to illustrate the application of the model.

Keywords- learning assessment, learning outcomes, unit of learning.

I. Introduction

The European Qualification Framework [1] is proposed to act as a translation mechanism across the different National Qualifications Frameworks (NQFs) in the European countries. Its implementation should help higher educational institutions and workplace organizations across Europe to exchange and compare learning outcomes presented by individuals. The primary goal of the EQF is to improve mobility of learners across European countries and educational systems. Currently, higher education institutions have not yet adopted standards for learning outcome definitions, resulting in inefficiencies for both outcome-based learning design and outcome-based discovery, access and re-use of units of learning [2].

In this paper, the ICOPER[1] project approach for developing outcome-based assessment and units of learning is presented. The alignment of assessment items to learning outcomes to be achieved by learners is discussed in a novel theoretical framework and reference model for assessment in outcome-based educational environments.

II. Key Concepts in Outcome Based Education

A. Learning Outcomes

Learning outcome means statements of what a learner knows, understands and is able to do on completion of a learning process. It covers knowledge, skills and personal, social and/or methodological abilities that a learner should attain when successfully having finished a unit of learning:

- **knowledge** means the *outcome of the assimilation of information* through learning [1]. Knowledge is the body of facts, principles, theories and practices that is related to a field of work or study. Example: *"learners are able to enumerate and explain the eight golden rules of interface design."*
- **skill** means the *ability to apply knowledge* and use know-how to complete tasks and solve problems [1]. Example: *"learners are able to design an interactive website that complies with Web Accessibility Guidelines."* – Note that in order to achieve this skill, learners will need to assimilate knowledge in web programming and web usability. They will be able to do something by applying knowledge, therefore it is a skill.
- **competence** means the proven *ability to use knowledge and skills* in work or study situations and in professional and personal development [1]. One key aspect of a competence is the degree of autonomy and responsibility with which learners are able to apply knowledge and skills. Example: *"learners are able to review the design and usability of a given system and formulate suggestions for improvement based on relevant design metrics and*

[1] http://www.icoper.org

guidelines with minimal supervision by a tutor." – This learning outcome requires the ability to use knowledge and skills: it requires knowledge about user interface design and usability metrics; it requires the skills of being able to do a critical review, apply usability metrics, and suggest improvements to the model. It is a competence because it adds information about the degree of autonomy by stating that learners are able to do this with minimal supervision by a tutor.

IEEE RCD [3] is the only widely accepted standard for describing generic learning outcomes. IEEE RCD is a continuation (and replacement) of the early efforts on the development of IMS Reusable Definition of Competency or Educational Objective [4]. It provides a way to capture the key characteristics of a learning outcome, independently of its use in any particular context or target group (persons). This model should enable the storage, findability and exchange of learning outcomes across learning systems that deal with learning outcomes data.

B. Outcome Based Unit of Learning

Learners aim to achieve learning outcomes by successfully completing a **unit of learning**. Each unit of learning targets the acquisition of one or more assets of knowledge, skill or competence. We define a unit of learning as a contextualized, complete, self-contained unit of education or training that consists of a teaching method and associated content (adapted from [5] p. 25). A three-months distance course on the effects of global warming could be an example of a unit of learning. A one-hour face-to-face lecture on the basics of academic writing could also be an example of a unit of learning. Hence, units of learning may differ significantly for attributes like duration or complexity of activities.

This definition outlines two important properties of a unit of learning: *contextualized* means that the unit of learning is situated in a specific subject context; *complete* and *self-contained* mean that the unit of learning includes all information and resources required including objectives, content, assessment, description of learning and teaching activities, and so forth.

Well-designed units of learning typically follow a strategy or **teaching method**. We define a teaching method as a *learning outcome* oriented set of activities to be performed by learners and learning supporters. Examples of teaching methods are the lecture method, problem-based learning, and the think-pair-share method.

A pivotal piece of information to be included in a unit of learning or teaching method is the set of intended learning outcomes (see Section II.A) that learners are expected to attain upon successful completion of (a run of) the unit of learning. We define that learners have successfully attained a learning outcome if they successfully passed the associated assessment that is part of the unit of learning. Information on the learning outcomes to attain is linked to each unit of learning in the form of learning outcome definitions. As described in Section II.A, we differentiate between knowledge, skill, and competence types of learning outcomes.

Typically, teaching methods are *generic* descriptions of activities, independent of specific content or an application context. Therefore, a teaching method is not directly put into practice by teachers: it needs to be adapted to a specific application **context** that gives meaning to it (e.g. subject, target learner group, IT infrastructure). Teaching methods are thus realized in units of learning within a specific context and with associated content. One unit of learning may employ multiple teaching methods that aim at several learning outcomes.

Another important aspect to be considered for the design of units of learning is the **learning assessment**. The learning assessment specifies which assessment resources and methods are to be used during the learning provision process to assess the achievement of intended learning outcomes. While a generic teaching method typically makes general statements about the **assessment method** (e.g., multiple-choice test, peer assessment, learning contract, oral examination), the unit of learning needs to specify in detail how the assessment method is implemented with a concrete set of **assessment resources** (e.g. tests, test items, peer assessment forms).

There is a design-time view and a runtime view on units of learning. All required descriptive information (metadata) related to a specific teaching and learning process is specified at design time. A running instance of a unit of learning is called a *run*. While each run may involve different groups of learners in different environments, all runs of a unit of learning follow the design specified in the unit of learning. There are many different ways of representing units of learning. Some widely used formats include narrative texts, structured descriptions following a uniform template, or formal machine-readable descriptions using a specialized language (like IMS Learning Design [6]).

C. Outcome Based Learning in Europe

The European Union is confronted with the challenge to make Europe more responsive to the labour market's requirements. In other words, European graduates should be equipped with the appropriate knowledge, skills and competences required by the workplace to meet the challenges of globally increasing competition.

In 1999, education ministers from 29 European countries signed the Bologna Declaration [7] and so committed to establish the European Higher Education Area (EHEA) that should promote coherence in European higher education by 2010. The EHEA is not intended to represent a centralized European-wide system of higher education, but rather offers reference points for national policies and actions, and it guides the implementation of common key features in the respective national educational systems, such as national qualification frameworks. The re-structuring of the educational systems to meet the requirements of the EHEA resulted in a change of paradigm promoting the idea of putting the learner into the centre of the learning process and of concentrating on the intended learning outcomes of this process instead of what has been provided as input by teachers and instructors.

The Bologna process offers the instruments required to bring about the shift from a teacher centred to a more learner-oriented approach to education for formal study programs. That includes the European Credit Transfer System (ECTS) [9] to express students' workload, the two/three cycles system (bachelor, master, PhD), the degree recognition to further the compatibility and portability of study programmes and the European Qualification Framework to make learning outcomes more transparent and comparable across Europe.

Of course, formal learning offerings (e.g. study programmes) cannot satisfy all the requirements of lifelong learners, therefore informal learning opportunities become crucially important. Anyway, integrated support for informal and formal learning is missing. Learning outcome development typically starts in the initial education context, which includes traditional school settings. But dynamic changes in the society and economy increasingly demand lifelong development of knowledge, skills and competences in the work context, encompassing both informal learning activities (i.e. intentional, but not accredited) as well as non-formal ones (i.e. as a side effect of other activities). A holistic picture of the educational process distinguishes its five phases: requirements analysis, design of learning strategy, development of learning offerings, provision of learning opportunities, and evaluation of learning offerings [8]. New approaches are needed to better map learning outcomes to units of learning, teaching methods, assessment methods and records, and context of study and work, analyse learning outcome gaps, and provide informal training to close these gaps. That is in addition to enabling exchange of graduates' learning outcome profiles between universities and workplace systems and between European universities.

In ICOPER, one key challenge will thus be to find ways that can effectively bring together educational achievements attained within formal as well as informal learning settings. That should result in evidence records (i.e. statements about the learner's attained learning outcomes based on assessment) of what a person knows and understands, and is able to do in terms of different application modes of knowledge and understanding at different levels of autonomy and responsibility.

III. Towards a Unified Model for Outcome Based Assessment

The most significant precedent reference model for the assessment domain is FREMA (e-learning framework reference model for assessment) [10]. Since its development, the technology enhanced learning field has however experienced an important evolution, which requires a renovated model. The most significant contribution of the ICOPER model proposed here is its emphasis on learning outcomes orientation, which is in line with current European policies and recommendations framed by the Bologna Process and its efforts towards establishing the European Higher Education Area. An additional contribution is its integration into a global holistic reference model for technology enhanced learning rather than focusing on just one aspect –assessment– of the learning process.

A. Conceptual Framework and Content Space

The ICOPER reference model [11] aims to provide a conceptual framework for common understanding of the learning outcome based Technology Enhanced Learning (TEL) area as well as the interdependencies of its key concepts. The objective is to facilitate the work of stakeholders to design, develop, implement and improve TEL systems with a focus on re-use and outcome based learning. For the field of assessment, a reference model supports the development and implementation process of assessment-related tasks and systems.

The Open ICOPER Content Space (OICS) [12] aims to provide access to integrated educational content and services, and acts as a proof of concept for the reference model. Figure 1 represents the architecture for the OICS.

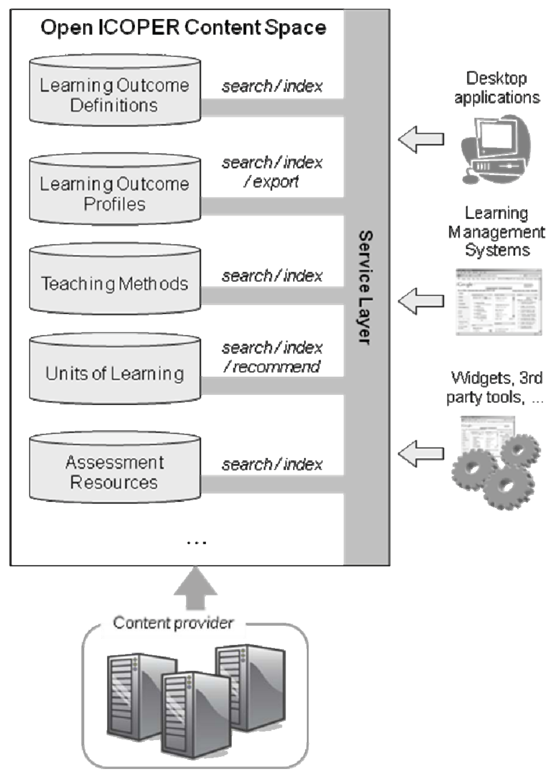

Figure 1. OICS architecture.

The OICS attempts to provide a service-based interface to access educational resources distributed among different content providers thus facilitating re-use. Accessibility of the resources relies on the use of metadata. Original metadata (as stored in the source repositories from content providers) are thus complemented with enriched metadata including complementary information associated to the resources according to the ICOPER reference model. The OICS implements a learning outcomes based approach to learning processes, providing access to the key educational resources defined in the ICOPER reference model: learning outcomes (including both learning outcome definitions as well as

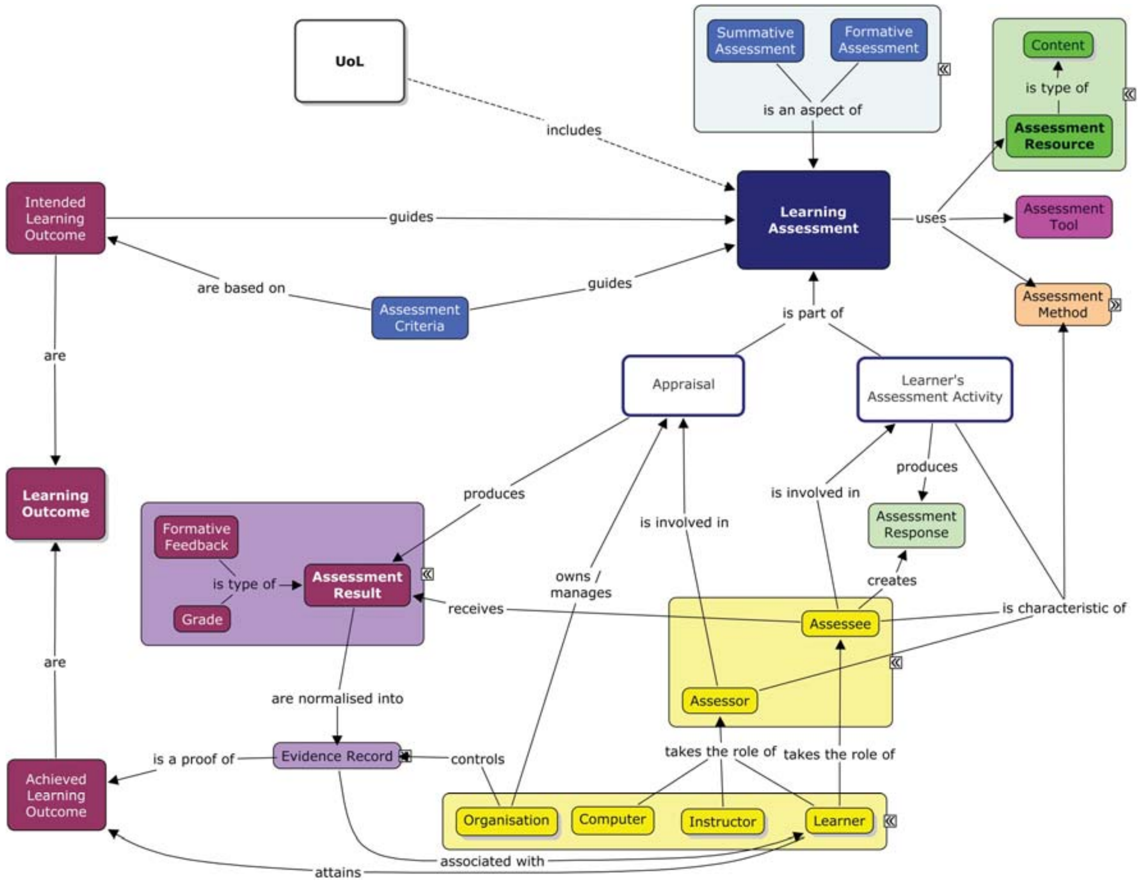

Figure 2 Conceptual map for learning assessment.

learning outcome profiles), units of learning and teaching methods, and assessment resources.

B. Unified Conceptual Map and Reference Model

There are two main concepts in any learning scenario: the learning outcomes that are intended to be achieved by the learner and the unit of learning as the means by which those can be achieved. In order to complete the picture, *learning assessment* appears as the process of testing the achievement of learning outcomes (knowledge, skills and/or competences) by an individual learner and providing the corresponding information reporting about the learner achievements and/or potential indications for improving them. It can be summarised as the process of identifying, collecting and preparing data to evaluate the achievement of the outcomes and educational objectives of a program [13]. Learning assessment is thus the binding process by which the intended learning outcomes defined by a unit of learning are accredited as actual learning outcomes acquired by a learner, transforming those learning outcomes from potential to factual.

The unit of learning makes use of the learning assessment process, in order to verify that the learner who participated in the unit of learning attains the intended learning outcomes. Learning assessment processes can be integrated into a unit of learning as activities which imply a response by the learner, and also generate information about his/her performance as results.

Two representative cases can thus be considered [14]. On the one hand, a unit of learning which includes a final assessment process to check whether the learners have successfully accomplished the intended outcomes. That is, a summative assessment, which provides a measure of achievement or failure, made in respect of a learner's performance in relation to the intended learning outcomes of the program of study [15]. An example of such a case is an exam at the end of a course on Object Oriented Programming. The unit of learning is in this case the course itself, which includes a series of lectures, programming exercises in the laboratory, etc. In order to adequately cover the assessment of the expected learning outcomes, the exam would be composed of a theoretical part with multiple choice questions addressing knowledge outcomes of the course *(e.g. Explaining the concepts of Object and Class)*; and a programming assignment for evaluating the student’s programming skills *(e.g. Developing a software program which involves inheritance)*. The learning assessment concept (cp. Figure 2) would comprise the whole process, including in this case both the activity of the learners taking the exam as well as the appraisal phase when the instructor gauges the learners’ responses and awards them the corresponding grades.

On the other hand, a learning assessment process can be a learning activity itself, aiming to provide formative feedback to the learner about his/her performance and support their progress [16] [17]. An example of this case is a peer review activity integrated as part of the unit of learning. Following the previous example, the same course on Object Oriented Programming includes a peer review activity consisting of assessing a programming project developed by the learners organized in teams of four members. Such activity aims at generic learning outcomes such as team-working and critical evaluation, in addition to other domain specific outcomes. The learning assessment can again be subdivided into two sub-processes: the development of the project by the learner (learner's activity) and the reviewing (appraisal).

Further analysis of the relationship between learning outcomes, unit of learning and learning assessment requires the introduction of the key concepts related to the latter: assessment resource, roles (assessor and assessee), assessment results, etc. Figure 2 represents these key concepts as well as the relationships interconnecting them.

In a similar way that a unit of learning uses learning resources for supporting the learning process, an assessment process also makes use of specific content. An assessment resource is a special type of learning content, which is used for assessment purposes and it involves interaction with the learner. Examples of assessment resources would be the test in the first case, with the set of questions and the programming assignment instructions. And for the second case, the assessment resource is the project proposal together with the rubrics and questionnaires for the peer reviewing. Assessment resources should include additional information besides the textual instructions provided to the learners. For example, information about the correct answers for the multiple choice questions in the first case.

Such assessment resources are proposed to be represented using the IMS Question, Test & Interoperability (IMS QTI) specification [18] (considered nowadays a standard de facto for assessment resources) enriched with extended metadata. Such metadata includes information about the learning outcomes (knowledge, skills or competences) that are tested by the assessment resource.

Two roles are involved in the assessment process: the assessor (responsible of the appraisal) and the assessee (whose learning outcomes are appraised). They typically correspond to the learning supporter and the learner roles defined for the unit of learning, respectively.

As a product of the appraisal done by the assessor, the assessment results are generated, consisting of information about the performance of the assessee, his/her achievement of the learning outcomes and/or formative feedback for supporting the learner's progress. Usually, assessment results can correspond to specific learning outcomes and may need further post-processing to inform about more generic learning outcomes. For example, it may be necessary to combine results from several assessments to accredit the attainment of a certain learning outcome. On the contrary, it is also frequent that a given assessment process considers several different learning outcomes. Here there is a need for a normalization process that transforms detailed assessment results into *evidence records*, which act as proof of the attainment of learning outcomes and can be included in the learner's *learning outcome profile*.

The evidence record acts henceforth as the binding between the learning outcomes that the learner can actually claim and the assessment process (when successfully completed). In order to be trusted and to provide complete information, evidence records should include data about the type of assessment performed as well as the responsible expert and institution that endorses this evaluation.

Finally, the description of the assessment process is formalized into the *assessment method* concept, which comprises the characteristics defining a certain assessment process (such as who plays the role of assessor, the type of activity posed to the assessee, the purpose of the process, the kind of results to be provided, etc.).

The assessment method is strongly influenced by the assessed learning outcomes. Different types of learning outcomes require different assessment methods. For example, knowledge-type learning outcomes can be assessed using multiple-choice tests while such kind of activity is less appropriate for assessing skills. Assessing the fluency and pronunciation skills of a learner in a course on English as a foreign language would imply the use of oral activity; whereas a written assignment may be used for assessing a learner's writing skills.

Different assessment methods can also be defined depending on the actors playing such roles. The assessor role can be played by the student him/herself, peer learners, the instructor or automatic assessment. Regarding the assessee role, learners can be assessed individually or in groups (collaboratively). Again, the learning outcomes can be determinant in the selection. Critical thinking is usually dealt with by self-assessment, and peer assessment is typically applied when evaluation skills are intended outcomes.

The assessment method is thus a concept that can be related to the teaching method defined for the unit of learning, as it plays an equivalent role for the learning assessment (namely, the generic description of the process) and can thus be considered an integral component of the teaching method. So the teaching method includes references to the assessment method(s) to be applied when learning assessment activities are included.

In the examples discussed above, different assessment methods are applied. In the final exam case, the assessment method consists of an individual, time-limited (duration: 2 hours), face-to-face written exam, combining a (constrained) multiple-choice test with a (constructed) development assignment; responsibility for appraising the learner responses corresponds to the instructor, who plays the assessor role; the purpose of the assessment is summative and grades are the only assessment results generated (no formative feedback is intended). Conversely, the assessment method in the second case (formative peer review activity) consists of a team project assignment (teams composed of four members), peer learners play the role of assessors and the purpose of the assessment is formative, thus formative feedback is provided to the learners as assessment results.

Figure 3 shows the conceptual map for the proposed learning outcome based assessment model, abstracting the detailed concepts and focusing on interconnecting key ones.

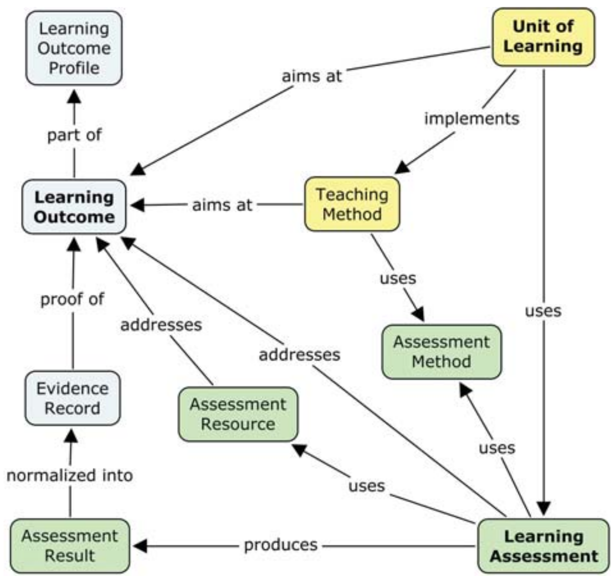

Figure 3 Concept map for learning outcomes-based assessment.

In summary, learning outcomes and assessment are connected in two ways:

- At design time: learning assessments are designed to evaluate the attainment of certain *intended* learning outcomes.
- At runtime (or provision time): learning assessments provide information about *actual* learning outcomes achieved by a learner; the assessment results are normalized into evidence records.

Typically, learning outcomes are acquired through participation in a unit of learning, and learning assessment can thus be integrated in such units of learning. Occasionally, learning assessment processes can stand independently, when aimed at just certifying the achievement of learning outcomes without an associated learning process.

C. Case Study

In this section a case study is discussed to illustrate the implementation of the unified model presented earlier. It aims at being a proof of concept for the model and to clarify the definition and connections of the key concepts. In summary, it consists of a basic English unit of learning composed of lectures, exercises, and a final assessment intended to evaluate the actual learning outcomes acquired by the learners.

During the design phase, the first step is to define the intended goals of the educational process, i.e., the intended learning outcomes. For this specific unit of learning, the learning outcome belonging to the skill category was specified as: *"Applying English grammar rules in everyday situations"* .

Following the definition of the learning outcomes addressed by the unit of learning, the next step is to define the process that will be used to assess the achievement of the learning outcomes. In this case, the assessment method will be one final exam, consisting of a multiple choice test, which is intended to be graded automatically by an assessment tool embedded within a Learning Management System (LMS).

Next, the teaching method to be applied needs to be defined. This sample course is taught using a series of lectures coupled with exercises that learners either perform individually or in pairs. A reference to the assessment method to be deployed (described above) is also required to be included in the teaching method description.

Once the structure of the course has been defined, the design process is completed with the selection of the learning resources (content) to be used, either creating new ones or re-using existing content. For the assessment process, such content would be the final exam used to evaluate the learners at the end of the course. In this example, this assessment resource is a multiple choice test on basic English grammar and vocabulary, consisting of a set of questions with the possible alternatives, including information about their correctness (to allow automatic grading).

Figure 4 shows the materialisation of the concepts defined in the proposed unified model for the case study discussed.

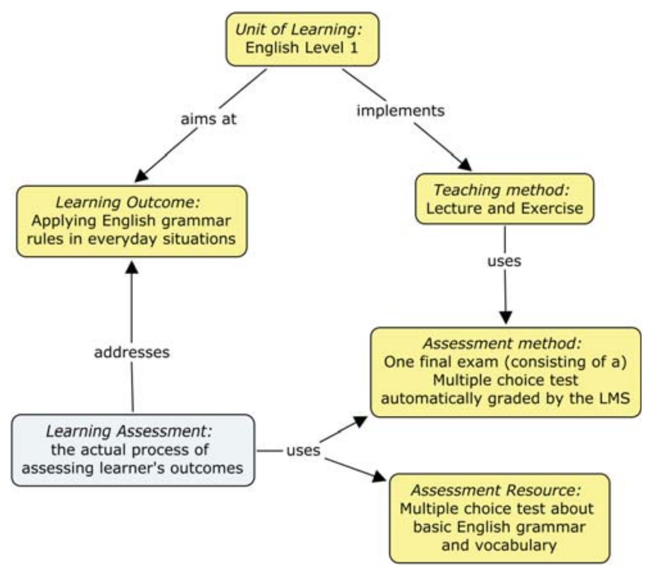

Figure 4 Outcome based assessment case study

IV. Application Scenario

The following application scenario illustrates the benefits of the proposed model for various stakeholders in the educational process both at design-time and runtime.

A. Context

A teacher is preparing a unit of learning about programming in the assembler language for the Pentium CPU. Intended learning outcomes at the end of the unit of learning comprise the following:

- *Knowledge*: being able to identify and name elements of the Intel Pentium CPU architecture
- *Knowledge*: being able to state the instructions of the assembler language
- *Skill*: being able to code a simple program in assembler including loops, conditional structures, and routines

B. Design time: preparing the learning activities

The teacher wants to provide the students with a formative assessment to be taken during the learning process, consisting of a test so that they can check their understanding of the basic concepts. The teacher, using a search functionality in an LMS that is connected to the Open ICOPER Content Space (OICS), searches and retrieves a test adequate for the domain, level and learning outcomes requirements.

The teacher also needs to include a final learning assessment which assesses if the students have successfully achieved the intended learning outcomes declared in the unit of learning. Thus, she searches the OICS for assessment resources adequate for the unit of learning (skill: being able to code a simple program in assembler). She finds a resource consisting on an assembler programming project (which should be developed by the students) accompanied by a rubric that will enable her to evaluate the validity and completeness of the coded program.

C. Runtime: updating the learners' leaning outcomes profiles

Once the unit of learning is completed, the learners' learning outcome profiles are automatically updated, for the learners who have successfully passed the learning assessment used in the unit of learning, to reflect the newly achieved learning outcomes with additional associated data like evidence records (e.g. certificate) and context (e.g. subject domain) of the unit of learning.

D. Conclusions

The scenario discussed above illustrates some of the advantages of the proposed unified model, which benefits a variety of stakeholders.

Authors and *teachers* can search for assessment resources adequate for appraising the achievement of the intended learning outcomes; either for supporting the learning process (by detecting gaps between the intended learning outcomes and the actual ones achieved by the learner), or for certifying the final achievement of the learning outcomes at the end of the process. This facilitates the design process.

Learners also benefit as they are provided with quality material which supports their learning process for achieving the desired learning outcomes, as re-use is expected to help refining and improving such resources. Additionally, learners would also have a learning outcome profile which reflects their state of achievements and is kept up-to-date automatically and transparently.

Finally, *other stakeholders* such as companies or employers may also benefit from applications of this unified model. The learner's learning outcome profile would provide a potential employer the information required for assessing the applicant's suitability for a given position. Additionally, knowledge management programs aim to provide (among other objectives) specific training to the employees according to their actual knowledge, skills and competences and the requirements posed by their job positions. Learning outcomes-based assessment would allow searching for specific assessment resources in accordance with knowledge gaps and define tailored training programs. Learner's assessment is perhaps one of the areas where this combination is proving to turn into a richer symbiosis. Information and Communication Technology (ICT) strongly facilitates the management of the assessment process, leveraging the teaching burden associated to it [19]. But apart from the logistic support, ICT empowers potential benefits of the assessment process (for example, fostering immediacy of feedback) as well as open new scenarios for student evaluation.

V. Conclusions and Future Work

Educational processes are shifting towards a learning outcomes based approach in the active learning model. Knowledge, skills and competences achieved by the learner play an increasingly important role as the professional life introduces new lifelong formative challenges. Learning assessment cannot be oblivious to this paradigm shift, either aiming at formative purposes in active learning or as a mechanism for accrediting the attainment of knowledge, skills and competences.

In this paper, a novel theoretical framework has thus been proposed for learning outcomes based assessment. The proposed ICOPER model captures the influence of learning outcomes in the learning assessment process, which determines appropriate assessment methods and resources to be used. Assessment plays a key role in acknowledging that a learner has attained the intended knowledge, skills and competences. This model is contextualised in the broader framework of outcome based learning, based on the unit of learning as the means by which the learners achieve such intended outcomes. Illustrative examples of scenarios and case studies are also provided to clarify the practical use of the model.

Future work includes the definition of a detailed taxonomy of assessment methods and an analysis of the appropriateness of the different assessment methods depending on the learning outcomes to be assessed. Also, ongoing work is aiming at developing a complete metadata model and binding that enables implementation and interoperability of the concepts in the unified ICOPER model in educational resource repositories (such as the Open ICOPER Content Space). Such analysis will provide a best practices guideline for learning outcomes based assessment that facilitates the actual deployment of this approach.

Current Issues With Assessment Formats and Interoperability

Abelardo Pardo, Álvaro Agea, Carlos Delgado Kloos
Department of Telematic Engineering, Carlos III University of Madrid, E-28911 Leganés (SPAIN)

Abstract—**Assessment has been one of the areas in computer supported learning where technology has been quickly deployed. Support for computer based assessment is found not only in all Learning Management Systems, but also as stand-alone tools. This large number of tools has led to the appearance of a large number of formats to store, retrieve and exchange assessment material. Although institutions such as the IMS Global Consortium have proposed specifications (e.g. IMS QTI) aimed to facilitate the exchange of this material, in the actual landscape, there are still too many formats that significantly hinder the reuse of this material. In this paper an analysis of the implementation of these formats is described.**

Keywords-assessment format, interoperability, IMS QTI

I. Introduction

In today's e-learning, the advance and support offered by technology is very uneven. Some aspects of a learning experience are fully supported by technology (for example assessment), whereas in others, technology is barely beginning to appear (for example, integration of generic services in a learning environment). Assessment has been one of the aspects where technology has had a very strong presence from the early times. Some computer-based assessment tools even pre-date the appearance of some learning management systems (henceforth simply LMS).

The issue of storing assessment material is intrinsic to computer supported assessment. Once a scenario where any form of computer supported assessment is performed the problem of how the material is stored and retrieved already appears. There are two dimensions in which this problem can be solved. The first one is considering only a single tool or product. In other words, given a tool for computer-based assessment (or an equivalent functionality present in a LMS), how can the assessment material be stored and retrieved by any instance of this tool.

But this issue, combined with the wide variety of solutions for computer-based assessment that are currently available, poses a second problem, that of interoperability. Suppose a scenario where Institution A has a rich set of assessment material that created using Tool A (or its equivalent service in the corresponding LMS). Analogously, Institution B has also a rich set of assessment material, but it was created with Tool B. Both tools are totally unrelated and therefore, store the assessment material in completely different formats. So far, none of the tools has acknowledge the other format as one that is supported. These two institutions have identified the potential of sharing this material, but it is not possible with the current formats.

The problem, then is to go beyond formats locally used by specific tools to a format that allows the exchange of assessment material among unrelated tools. The approach followed by international bodies such as the IMS Global Learning Consortium [1] has been to gather a set of experts in the field, analyze the current scenarios where computer-based assessment was being used and propose a format such that any tool would be using to both export and import assessment material. This format proposed by the consortium is IMS Question and test interoperability [2], henceforth IMS-QTI.

The appearance of this specification changed the landscape of assessment formats. For any tool providing computer-based support, the question of supporting IMS-QTI appeared. But the evolution of this specification over the last nine years shows numerous examples of the effect of several design decisions. Of course, it easy now to evaluate how appropriate a specification is to represent assessments. But computer based assessment has reached a stage which can be considered main stream and therefore there is some value in looking back and see how the once foreseen effects really shaped. In the following sections an analysis of the current landscape with respect to this format is analyzed. First a brief description of the aspects covered by IMS-QTI and the different available versions is given. Then a brief account of the type of support offered by the different tools is described. It follows the description of a case study in a scenario in which true cross-platform interoperability was needed. Finally, some conclusions are proposed to improve the level of interoperability among current computer-supported assessment tools.

II. IMS Question and Test Interoperability

The IMS Question and Test Interoperability format was initially proposed by the IMS Global Learning Consortium and its version 1.0 was released as a public draft in February of 2000 and as a final specification in May of the same year. The proposal was based in QML, a structured language proposed by Question Mark Computing Ltd [3] in 1997. The idea behind this format is to capture the structure of assessment material with as least information as possible about how it should be visualized. The format used a syntax similar to an XML document, and even an XML Schema definition has been published.

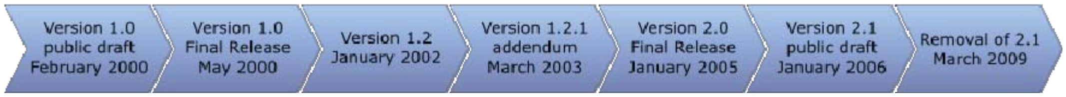

Figure 1: Evolution of the Question and Test Interoperability Specification

In general, IMS-QTI describes the structure for representing two elements: the question, and the assessment. The structure of a question includes information about the body of a question, possible answers, feedback and even grading procedures. The structure of assessment is more related to how a set of questions are organized, subdivided into sections, and how are the values obtained from individually grading the questions are combined to obtain an assessment grade. With this structure, the objective of this format was to allow the exchange of three elements of computer-based assessments: items (that is questions), assessments (different groups of items) and results.

After the first version, the consortium published version 1.2 two years later in 2002 which included a much more comprehensive set of documents describing its structure. Aside from a description of the information model, XML bindings and a best practice guide, version 1.2 also included documents describing how to select and order items, how to process outcomes, how to report results and an overview document. The evolution of the specification is shown in Figure 1.

But the aim to cover the three aspects of assessment management (questions, assessments and result manipulation), led to a specification that was fairly elaborated. As a consequence, a simplified variation of QTI version 1.2 was released with the name of QTILite. QTILite is a subset of QTI version 1.2 that represents an entry level into version 1.2. The main simplifications were:

- Reduced number of question types: Yes/No, True/False, Likert scales and multiple choice.
- Simple response processing with default mechanisms.
- No support for hints, solutions, etc.

As a consequence, tools supporting QTI had to choose between two versions (one a subset of the other) to guarantee some degree of interoperability. Some small amendments were introduced in Version 1.2 to obtain version 1.2.1 in March of 2003.

The next significant leap in the specification came with version 2.0. The assessment process needed to be taken into account but as yet another piece of the complex mosaic of e-learning procedures. For example, an assessment could be included in a more complex set of activities that need to be sequenced following certain rules. The result of an assessment could be used to decide the sequencing of activities (as it is conventionally done in multiple learning scenarios). Version 2.0 was conceived to accommodate this new emerging reality as well as to polish certain aspects from version 1.2.1. This major version change came when several commercial e-learning systems had already included support for QTI v 1.2.1 and meant an additional effort to accommodate the proposed changes.

But to guarantee that this reviewing process reached the e-learning community quickly, the scope of the changes was intentionally reduced to individual assessment items. The aspects of aggregation of items into sections and assessments and result reporting were left out of the review.

These two aspects were reviewed and published as a first public draft (revision 2) a year later in June 2006. Both aggregation and result reporting support were reviewed. At this point, tools supporting version 2.0 of the specification were scarce, and the lack of activity in this draft to become a final specification led the consortium to remove it. The reason was the lack of activity to push this specification forward. As a consequence of this decision, numerous institutions complained that they needed the specification to guide their current developments. As a conclusion, it seems that there is a number of companies and institutions using version 2.1 of QTI, but the participation of these institutions in the process to push the specification to a final stage is scarce. Although the specification was later re-published, the consortium warns that as is, the document is incomplete and in the process of evolving it based on input from the market participants.

Angel		2.1
ATutor	1.2	1.2, 2.1 (experimental)
Clix	1.2	1.2
DB Primary		2.0
Diploma	1.2, Lite	1.2, 2.1, Lite
Dokeos	1.2	1.2, 2.0
.LRN	1.2	1.2
Moodle	1.2	2.0
OLAT	1.2	1.2
QTI Tools	2.1	2.1
QuestionMark Perception	1.2	1.2
Respondus		1.2
Sakai	1.2	1.2

Table 1: QTI support in different tools

The future of the QTI specification is a bit uncertain. Although version 1.2.1 seems to be widely used (the IMS Common Cartridge initiative [5]includes it as part of its formats), and the need for an improved version is perceived, there is not a clear path on how to obtain such improved version.

III. TOOLS SUPPORTING QTI

With this landscape, tools for computer-based assessment started to choose which version of the QTI specification support. A summary of this support in only a subset of e-learning tools is shown in Table 1.As it can be seen, version 1.2 achieved a fairly high level of support. This support has been increased as a consequence of this version being in included as part of other initiatives within the consortium such as IMS Common Cartridge [5]. This format bundled together two previously created specifications, IMS Content Packaging version 1.2 and IMS QTI version 1.2.1 together with additional meta-data to manage learning content from the point of view of the producers as well as the users.

The final consequence of this situation is that when it comes to capture the structure of assessment material such that it can be exchanged among different tools, the most widely supported format is version 1.2.1 which has not evolved since 2003.

IV. ASSESSMENT INTEROPERABILITY: A CASE STUDY

In order to experience first hand the problems that arise when trying to exchange assessment information among unrelated LMSs, an case study was prepared. The study has been carried out within the frame of the ICOPER project. This project is a Best Practice Network that started in September 2008, funded by eContentPlus programme of the European Commission. As part of the ICOPER objectives, an analysis of the best practices in the scope of assessment, and more precisely in the issue of interoperability has been proposed. The project must explore also the different level of adoption of the specifications and standard currently used in e-learning, and the issue of interoperability has been identified as one of the main burdens to overcome to increase adoption.

The case study was designed to include several institutions related to higher education (both educational institutions and commercial vendors) and explore the problems that appear when trying to exchange assessment material. The organizations involved in the study were the Open University of the Netherlands, Giunti Labs, IMC Ag and Carlos III University of Madrid.

The objectives of the study were:

- Obtain a sample of the tools and formats being used to perform computer-based assessments
- Identify the interoperability problems

The type of interoperability problems that were specifically targeted were:

- Exchange of assessment material at the level of "exams", therefore, not only at the level of question items.
- Exchange of generic exam annotations.
- Connection with Learning Outcomes.

The LMSs used by the institutions participating in the study is shown in Table 2.

	Moodle	.LRN	Clix
UC3M	X	X	
Giunti Labs	X		
OUNL	X		
IMC			X

Table 2: LMSs used by the different institutions in the study

The first step was to analyze the import/export capabilities of the LMSs to see which information exchange flows were possible. The format that was commonly supported by the three sampled LMSs was (as expected) IMS QTI. The support for QTI import/export in its different versions is shown in Table 3.

The first observation from the table is the total absence of any kind of support for QTI version 2.1. These three LMSs were implemented when version 1.2 was available, and the migration to the new format was not considered. A different situation appears when considering QTI 2.0. A partially implemented export module was found but with significant shortcomings. The module simply placed a subset of the information contained in the questions in certain special fields of the QTI file but certain special information was not included. The file exported by Moodle then, was not possible to be used in any other platform (nor even Moodle itself because it lacked the import functionality).

	QTI 1.2	QTI 2.0	QTI 2.1
Moodle	No	Export	No
Clix	Import/Export	Import/Export in development	No
.LRN	Import/Export	No	No

Table 3: Import/export support of different QTI versions

Several attempts at providing support for QTI in Moodle were detected in the developers community, but none of them was considered mature enough to be considered. A special situation was seen with respect to the Respondus [7] tool. Respondus is a tool for designing and deploying assessment in e-learning platforms. In principle the product is self-contained, that is, it offers an authoring environment to produce assessment and a deployment environment to use them in a learning experience.

But in order to increase the interoperability, the company produced what is called a "Respondus plug-in" for Moodle that imports assessment material create with these products into a Moodle platform using QTI version 1.2. Being a separated assessment product, the company already has modules to incorporate assessment material created with their product suite into the main LMSs (Atutor, Blackboard, eCollege, etc.) but in the case of Moodle, and because the product is open-source, the uploading of material is based in QTI version 1.2.

This plug-in could be considered as a suitable vehicle to import generic QTI documents into Moodle, but a closer inspection quickly revealed that the QTI produced by

Respondus to be then imported into Moodle was not compatible with the other LMS in the study. The company itself clarifies that the module is not a regular QTI importer but one specifically for the Respondus system. The main reason to avoid claiming to have a generic QTI version 1.2 importer is because only certain uses of the specification are supported. A generic QTI file using other aspects of the specification cannot be handled by this importer.

As with the rest of LMSs, in principle, a potentially effortless exchange of material was possible between .LRN and Clix (if QTI version 1.2 was used). However, upon a closer inspection, again the difference in implementation in the import/export functionality of different platforms made this possibility non-trivial.

The main difficulty when exchanging assessment material is the level of flexibility offered by the specification. There are several forms in which a set of questions making an assessment can be included in a file and comply with the QTI specification. The existence of these different versions, although potentially positive from the point of view of flexibility it is a huge obstacle for interoperability. The amount of possible scenarios to consider when writing an import module derived from the specification rules it too complex.

Furthermore, the specification, to increase flexibility, leaves a large number of elements totally optional. This functionality also poses problems. For example, institution A exports a large number of true/false questions, but none of the questions in the file mark the correct answer. The file would still be in compliance with QTI, yet, most of the current tools would rule it unusable, or even worse, produce an incorrect import.

The trade-off between flexibility and widespread use needs to be carefully considered. Widespread use is very important for a specification such as QTI to be truly useful. But if the adoption is in part fostered by a specification with too much flexibility in its definition, the adoption will be uneven and interoperability will be significantly reduced.

A promising venue that is being explored to compensate this situation is the use of "profiles". A profile is a simplified or reduced version of the specification derived from a concrete scenario of application. Several initiatives have appeared that have contributed different QTI profiles such as, for example, questions in the area of mathematics.

The interoperability problem can then be re-stated in terms of profiles. Two platforms may exchange assessment related information effortless as long as they are encoded using the same QTI profile. But again, the essence of a common specification is lost.

Together with the problems when exchanging information about assessment, the study case revealed some interesting new venues to explore. None of the institutions participating in the study was annotating assessments or question items with information obtained from their use.

Although QTI, with its great flexibility, allows the inclusion of almost arbitrary meta-data, this type of annotations, although perceived by all participants as relevant, were not present in any of the used samples. The process to back-annotate assessments is still far from main stream and requires still an intuitive tool to facilitate the work. This type of annotation becomes very important when assessment material is shared in a wider scope such as federated searches of learning material.

There are currently multiple initiatives to offer federated content available to multiple institutions. The key feature to offer is a powerful search functionality. But a powerful search itself is based in a powerful labeling of the pool of available objects.

|In the context of assessment, if a teacher is searching for relevant assessment material, the search engine should know what type of questions are included in an assessment, if they have been used successfully, the type of scenario in which they were used, etc.

An the third shortcoming found in the study is the lack of connection between QTI and the higher level instances in which it develops. An assessment is usually tied to some sort of learning unit. Even worse, the objectives of a learning unit (in the most general sense) should be connected with the assessment methods, and more precisely with assessments described in QTI.

But this connection between assessment and learning outcomes (learning results, learning objectives, etc) is totally absent from today's elearning landscape. In the future, when massive amounts of learning resources are made available, the search engines should find the appropriate resources to achieve a given objective and attach the appropriate assessments to them. In order for this relation to be detected, it needs to be explicitly included in the document capturing the assessment.

V. RECOMMENDATIONS TO ENHANCE INTEROPERABILITY

The case study described previously showed several venues that can be explored to increase or enhance the level of interoperability of QTI and assessment material in general. Although we are certain that perhaps all of them were discussed by the groups of experts that designed QTI, we think there is some value in reviewing them, specially after the significant changes that re-shaped the e-learning landscape in the last years.

A. Simplification of the specification

The specification tries to cover with its structure a large number of scenarios with almost no adjustments on the scenario side. Although desirable, this is unrealistic. A simple specification capable of capturing all scenarios, even when some adjustments are needed should serve the purpose of interoperability better. Profiles are an example of this pragmatic approach. If the specification comes closer to these profiles (yet remaining unique), the need for a special solution for a specific context might decrease.

B. Focus on the essential aspects

The aim of the initial specification was to cover perhaps too many aspects of the assessment scenario. One example of the vast set of possible situations is grading. The number of possible grading policies is enormous. Providing a specification to describe all of them is equivalent to design a new programming language, or some new calculus notation. In our experiences, the basic functionality expected from the teaching staff when it comes to exchange assessment material is to be able to obtain a set of questions and answers from a given topic from a colleague. The instructions about how this material is graded is typically considered as highly dependent on the context of the assessment and therefore not perceived as essential.

Something analogous happens with the structure used to group a set of questions. In a certain course in an institution, a set of questions should be organized with a fairly special structure. If the course is divided into three topics and they need to be passed separately, the exam should reflect this situation. But when these questions are re-used in a different institution, these details are very unlikely to be re-used. Thus, a format leaving out this information would have a higher probability of being used.

A similar situation appears when assessments are transformed in “sequences”. That is, rather than having a set of questions that are shown to the students all at once, there is some agent in charge of showing some of these questions, and even deciding which ones to show. This type of functionality, as in the case of the exam structure is highly dependent on the context. A better approach could be to adopt a “separation of concerns” approach. The set of questions are perfectly captured by a specification, and the different sequences to consider are the role of another specification that can be used in combination with the previous one. With this approach, institutions only interested in the plain exchange of questions would still be tempted to adopt the appropriate format.

C. Follow an incremental approach to deployment

This aspect is related to the previous one. For the sake of completeness, it might be necessary to tackle some additional aspects surrounding assessments. In the previous section we argued that a clearly separated set of formalisms could be more appropriate. Together with this approach, a gradual deployment of these different specifications could greatly increase the level of adoption.

More precisely, if institutions have a simple path to question interoperability and make that an essential part of their day to day operations, they could be less reluctant to adopt a specification than enhances their procedure.

For example, if institutions exchange questions and answers with a simple specification, they would be more likely to adopt a specification to relate those questions with precise learning objectives that are already included in their courses. Providing a global and exhaustive solution in one single specification can be perceived as a much steep adoption curve and requires a more intense effort.

D. Acknowledge context without increasing the complexity

Considering assessment as a stand-alone e/learning process is no longer acceptable. In the past, many courses would perform assessment procedures in platforms or contexts completely disconnected with the rest of a learning experience. But a proper design methodology needs a strong binding between learning objectives, activities, and assessment. Any specification to formalize assessment must be aware of this connections, although at the same time should minimize its impact in the complexity. Connecting an assessment with a set of objectives not only makes sense when designing a learning experience, but also allows that assessment to be easily found when searching for material in a much larger repository.

But the inclusion of these connections cannot mean a significant increase in complexity. Perhaps the most appropriate approach is to decouple these connections into its own formalism that may flourish on its own depending on the adoption, but at the same time maintains question management at a reasonable level of complexity.

VI. Conclusions

A review of the most important issues in the context of assessment formats has been presented. Although the IMS QTI specification was conceived to offer a formalism to facilitate the exchange and reuse of assessment material among different platforms, the landscape after several years of evolution is somewhat confusing. QTI Version 1.2.1 has a significant level of support, although its intrinsic degree of flexibility turns into difficulties when it comes to implement a fully compliant import/export agent in a tool.

The scope of the specification as well as the number of structures and annotations that are considered optional offers a wide spectrum of possible solutions to encode assessment material. This richness has turned against interoperability as the complexity derived from this large number of solutions needs to be absorbed by the import/export agents.

A case study has been presented in which four institutions related to education (two universities and two e-learning commpanies) tried to exchange assessment material based on the IMS QTI specification. Three learning management systems were studied from the point of view of compliance with the process.

The study clearly shows the complex landscape derived from the flexibility of the QTI specification. Only two of the three platforms considered had the functionality to import/export assessment material in a common version of QTI. And still, the process could not be accomplished automatically because the resulting QTI files needed to be manipulated to accommodate certain specific features of the import/export modules of the other LMSs.

The recommendations to increase the adoption of QTI derived from this study are presented along four main strands|: simplify the specification, focus on the essential aspects of the assessment procedures, follow an incremental approach for deployment and acknowledge the context in which assessment is taking place without increasing the complexity.

***Abstract*—This paper presents a teaching experience related to the learning methodology in embedded systems within the European Higher Education Area (EHEA) frame. A Problem Based Learning (PBL) methodology has been applied for combining two courses of a bachelor degree in computer systems. The objectives are the integration and application of previously acquired and new knowledge to create an application for the supervision and control of a mobile robot. Technologies used during the development of the project include real-time programming using Ada language, digital control theory and communications.**

***Index Terms*—PBL, real-time systems, digital control, supervision.**

I. Introduction

TRADITIONALLY, technical courses at engineering degrees are organized following a logical sequence, being the earlier the base for the later. However, almost no effort is put on presenting the students with the idea that the integration of the different knowledge and technologies acquired along the different courses, is a fundamental skill in order to be able to solve complex multidisciplinary problems, like the ones they will have to face at disciplines like systems engineering, computer systems engineering, or embedded systems engineering [1]. After completing an engineering degree, the students end up with a wide collection of weakly related concepts and skills organized as watertight compartments [2]. This paper describes a model to mitigate this main drawback by combining two courses in a collaborative way. These courses are Supervision and Control of Systems (SCS) and Real-time Systems (RTS) which are part of the Computer Systems degree offered at the Bachelor Technical School of Computer Systems Engineering at the University of Oviedo, Spain.

The PBL methodology has traditionally been used in higher education, mostly in medical training, and has proof to be a very powerful contextual, collaborative and constructivist learning model [3]. The PBL methodology [4] allows posing a complex problem, which requires integration of knowledge, before learning [5]. Following this methodology, the students are able to discover that in order to solve the problem they first need to acquire new knowledge. However, an eye must be kept on PBL detractor's arguments which suggest that students taking courses based on PBL model show potentially significant gaps in their cognitive knowledge base and do not demonstrate expert reasoning patterns [6].

A blended learning model was adopted by both courses in order to get the best from PBL and minimize its drawbacks. On one hand, PBL was selected as the learning methodology for the hands-on laboratory classes, so the students were able to develop their constructive, self-directed, and collaborative capabilities. On the other hand, a more classical learning methodology was maintained for the theoretical classes, thus assuring that the students developed their cognitive knowledge base and expert reasoning skills. Besides, an innovation was introduced to the PBL methodology so multidisciplinary problems solving objective was achieved: both courses shared a common complex assignment by yielding part of their class time for its commissioning, merging together students from both courses at the same laboratory and class time. The professors of both courses collaborated by merging partial objectives into a common global one, and working side by side as tutors or facilitators.

A common assignment was selected as the final evaluation method because implementation of real-time control systems requires, in general, the interaction between different process layers: real-time control of individual systems, real-time coordinated control and supervision. Often, these layers are programmed in different languages and require the use of different tools in order to build the overall system. The inner control loop is usually implemented in a specific hardware, such a microcontroller or a DSP. In these systems, the programming language is usually C or assembler. For this particular project a DSP microcontroller programmed in C was chosen. For the outer control loop, there are many possibilities depending on the particular application. The running platform can be a computer, an embedded system or a PLC. The platform requirements at this level are related to the need of communication with both the inner control loop and the supervision layer and to the tasks synchronization. A common used language for fulfill this requirements is Ada [7], [8]. Finally, the supervision layer is usually implemented in a language allowing designing the graphical user interface (GUI) as well as tools for data visualization and storage. Common choices are C++, C# or Java. For the development of this course we have selected C++.

In order to carry out such assignment the students must not only apply the concepts acquired at these subjects, but also using some other knowledge from other courses of the degree. The students need to search for new sources of knowledge, to combine different sources of information, to make use of a wide variety of technologies, to improve their capability of self organizing and self learning and to develop their skill of team working. Each student (or group of students) must reach a milestone before going ahead with the next. One of the evaluation criteria used was to measure how much help from the professor was needed by the student to fulfill each milestone. Every student has to register her/his work progress in a portfolio clipboard [9], which includes: managed sources of information, tasks, achieved goals, acquired knowledge and main difficulties. The new teaching methodology requires a more active role from the student in the learning process. A big effort was invested in carefully explaining the students the new rules: the milestones protocol and the evaluation criteria. By doing so, the students evolved from a tolerance attitude into a proactive participative one, making the experience theirs. At the end of the course, every student was faced a course evaluation form containing questions to measure out their view of the experience. Most of the students found that collaborative assignments help them to improve their skill of solving multidisciplinary problems.

This paper presents a collaborative experience between two courses related to the embedded systems engineering, which aim is to complement engineering student's knowledge acquired at the different degree courses, with the capability of facing complex multidisciplinary problems. PBL is used as the learning methodology for the hands-on classes. The way both courses collaborate and how PBL is extended is explained then. Finally, student's opinion about this experience is analyzed by means of one questionnaire.

II. Courses Description

A. Students

The students can take one or both courses. These two courses are in the third year of the Computer Systems degree. Before these topics, students are supposed to have passed topics in programming methodologies, electronic technology of computers, algorithms, data structures, industrial computing and networks.

One might think that the best learning outcomes will be obtained if all students take both courses, so all of them would have studied the theoretical concepts of both courses before facing the final assignment. But the experience has shown that because of this collaborative model, even in the worse scenario where no student has taken both courses, it produces great benefits, because it allows them to develop their team working skills. The key idea is to set up balanced groups made up of students from both courses. No group must be made up of students taking only one course. Those students that do not take one particular course get its basic concepts by interacting with those that do take it, because they need to understand that part in order to understand the whole picture. It is true that such students are not going to develop their expert reasoning at that particular topics of that course, but still they will get a flavor of them, that will allow them knowing its nature, its application, and its justification, and maybe raise their interest in that field, with little effort.

B. Courses organization

Both courses duration is 4.8 ECTS and are organized as follows. There are four hours every week separated into two lectures of two hours each. During the first bimester, first lecture is on theoretical content and second one a hands-on laboratory. It is worth noticing that even at the theoretical lectures students are in front of the computers. Every key aspect of the systems control or real-time theory is tested using computer simulation. Simulink was used for the systems control part and Ada over Linux for the real-time one. During the second bimester, all four hours are laboratory ones in order to provide the students with enough time to make the final assignment project.

Theoretical contents during the first bimester are headed to make the students learn the basics on real-time and embedded systems, following the timetable shown in Table I.

Course materials are stored in a mediaWiki [10]. The use of a wiki allows to easy share materials needed in both courses as well as materials from other courses taught within the Department.

C. Assessment method

Engineering educators recognize that student's exams, class exercises and homework can effectively measure mastery of facts and formulas. However, these sorts of assessments do not encourage students to develop their analytical capabilities as they do not measure the student's skills to understand and apply what they had learned. Nowadays, industry is demanding engineers with a set of skills that are beyond the knowledge that a student can achieve studying a book. In contrast, projects, allow educators to emphasize "the important role that experience plays in the learning process" [11]. We focus our subjects in problem based learning. Our teaching style combines the lectures and labs with the development of some projects. Usually, the students do not have all the pieces to develop their assignments, but need to search in the additional contents presented in the web page of the subjects, in Internet or other media to achieve their projects. Obviously, a traditional exam is not a valid media to measure the efforts and the learning of the students in the problem based learning. For this purpose, we use a portfolio. "A portfolio is a purposeful collection of student's works that demonstrate their efforts, progress, and achievements in selected areas of the curriculum" [12]. It can include the best works, but also preliminary designs or any artifact that could show the progress of the student. Usually, most of our students focus their efforts in programming instead of thinking or analyzing the best solution. Classical assessment based on exams does not promote the critical thinking. Many times when they do team work their tactics is dividing and joining. Each member of the group focuses in one aspect of the problem. This is not the best approach to team working. By using a portfolio, the students can incorporate the results of their meetings, the changes that they have agreed and how they are learning.

Besides, with the portfolio development, the students can improve their ability on writing technical documents. This is recognized as one of the key aspects needing improvement on the new engineers [13]. Portfolios have also been suggested as a direct source for research into student knowledge [14].

The most difficult aspect of a problem based learning course is determining if the desired goals and objectives have been

achieved. Student's feedback is used extensively to evaluate the performance of both the teaching staff and the subject. Again, traditional assessment methods reveal as a poor tool to determine the achievement of the objectives. Portfolio is an efficient way to demonstrate the achievement of the skills that are signaled as objectives to the course. Student portfolios are listed as a possible means of assessment under the basic level accreditation criteria according to the Accreditation Board for Engineering and Technology (ABET) "Engineering Criteria 2000."

We are using electronic portfolios in a semi-structured way. Because that is our student's first attempt, we suggested them some minimum elements, thus giving them a template than they can freely improve. The student portfolios, include student goals for learning, works in progress, and reflection on the work and processes. Table II shows how any aspect of the evaluation is reflected in the portfolio information.

The use of the portfolio as the evaluation method has proved to be quite satisfactory. The tasks the students needed to complete has been achieved and the implication of students was high, according to the students response shown later in section V.

III. LECTURES

A. Lectures description

1) Supervision and Control of Systems:

- Basics on Control Systems: Introduction to the problem of control. Through the use of a model that does not incorporate dynamics, the effects of disturbances and open loop/close loop behaviors are explained.
- Introduction to Dynamic Models and Feedback: The model presented in the previous lecture is extended in order to incorporate dynamics. Linear and invariant systems. Lapace transform and impulse response. Effects of dynamics in the velocity control of a vehicle are shown.
- Time response: Analysis of time response when arbitrary input is applied to a system. Convolution integral. Step and ramp response. Systems order. Position control of a vehicle.
- PID control: Impact of controller actions (P,I,D) in the close loop response of a controlled system. Reference tracking and disturbance rejection. Control design for electromechanical systems: Truxal pole cancellation. Formulation and implementation of a speed control for a DC motor.
- Introduction to digital control: Analog control vs Digital control. Additional elements in the control loop for digital control implementation. Signal Sampling: sampling theorem and aliasing effects. A/D conversion. Quantization effects. D/A conversion and PWM.
- Discrete systems: Sequences and discrete systems. Difference equations. Discrete time implementation of integral and differential operations. The discretization problem. Linear and Tustin approximations.
- Digital control implementation: Foundations for using the theoretical concepts in a microcontroller based system. Events driven programming. Interrupts. Program structure for digital control realization.
- Basics on supervisory control and data acquisition (SCADA) applications: data acquisition module, graphical representation of the process, alarm handling, data base module, graphical representation of signals, etc.

2) Real Time Systems:

- Introduction to Real-Time Systems: Description of the characteristics and main properties of RTS.
- Languages for RTS applications; Ada: Description of the desirable characteristics that a RTS programming language must cover.
- Reliability and error processing: Study of the aspects

related to the construction of free error programs and what can be done when errors appear during the program execution. Ada mechanisms for error management are shown. Fault tolerance and exceptions handling.

- Concurrency: Concurrent aspects of the RTS. Tasking. Interprocess communication. Shared memory and programming with Protected Objects in Ada. Interprocess communication and message passing mechanism, rendezvous in Ada. Practical cases solving.
- Real-Time Programming: Time management, programming applications using time functions. Practical cases solving, time-outs, asynchronous transfer control, periodical tasks programming, sporadic tasks programming. Scheduling and time requirements. Solving priority inversion problem. Ada programming facilities to solve all these aspects.
- Low level software programming: Requirements to constructs programs adapted to the characteristics of hardware devices. Interfaces between Ada and C.
- Real time software design: Hrt Hood Methodology. Study of a practical Case.
- Real time operating Systems: Description of the of the desirable characteristics that a RTS Operating System must has. Examples.

B. Labs description

1) Supervision and Control of Systems:

- Matlab/Simulink (I): Introduction to Matlab/Simulink. Implementation of a velocity control for a vehicle without dynamics. Comparison between open loop and close loop control strategies.
- Matlab/Simulink (II): Transfer functions in simulink. Import of model parameters and export results from/to Matlab. Implementation of a velocity control for a vehicle incorporating dynamics.
- Analog units: (Fig. 1). Time response of first and second order dynamic systems by using analog electronic circuits. Measurement of electrical variables using a digital scope. Measurement of system properties such a settle time, peak value, overshoot and final value.
- DC Motor Control: (Fig. 2). Control of a DC machine using analog units and *Feedback*® mechanical unit. Current control, velocity control and position control. Relation between the electrical variables (armature current) and mechanical variables (speed/position). Selection of controller's gains an impact on the control dynamics.
- Microcontrollers (I): DSPic 30F6010 features. Introduction to MPLAB. Configuration of I/O ports, Timers and AD converter. Using the simulator for testing purposes.
- Microcontrollers (II): Configuration of PWM and motor PWM modules. Serial communications. Interface between Matlab and the DSPic.
- DC motor digital control: (Fig. 3). Implementation of a speed control for a DC motor using the DSPic 30F6010. A low level library for programming the dspPIC has been developed by our own, so making possible for the students to focus on the control problem instead on the digital system hardware configuration.

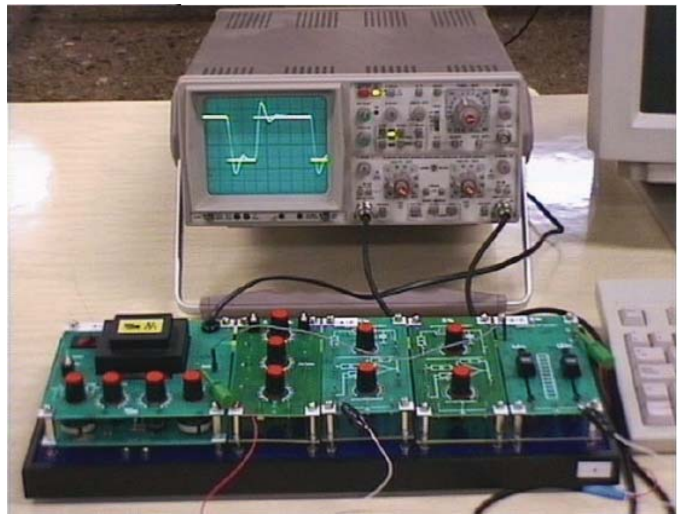

Fig. 1. Analog units for system response measurement.

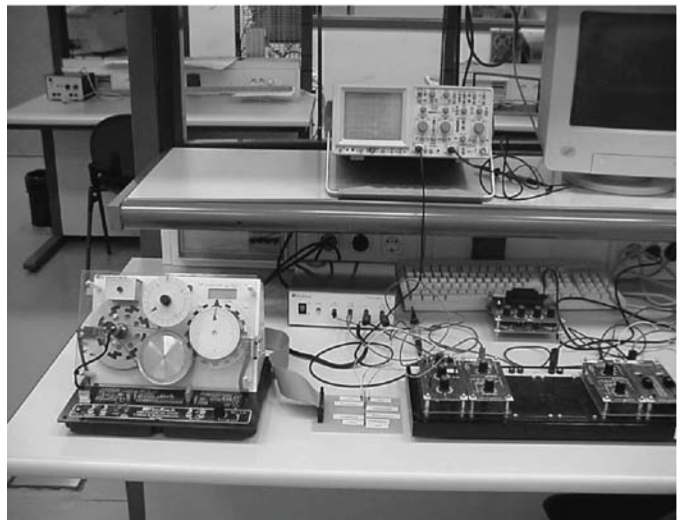

Fig. 2. *Feedback*® mechanical unit educational system for the control of a DC motor.

- SCADA (I): Design and implementation of the skeleton of the data acquisition module using the publication/subscription paradigm. TCP/IP technology is used to implement the communications to the Ada control layer.
- SCADA (II): Design and implementation of the skeleton of the graphical interface of the system that allows following the evolution of the robot.

2) Real Time Systems:

- Initial programming in Ada: Basic structures and data types to implement and Ada program. Modular decomposition.
- Fault tolerance programming applications.
- Modular programming. Generic Units and package.
- Concurrent Programming. Tasks creation. Solving synchronization problems.
- RTS Design Methodology. Using Stood to create a model to solve a RTS problem .
- Lego Sumo robot (Fig. 4(a)): Construction and programming of a Lego boot using Ada. This is a team

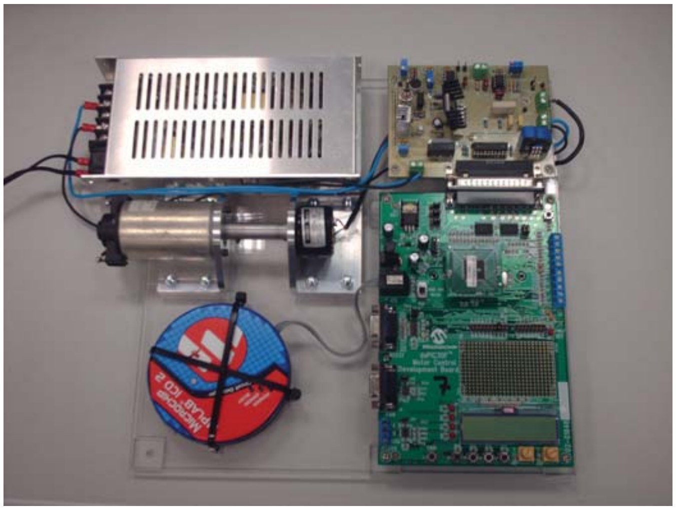

Fig. 3. dspPIC an custom board for the control of a DC motor.

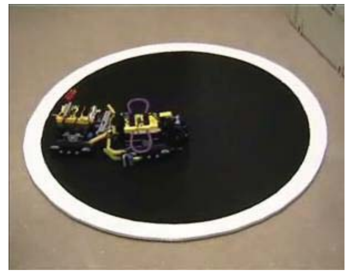
work where the students have to build their own sumo bot, searching information on the net and books, and programming them using an Ada Compiler developed by [7]. With Lego RCX is easy to construct a robot, including different sensors and motors without electrical or mechanical knowledge. This set is frequently chosen for its low cost and ease of use. However, most of the work being done with it is in teaching reactive robotic architectures, [15], [16]. As the robot is a sumo bot, its behavior depends of its rival and also on the limits of the fight pitch. In this team work students must write their portfolio to collect their advances and decisions in order to improve the original design. After a first combat they have an opportunity to re-design their bot for a new combat.

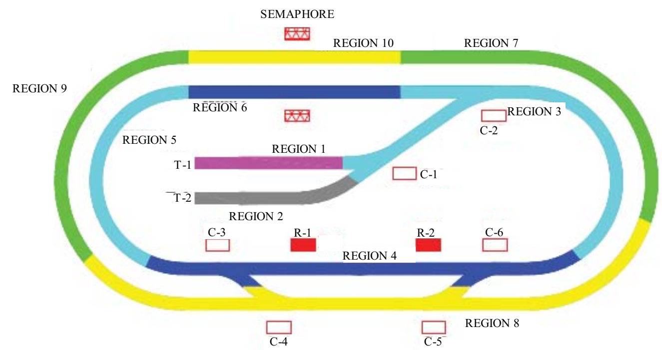
- Programming a railroad model (Fig. 4(b)): Using simulators is many times perceived as a poor experience by students due to the fact that they are only using software instead of a real plant. A richer experience is achieved when is possible to use a physical model. Model railroads provide a wealth of problems from both the discrete and continuous real-time domains. The electronics are easily understood by most undergraduate computer science students. Students are highly enthusiastic about writing software to control a model train layout [8]. We have a simple railroad with two concentric ovals and the tracks to change from one to another. Train's reference position is obtained through two cameras and a computer that process images. The team must control the movement of two trains so they follow a pre-defined trajectory with no collisions and as quick as possible. The team work must collect results at their portfolio.

IV. Final Assignment

In order to practice the learned knowledge, students are faced to a final laboratory project at the end of the semester. In this project, students work together in groups of two or three people. The main idea of the project is to force



(a)



(b)

Fig. 4. RTS labs. a) Lego Sumo robot, b) Railroad model.

the students to discover that using the previous acquired knowledge is possible to solve more complicated problems. Besides, the students need to make use of formerly acquired knowledge and technologies such as: TCP/IP communications, C++ programming, data bases, RS-232 serial communications, graphics plotting, and using a professional development suite, in this case Microsoft®Visual Studio .Net or CodeGear® Builder. Each group of students programmed the whole system and made a presentation of the work during the last lesson.

Robotics, and in particular mobile robots, is an attractive platform where the students can put in practice the topics of the course [17]. A two steering wheel mobile robot was selected as the target platform for the collaborative assignment [18]. We used several platforms and tools to integrate the different process layers described before: real-time control of DC motors (implemented in a DSPic), real-time coordinated control (last course implemented in a PC but moving to an embedded system –TS-7250 from Technologic systems®– platform running an ARM processor in the next course) and supervision (remote PC).

For the proposed problem, a hardware platform has been designed by our own. Schematic representation of the designed platform is shown in Fig. 5. As shown, two of the wheels are manned by a DC motor, each of one driven by a H-bridge module connected to the PWM outputs of a DSP microcontroller (*Microchip® dsPIC30F610*). The angular velocity of the machine is measured using a speed sensor connected to the axis of the machine. The setup for the simulation of each wheel is shown in Fig. 3.

The inner control loops are responsible of controlling the angular velocity of each machine by means of a PI controller. Both DSP's are connected through a RS-232 interface to a

PC running the higher level real-time control algorithm. This control layer is implemented in Ada and its objective is to generate the velocity commands so the robot is able to track the desired trajectory. In addition, the Ada program must communicate with the supervision layer though a TCP socket interface. The supervision layer implements the interface to the process. It includes the GUI that allows the user to select the desired trajectory to follow from a base of trajectories. It also represents the reference trajectory and the actual one. It provides storage capabilities for generated data and for the representative values of the state of the process. Relation between needed skills and assessment main tasks as well as the course where the needed skills are learnt are shown in Tables III and IV, respectively.

A. Assignment development

The first PC (PC/HMI) is running the supervision application. The application runs two different tasks implemented using threads. The main thread is the responsible of attending the GUI events, painting in the screen the output of the process and storing the results in a database. The second thread, is executing the communication task. Communication is implemented using a TCP/IP socket, being the supervision PC the client. Although the students decided what was the information needed in order to track the process, a recommendation was made to receive at least the variables containing the robot position, (x, y, θ).

The second PC was running the outer control loop, programmed in Ada. The PC was equipped and configured with the needed Ada tools. The application was executing also two different tasks. The main task, responsible of the generation of the velocity commands to the two wheels, was implemented as a cyclic task. The sample time was established to $10ms$. The actions programmed in this task were as follows: 1) read from the two RS-232 interfaces –one for each microcontroller– the actual wheels velocities, 2) using the equations described in section IV-B, calculate the actual velocity and position of the vehicle, 3) compute the new velocity commands for the wheels and, 4) write the commands to each RS-232 interface. The second task, running in the idle time, was attending the communication with the supervision PC. Communication was implemented using TCP/IP sockets and the Ada PC was configured as the server. The data sent to the client was the estimated position of the robot.

Finally, each microcontroller was running the inner control loop. This control loop was asserting that the motor velocity was following the command. Sample time for the control was set to $1ms$. Control loop was implemented in the interrupt service routine of the A/D converter. Actions taken in the routine were as follows: 1) read velocity from the velocity sensor, 2) take the reference received from the Ada through the RS-232, 3) calculate the new control action –voltage– as the output of the PI regulator, 4) update the PWM and, 4) write the measured velocity to the RS-232 interface.

B. System modeling and algorithm description

During the theoretical lessons on control theory within the SCS topic, the students are headed to the objective of designing a close-loop control for the mobile robot. Using *Simulink*®, the dynamic model of the system is explained, built and simulated. The proposed dynamic model has been taken from [18] as shown in Fig. 8. For the implementation of the control, a simplified version neglecting the feedforward decoupling mechanism shown in [18] has been implemented.

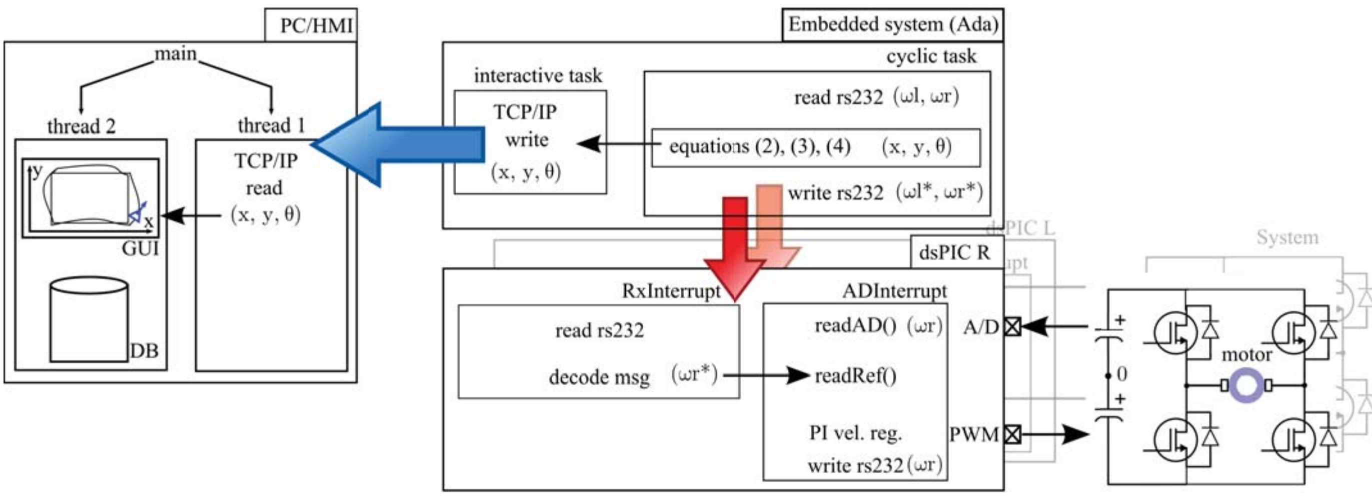

Fig. 7. Logical diagram of the final assignment. It shows the three systems interaction as well as key processes running on each system. For the sake of simplicity, only one microcontroller is shown in the top layer of the diagram.

From here, the complete model equations are described. The derived equations are provided to the students along with the aforementioned paper [18], so they can focus on the implementation details. In the subsequent subsections, first the cinematic and dynamic model of the vehicle are explained and second the implementation of a trajectory tracker is explained.

1) Dynamic model: Dynamic model is explained though the decomposition into three different models: steering cinematic model, vehicle cinematic model and vehicle dynamic model.

a) Steering system cinematic model: Cinematic model of the steering system allows obtaining linear and angular velocity of the vehicle from angular velocities of the wheels, as shown in (1).

$$\begin{bmatrix} v \\ w \end{bmatrix} = \begin{bmatrix} \frac{R_R}{2} & \frac{R_L}{2} \\ \frac{R_R}{T} & \frac{-R_L}{T} \end{bmatrix} \begin{bmatrix} \omega_R \\ \omega_L \end{bmatrix} \tag{1}$$

where, R_x and ω_x are the wheel radius and the angular velocity of wheel x respectively and T the vehicle wheelbase.

b) Vehicle cinematic model: Vehicle's cinematic model relates linear and angular velocity with vehicle position in a 2D space. It is worth noticing that vehicle position is given not only by (x, y) coordinates but it is needs to include a third component for the robot orientation (heading), so (x, y, θ) is the full state. Relations are shown in (2), (3) and (4)

$$\theta_{(t)} = \int_0^t \omega_{(t)} dt \tag{2}$$

$$x_{(t)} = \int_0^t v_{(t)} \cos \theta_{(t)} dt \tag{3}$$

$$y_{(t)} = \int_0^t v_{(t)} \sin \theta_{(t)} dt \tag{4}$$

c) Vehicle dynamic model: The dynamic model of the system allows relating the generated forces –dc motors torque– with the change in the actual position. This model is used in the simulator in order to allow isolate testing of each block in the project. A diagram for the dynamic model is shown in Fig. 8. For the proposed model, and using Newton's second law of dynamics, is possible to simulate the reaction of the vehicle to changes in the torque reference to the motors, as shown in (5) y (6)

$$\sum F = ma = m\frac{dv}{dt} \tag{5}$$

$$\sum \tau = J\alpha = J\frac{d\omega}{dt} \tag{6}$$

Using the equations from the steering cinematic model:

$$v = \frac{R}{2}(\omega_R + \omega_L) \Rightarrow \frac{dv}{dt} = \frac{R}{2}\left(\frac{d\omega_R}{dt} + \frac{d\omega_L}{dt}\right) \tag{7}$$

$$\omega = \frac{R}{T}(\omega_R - \omega_L) \Rightarrow \frac{d\omega}{dt} = \frac{R}{T}\left(\frac{d\omega_R}{dt} - \frac{d\omega_L}{dt}\right) \tag{8}$$

where wheel's radius has been assumed to be the same and equal to R for the sake of simplification.

By algebraic manipulation, and following reference [18], expressions (9) and (10) are obtained.

$$\tau_{MR} = A\frac{d\omega_R}{dt} + C\frac{d\omega_L}{dt} + E\omega_R \tag{9}$$

$$\tau_{ML} = B\frac{d\omega_L}{dt} + D\frac{d\omega_R}{dt} + F\omega_L \tag{10}$$

where,

$$A = \frac{1}{g_R}\left(g_R^2 J_{MR} + J_R + \frac{R_R^2}{2}\left(\frac{M}{2} + \frac{J}{T^2}\right)\right)$$

$$B = \frac{1}{g_R}\left(g_L^2 J_{ML} + J_L + \frac{R_L^2}{2}\left(\frac{M}{2} + \frac{J}{T^2}\right)\right)$$

$$C = \frac{1}{g_R}\left(\frac{R_R R_L}{2}\left(\frac{M}{2} - \frac{J}{T^2}\right)\right)$$

$$D = \frac{1}{g_L}\left(\frac{R_R R_L}{2}\left(\frac{M}{2} - \frac{J}{T^2}\right)\right)$$

$$E = \frac{1}{g_R} b_R$$

$$F = \frac{1}{g_L} b_L$$

2) Trajectory tracker: Trajectory tracker module's main objective is to generate commands for the velocity control loop of the motors driving the wheels. At each sample time, available information is the desired trajectory selected at the supervision layer and actual position estimation. Then, the trajectory tracker needs to implement an algorithm allowing the following transformation:

$$[\omega^*_{r,}\omega^*_l] = f\left(x^*, y^*, x, y\right)$$

where x^*, y^* are the coordinates of the commanded trajectory, x, y estimated actual position and $\omega^*_{r,}\omega^*_l$ velocity commands to each motor.

As explained before, implementation of the trajectory tracker is made in Ada language. The module communicates with the inner control loop through the serial port. In addition, it has to receive the precalculate trajectory from the supervision layer. This communication is done by TCP sockets.

The algorithm to generate velocity commands is based on the cinematic model of the vehicle and in the measurements given by the velocity sensors at each motor.

3) Algorithm description: Mobile position in x, y plane (the movement is constricted to this plane) is determined by the estimated system state (x, y, θ), where x is the projection in the x axis, y the projection on the y one and θ robot heading. Comparison between commanded position (x^*, y^*) and estimated one (x, y) from the cinematic model, allows to generate velocity commands. Because the given trajectory does not include heading command –θ^*–, first step is to know if given the actual position and the reference, a change in the robot heading is needed in order to reach the next point of the desired trajectory. Heading command is calculated as (11):

$$\theta^*_{[k]} = atan\frac{y^*_{[k]} - y_{[k]}}{x^*_{[k]} - x_{[k]}} \tag{11}$$

Once heading command has been obtained, it is already possible to get linear and angular velocity commands using the discrete derivatives by Tustin approximation from the cinematic model of the vehicle (12) to (14).

$$\omega^*_{[k]} = 2\frac{\theta^*_{[k]} - \theta_{[k]}}{T_s} - \omega^*_{[k-1]} \tag{12}$$

$$v^*_{x[k]} = 2\frac{x^*_{[k]} - x_{[k]}}{T_s} - v^*_{x[k-1]} \tag{13}$$

$$v^*_{y[k]} = 2\frac{y^*_{[k]} - y_{[k]}}{T_s} - v^*_{y[k-1]} \tag{14}$$

$$v^*_{[k]} = \sqrt{{v^*_{x[k]}}^2 + {v^*_{y[k]}}^2} \tag{15}$$

where T_s is the sample time.

From linear and angular velocity commands v^* and ω^*, references to the inner velocity control loop ω^*_r and ω^*_l, are obtained from the inverse cinematic model of the steering system (16)

$$\begin{bmatrix} \omega_{rR} \\ \omega_{rL} \end{bmatrix} = \begin{bmatrix} \frac{1}{R_{rR}} & \frac{T}{2R_{rR}} \\ \frac{1}{R_{rL}} & -\frac{T}{2R_{rL}} \end{bmatrix} \begin{bmatrix} v \\ \omega \end{bmatrix} \tag{16}$$

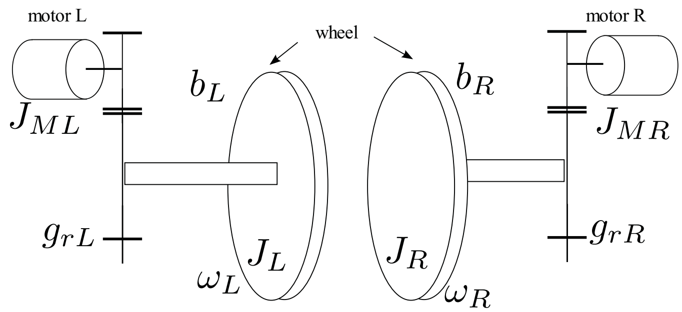

Fig. 8. Mechanical model for the two steering wheel mobile robot.

V. Students Response

Student's opinion about the presented courses has been obtained through the use of one questionnaire. The questionnaires were fulfilled by the students after the final assignment presentation was done and before the evaluation results were issued. The questions about the collaboration of both courses is shown in Table V.

All the students agreed that it has been a good experience. It is worth noticing that lower marks are in the questions related to the effort required to pass the courses as well as to the materials. About this last question, we are working on improving both the materials for the hands-on laboratories and also the documentation in the web page. The experience taught us that the question about the course difficulty is related to how easy the information needed to complete the project can be found. Therefore, we think this mark can also be raised with more documentation about some specific problems they encounter. In order to avoid returning to the previous teaching method, where all the materials were immediately available to the students, we will keep the information filtered. It will be shown to the students in fragments, and only after assuring that they have searched the information by their own.

Additionally, in order to avoid tendency of the students to delay the tasks until the last weeks of the course, more milestones are going to be established during the first bimester. This will help to minimize the overload sensation because of too much effort concentrated in the last weeks.

Finally, taking into account that this is the first year of the experience, we think the results are quite satisfactory.

VI. Conclusions

This paper has presented a collaborative experience between two courses related to the embedded systems engineering. A blended learning mode has been applied. PBL has been used as the learning methodology for the hands-on classes, and

TABLE V
STUDENTS RESPONSE QUESTIONNAIRE. MARKS RANGE IS FROM 0 TO 5.

Question	Result	
I think...	mean	std
...it has been important for my curriculum.	4,13	0,64
...it is positive to make common assignments.	4,63	0,52
...it is positive to blend different topics in the same assignment.	4,75	0,46
...the effort needed to pass the courses is adequate.	3,5	0,53
...the materials are appropriated.	3,63	0,52
...the common assignment is challenging and motivating.	4,63	0,74

a more traditional teaching for the lectures. Description on the evaluation method using a portfolio has been extensively explained. Common final assignment design as well as implementation details have been included. Students opinions about the experience has been reported and analyzed by means of one questionnaire.

Results demonstrate that the experience is positive for the develop of reasoning, critical thinking and use of acquired knowledge. This is an agreement with other authors [19], who conclude that the successful completion of an embedded design gives the student a sense of achievement which is lacking in more conventional engineering courses.

Abstract—**The Telecommunications Engineering degree contains the study and understanding of a wide variety of knowledge areas, like signal theory and communications, computer networks or radio propagation. This diversity of fields makes it hard for the students to integrate all these knowledge, which in turns results essential to tackle real and practical problems that involve different subjects. As a response to this need of integration, in University Rey Juan Carlos an educational project based on Problem Based Learning (PBL), called the Wireles4x4 Project, has been carried out. In this project, groups of students build a complete system that is able to autonomously drive a radio controlled car, involving different technologies such as wireless communications, positioning systems, power management or system integration. The objectives of this educational project are: (1) The development of an active learning methodology, by which the students acquire integrated knowledge and skills on a variety of subjects; (2) The acquisition of professional skills like teamwork capabilities, oral and written communication, and long term task scheduling; (3) The participation of the students in an interdisciplinary engineering project with time and budgetary constraints. The results show that the participating students improve not only their specific knowledge on the involved issues, but also their capability of integrating different subjects of the degree and the skills for autonomous learning.)**

Keywords: integrating learning; problem based learning; professional capabilites training; telecommunication engineering.

I. Introduction

The Wireless4x4 project is an annual educative project developed by students and educators at Universidad Rey Juan Carlos, in Fuenlabrada, Spain. Specifically, the participants of this learning experience are members of the Telecommunication Faculty (ETSIT, from its Spanish name *Escuela Técnica Superior de Ingeniería de Telecomunicación*), in which three five years degrees and one six years degree are offered, all of them closely related with information technologies.

Each of these degrees contains the study of a wide variety of knowledge areas and professional skills, like signal theory, communications theory and practice, electromagnetic fields and radio propagation, computer networks, data processing, programming fundamentals or electronic design. Along its five or six years, the students follow a plethora of different courses which sometimes are not conceptually connected. Therefore, it is often hard for the students to integrate all this knowledge and skills, which is itself an essential capability that a telecommunication engineer is expected to apply in his professional career. Moreover, the professional market requires engineers that not only manage different technical knowledge and skills, but also are used to face with real problems with real constraints and are able to work in teams, organize a long-term work and make public presentation of their results with clarity and determination. All of these professional skills are hardly acquired with the classical learning methodology.

Therefore, the Wireless4x4 is an innovative learning experience, based on Problem Based Learning (PBL) techniques [1], [2], which represents an effort of Universidad Rey Juan Carlos to overcome these limitations of the conventional educative procedures. Then, the main objectives of the project are:

- The development of an active learning methodology, by which the students acquire integrated knowledge and skills on a variety of subjects.
- The acquisition of professional skills like teamwork capabilities, oral and written communication, and long term task scheduling.
- The students' involvement in an interdisciplinary engineering project with real time and budgetary constraints.

The project is organized as an extra course, recognized as a sixty hours course. Moreover, the students' designs are tested in a final public competition, which is a race in a pre-set circuit in the ESTIT campus. The best design is awarded with a prize for all the members of the winner group, like PDAs or laptops. The participants of this project are students of each of the degrees of the ETSIT, who are in their third or higher year. This constraint is necessary to count on the participation of students with a minimal base of knowledge on communication systems, electronics and programming. Before the final exams in June, the following year project is presented in the classrooms and with posters, in order to motivate the participation of the students.

The students participate in groups of three members, which during these years has shown to be an appropriate number to develop all the tasks, while avoiding the problem of having parasite students in the project. Because of resources constraints, the project can hold three groups (this year has grown up to four) per year, so among the candidate groups (this

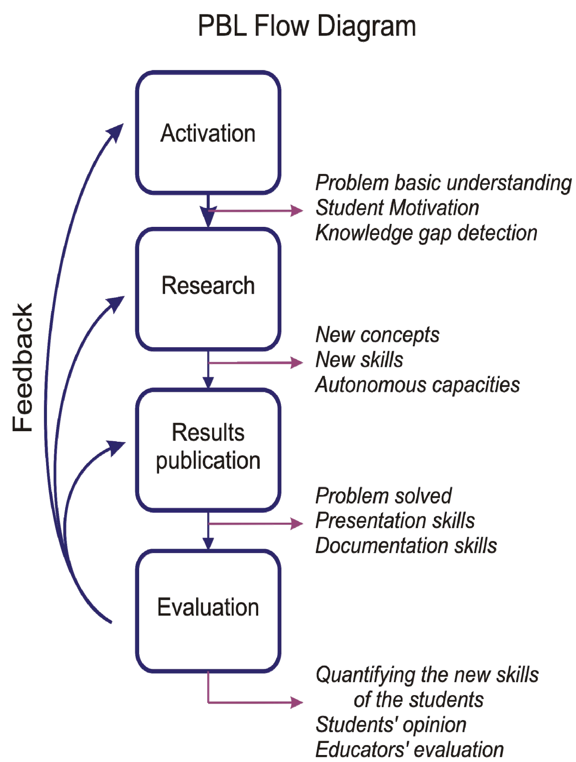

Figure 1. A typical PBL diagram with four phases and the expected results for each phase.

year there were six) a selection procedure is carried out, which is in turn a first step in the motivation-activation phase of the PBL project.

From a technical perspective, in this project the groups of students build a complete system that is able to autonomously drive a radio-controlled car. The control of the vehicle trajectory is carried out by an autonomous algorithm, that is executed by a control computer away from the vehicle, using the GPS (*Global Positioning System*) coordinates obtained by an on board computer.

The on board computer is also capable of controlling the servomotors which controls the speed and direction of the vehicle. A WiFi network performs the communication between control and on board computers. The power of the on board system is provided by a common battery, so a power management system is also implemented. Then, different knowledge and skills related to signal processing, positioning algorithms, wireless communications, electronic, programming and system integration are needed to complete the Wireless4x4 project.

The remain of the paper is organized as follows. In Section II, a brief introduction to PBL methodology and phases is provided. Then, the learning methodology and the project description are described in depth in Section III. The results of the three-fold evaluation procedure are given in Section IV, and in Section V the main conclusions of this experience are drawn.

II. Problem Based Learning

According to H. S. Barrows [3], the father of the PBL methodology, problem based learning is "a learning method based on the principle of using problems as a starting point for the acquisition and integration of new knowledge". In general, the student's learning process is stimulated with a problem, and for solving the problem, the student discover what to learn and how to do it. The main function of the problem is, then, to motivate the learning process. At the end of this process, the students not only has acquired a set of skills and competences, but also has learned how to autonomously acquire new ones [4], [5].

On the one hand, the main advantages of this active methodology is that the students learn very important professional skills, like how to search information, solve problems, work in teams and build new knowledge. Moreover, the students are demanded to deeply investigate the subject of the problem, not only to learn basic theoretical concepts. On the other hand, the main drawback of this learning approach is that it requires more time to cover the same amount of knowledge than a classical approach. Moreover, the cost of this kind of learning experiences is higher, and the number of students in each group needs to be reduced. However, with more reduced and realistic syllabus, and the help of information technologies these drawbacks tend to be minimized.

Figure 1 represents a general flow diagram of the four main stages of a problem based learning procedure [6]. Firstly, a motivation phase is needed for activating the previous knowledge about the subject, define the new knowledge that the students will need to acquire, preparing a scheme to deal with the problem, and properly motivating the students. Secondly, in the research phase the students autonomously search, filter and interpret the information needed for solving the problem. Then, in the third phase, the solution is documented and published.

Finally, the very important evaluation phase is critical for the improvement of the educative project. This evaluation phase should contain objective criteria and subjective opinions from both the students group and the participating educators. Since this project is repeated each year, the feedback from this stage to the previous ones is needed to modify the planning for the future.

III. Methodology

In this section we describe the Wireless4x4 project using a two-fold approach. Firstly, we emphasize the learning methodology as a particular case of the general four-stage scheme presented in Section II. Secondly, a description of the project is presented to clarify one of the main aspects of this experience, which consists of the integration of knowledge from different subjects of the telecommunication degree.

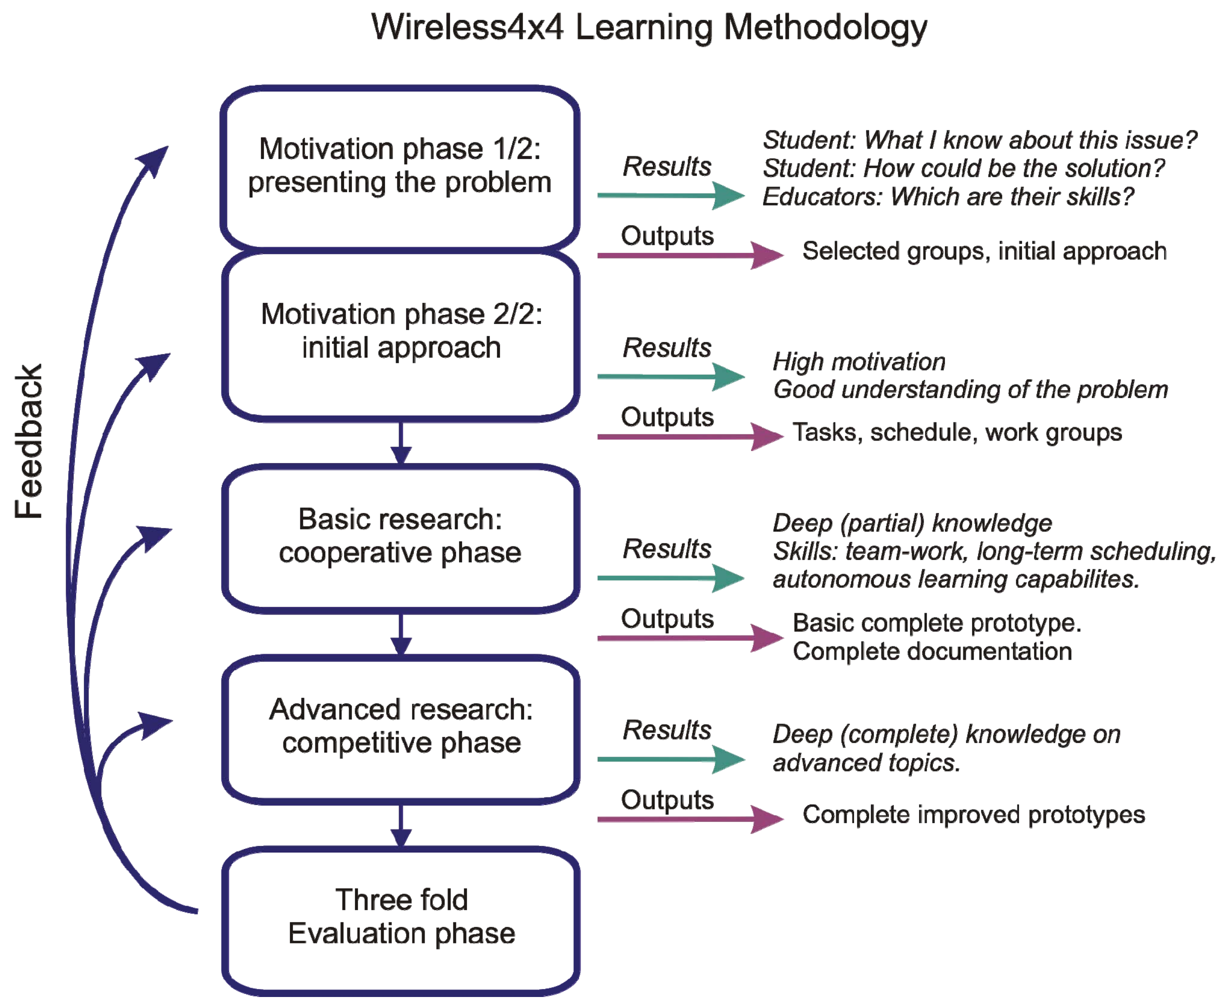

Figure 2. Wireless4x4 learninng methology: flow diagram with the expected results and the objective outputs of each phase.

A. *Learning Methodology*

Figure 2 represents the learning methodology of the Wireless4x4 project. Four phases are used (the first one being divided in other two). The expected results of each phase and the objective outputs (products, documentation, indicators) are also shown.

1) Motivation phase.

The main two ideas of this project are that the students develop an autonomous learning effort for solving a real life problem and that they acquire a integrating perspective of different technologies involved in that problem. For this purpose, it is essential that the students are motivated enough to face inherent difficulties of those both ideas. To accomplish this, in the motivation phase the students participate in a group interview in which only the best and most motivated groups are selected for the experience. In the selection procedure, both the students' records and the motivation of the group are taken into account. Furthermore, in this first interview, a global perspective of the problem is provided, and the students are requested to design a solution during fifteen minutes with the help of a computer connected to the Internet. This way, three objectives are attained. Firstly, the students discover what they know about the problem and the main gaps they have to cover for fulfilling the task. Secondly, they begin to feel curiosity about what could be the best solution. Thirdly, the educators gets a global perspective about the qualification of each group, which, in turn, on the one hand helps in the selection procedure and on the other hand underline which knowledge and skills should be learned by the students in the following phase. This is also the first evaluation point of the project. The result of this first part of the motivation phase is therefor a selected set of participating groups and a base of motivation for all the participants.

In the second part of the motivation phase, the problem is described in detail, and a first approach of the solution is investigated. For this purpose, a group session involving all the selected participants and the educators is carried out. In this session, the educators present the problem and the time, resources and cost constraints. Also, a previous simplified version of the project is shown to the students. Then, using a brainstorming approach, the general solution is investigated by the students. The output of this phase is a design of the different parts that are involved in the project, and an assignment of the tasks of each part to a different group. Also in this session, the initial groups are interleaved, according to the preferences of the students and the difficulty of each task. The result of this phase is that each student is highly motivated to try to complete his task, since they have selected it and they know that the whole project depends on each single participant.

2) Basic research and resolution phase

After the motivation phase, the interleaved groups start the second block of the project, which is the basic research and resolution phase. In the session described above, each of these groups was assigned a particular task. Moreover, all the students and the educators know the main gaps that the groups have in their knowledge and skills. Therefore, in this phase each group carries out a deep research in its own part of the project, propose a solution for the specific sub-problem, design it with the appropriate tools, implement the solution, test it, and prepare a detailed documentation. The main task of the educators in this phase is to lead each group with suggestions about how to find the solution, provide the students with the necessary tools, and supervise that each task can be completed on time. Finally, all the groups incorporate their respective parts of the solution to a common platform, thus building a first basic solution for the whole system. Moreover, in an intermediate group session, each group presents its solution to the rest of the groups. This is the intermediate evaluation point of the project. The result of this phase is that each member of each of the initial groups has acquired a deep knowledge of a part of the project, but adding all the expertise of each of its components, each group has a full vision of the final solution.

3) Advanced research and resolution phase

This intermediate group session is also the starting point for third block of the project, the advanced research and resolution phase. Here, the initial groups are restored and their main objective is to improve the basic solution implemented in the cooperative previous phase in order to improve their final prototype. For this purpose, each group will propose an improvement to the educators, who will lead them to find the information needed for its development. In this phase each group gets an advanced expertise about one or more particular issues related, for example, to control theory, location algorithms, electronics or signal processing. The output of this block is a finished prototype for each group. The result is that, within each group the knowledge of the previous phase has been shared, and knew knowledge and skills have been acquired by all of its members.

Finally, a competition among all the groups is organized. The main objectives of this phase are to evaluate each one of the final solutions found by each group and to develop an interesting marketing task for the next year project among possible new participants. This is the final evaluation point of the project. Moreover, this competition and the prizes are part of the initial motivation for the students.

4) Evaluation

The project has a three-fold evaluation. Firstly, an evaluation of the technical knowledge and professional skills acquired by the students is made using the results of the three evaluation points (initial, intermediate and final) described above. Secondly, a survey of the students' opinion was carried out, investigating the main aspects of the project, that is: its interdisciplinary content, the practical approach used, and the general methodology (see Section IV for details). Thirdly, a final evaluation was made among the participating educators, related to the educational aspects of the project and the workload.

B. Project Description

The Wireless4x4 project follows a practical and integrated approach of several knowledge areas that are tackled in different subjects of the ETSIT degrees. The project is based on PBL methodology and hence the students are responsible to acquire the knowledge and skills needed for the achievement of the objectives and requirements described at the beginning of the project. Moreover, the students must face the technological, time and budgetary constraints that are typical in engineering projects.

The final aim of the Wireless4x4 project is the design, implementation, test and demonstration of a complete communication system that is able to autonomously drive a radio controlled car. The control of the vehicle trajectory must be carried out by an autonomous algorithm, which is executed by a control computer away from the vehicle, using the GPS coordinates obtained by an on board computer. A WiFi (IEEE 802.11b) network performs the communication between the control and on board computers. Hence, the knowledge areas involved in the project are:

- Analog circuit design and implementation: for the on board power supply system.
- Digital communications: for the implementation of the WiFi network.
- Embedded software and hardware systems integration and configuration: for the design and implementation of the hardware and software platform.
- Signal processing and control theory: for the implementation of the autonomous driving algorithm based on the GPS information.
- Software development: for the implementation of JAVA programs running in both control and on board computers.

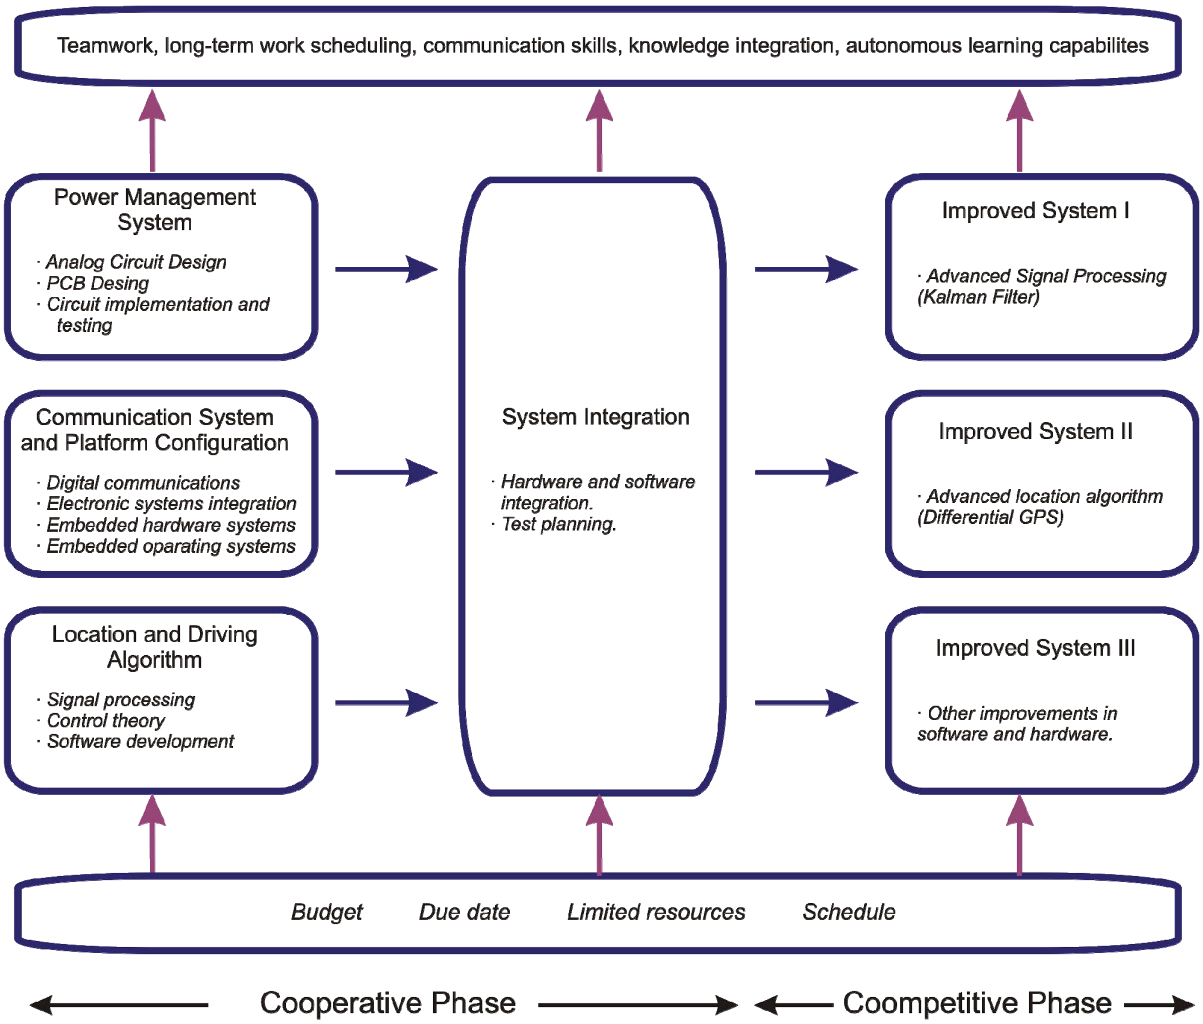

Figure 3. Wireless4x4 learninng methology: flow diagram with the expected results and the objective outputs of each phase.

- System integration: for the integration of hardware and subsystems to complete the whole system.

The students should be able to relate the concepts from these knowledge areas and to adapt them for solving the real problem considered in this project. At the end of the project, each group of students will have to build a fully functional prototype, within the proposed deadline, and to participate in the race against the rest of groups. Therefore, the student faces a realistic environment with task deadlines, budgetary constraints and limited resources, all of them shown in Figure 3 as lower inputs of the process. Moreover, as shown in that figure, the Wireless4x4 project is divided in two phases, cooperative phase and competitive phase, corresponding with basic research and advanced research phases, respectively. Now we describe the particular tasks that the groups must carry out in these two phases.

1) Cooperative Phase

As explained above, there are several areas of knowledge involved in the project. Thus, the students have to face up a hard initial learning curve in the first months of the project development. Hence, in this initial phase, the three groups cooperate in order to reach a common target: the construction of a basic prototype of the radio controlled vehicle with autonomous driving. Three working groups are created to develop tasks in three well separate areas. Each working group is composed by three students coming from the three original groups, so, after this initial phase, in each group there will be an expert student in each one of the three areas, and this expert student will transmit his knowledge to his teammates during the next phase. These first three tasks are:

- Task 1: Design and construction of the power management system with the requirements of the on board computer. There are several elements connected to this computer like an USB GPS receiver, an USB

Figure 4. Finished prototype with the electronic circuits on a transparent box on its top.

Figure 5. Participating students in Wireless4x4 2009 project

WiFi transceiver and a servo controller (also connected to the servos that handle the vehicle direction and speed). From a battery of 11.1V, the power supply circuit must provide the levels of voltage and current required by all the on board systems. This task also includes the physical construction of the power supply circuit on a Printed Circuit Board (PDB). The specific skills acquired with this task are: analog circuit design, computer-assisted design (OrCAD) of electronic circuits, and PCB construction.

- Task 2: Implementation of a WiFi network for the communication between the control and on board computer, and implementation of the hardware and software platforms. During this task, the students must select a suitable USB WiFi device, analyze the WiFi coverage in the campus and program the required software for the WiFi link establishment between the two computers. Moreover, the students install and configure an embedded computer with a Linux operating system, and mount the basic platform composed by the on board systems. The specific skills acquired with this task are: link budget analysis, WiFi coverage analysis and WiFi network deployment, embedded computers and embedded operating systems configuration.
- Task 3: Implementation of a driving algorithm based on GPS information. The students participating in this task must select a suitable USB GPS receiver, analyze the received GPS information and program the driving algorithm for the autonomous driving of the vehicle along a previously fixed circuit. The specific skills acquired with this task are: GPS signal analysis and processing, basic control theory and software development.

After these three tasks, all the students have to put their knowledge and designs together, in order to carry out the next task.

- Task 4: System integration to complete the autonomous driving of the vehicle. In this task the students put all the pieces together and solves the integration problems that usually arise. The specific acquired skills with this task are: systems integration capabilities.

With the conclusion of this task, the students have reached the project basic goal and the competition between groups begins.

2) Competitive Phase

For this last phase, the students return to their original groups to develop specific system improvements. The aim of this phase is to make the project more attractive to the students, improving their inventiveness and own initiative. Hence, this phase has only one task for the three groups:

- Task 5: Development and implementation of system improvements. The students suggest the system improvements (in the driving algorithm, signal processing or location method) and, after the educators' authorization, implement them in order to win the final race against the others groups. Examples of improvements carried out this year are: improvement of the GPS positioning using a tracking technique by means of a Kalman Filter or improvement of the positioning using a differential GPS.

During all these five tasks, the students also acquire several professional capabilities and skills, represented in Figure 3 as upper outputs of the diagram. Specifically, the main ones are related to: teamwork, long-term scheduling, communication skills, knowledge integration and autonomous learning.

IV. RESULTS

In this section, the results of the three-fold evaluation described in Section III are analyzed.

A. Technical knowledge and professional skills

We now analyze the objective results that have been reached in the project. For the end of the project, the three groups built their fully functional prototypes and competed in the successful race. The winner group implemented a differential GPS system and improved the speed control. However, before the race some last time adjustments were needed in all the vehicles because the designs were not robust enough. Indeed, one of the prototypes did not finish the race because of a bug in the autonomous driving algorithm. After this bug was fixed, the vehicle was eventually able to complete the circuit successfully. A picture of a finished prototype is shown in Figure 4.

Moreover, through the three evaluation points described in Section III, the educators observed the improvements in different knowledge areas and skills like programming, electronic circuit design, embedded system configuration or wireless networks in all the students. Hence, all the students had a positive evaluation due to their participation, initiative and the quality of the prototypes.

B. Students' opinion

A survey of the students' opinion was carried out at the end of the project. The survey was composed by nine closed questions about the knowledge and skills acquired by each student, and two open questions to evaluate the best and worst issues of the project. Table I shows the mean and mode values of the survey answers. Several aspects of these results are noteworthy. All the results show a high satisfaction level about the learning aspects and the general evaluation of the project. Interestingly, all the students confirm that their knowledge and skills related to the different areas of the project have been improved, even in the areas that were not related with their specific task in the cooperative phase.

However, if we break down the results of items two, three and four in Table I, it shows that, for each student, a slightly better result is obtained for the areas involved in his particular task. Although the general evaluation item mean value is very high, it is important to point out that the item related to the acquired autonomous learning capabilities has one of the lowest values.

In the open questions, the students emphasized as the best points the teamwork, the work in a real scenario and the variety of concepts learned. The worst point is the lack of resources and a sometimes-poor organization. Examples of the most outstanding answers of our students are: ``I loved the experience, beyond my wildest expectations, I would recommend it to anyone and my only regret is I cannot do it again."; ``If it hadn't been for my mates, I'm sure I'd have crashed into more things".

C. Educators' opinion

All the educators agree on that the educational value of the project is very high, in terms of both technical knowledge and professional skills. Moreover, the educators also agree with the students in most of the observations given in the previous section, in particular in the organization shortcomings. The main reason for this is the high workload that this project has represented for the involved educators. However, they still are really pleased with the final results of the project.

TABLE I. RESULTS OF THE STUDENTS' OPINION TEST

Item	***Mean***	***Mode***
Through this project my teamwork capability has improved	4.08	4
Through this project my knowledge in analog electronics has improved	3.83	5
Through this project my knowledge in software development has improved	3.42	4
Through this project my knowledge in system integration has improved	4.17	5
Through this project my problem solution autonomy has improved	3.92	4
Through this project my problem solution capacity with time and budgetary constraints has improved	4.08	5
The project is a good integration of knowledge from several areas in Telecommunication Engineering	3.92	5
The project has fulfilled my expectations	3.75	4
Project general evaluation	4.58	5

V. CONCLUSIONS

The Wireles4x4 project is three years old, and at this moment is in the cooperative phase of its fourth year. The results described in Section IV show that the main objectives of the Wireless4x4 project have been fulfilled. Specifically, the knowledge and skills acquired by the students and tested in the three points evaluation are really significant and useful.

Moreover, from the three points evaluation and the student survey, it can be seen that the students acquire an integrated vision of the different technologies involved in the project. In this sense, the main limitation is the difficulty that a student has to acquire those skills that are not related with his specific task in the cooperative phase, as can be observed in the student survey. To overcome this limitation, two improvements are being developed this year: the documentation and the final presentations of the cooperative phase are being improved, and the competitive phase is longer in order to give more time to the students to analyze the whole system.

Moreover, the organization issues of the project have been improved over these three years, but they still are one the weakest aspects of the project, due to the high workload that the project represents for the educators. This year, more professors participated in the organization of the project, and from the beginning, a list of task and a Gantt diagram has been developed and is known by all the participants.

Finally, the summarized opinion of the educators involved in the project is quite encouraging, and the authors are able to predict that this project has still a wide margin for future improvements.

A. Figures and Tables

1) Positioning Figures and Tables: Place figures and tables at the top and bottom of columns. Avoid placing them in the middle of columns. Large figures and tables may span across both columns. Figure captions should be below the figures; table heads should appear above the tables. Insert figures and tables after they are cited in the text. Use the abbreviation “Fig. 1”, even at the beginning of a sentence.

Abstract—**The cooperative assessment system promotes teamwork, increases the mental practice and develops the social skills that are so necessary in the working life. In this paper we present the experiences and methodologies undertaken to assess the subjects "Local Area Networks" and "Networks Integration" of the Degree in Technical Engineering in Telecommunications of the Higher Polytechnic School of Gandia of the Polytechnic University of Valencia, Spain. This courses attempt to stimulate the students' motivation and teamwork through various activities and to provide the appropriate training to safely resolve situations that may be happen in real life. This article shows the opinions of the students, their feedback and their marks. All these data will be used to improve the teaching methodology for the next year. Finally, we can say that the main aim of the courses has been achieved, because the survey results, the opinions of these students, and their marks have been very satisfactory.**

Keywords- Cooperative assessment, Collaborative groups, Work in groups, Problem-Based Learning.

I. INTRODUCTION

The assessment of the student's training, as an individual or as a part of a group, is a process that has to be continuously done along the course. Moreover, the end of the teaching period carries a closure and any closure involves some results review. But, what and how should we evaluate it? These questions are very difficult to answer when a complete assessment of the skills of the students is wanted.

The evaluation can be conceptualized from different points of view. It is important to know the difference between the formative evaluation and the summative evaluation. In the first type of evaluation, the information is used to guide and to improve the learning and training processes. In the summative assessment, the information is used to determine the student's final mark, which gives the learning level of the student, and the marks that are added to the final part.

Sometimes the assessment process may be understood as a set of useful tools in order to improve the quality of the teaching-learning process. The relationship between the quality of teaching and the evaluation is narrow and, generally, it is difficult to mention one of them and forget the other concept.

According to [1], the training assessment is not only to measure, qualify or to grade the student answers. It is neither to sort nor to examine the students. Nevertheless, the assessment is usually related to many activities like qualify, measure, edit, sort, certify, review or pass the tests, etc. Both concepts share a semantic field, but it should not be any confusion between them. Both concepts are differentiated by the resources, its use and its serving purposes. The training assessment allows improving the practice. The non-training assessment, where you cannot learn from the assessment, should be excluded in the basic levels of education. The evaluation process should be a resource for training and a learning opportunity.

In [2], Rodriguez et al. recommend that a practical assessment has to be objective, comprehensive, brief and very practical. In [3], we can see that practical assessments carry some difficulties. There are some problems that often appear when a hands on skills session is given in the laboratory. These are me main ones:

- The lack of attention to the lecturer explanations. When the students have a computer connected almost always to Internet, while they are in the laboratory, they usually read the mail, see some Social Network like Facebook, Friendster or Hi, finish the hands on skills of previous sessions, etc.
- The lack of customized attention. The overcrowding of the laboratory classes force large groups of students, thus the individual attention is very limited. Not so much time can be devoted for each student.
- It is difficult to detect possible problems of understanding before the final correction of the practice is done. Questions like "do you understand?", "is there any question?" or "is there any doubt?" usually do not provide any feedback from the students.
- The lack of material resources and equipment is a problem that must be considered. Usually the laboratory equipment has to be shared by several students.
- Practical sessions imply a greater dedication by the lecturer in the stage of activities preparation and in their correction.

In contrast to the issues previously mentioned, and due to the technological advances, the learning process is being centered on the student figure (learning) and not so much on the lecturer figure (teaching) [4]. For this reason, problem-based learning (PBL) methods are used. According to [5], PBL can be defined as the learning method that ensues to work towards the knowledge of the problem resolutions. The PBL method is based on the following rules [6]:

- The students have to assume the responsibility of their own learning.
- The problems should be intentionally unstructured and it should allow free interpretations.
- The learning should be directed towards a wide range of possibilities, not towards a single knowledge specialization.
- The concepts learned in the study stages and in the independent learning must be applied to the proposed problem.
- On one hand, it is necessary a final synthesis of the learned information and, on the other hand, it is necessary to define what concepts have been learned, and which ones would be necessary to be reinforced before initiating the evaluation process.
- The evaluation and auto-evaluation must be done when a problem is finished and at the moment of ending the chapter.
- The individual student evaluation must be realized always bearing in mind the proposed aims.
- The topics and the activities should be focused always to real-life examples and these activities should contribute the values of the social and professional areas.
- The cooperative teamwork, the collaborative learning and the personal autonomy, have to be taken as the essential keys of the work.
- The PBL should constitute the pedagogic base of the curriculum and not only a part of the education.

The students assume major freedom of action and responsibility in PBL. Moreover, the lecturer takes a new role, that is, to direct the students through the learning process. The success of the PBL highly depends on the preparation, the background and the training of the lecturer. In general, PBL must allow developing the professional qualities that are demanded in the current world: constant learning, autonomy, teamwork, critical spirit, communication capacity and planning.

One of the main problems in the cooperative methodology assessment is to evaluate the individual marks of the student's knowledge about the content of the subject. To evaluate the cooperative competences learned during their cooperative tasks is also difficult. The lecturers must also control shirk students and the students' cooperation [7] [8].

The rest of paper is structured as follows. Section 2 describes some works and gives some related experiences about the assessment process of the student's training. Section 3 explains our didactic methodology and cooperative assessment. The teaching process and a survey performed by the students to evaluate the method are explained in Section 4. Section 5 shows the students' opinion. The student's marks are presented in section 6. Finally, Section 7 gives the conclusions.

II. Related Work

A special interest in the use of collaborative teaching methodologies in the teaching-learning process of student [9][10] and lecturers [11] is in the university training. This happens mainly due to the benefits provided by these methodologies to the students, in addition to the skills that they develop.

One of the first questions we must be asked before starting any collaborative methodology is what issues must the teachers bear in mind before designing a cooperative learning program?. It was discussed by E. G. Cohen et al. in [12]. They presented different pedagogical methods performed in the Toronto University that are related with the cooperative learning. There are other pedagogical methods for Classroom Practices that are based on cooperative learning such as the ones presented in [13]. These ones have inspired us to perform our methodology.

With the renewal of the study plans and the migration towards the Bologna Process, many schools and centers have included modifications in some of their subjects and have gathered the results at the end of the course to compare it with the previous experiences. An example is given by the EUETIB (Escuela Universitaria de Ingeniería Técnica Industrial de Barcelona) [14]. It has reviewed and improved the objectives and programs of different subjects applying the techniques of CL (Cooperative Learning). A. Perez et al. show in their paper the academic achievements in the first year of implementation of these subjects. The results were satisfactory and the cooperative learning experiences have proved to be a motivational tool to improve the academic outcomes compared to their performance in individual tests. In addition students appreciated the functioning of these subjects.

Another related work about practice training is shown in [3]. It is presented by M. Riesco et al. The authors analyze the consequences of implementing the system of electronic answer (Electronic Response Systems), also named Classroom Communication Systems. This system has been used from the ends of the 50s as a reinforcement to the teaching of different matters at different levels. These systems attempt to provide a technical element to each student and allow them to interact with the lecturer. The authors say that despite of its diffusion throughout the world, there is no record of an employment in Spanish universities.

Another example can be found in [15], where M. Marques et al. explain the experiments carried out with some students. Their main goal was to improve the students' motivation through different activities. These experiments are applied in a subject called "Design and management of databases". They change the training methodology and even the qualifications weighting, giving, for example, major weight to the practical activities than to the theoretical ones.

Since several years ago, several lecturers of the Higher Polytechnic School of Gandia, of the Polytechnic University of Valencia, are working with the introduction of different types of training methodologies. These skills are applied to different subjects of the Degree in Technical Engineering in Telecommunications [16]. Collaborative Learning is the method that is used in the subjects "Local Area Networks" and "Networks Integration". Both subjects are placed in the third course (last course of the degree), thus it is the best place where collaborative learning could be implemented because when the students finish they would collaborate with other partners in the enterprise.

III. COOPERATIVE EVALUATION

First of all we must define the meaning of cooperative learning. In general, it is a pedagogic skill where the students work together towards the attainment of a common target and every individual will reach the aforementioned target if – and only if – the rest of members of the cooperative group also reach it [17].

In order to evaluate the teaching-learning process, the following methodology of cooperative assessment has been designed. The activities that will be explained are focused on learning methods based on problems (PBL). These activities serve as a preparation for the student in order to meet several scenarios that emulate real world problems. When this stage is finished, several problems, similar the previous ones, will be followed as evaluation criteria in order to value the attainment of the proposed targets. This assessment system has been performed for several years in the third course in Degree in Technical Engineering in Telecommunications of the Higher Polytechnic School of Gandia, Valencia, Spain. The overall length is eight months divided into two parts. The first four-month period prepares the students to overcome problems in the field of local area networks (the subject is called "Local Area Networks"). In the second four-month period the complexity is higher because the students work with wide area networks and they should be able to integrate these networks (the subject is called "Networks Integration").

One of the best teaching methodologies to perform this procedure is through practical training. The lecturer accommodates the theoretical contents previously learned in the classroom to the practical training. In each practice there is a theoretical introduction to the practice that has to be done by the students. The students use a guide to follow the practice. The guide introduces the student to the different activities that have to be performed. Along the guide, there are various items that the students must fill up as process control in order to encourage their self-assessment and their learning. We must highlight the cooperative aspect of the practical activity, because even though the students have a guide that helps them to carry out the practice, they will not be able to finish it until the partners don't finish their part correctly. After it, they will be able to check the proper running of their configuration.

During the first four-month period the general concepts and objectives to be evaluated are the following ones:

- The knowledge of the basic elements of a local area network and the network configuration of Windows XP Operative System.
- Windows XP network commands and network troubleshooting.
- Setting up a Windows 2003 Server.
- Wire Cabling, crimping and test.
- Configuration of Linux Operative System.
- Network Configuration of Linux Operating System.
- Installing a WLAN network.
- Allied Telesyn switches configuration.
- Cisco Catalyst switches configuration.
- Routing between VLANs using Allied Telesyn devices.

Along the second four-month period the general concepts and objectives to be assessed are:

- Routing between VLANs using Cisco Systems switches and routers.
- NAT and PAT configuration in Cisco Systems Routers.
- NAT and PAT configuration in Allied Telesyn routers.
- Cisco router Command Line Interface.
- RIP routing protocol configuration with Cisco Systems routers.
- RIP routing protocol configuration with Allied Telesyn routers.
- OSPF routing protocol configuration with Cisco System routers.
- OSPF routing protocol configuration with Allied Telesyn routers.
- LANs interconnection using 3COM ISDN routers.
- LANs interconnection using HDLC and PPP in Cisco Systems Serial interfaces.
- Installation and configuration of a Frame Relay network using Cisco Systems routers.
- SNMP management.

We can observe that the practices touch a wide range of topics related with local area networks (in the first four-month period) and integration systems (in the second four-month period). They have been elected in order to cover all knowledge needed by a student to build a local area network of an enterprise in the first one and, in the second one, to interconnect data networks from different locations (headquarters with its branches, central office with remote or mobile workers, etc.)

The evaluation criterion is established according to the following objective: The student will pass the subject only if the lecturer will recommend that student to an enterprise when it looks for someone to carry out the same issues in the real world.

The main goal of the assessment system is to motivate student's continuous learning, promote the team working and to develop the student's communication and scheduling abilities. The evaluation is mainly divided into two stages in each four-month period.

In one stage the student applies the acquired theoretical knowledge to practice sessions. In order to do so, a guide with the steps to follow for each practice session is developed. Initially, the practice is performed individually, but in a certain stages, it can't be completed unless another student has finished his task, so it is needed collaboration. That is, the student needs a partner to carry out his/her task because if they perform their part correctly, all the system will function properly. On the other hand, if a student has any sort of doubt he/she may exchange his/her opinion with other students. This learning process will always be supervised by the lecturer. The supervision will be focused on the group dynamics when it is required or whenever he considers necessary for the optimum development of the activity. In order to pass to the next stage, the student has to complete the 80% of the practical activities at least.

In the assessment stage, a final practice assessment using students' collaboration is made. In order to complete the this stage, the student will have at his/her disposal all the devices and tools he/she may need (wire, crimping tools, routers, switches, Personal computers,…) in order to carry out the assessment. These devices and tools are the ones that have been used in the practical activities performed in the first stage. A laboratory is also available during several days for the students that want to repeat the practices or to practice with new situations. During the week before the practical assessment, the lecturer will answer the questions made by the students and will propose similar topologies in order to improve their practical knowledge. The participation and assistance during this week is optional.

In the final practice assessment a real situation is simulated. It is presented to the students 24 hours before the exam date. It lets the students to prepare it and to plan an appropriate organization to face the problem raised. During those 24 hours the students are able to consult the practices they have done before and go to the laboratory in order to test any configuration. They can also exchange information with other students in order to find the correct configuration.

When the final practice assessment takes place; the lecturer randomly assigns students to several groups (although it can be done letting them to organize the groups). The students must collaborate with their partners in order to perform their task. The tasks will also be assigned randomly, but the lecturer could introduce some new problems, even discrimination, because every task shows different level of difficulties.

The information given to the student is the following one:

- The lecturer is only an observer of the work. He/she will not give solutions or give any clues about the proper solution.
- The individual task has to be fully configured in 2 hours. There is also half an hour for helping other students.
- The assessment is evaluated as follows:
  1. Group task:
     - Cooperating and collaborating between the members of the group.
     - Total time needed to configure the network. If it has been done in less time, they will be awarded.
  2. Individual task.
     - The correct configuration of the individual task.
     - Level of difficulty of the task assigned (notice that it is more important to correctly terminate an easy task rather than not finish a harder one).
- Recommendations to do the exam:
  1. To make democratically a work plan among the group members to perform the activity.
  2. Assign the roles of the group members. But, with no student names assigned to them.
  3. Execute harder tasks with the help of other students (more solutions in case of not having the right result).
  4. Do not install or uninstall drivers unless it is necessary. These should be fully working.
  5. It is recommended to set hardware to default settings (switches, routers, access points,…)
  6. Support each other in order to solve the tasks and promote a good environment between the members of the group.
  7. Always be in calm in case of having any problem during the activity.
  8. Have an alternative plan in case undesired results.
- Test goals:
  1. The network should be finished in a given time.
  2. Obtain the proper results when the lecturer tests the network.

- Gather the network assessment data, solve the problems found during the assessment and answer the questions.

To conclude the description of this assessment system, we now shall talk about which is the criteria used to put the students' marks. The group mark will depend on the global results obtained by the group for the hands on skills assessment. The individual mark is obtained according to grade of correctness and the collaboration or the information exchange between the students during the exam. The final mark is obtained from both, the individual and the group mark. The lecturer assigns the mark based on his observation and supervision when the practice assessment is done. The lecturer checks that each task is performed correctly and that the dependences between tasks are well done. These dependences help the lecturer to know the collaboration between the students in both individual and between the members of the group.

Generally, if the student's task is not well done, his/her mark is bad. Moreover the group's mark will be affected. It happens because the lecturer considers that the group has not collaborated with this student enough to carry out that task. Thus, if there is not any collaboration between the students, it will affect negatively the final mark of the group.

IV. Students' Opinion

Once the final practice assessment and the test performed by the lecturer are finished, the student receives a questionnaire in order to know their opinion. The questions are shown in Table I. The questions give their opinions about the course, theoretical contents, if they enjoyed the practice classes and the improvement areas for a further course. The questionnaire was fully anonymous.

TABLE I. Questionnaire

Nº	Questions	Valuation			
		None	*Little*	*Quite*	*Very Much*
1	Was the theoretical knowledge enough for the practice classes?				
2	Was the material adequate?				
3	Did the facilities made easier the teamwork?				
4	Was the length of the practice classes adequate?				
5	Was the number of practice classes enough?				
6	Was the final practice assessment difficult compared to the practice classes?				
7	Does the collaborative work system make easier the learning process?				
8	Is the system used to assign marks adequate?				

A part of this questionnaire, the Polytechnic University of Valencia makes its own regular questionnaire for all subjects that are taught in every school and faculty of the university. This questionnaire is presented to the students few weeks before the course ends. They are also fully anonymous, to protect students towards any lecturer's reprisal. They evaluate aspects like didactic material, slides and books, the resource usage, quality of the master class, etc. The results are presented to the lecturer once the course has finished, thus he can self evaluate and improve his training method. But university questionnaire is different of the one presented by the lecturer at the end of the final assessment, which is more focused on the teaching method.

As a result of the questionnaire made along this work, a serial of graphs were obtained from the information gathered from all groups. The results are shown in the next section.

V. Results and Discussion

The following graphs show the results of the questions. We show the answers obtained for each question. The average marks are rated over 100% of all answers obtained from the students.

Fig. 1 shows if the theoretical knowledge is enough for having the hands on skills. The 62% of them totally agree with this statement, around 38% believes that the theoretical knowledge should be wider. Assuming that students can extend their theoretical knowledge on their own, and with the huge amount of satisfied students, we conclude that theoretical knowledge and hands on skills are balanced.

The results for the second question are shown in Fig. 2. Half of the students have total grade of satisfaction with the used material, meanwhile the other half quite agree. This happens because the Higher Polytechnic School of Gandia has very well equipped laboratories in both quality and quantity. It makes the students to work very comfortable during their practical classes.

In fig. 3, the results show that almost 50% totally agree that the facilities make easier the teamwork. A 38% thinks it should be improved some how. Approximately 12% of them disagree this statement. We think that these results have not been higher because in the actual educational system the students do not work in groups. At the beginning is harder for the students and they do not notice its advantages.

Fig.4 shows that half of the group disagrees with the hands on skills length. This is mainly because if any problem appears, the time needed to finish practice increases significantly. It is important to notice that 35.50% quite agree and 13% totally agree. In further research, we will take into account if the student has previous experience. These results may give some new criteria for group formation.

Fig.5 shows that 63% of the students agree with the number of hands on skills made toward 37% that disagree. We should remember that this is a hands-on-skills-based learning method and the number of practices is quite high. The total amount of work is high, thus some students get carried better than others (which is reflected in their results).

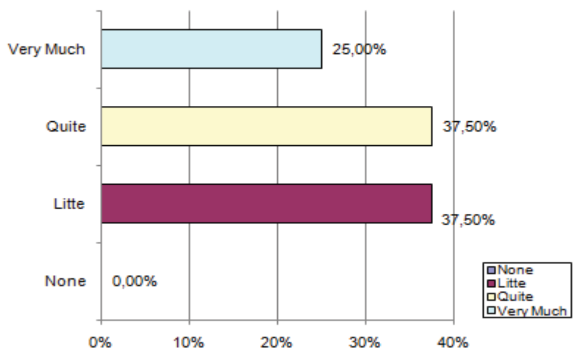

Figure 5. Results Question 5

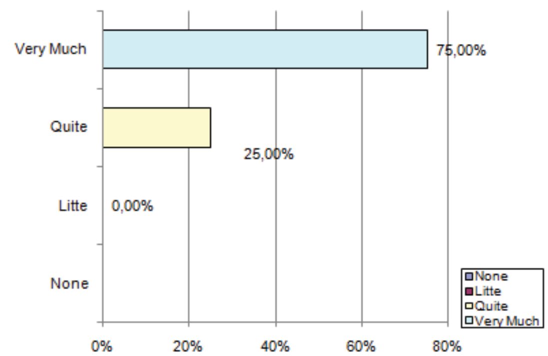

Figure 6. Results Question 6

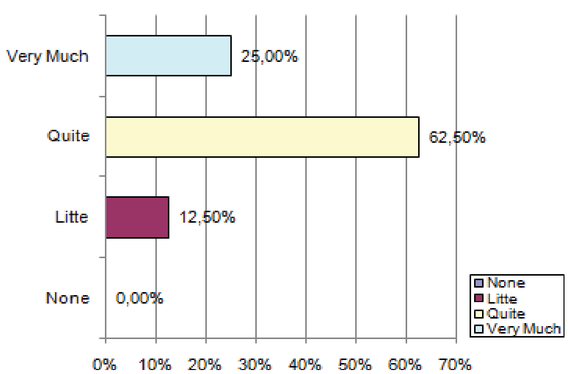

Figure 7. Results Question 7

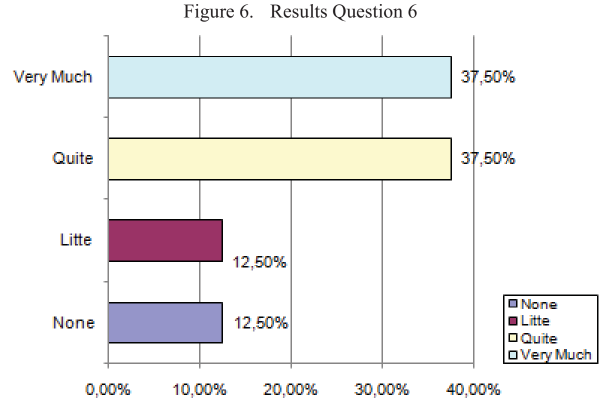

Figure 8. Results Question 8

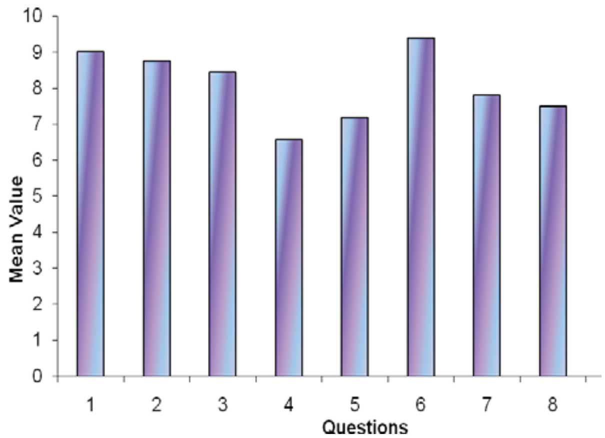

Figure 9. Mean Value about over 10 about the survey result.

When we asked the level of difficulty of the hands on skills, we see that students feel absolutely satisfied with them. Their answer is shown in fig. 6. Thus, we have achieved the goal of having the same level of difficulty in the hands on skills than in the final assessment practice.

In the question of the balance between degree of learning and team working, we obtained the results shown in Fig. 7. 87% of them agree or totally agree and very few disagree (13%). This question is quite related with question 3. The students that don't see the benefits of the teamwork will not appreciate its influence in the learning process in a collaborative work. Some students think that the collaborative work is an extra load added to the existing work instead of an exchange of experiences and knowledge. It mainly happens in those students which knowledge overcomes the others.

In the assessment system, there are different opinions. Fig.8 shows that 74% agree and 26% disagree. Notice that their mark is obtained from both, the individual and the group mark. On one side, this system let the students, which couldn't reach high marks individually, take advantage of the group marks. But, on the other side, the individual marks let us to reward the effort of the distinguished students.

In fig. 9, we see that, in a general way, students do appreciate the method used in these subjects. All questions have an average value higher than 8. Assuming that with these questions, to reach a vast number of variables is wanted, which are involved in the training-learning process, we understand that the global average of these questions are significant indicators of the degree of satisfaction and perception seen by the student.

VI. STUDENTS' RESULTS

In this section we show the results and the global average marks obtained by the students that have undergone this training method. We highlight that the whole number of students that carried out this assessment was low because the classes are formed by reduced groups. In Local Area Networks subject there were 8 students in 2007-08 course and 14 students in 2008-09 course. In the Networks Integration subject there were 22 students in 2007-08 course and 11 students in 2008-09 course. As it has been aforementioned in this paper, we gathered data from the students of both subjects. Therefore this section shows the results obtained from both subjects during the academic years 2007-08 and 2008-09.

Table II shows the subject "Local Area Networks" during the course 07/08. There were 8 students. 6 of them made the final assessment. The average marks obtained by the students that pass the exam were 8.1 points. Figure 10 shows that the 75% of the students passed the exam, but the 12.5% did not pass it.

Figure 11 shows the global marks taken by the students of "Local Area Networks" subject during the course 2007-08. Most of them have a mark higher than 7. We can see that the students obtain high marks.

In the next year, the same subject was attended by 14 students and in this case, 11 of them made the exam. The global average mark obtained by the students that pass the assessment in this course was 7.85 points. This information can be seen in Table III.

Fig.12 shows that approximately 7% of students failed the exam, compared to 71.43% that it passed it. It demonstrates that the number of students that pass the subject is quite high.

Fig.13 shows the average marks of the students during the course 2008-09. We can see that almost all obtained marks between 6 and 10 (3 students obtained a mark between 6 and 7 and between 9 and 10, and 2 students obtained a mark between 7 and 8, and between 8 and 9).

The subject "Networks Integration" is taught in the second four-month period. During the course 2007-08, 22 students were enrolled in this subject, but 2 of them did not take the assessment. The global mean mark obtained by the students that pass the exam was 7.29 points. These values are shown in table IV.

Fig. 14 shows that only 9% of the students decided not do the final assessment. 18.18% of the students failed, but, on the other hand, the 70.72% passed it.

The average marks of the students that passed the assessment of the subject "Networks Integration", during 2007-08, remained close to 8. We can see in Fig.15 that most of the students had a mark between 7 and 8.

Network integration subject had 11 students during the year 2008-09. In this case 7 students made the exam. The average mark obtained by the students that passed the assessment of this course was 8.87 points. This information can be seen in Table V.

Fig.16 shows the percentage of the students that passed, failed and didn't do the assessment of the "Networks Integration" subject during the year 2008-09.

Finally, Fig.17 shows the students marks of the subject network integration in the year 2008-09. The mean value of the marks is between 7 and 8.

VII. Conclusions

In this article a hands on skills collaborative assessment method has been presented. It is carried out in the subjects "Local Area Network" and "Networks Integration" of the Degree in Technical Engineering in Telecommunications of the Higher Polytechnic School of Gandia of the Polytechnic University of Valencia, Spain. This study shows that the method had a positive acceptance by the students. Compared to other subjects, students have higher final marks and there are more students that pass this subject than other subjects.

This study also gives us enough reasons to prove that the didactic method used in these two subjects is effective. The training-learning process has a positive feedback for the lecturers because the students are more motivated. The active learning style makes easier to acquire knowledge, which is the main goal for the lecturers and students. The hands on skills in the laboratory and the collaborative assessment push the students to learn from real situations and problems, and from the experience.

The main drawbacks or difficulties observed from the point of view of the teacher have been that the lecturer has to be a high expertise in the topics of the subject. He/she has to be able to solve any issue quickly and, always, giving an appropriate explanation. Moreover, he/she has to be updated about the new technologies in existence in the market. It is also recommendable to be in the enterprise for several years in order to learn from this environment its difficulties and problems. Then, it will be easy to transmit these skills to the students. Finally, we have to say that the first year is the one that more time is needed to implement it. The lecturer uses a lot of time designing the method and solving the holes derived from implementing a new idea. The second year is used to fix any issue observed and to systemize some parts in order to make an easy and quick implementation method.

We suppose that there is high number of students which are interested on these subjects, motivated and, finally, have passed the assessment because of the type of methodology used. Both subjects are practical and both have hands on skills assessment, which make the students to be initially interested in enrolling in it. At the end of the two subjects, students are positively surprised, because the practices that they carried out can serve them to enter a workplace and perform their duties without problems.

Now, we are working in several issues in order to improve the methodology. On one hand, we shall exhaustively analyze the way to form the assessment groups. It may be formed using any type of criteria (according to their knowledge, temper, special interests, etc.). On the other hand, we shall study the number of members in each group and their impact in the final mark.

Abstract— **This paper presents a web application designed to allow better workload distribution during a semester. The tool was designed to face the new goals that are required for teachers that work within new methods that are fostered by the Bologna Treaty implementation. The tool can help course administrators to improve the effect of some extra-initiatives (talks, workshops, tours, short courses, amongst others), without compromising the performance of students on their work scheduled for the course activities. The paper presents and discusses the motivation and the developed tool.**

Keywords-Internet; education; workload; pedagogy; interaction

I. INTRODUCTION

Nowadays high education institutions, all over Europe, are getting the first results from the implementation of the Bologna Treaty guidelines. According to [1] this treaty's main goal is "… to create the European higher education area by making academic degree standards and quality assurance standards more comparable and compatible throughout Europe, in particular under the Lisbon Recognition Convention…"

After the treaty implementation, in several Universities, Polytechnics or High Schools, the results begin to emerge and are in some cases reasonable but on the other hand there are some unsatisfactory results. These results depend not only on the institutions where the treaty was implemented but also from the actor's (teachers, students, etc.) point of view. According to [2], one of the consequences of the Bologna treaty is that "Teacher-centered knowledge-based teaching, resulting from memorization, turns into more democratic and balanced model where the student and teacher are closer and where personal contact is more prolonged and with more benefit for both. In this new model the student is responsible at a different level his/her work being more independent, autonomous and creative.". This means that the student's learning process is more based on the work and research they do, in an active way, than on the passive listening to what teachers say. A consequence is that teachers propose several works that must be done by students in the scope of the classes/subjects that they are registered on. This can lead to an excessive workload during certain phases of the semester or academic year.

It isn't our purpose to analyze the Bologna treaty implementation in this article. Our goal is to present an application that was designed to help the supervision of students' workload and to help teachers to have an idea about the amount of work of their students, having also in consideration the other teachers work proposals to those same students. This necessity was detected throughout the students' feedback that complained about the excessive workload required by the teachers during the semester. As consequence of this excessive workload we have notice an increasing class absence of students in the last weeks of the semesters because the deadlines to finish and deliver their works are generally in this period of time. If students have subjects from previous academic years, due to failure in past year(s), this scenario becomes even worst. To try to smooth the student's workload and give a different perspective to the involved teachers, a web application was designed and it is the main contribution of this paper.

II. THE TARGET SCENARIO

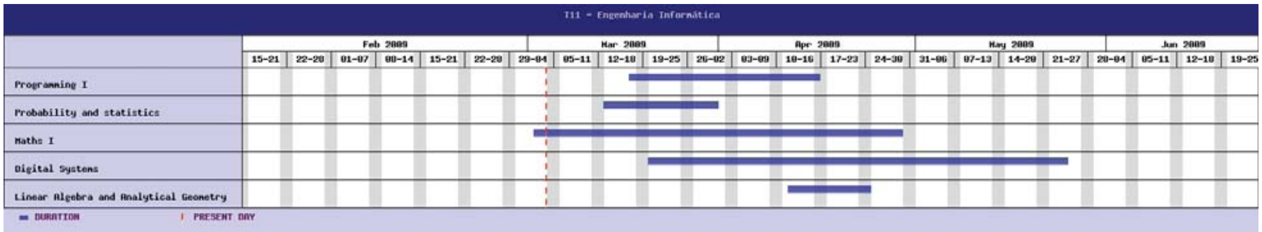

Figure 1. Gantt chart (Student's view)

In our department, Computer Engineering department of a Technological Engineering School in Portugal, before the adjustments to the Bologna Treaty guidelines, we had several courses with a ten semester's curriculum to achieve the degree of Licentiate. The five years required to graduate was at that time accepted by the national Engineers Professional Organization [3] (OE) as the minimum requisite to be its member; in other words the time needed to be allowed to develop a professional engineering activity. On the other hand, students could finish the course in the end of the 6^{th} semester and obtain the Bachelor degree. They could then begin to work, but with only these three years formation they could not apply to bean OE member. Nevertheless they could be recognized professionals by another institution, the Technical Engineers organization [4]. After taking their degree, students can continue their studies, masters or PhD, in other education systems, mainly universities in the specific case of the PhD.

Nowadays, in the Bologna era, courses passed from 5 years to 3 or 4 years duration, and the bachelor degree has disappeared. Post-Graduations and Masters became a 1 or 2 years complement and the PhDs became a 3 years program.

In this new scenario, after the course adaptation to the Bologna Treaty format, and based on our experience dealing with the students of our degrees (courses with 3 years duration), we have notice that students, complain about the excessive workload in the last half of the Semester. On the other side teachers don't have any information concerning the workload requirements by all the other subjects on a certain academic semester of a particular course. This "blind" reality, even to those institutions that possess e-learning platforms, fosters to situations that leads to an excessive workload. This can affect the students' performance/success. To give visibility to the work demanded by the several subjects of a given course, and to provide a clear overview of the work required from students, we propose a web tool that will be explained in the next section of the article. This beta version will be available in the next academic year and we expect to improve the work planning process from the point of view of students and teachers.

To resume, as previously referred, teachers suggest work proposals without knowing the others subjects' schedules/workload, and no previous knowledge about other activities (exams, workshops, study trips, etc). This led to students complains about an excessive workload in specific periods of the semester and inefficient work distribution during the semester. This motivates the design of an application to make visible the demanded student's work for all actors (teachers, students and course coordinators), to make easy to share information about the proposed works deadlines, to allow a global view about the course activity deadlines, and to allow all actors to contribute and interact with it. The tool presented in this paper was designed to allow these requirements. It is a web application that is described in the next section of the paper. This tool was already described on [5], and in this paper we add some new features that were adjusted/included after feedback from users that used a preliminary release of the tool.

III. The Tool

To implement the proposed tool, a web application was developed to enable all the management and view of the expected workload for a class/subject/course. The actors are the students (targets of the work proposals) and teachers (acting as general chair and the others acting as work proponents). The system was developed as a PHP [6] application with a MySQL [7] database engine. The back-office and front-office parts allow the management of all the interactions between the actors (registration and user hierarchy) and also the user-system interface respectively. In our opinion the interesting contribution of this paper is not the software application – because it is common to others already available - but the target application in terms of pedagogical issues and goals.

In the case of the proposed tool, some of the actions allowed for each actor are:

Administrator: validate teacher's registration; define the subjects for each course; consult any information in the system;

Students: See the time schedule and time duration of the proposed works and estimate the expected workload for a

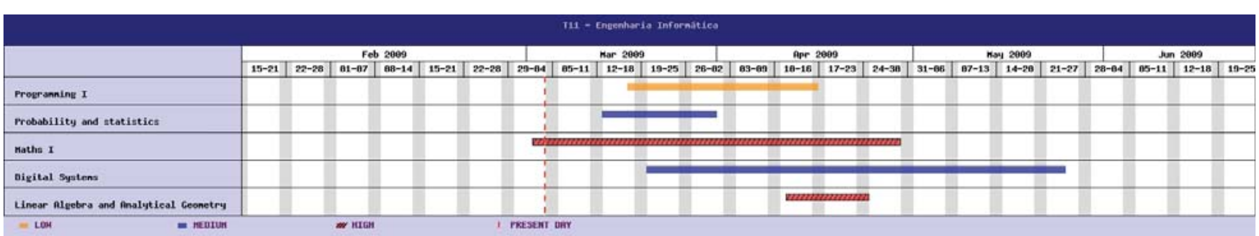

Figure 2. Gantt chart (Teacher's view)

semester/course.

Teachers: Insert/change/delete a work proposal (time duration and difficulty). See all the already proposed works for certain class; visualize the global workload of their students.

Fig. 1 shows a screenshot of the application from the students and the visitors' point of view. Here we can find information about each subject of the semester. In our case, during a semester for a certain academic year (3 years to obtain licentiate degree), there are a large number of classes (usually a class has approximately 25 students enrolled in it). In Fig. 1 is presented the case of the class possessing the ID T11 (1st year, 1st class) for the "Computer Engineering" (in English) / Engenharia Informática (in Portuguese)" course. Using this view, the visitor can easily observe the Gantt chart of scheduled works. Teachers also have a similar view of the already proposed works, by other colleagues, thus having an idea about the required effort, because the work difficulty estimated by the other proponent teachers can be observed and distinguished by different colors (Orange - Low difficulty, blue - medium difficulty, Red - high difficulty), Fig. 2. By consulting this view, teachers can analyze the scenario before launching their work proposals/plans.

Students are not allowed to see the color code, because after feedback from colleagues, we conclude that this is not intended to limit the work's difficulty or to be used by students as excuses. The goal is to alert and help to improve their schedule and not to limit the teacher's goals for their subjects. The teacher will always have the last word, but knowing the global scenario that is being impose to his students, in a non-blind scenario. Fig.3 presents the GUI for students to choose classes. After that, they can consult the Gantt chart for the selected class, interface will be then similar to Fig. 1.

Teachers are validated by the systems' administrator. They are allocated to subjects of certain course. A teacher can only edit the time schedule for his subjects. But when editing the workload for his subject he/she views the scenario expected for the student's semester, in other words, all the works already scheduled for a particular academic year and semester. The teacher's view using the GUI to insert/edit a work for his subject is showed in Fig. 4.

As we can observe in Fig. 4, the teacher in the left can see and choose to edit the settings for the subjects allocated to him by the supervisor. In this example the teacher Jose Metrolho has two subjects for this semester which are: "Software Development" and "Computer Architecture". For each of these subjects it will appear in the right area the global scenario according the course curricula. For example, in case of "Computer Architecture" it will appear in the right area the already scheduled works for other subjects of the same course and semester. This means that before editing/inserting a work proposal, the teacher has a perception of the already demanded effort to those students. This is the goal of the application.

To insert a new work a form must be filled, as can be observed in the right down area of Fig. 4 (Title, beginning and deliver date, difficulty level, if it is a written exam (in this case will be set only the start date) and optional about that work details that will be available for all visitors).

Figure 3. Graphical User Interfacefor students to choose the their classes (minimum of one) within certain course. Each class has several subjects. Each subject as a Time Gantt chart similar to the one showed in Fig.1.

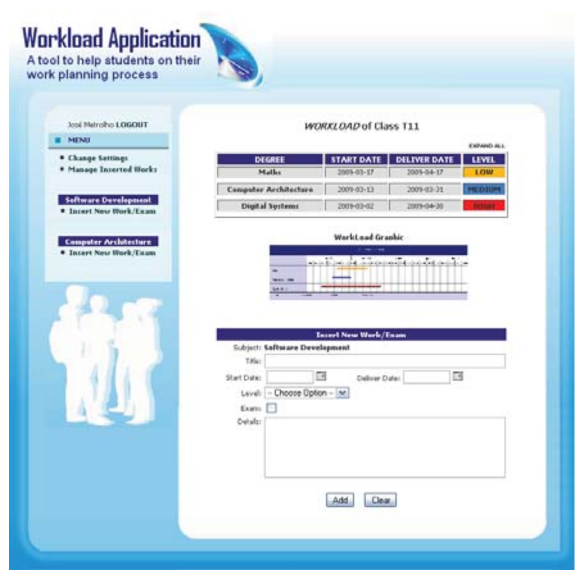

Figure 4. Graphical User Interface to propose a work by a teacher

The administrator is responsible to define the set of subjects for a certain course, insert all the courses and corresponding curricular plans. Fig. 5 shows a screenshot from the subject vs. course correspondence. A subject can be common to one or more courses. He is the one also that inserts the teacher's name and the corresponding email address, Fig. 6. The password is automatically generated for each registered teacher and the system sends it by email. The teacher-subject correspondence is also set by the administrator at the beginning of the academic year.

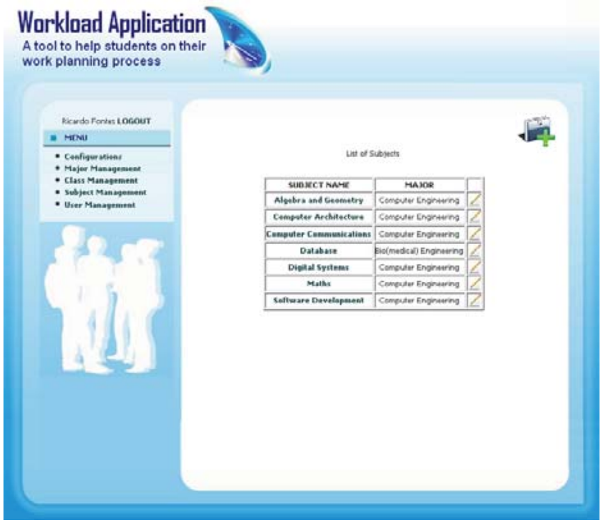

Figure 5. Graphical User Interfaces of the Administrator's back-office to define subjects of a cource

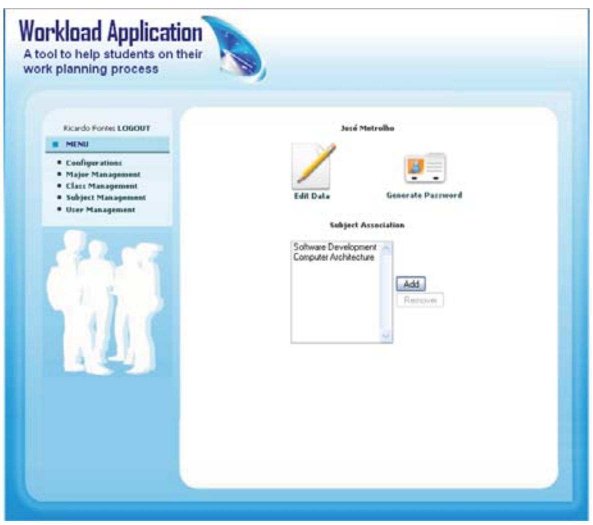

Figure 6. Graphical User Interfaces of the Administrator's back-office to edit data about a teacher's profile

IV. Conclusions

This paper introduces a web tool to allow better assessment and workload distribution along a Semester. The tool was designed to face the new goals that are present for teachers that work with new methods that are fostered by the Bologna Treaty implementation. This is the case of computing, programming, communications or embedded systems, amongst other courses.

In our opinion, this tool can also help course administrators to improve the effect of other initiatives (talks, workshops, tours, short courses, among others), without compromising the performance of student on their scheduled work for other course subjects. This view of the time table can lead to a better organization of extra activities in periods that do not compromise the students work production.

Another feature is to improve the students' organization skills.

The contribution is to improve the student's performance and not to impose limits to the number and difficulty level of their workload. The number and difficulty are responsibilities of the involved teachers, so the system doesn't have means to impose limits. The system just gives to the users an overall view about all the demanded workload, this information can then be used to achieve better results by smoothing the student's workload as possible, through a correct work planning.

The tool will be used in the next semester and the expected results are: improve the course(s) coordination; improve the work balance; improve indirectly the work's quality; improve the student's success rates, improve the student's grades and improve the impact of extra activities. In terms of software application we pretend to improve the application based on user's feedback, make available the application to be used by colleagues of other Institutions, and improve the design of the GUI. Actually we are implementing, as ongoing work, and advisor module (alert about the deadline approach by email for the registered students and teachers).

Acknowledgment

Authors acknowledge the collaboration of the teachers that used the system along the experimental period.

Abstract— **this paper has information about the elaboration process of a knowledge Portal based on the relation between university and company. During this process, a study about knowledge management technologies was done to guaranty that the knowledge-life-cycle will be present in the relation between Universities and Companies; it could be implicit or explicit knowledge. One of those technologies used were knowledge management models (we present an alternative knowledge management model focus on University-Company), knowledge maps to identify and locate the knowledge present inside the organization. Theoretically the contribution of Eduardo Bueno [1], gave us a support to set the model based on his proposed model Intellect.**

The Project was proposed as a solution to the detected problems because of the lack of communication between University and Company. One of the problems that we found was social problems and others were technological problems, both of them appear as a result of the economical crisis around the world.

Keywords-component; Knowledge Management; Knowledge Portal; Organizational learning; TICs; University-Company; knowledge maps; knowledge management model; Web 2.0.

I. INTRODUCTION

The Project was proposed as a solution to the detected problems, caused because of the lack of communication between university and company. One of the problems that we found was social problems and others was technological problem; both of them appear as a result of the economical crisis around the world. So, it is important to create a different way to solve this problems, identify problems and solve it in order to improve human conditions should be the principal goal inside research groups. Moreover, if company and universities united their efforts to apply these solutions, it could be an economical change.

The current crisis, produce unemployment talking about the people who had just graduate or the amount of company that become bankrupt because of the lack of innovative process, products and services that allows them to be competitive in the rising marketing. However, inside the university there are innovative developments of products more specific inside research groups. Sadly, most of the times, these products are not use properly and became obsolete.

These products could be implemented inside companies so that they can generate innovative products and services in order to be competitive. So, the purpose of this project is divided into two different goals, they are: set a new knowledge management model (UNEM "Universidad- Empresa", that identify the knowledge every person in the organizations has and its behavior, it means, how it knowledge is use inside the organization to generate utilities, new process or create new products and services, developing a Knowledge Web Portal supported by a robust standard (J2EE "Java 2 Enterprise Edition"), with implementation of different tools of Web 2.0, among other systems that allows the interaction between the portal users, as well as easy share information, such as, products and services of companies and research groups of Universidad Distrital Francisco José de Caldas. Based on a model that was proposed, the idea is use knowledge management to change the organizations (University-Company) minds and made they learn to learn of themselves.

Also, is important that University and companies understand the importance of communication between every single person in the organization. This Project is a technological alternative to the organizations that really wants learn to use existing resources and learn to generate strategies and opportunities to the members, talking about Universities, students, teachers and researchers [2].

Knowledge management allows manage human resources and streamline processes within the organization. It detects the knowledge and finds the way to used it for all people and then generates new knowledge. There are a tool that allows Knowledge management applies models, is known as a knowledge portal, it is a way to organize all the information in order to be presented easily to the community and also be used in the best way, improving organizational processes.

Within its functions knowledge portal allows easy communication between portal users.

A problem that we found in our research was the lack of communication between Universities and Factories. Communication must be the principal challenge inside organization who wants to apply a knowledge management model. It could be the way to learn from the organization. But also, is the way to create new innovative process.

Being the knowledge that the persons possess one of the most useful resources inside the organization and the society and a different resource from other resources with which an organization arranges (land, machinery and capital), often it is not taking into account, for this reason it becomes obsolete in certain time. That is why there is a need to manage this knowledge. But first, it is important to identify where the knowledge is and who is the owner. For that, it is important to use knowledge maps and try to do it as personalized as possible. Once the organization has a map with all the information about knowledge they have it is important to share this knowledge but also identified what is the knowledge that the organization do not have it means identify the what kind of knowledge is needed. It could be the way to improves dramatically the organizational processes.

From the university and the company perspective, knowledge is constantly developing and it is necessary to identify it, use it, adapt it and disseminate it to obtain new knowledge that can be used for the organization (both University and Factory) and the people inside this one.

Within the developing process of the portal was performed an organizational analysis at the University and Company, to determine these critics nodes, as well as actors and sources of knowledge. It was also established the role of each of the nine players with which the portal counts, it was identified the concerns of each organization to establish contact and other content for the portal. Having identified the nodes were raised following the development of the subsystems to solve the different problems found, within the subsystems are: i) registry Subsystem, ii) Storage Subsystem iii) Research Groups and Companies Subsystem iv) Aid Subsystem v) Communities Subsystem vi) News Subsystem vii) Interaction Subsystem viii) Training Subsystem ix) External Links Subsystem x) Manager of employment Subsystem.

After the subsystems raised with the help of knowledge management model and the knowledge maps, facilitating the process of bringing it to a web environment, thanks to the implementation of J2EE specification and other development tools such as PostgresSQL (base engine data), JBoss (application server), which finally allows interaction and feedback from players whom are students, teachers, director of research group, factory director, company staff, factory, research groups, students and Administrators of the portal.

It is important to understand the role of technology inside organization (Neyra, 2006) [3]. If an organization wants to be competitive need to use technology. Also it is important for organizations to understand the importance of knowledge or know what they know [4].

II. KNOWLEDGE MANAGEMENT

A. *KM Historical Review*

Knowledge Management is used from unmemorable times, even in the migration of the people, the different cultures and knowledge they were shared and then different cultures arose, also we see it in the debates, meetings of the people, meetings, workshops, conferences, all these are ways of manage the knowledge, the idea of this one is to do that the knowledge that the persons possess will be transferred to others by the intention of creating new knowledge [5].

Though the term of management of Knowledge is relatively new already different sources of information exist where we can find information of this one. The management of knowledge has been present in the organization during already a lot of time ago, but it was known as the analysis organizations, the difference is that the knowledge management allows us to know the company, gives us the basic points to take the knowledge that the organization has to turn into new knowledge and of this form to achieve that strategies appear to future.

The Knowledge Management is so a useful term for the organizations and nowadays all with different modalities, to be able to capture and carry out all the processes of the knowledge inside the organizations, inside these we find the Knowledge Portals [6]., without leaving behind other technologies that are implemented at present as well as mobile applications applying Knowledge Management and the production of knowledge maps for each of the users of the portal, already there exist users who alone wish specifies information, for this the knowledge maps are useful to identify that a person possesses some kind of knowledge and since this one can be transferred to another person who needs it.

B. *KM Concept*

Knowledge management is defined ace all activities taking place inside an organization to uses, audience share, and develop the possessed knowledge by individuals within the same order that they ploughs geared towards obtaining the best aims of the organization. To implement the knowledge models we uses different tools to develop Web portals such ace the site of which we speak in this paper whose name is UNEM.

To knowledge portal is that one that establishes to relationship between people who access the knowledge and the knowledge that have been established at to steal when in the Web for the benefit of an organization.

To foster this relationship between users and portal, this latter count with the help of forums, chat, and definition, sometimes virtual communities interested in sharing and feedback to obtain a new knowledge based on knowledge already possessed.

A knowledge portal structure must suppot the life cycle of the organization allowing it to be able to continue with the cycle of knowledge and finally the publication of knowledge. Therefore, a knowledge portal is an influx of information, knowledge and applications through Web.

The portals are an essential component of a knowledge management model and knowledge itself, since it is one of the means used for the transmission of knowledge that is captured through the processes in each of the models.

They come with the aim of ensuring that knowledge comes in a timely and clear to the users ones they require it in certain moment. The portals allow the user access and allow for the exchange of information.

A knowledge portal specializes itself in a topic, so that this should be dealt in depth, thus providing full coverage and led to a community of users.

In the current world of set up of new virtual companies the representation of knowledge portals is something fundamental in this step, providing a point of personalized access to optimize the power supply decisions. Not only virtual enterprises enjoy the benefits of a knowledge portal in general all organizations can deploy using them to improve productivity by innovating organizational processes.

ICT (Information and Communication Technologies), make this kind of technology very broad allowing them to be implemented with a number of tools; this concept is too wide because the knowledge management philosophy are not even institutionalized. Now with the help of ICT is not necessary that the exchange of knowledge is in person or to obtain necessary information by going to the office branch of the organization, these new technologies enable the digitization of information by making it easily accessible and allowing a easy communication through chat rooms, forums, blogs and wikis.

C. Importance

The knowledge management is useful for all and each one of the organizations, because according to the knowledge management model which is defined the innovation of the processes is guaranteed inside the organization that will meet reflected in the increase of utilities of the organization, thanks to the optimization of the processes of knowledge.

For the implementation of the knowledge management model technology puts to our scope the tools that facilitate this process in an Web environment doing that the users of the portal could know all knowledge process, doing that it contribution to the company is every time better in terms of profit. It is necessary that the persons know the organization.

III. DESCRIPTION OF THE SOLUTION

One interesting thing about this research project is the model that we create. In order to create the model it was necessary made a knowledge map. It is an important tool to identify not only the knowledge that the organization has but also the one that it do not has. The map also shows the different roles inside the organization, it means that doing the map helps us to know who has the knowledge. Fig. 1 shows a resume of the knowledge map.

Once the map was done, there was necessary to create a Knowledge management model, to guaranty that the process of knowledge succeed in complete their cycle. Nonoka [7], presents the important of make tacit knowledge explicit, that is the way that process that knowledge have to do.

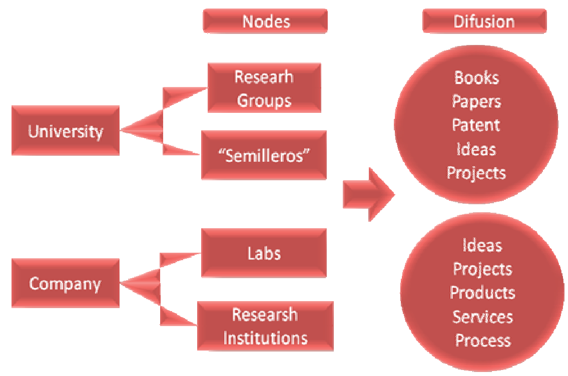

Figure 1 Knowledge Map (Resume)

Also, the knowledge portal was developed on a technological platform that was studied and considered to be appropriate for its implementation. Talking about the programming part we employed the standard J2EE because it give us a business environment and an application handles multilevel to give more safety to the application; this sort of standard handles the persistence cap, the logical cap and the cap of presentation of an independent way but each one connected with the previous one.

To handle the persistence of information we rely on the help of the Engine of Database Postgresql-8.1.3 that facilitates the managing of the information of the users, the portal as well as the information of the groups and the companies associated with the portal.

And finally as applications server we used Jboss-4.0.2 which supports the functioning of the application in the Web. The server is mounted on Operating system Linux.

The platform technology is necessary to implement the model of knowledge generated after the organizational analysis, the study of knowledge management in addition to the mapping of knowledge. This has a friendly user interface that allows people to put participants in the processes of knowledge and continuous creation and transfer of knowledge present in person the most important resource of the organization.

All the tools created in the portal born as a result of the knowledge model and try to solve the problems of knowledge inside the organization detected in the knowledge map.

IV. METHODOLOGY

In this section we will explain the methodology used for the elaboration and afterwards putting in action the Knowledge Portal to foment the relation between the University and the Company in the Electrical Sector, the general methodology is described in the following table.

TABLE I General Methodology

Stage	Description
Analysis of the organization	Inside this stage the organization is known, and there are identified the sources of knowledge and the nodes of the organization. It is important study the organizations looking for the organizational learning [8].
knowledge Management	There is guaranteed that there are fulfilled the processes of knowledge management. Inside the processes of knowledge that we find; apprehension, organization, to share, to learn, to apply, to evaluate. The necessary thing here, is to guarantee that is learned and the knowledge is applied for the approach of strategies .
Functional scheme - knowledge management model.	In this stage the model of km appears. That must satisfy the needs of the company and allow that the processes of knowledge should be fulfilled totally. In order that the platform will be as ideal as possible.
Technological platform	This stage is the Model implementation of KM in a Knowledge Portal working in the Web and fulfilling the knowledge processes, doing of the organization an entity that learns constant.
Implementation	After the developing of the portal it is necessary to do the assembly in the Web, in order that it is used and evaluated by the direct users. In order to improve it constant.

For the elaboration of the Knowledge Management Model an analysis of the organization was realized in order to guarantees to know all the sources of knowledge inside this one, as well as the selection of the knowledge, it is necessary because there exists knowledge that odd is useful to the organization. This model is a general scheme of what must form of the application Web.

In a general way, fig 2 describes the knowledge management model, the result of analyze University and Factory. It shows the principal systems to develop in the portal, also shows the nodes or the different roles to use the portal, also the portal describe the source of knowledge inside the organizations (University and Factory).

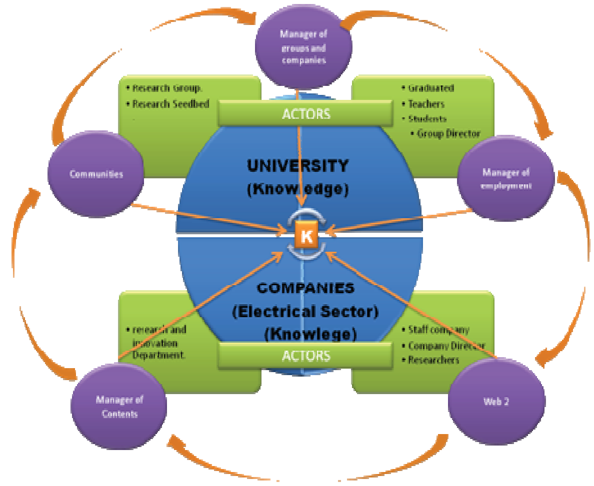

Figure 2 Knowledge Management Model

There are different models but this model is based on postulates of Eduardo Bueno (Bueno, 2004), who talk about the knowledge as an active of the organization as well as Human Capital [9].

A. *Organizational Analysis*

In conducting the analysis within the Organizational and Business University different active nodes were identified, among which are; with sub-nodes University Research Groups and Seed Research, the Electricity Sector Enterprises. The first node includes a University subnodo very important for the development of the knowledge portal for Research Groups and Seed Research who are the largest producers of knowledge within the university, it is clear that within these nodes are located; students , Head of research groups or seed, faculty, alumni, we consider them as producers or makers of knowledge. The second node is detected the Enterprise around which argues the knowledge previously acquired through practice.

B. *Knowledge Management*

Inside the frame the knowledge management, persons are the most important resource of the organizations.

The most important within an application within the parameters of knowledge management is to ensure compliance with the various processes of knowledge that make this a tool for creating innovative processes within organizations that apply its principles.

Among these are: Organization, Sharing, Learning, Implementation and Evaluation. Within the knowledge organization the most important thing is to identify the sources thereof within the organization and thus able to make a classification and identification of obsolete knowledge within the organization, this process may be known as discovery of knowledge.

Sharing knowledge is the principal key in knowledge management process that ensures that knowledge is not lost, because it must be owned by each members of the organization, without running the risk that this is own of a single person, on the dissemination of knowledge makes this knowledge better.

Once knowledge is disseminated by different means (between which the portals of knowledge stand out), this should go through a learning stage, the learner must assimilate this new knowledge and apply it to ensure that the transmission of that Knowledge was a success.

As the object of knowledge management is the optimization of the processes within the organization which generate innovative models within the same, it is at this point in the process of understanding where they should strive to achieve this goal. The process that describes this innovation is the application of knowledge within the organization, with the knowledge has been gained from it, to ensure the implementation of innovative schemes to the organization, the result of the analysis of knowledge was present among the people in the organization and making it possible to satisfy the different processes.

The last step is the evaluation of performance and existing knowledge; it is worth clarifying that the processes of knowledge describing a cyclical pattern, the processes must be in continuous motion.

V. RESULTS

The results of this project are the implementation of the Portal in the Web, which contains the information of the associate companies and the research groups of the university, besides different systems that give solution to the problems found by the lack of communication between the companies and the University.

The portal allows that the processes of knowledge should be fulfilled in a suitable way and that the creation and transference of knowledge will be in a cyclical way, guaranteeing that the processes implemented in the organizations are innovative in all the aspects. In Fig 3 we can see the results of the different subsystems of the portal. The final Portal is known as a UNEM because of its Spanish meaning (Universidad Empresa).

Currently the portal is been proved. One company of the electrical sector is helping us to prove the portal; this company is working with the "Universidad Distrital Francisco Jose de Caldas", which is the University where we developed the project. There is a huge communication problem and with this project we are trying to solve it. However, it is a long process in which the portal is going to change according with the necessities.

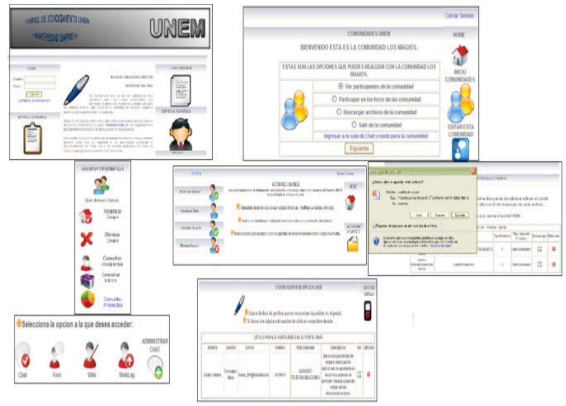

Figure 3 Project Results

This project will raise the design of a knowledge portal that allows users to interact and most importantly allowing users of the knowledge portal to access information in an easy way and search for information more effective. It portal has the following subsystems:

- Registry Subsystem: allows the management of users in the portal to facilitate the collection of contact details for them.
- Research Groups and Companies Subsystem: It allows the information management of groups and companies.
- Aid Subsystem: It allows browsing by the portal is easy.
- Communities Subsystem: The communities that allow users interested in specific issues, easily find information on this, in addition to being with others who know the subject.
- News Subsystem: Este sistema permite la comunicación de noticias y eventos a todos y cada uno de los usuarios del portal.
- Interaction Subsystem: It is one of the most important systems because it allows the permanent communication between the users of the portal.
- Training Subsystem: thanks to Moodle can be programmed courses for University or Companies.
- External Links enables users to include links of interest.

VI. CONCLUSIONS

There is not a unique knowledge management model, because the companies internally are different, so it is necessary to do an analysis of the organization in order to know the functioning of the organization.

The most important resource of the organizations are the persons specially their knowledge, so it is necessary to find the way of implementing systems that allow that the persons should interact in order to guarantee that the processes of the knowledge are implemented satisfactorily.

Do not exist a unique knowledge management model, because the companies internally are different, so it is necessary to do an analysis of the organization in order to know the functioning of the organization.

The most important resource of the organizations are the persons specially their knowledge, so it is necessary to find the way of implementing systems that allow that the persons should interact in order to guarantee that the processes of the knowledge are implemented satisfactorily.

The elaboration of the knowledge management model allows identify which are the nodes to take into account in the knowledge portal.

Wikis and blogs are very simple but also very powerful tools. If you managed it well, it could be fundamental engines in the knowledge management talking about the organizations.

It is important for organizations implements knowledge portals if they want to improve the internal processes.

The knowledge portals are indispensable in the organizations that want to improve the internal processes.

Abstract—**This document reflects the results of the study at the end of the course, which justify how the application of problem-based learning and collaborative learning help the student to take on board in the most appropriate way the study material. An analysis of the results of the surveys carried out amongst those students learning Communication Systems in Industrial Technical Engineering was undertaken, in order to evaluate whether the application of Problem-Based Learning (PBL) methodology together with Collaborative Learning (CL) was likely to improve the rate of development of their ability indispensable in today´s business world, and also to achieve those objectives set out in the course. By far the majority of students showed a very positive attitude towards this methodology, their objections being very limited. A comparison was carried out with the results of those courses of a similar nature at the University of Cordoba, as was the attitude of the students towards this new methodology, with very comparable results.**

Keywords- collaborative learning, learning management system (LMS), problem-based learning (PBL), communication system, education.

I. Introduction

Despite educational methods have changed over the years according to the results (successes and failures) that the system imposes, as teachers we must find a way of looking at the challenges our future engineers face, using new ideas, developing their creativity in such a way as it improves their own knowledge and that they learn the study material at the same time as resolving a problem or proposed project. If, to this way of constructing knowledge using the problem-based learning method (PBL), the achievements of which have been collected in various bibliographical reports, we add collaborative learning to develop the intellectual capacity and the social skills of our students through interaction with their colleagues, as teachers we will have achieved two very worthy objectives: that of giving them knowledge and of providing them with a range of abilities for their future professional development.

Although it was in the Faculty of Health Sciences of the University of McMaster, that the new educational system now known as PBL was established in the 60s [1], this methodology has since been implemented in both primary and secondary education, given its demonstrable efficiency, thanks to the numerous publications that praise the positive effects of its implementation in engineering courses [2-4].

The use of Moodle, a learning management system (LMS) adapted to the course, contributes to interactivity and the meeting place of our students outside of the classroom, so important for this cooperative learning, the philosophy of which is based on development and analysis.

II. The Main Objective

This article is based on the analysis of results obtained from the students of the final Industrial Engineering course, following the application of the teaching method Problem-Based Learning (PBL) using Collaborative Learning (CL).

Communication Systems subject is elective subject undertaken during the last term of the last year of the Industrial Engineering, Industrial Electronic speciality, degree. Its aim is to analyse different systems for high speed Internet accessing. Most of the students arrive with any knowledge of this matter, due to they come from the area of Industrial Electronics.

Due to the use of both the PBL and the CL, the students develop the learning process in groups by the project solving, achieving the subject goals by experimenting and searching information sources. This methodology helps the students to understand and assimilate the knowledge through the use of basic assumptions versus the conventional method used previously mainly based on the master class. In the PBL method, the problem is first presented to identify the learning requirements and then it is essential the information-gathering process to, finally, return to the problem. Hence, the learning process is reversed. The foundations of the PBL methodology are the Cooperative Learning and the Constructivism, where the students acquire skills through problem solving.

The advent of the modern knowledge society requires changes in educational processes [5]. Everything seems to indicate that the PBL method is a better way of imparting education in communications systems, or even technology in general. PBL course students learn social skills through interaction in small groups, how to identify and define a problem, and how to look for and filter out relevant information [6]. PBL promotes engagement in meaningful learning and cooperation among students [7]. In the same way, collaborative learning changes the structure of learning in the classroom, permits interactions and makes easier and develops basics skills such as dialogue and solidarity, amongst other things. The methodology and its application for education in communication systems will be discussed in this paper.

Despite a wide-ranging bibliography which defends the positive results of the application of these methodologies, as investigators we are bond to question whether it is the most appropriate method for our engineering students, given the recent nature of its implementation in the course and the fact that as human beings we are naturally slow to adopt new ideas. Because of this, using a series of surveys, we managed to discover how people felt about the implementation of this method compared to traditional teaching methods, taking into account the final results of the evaluations of knowledge gained and cross-referencing abilities.

III. METHODOLOGICAL APPROACH

A survey at the end of the course showed that students were satisfied with the pedagogical approach. These results are based in a questionnaire with four items, where the students are asked about the effectiveness of the method applied during the semester versus the traditional method (master class) to attain the subject goals. The interrogated students were a total of 22. The contribution was compulsory and anonymous. The students take an average of 10 minutes to answer the questionnaire. The opinion of the students, allows us to tell whether this methodological practice is the most appropriate for the teaching development of the communication systems course, taking into account not only the assessment of the students involved, but also the final academic results of the students compared with the course records, which allows us to demonstrate objectively how the application of this methodology obtains better learning results, not only at an academic level, but also in the way the student is more involved in the learning programme and gets from it greater personal satisfaction. The knowledge evaluation carried out on the students, in terms of end exams, shows that there was a significant difference in the knowledge gain. The skill sets acquired were definitely greater than those acquired by the students of traditional education as was demonstrated by the results of the skill test conducted at the end of the course.

Following analysis of the observations made by the students, we can divide the evaluation of the methodology into Very Positive, Positive and Negative. Table I shows the results with the corresponding percentages.

Following are some of the comments made by the students in defense or rejection of the new methodology (Table II).

IV. ACADEMIC RESULTS AND OBSERVATIONS

Many questions have arisen and for the most part they have been assessed favourably. Equally, a small percentage shows up of students who continue preferring to develop their work in an individual way, believing that their final results will be better. The rejection by some students of the methodology in the initial phase of its application has already been described by Felder [8].

Looking at these results it can be claimed that despite the recent application of the method in the course, the Very Positive evaluation is overwhelming, in the students words "interesting", "engaging", "dynamic" working in a collaborative way in the development of the PBL methodology, favouring the exchange of opinions with those with whom they had not previously worked, given that the those people making up the groups had been chosen arbitrarily by the professor. Many underline the importance of working in a group as being a stepping stone in the way they will inevitably develop their professional careers.

TABLE I. PERCENTAGE OF EVALUATIONS

	Percentage
Very positive	63,6%
Positive	27,3%
Negative	9,1%
Total	100%

TABLE II. ARGUMENTS FOR AND AGAINST THE APPLICATION OF THE METHOD ACCORDING TO THE POSITION OF THE STUDENT.

	Arguments for and against
Very positive (63,6%)	It is an interesting method which allows for the expression of contrasting opinions, unlike traditional teaching methods where the opinion of the professor is the final word and we the students must accept that. It is more engaging being able to exchange ideas and participate. The class is more dynamic. It is a good method for interchanging ideas. It allows you to listen to the opinions of others and compare ideas. It makes you think and it is easier to retain information. Because you work in a group, the class is more active. It brings benefits such as being able to work with class-mates. One learns the opinions and proposals of ones class-mates. It is easier to understand certain things when a class-mate explains them.

	Working as a team has made it easier to resolve problems. It allows one to share the different view-points of the whole group, to learn to fit in and to work as a team. I would do the same thing again in other courses.
Positive (27,3%)	It is a very good methodology but sometimes one works better alone. Working as a team is good when all of the group members pull together. It works well when there are few people in the group, but it is better working alone when the groups are very big, given that it is much harder to make headway when so many have to be in agreement. Not all the group members put in the same amount of effort. It is a good method, but not necessarily for the entire course. Sometimes it is good to have a traditional theory class.
Negative (9,1%)	I prefer working alone. I don´t feel comfortable. I prefer the traditional method.

The students point out the fact that working in a group and with their classmates explaining certain concepts (and therefore those they consider as equals), helps with understanding and retention.

There is a certain group of students who, despite showing a positive reaction to this type of apprenticeship, allege that the application of this methodology requires more time to develop the activity than that of traditional teaching methods. Others claim that the student only really understands the part they have worked on, which shows that they do not understand the philosophy of this methodology, the point of which is that all the students achieve the objectives laid out in the course through the development of the problems or projects put forward. The fact that no one component part of the group is able to provide an adequate solution to the problem may be a negative factor in the development of the work. Finally, the lack of involvement of some of the members may also unbalance the work of the other component parts.

Amongst the negative opinions, that which stands out for a small minority of students is the refusal to accept the changes in methodology and the simple fact that the implementation of PBL involves dedicating more time to and being dependent upon a group of people who perhaps are not committed to the activity, undermining the end results.

Following we show the academic results compared with those of the two previous courses (see Figure 1, 2 and 3), in order to highlight the effectiveness of the application of the method in a teaching environment, given that the ultimate purpose of pursuing its application is to show the level of effectiveness of this methodology. It is important to point out that the enrolment number were 20 in 2006/2007 and 23 in 2007/2008.

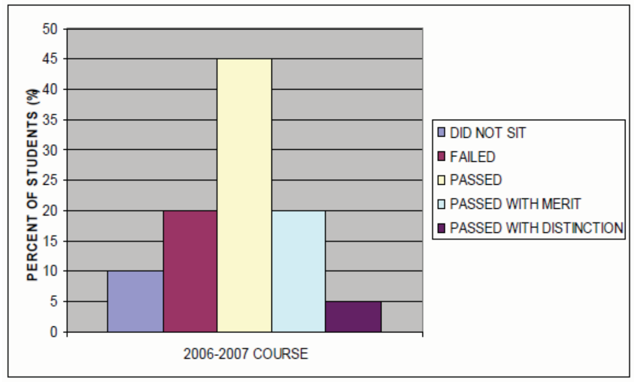

Figure 1. Results of the student evaluation: overall grades (2006-2007). University of Valladolid, Spain

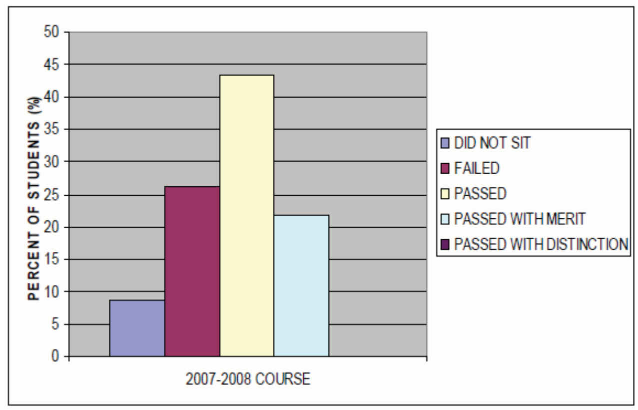

Figure 2. Results of the student evaluation: overall grades (2007-2008). University of Valladolid, Spain

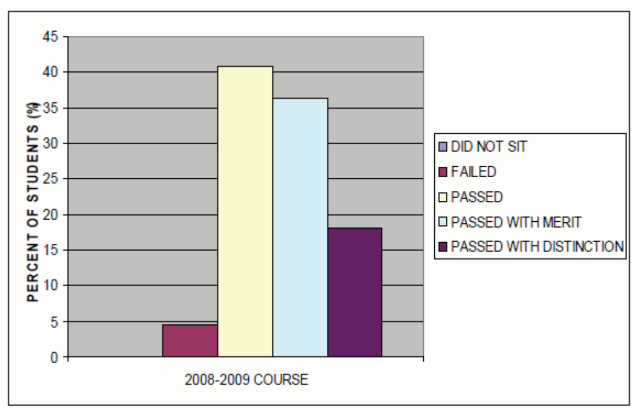

Figure 3. Results of student evaluation: overall grades (2008-2009). University of Valladolid, Spain

V. CONCLUSIONS

Thus, this article reflects the results of the study which justify how the application of problem-based learning and collaborative learning help the student to take on board in the most appropriate way the study material and improve their social skills. The social skills gaining were also observed by the students. They admit through the survey that the group working let them share, integrate, and even learnt to work in group and to listen to others, better communicating their ideas.

From this information it is obvious the need for a change in the conception of the teaching-apprenticeship process, although this does not necessarily imply that the traditional classroom environment no longer has its place. What stands out from the gathering of data is how the joint application of these methodologies is generally well-received by the student. The fact that the surveys were carried out anonymously leads to the belief that they are valid and the fact that the grades of the students have improved considerably, confirms once again what the studies have demonstrated in accordance with the application of this methodology: its effectiveness in the appropriate development of conceptual and cross-referencing skills of those students taking engineering degrees.

It is also worth noting that the statistics of this study have been compared with those of degree courses of a similar nature in the field of engineering, of the department of computing and numeric analysis of the University of Cordoba, where the PBL methodology has been applied in a similar way, together with collaborative learning. We appreciate an improvement in the final grades in both Universities (see Figure 4 and 5).

We can also see a high level of satisfaction amongst those students questioned about the benefits of this new way of acquiring knowledge.

We believe it would be interesting to extend this study to different courses and degree subjects, with the idea of soliciting the opinion of the students of this technique for the different subjects of the study, given that it may not be so easy to apply.

The results could differ according to the contents, adapting the most appropriate methodologies to each course to gain the necessary skills. Only by finding the most appropriate method using the feedback of the interested parties, we will be able to obtain the best results and the highest level of satisfaction amongst students. As professors we must take into account the opinions of the students with respect to the methodology which sparks the most interest, motivates and improves results.

Platform for teaching of location technologies based on Zigbee Wireless Sensor Networks by learning-through-play theory

Ana Vazquez Alejos, Manuel Garcia Sanchez, Jose A. Gay Fernandez, Iñigo Cuiñas
Department of Teoria de la Señal y Comunicaciones
University of Vigo
Vigo, SPAIN
analejos@uvigo.es

Abstract—**In this paper an experimental Wireless Sensor Network (WSN) platform is introduced as an aid in teaching location techniques based on RSSI (Received Signal Strength Indicator) in the frame of a an radiolocation course at graduate level. The platform is implemented using low-cost commercial modules and one easy-to-use software program. The teaching methodology tries to develop the *learning by doing* theory and it is completed with a final practice that implements the *learning-through-play theory*. Both techniques have resulted in positive learning outcomes by enhancing the student role in the learning process.**

Keywords- learning through play, learning by doing

I. Introduction

The development of innovative material as well as new methodological approaches will be a demand in the new study plans that incorporate the European Higher Education Area (EHEA) requirements for the imminent future of European universities.

The introduction of new teaching-learning methodologies in classical areas as engineering has found large reticence mainly due to some risks supposed to innovative methodologies, such as loss of contents, incorrect timing dimensioning, not enough number of resources (labs, material …) These and other lacks have discourage instructors.

The use of active learning methodologies results largely suitable for the teaching of technical disciplines since they facilitate that students learn both engineering processes and content knowledge. Simple experimental tests can facilitate the acquisition of most important concepts that students will need to use and apply as professional engineers after the graduation.

In this paper we present an educational platform for approaching the teaching of wireless technologies. For our case, the 2.4GHz band was selected, due to its unlicensed feature and the interest of actual applications developed in this frequency, especially the wireless sensor networks and the use of them for location and tracking applications.

Similar experimental systems have been previously developed regarding WSNs [1, 2], but they can be also found in the field of electromagnetism teaching as [2-8]. In [2, 6] we can read the importance of the instrumentation in the radio courses curriculum and how the RF instruments and experimentation can help to emphasize signal and system theory concepts to students. In [7, 8] cost-effective solutions are implemented to design educational modules used in wireless communication courses showing a good performance.

In our case, a commercial kit has been used to deploy a WSN. The system was completed by programs developed in MATLAB software. This allows planning different experiments focused on the main concepts related to location estimation based on RSSI technique, as well as routing in a Zigbee network.

One initial practice will introduce students in the deployment of a Zigbee WSN, the location estimation according to the RSSI measurement and triangulation principle. The experiment has as goal to achieve the full operation of the WSN and the real-time estimation of the user nodes, tracking their positions by using the specific software tool.

After this a challenge is developed as a practical implementation of the *learning-through-play* theory: the TUs are randomly activated and distributed all over one indoor scenario, and the student teams have to determine which one of them are active and their corresponding positions.

The first application of the system here introduced was for the development of two Master Thesis that finally achieved one conference publication [9]. In the present paper we introduce the first year of the experience, a pilot version carried out with a small group of twelve students offered as volunteers from the total of students registered in the course.

In section II we introduce the theoretical background of the teaching experience. The developed teaching methodology is explained in section III, including the implementation. Finally, in section IV, we present the evaluation method followed to infer the progress and success of the experience. In the last section, we offer the conclusions to this research work and indicate some ideas for future work.

This research work was supported in part by the Xunta de Galicia under Grant CO-199-07.

II. ACTIVE LEARNING IN THE CLASSROOM

Traditional lectures are the more extended teaching method that can be found in the colleges and universities. But in the last two decades this traditional methodology has suffered a clear evolution toward other forms of understanding the knowledge acquisition [10-15].

The development of material that incorporates active learning experiences is a challenge for the instructors that are not usually encouraged to face this step. Among other reasons, the EHEA process has determined the university and studies structures but not the training methodologies that should consider the use of active methodologies to improve the student learning process [16-19].

In this section we analyze two main methodologies that try to incorporate active learning teaching: learning by doing and learning by play. We have selected them among other ones due to the suitability to our goals and contents.

A. *Learning by doing*

The learning based on the experience, experiential, factual, "learning by doing" or "hands-on learning" is generally framed in the active learning methodologies. This supposes to encourage people to discover by themselves the principles of operation of the systems, processes, etc. through the experimentation and the exploration [20-24].

This kind of methodology promotes the construction of deep cognition and increases the comprehensive as well as the effectiveness and efficiency to put in practice the learned skills [21] according to a succession of stages as indicated in Figure 1. This feature is largely interesting to give the students a practical view for their imminent professional future.

B. *Learning through play*

Students must learn the fundamental concepts and the necessary skills to apply them effectively in a game-based experience. This methodology has been widely applied in computational and engineering teaching field [26-28] showing a large level of satisfaction, and becoming also largely effective at the cognitive level.

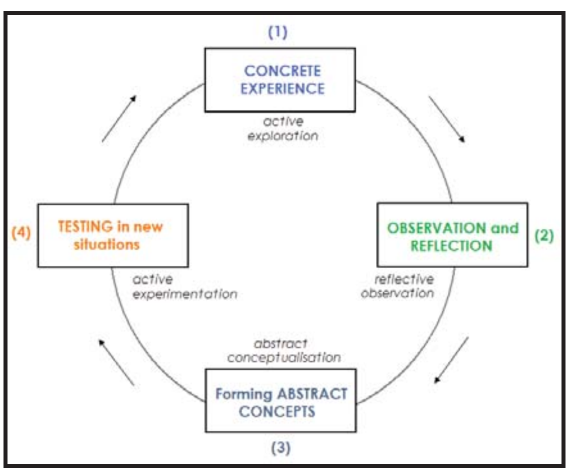

Figure 1. Stages in learning by doing (experiential) method [21].

III. TEACHING METHODOLOGY

The experience described in this paper tries to approach the teaching of one primary location technique that can be widely found in radio wireless applications. It is inscribed in the framework of the graduate-level course *"Radio determination"* offered in the last year at the Electrical and Computer Engineering degree at the University of Vigo, Spain.

This course is optional, so students decide to select it according to a criterion of the curriculum/profile that they desire to develop. Usually, students with specialization in radio select this course, but it is common also to find students from the networking or electronics branches. Among the criteria that students hold to select an optional course, the attractive offered by the course and the grade of update showed are factors playing an important role.

The contents of the course include radionavigation and radiolocation systems used in aeronautics and aerospace, as landing aid systems (ILS, VOR), or navigation aid (GPS, Galileo, GLONASS). The theoretical contents are given following traditional lecture classes, and lab practices have been designed according a learning-by-doing methodology.

In the last years, the radio location techniques are spreading the field of use and they are commonly found in many dairy applications. Some of the radio locations have become very popular thanks to the emerging wireless communications in unlicensed bands, especially the Wireless Sensor Networks (WSN) case have awaken a large interest due to the attractive features. The incorporation of Zigbee protocol offers additional value and facilities to these networks.

In an attempt to update, the course has incorporated the teaching of radio location techniques in the frame of WSN as a third block in the contents of the course, with theoretical classes and practical experiences.

But this technique can be hardly understood if only theoretical explanations are provided, and even if simulations are employed. On the other side, one objective of the active learning is to attract the attention of the students and keeping their motivation. A combination of learning-by-doing and learning-through play has considered the optimal solution to join both teaching and learning milestones.

In the following sections we present the resources that have been used and developed in this experience, and some details of the practical implementation.

A. *Resources*

Learning by doing experiences based in field experiences imply the use of material that sometimes is not covered by the general purpose instrumentation. The acquisition of specific educational material is large-cost and not usually affordable.

But many solutions exist in form of development kits available for the industry and perfectly valid for academic purposes. It has been our case, and we proceeded to acquire a Zigbee WSN commercial kit with the feature of estimating the power of the received signal. The core chip used by this kit incorporates the transceiver front-end as well as an 8051 core to program the user applications.

In order to implement a radio location system to estimate the position of a mobile user, three elements are mainly necessary:

(1) Reference units (RU) at known positions transmitting a predefined value of power. They act also as routing elements of the information transmitted from the mobile users.

(2) Mobile terminal units (TU) with unknown positions that estimate the power received from the RUs (Received Strength Signal Indicator, RSSI) and feedback this value to the master node (MN) using the network of RUs.

(3) Master node: in our case, this node is the responsible of estimating the TU position by triangulating the power received from it at the RUs. The triangulation implies the assumption of one radio mobile channel, one important concept of this experience besides the own triangulation technique. The MN is connected to a computer via RS-232.

In Figure 2 we show the three elements above described, and it can be shown that they share the same chip board. A brassboard has been designed for the TUs, containing one led-push button, reset button and one inclinometer. Sensors can be easily incorporated for future use.

Additional software elements have been designed to complete the material of this experience. The tools developed will facilitate to the students the development of the experience helping them to focus on the targeted concepts:

(1) Compiled C Code for RUs: it includes the functionalities of network routing and power message transmission.

(2) Compiled C Code for TUs: it includes the functionalities of network routing and power messages reception. Automatically selects the frequency channel of operation, and it recognizes the

(3) Compiled C Code for MN: it includes the functionalities of network routing and the serial communications with the computer.

(4) Student program: implemented in Matlab, it receives the data needed for the triangulation according to the propagation model.

The code corresponding to RU, TU and MN has to be uploaded to the core chip via JTAG programming tool as indicated in Figure 3.

The student program has become fundamental for the development of the experience. It provides functionalities to dimension the network, to assign a role to a board chip (TU, RU, MN), to fit the propagation model and to perform correctly the triangulation. In Figure 4 it is shown the main screen of this tool.

B. Implementation of the experience

A learning-by-doing methodology has been estimated as an optimal solution to present the *modus operandis* of real time positioning systems based on the estimation of the received signal strength. Firstly, a set of four short practices introduce the different objective concepts. One session of two hours has been assigned to each practice. Students elaborate one four-page report after the completion of the four practices.

(a)

(b)

(c)

Figure 2. (a) Master node (b) Reference node (c) Terminal user

Figure 3. Programming facilities.

Following we briefly describe the main milestones of the initial four short practices:

(1) Dimension the network and assignation of one role to the chip boards. Some parameters of the RUs and TUs as ID, and position (X, Y, Z) have to be predefined. In Figure 5 the node setup menu is shown. In Figure 6 it can be observed an example output of this practice.

(2) Test of communication: the different elements are activated and the network deployed in an actual indoor scenario. Test messages are routed among the nodes. A mesh topology is followed.

(3) Fit the propagation model: one main parameter of the propagation model has to be set: *N*. It approximates the power decay curve for the signal transmitted from one RU and received by one TU. This propagation model is commonly used in indoor scenarios, and as is called log-distance model. The accuracy in the estimation of *N* is deeply related to more accurate position estimation. In Figure 7 it can be observed the model fit menu.

(4) Triangulation: students have to implement the algorithm for position estimation based on the equilateral triangulation technique of received RSSIs.

The methodology is completed with one final practice that summarizes all the learned concepts and is valid to put in practice the skills learned and developed by the students. It is presented in form of through-play.

As an outcome of the initial practices, the students are in position of estimating the location of any TU, as well as the ID of the available RUs, in the deployed network always that the learning process has been successfully completed. So, in the next step they have to determine under blind conditions, which RU nodes of the network are working, how many TUs are active and also they have to determine the TUs location.

If the software tools have been correctly fitted, and a comprehensive cognition has taken place, the students will pass this challenge with less effort that if it is planned as a single practice.

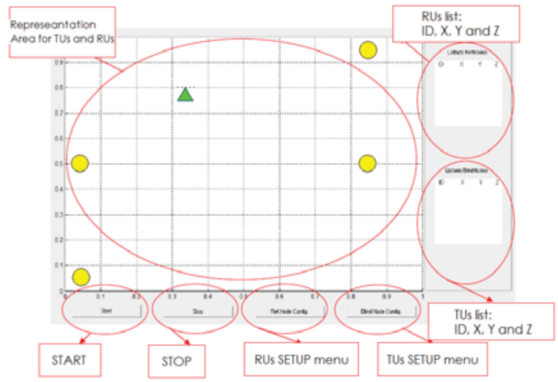

Figure 4. MATLAB student's interface program.

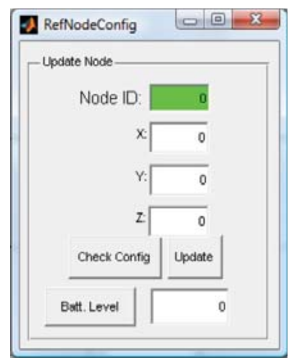

Figure 5. Node setup menu.

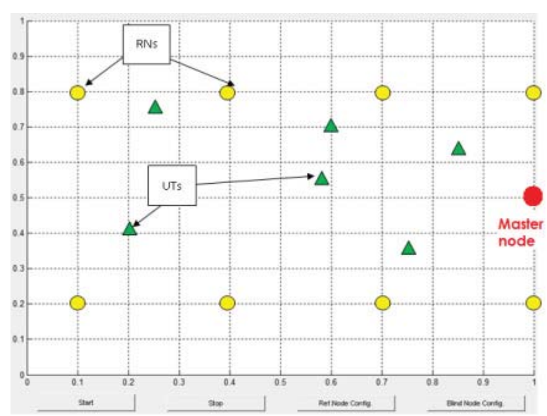

Figure 6. Geometrical disposition of elements in the Zigbee mesh network.

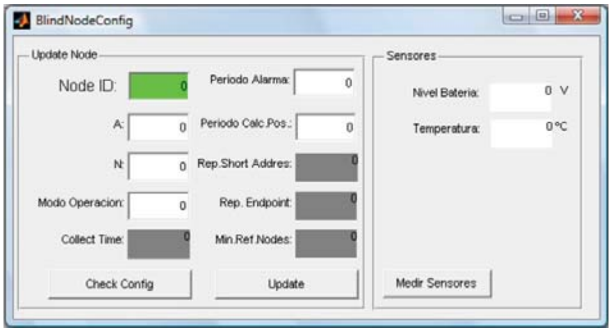

Figure 7. Propagation model fit menu.

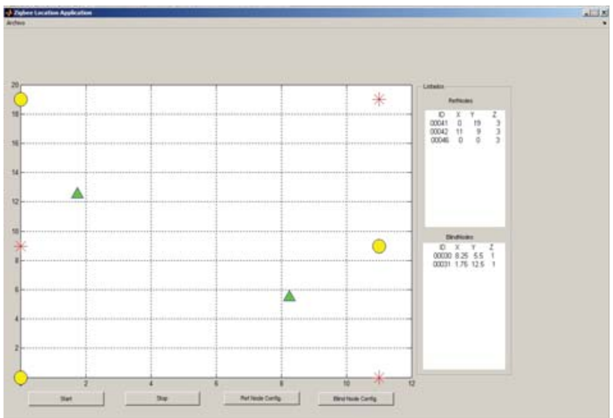

Figure 8. Example of final challenge scenario.

It will result useful in a double sense: firstly, it summarizes the concepts and skills object of this block of the course content; secondly, it allows the student a general scope of the technique here presented that can help to clarify some remaining doubts. In itself this challenge constitutes an auto-evaluation of the previously learned concepts. In Figure 8 it can be observed one example of scenario for this challenge.

IV. Evaluation of Results

Another not less important aspect to consider along the development of this kind of learning is the way of evaluating the acquisition of knowledge [29]. It is essential to collect information in the cognitive and in the affective dimension. This information has to be analyzed to evaluate a classical trade-off: the satisfaction level and the effective cognitive learning.

The evaluation of the subject was divided in two parts. The evaluation of the theoretical contents follows an innovative method based on online surveys provided via a web educational platform that uses the open source eLearning and eWorking platform *Claroline* [30, 31]. The surveys include ten short questions regarding the theoretical part. In Figure 9 we can see the home page of the website dedicated to the eLearning platform.

Figure 9. Screen shot of *faitic.uvigo.es* web.

The number of students attending the subject last year was 70. For the lab practices, they were divided in groups of two, and later assigned to one turn controlled by a different teacher. Three blocks of practices were designed, and the experimental experience regards block #3.

Volunteers were solicited to develop this pilot experience and a total of 12 students attended the call. A different task was assigned to the students that did not participate in the pilot group, consisting in a documentation work to be exposed at the classroom. These works were evaluated by the rest of groups.

For the evaluation of the other practical contents a traditional method usually extended in engineering was used, consisting in the elaboration of reports regarding the lab practices.

In order to evaluate the cognitive level, for each practice a set of questions are included in the memory to be solved and answer by the group. So, individual scores cannot be evaluated separately. This can result in an unfair score for students and does not reflect the individual effort.

A statistical analysis based on boxplot results a powerful tool to analyze the deviation of the individual, group and turn scores with respect to their respective medians. This simple analysis offers a good graphical inspection tool of influence factors as important as: teacher in charge of the turn, difficulty level of the practices. Students requiring reinforce can be identified.

Generally, for practical block 3, groups achieved larger scores in the pilot experience than for the documentation work. Among the reasons to explain this fact, we can remark that usually the level of effort is less in this kind of tasks and also the level of motivation. We have detected also that some of the works were identical to the last year. In general, the level of deepening in the topic assigned is not large and the students tend to minimizes effort and time. The result is that a 10% of the students fail this practice with scores under 5.

The success of the experimental practice can be explained also by the large level of control that the experience provides for its development. All the steps are predefined and the objectives are presented in a piecewise mode, from simple to complex levels, so it results in a straightforward progress for the student.

The satisfaction level was inferred from the surveys that our institution passes each semester to every subject. The surveys demonstrated a good performance in the affective dimension. This can be inferred also form the results of pilot experience scores.

V. Conclusions

After In this paper we have analyzed one pilot experience developed at the graduate level of an engineering degree. We can state that education has evolved from a teaching to a learning focus and the incorporation of active learning is the way for this transformation. Active learning based methodologies have demonstrated to be more effective than passive learning. We analyzed that the use of active learning methodologies results largely suitable for the teaching of technical disciplines such as engineering.

We conclude that simple experimental tests can facilitate the acquisition of most important concepts that students will need to use and apply as professional engineers after the graduation.

We presented the methodology developed and the material needed to carry out this practice. The pilot experience showed a large level of enthusiasm and satisfactory feeling among students.

In the evaluation method, it results necessary to implement a form of differentiating the individual and the group scores in the lab practices. The design of individual surveys may be a solution and it is of easy implementation thanks to the available eLearning platforms.

The good results achieved encouraged the teachers to repeat the experience next year trying to introduce some novelties thanks to the developed and tested methodology and the available material, as well as the experience acquired by the teachers.

Abstract—**This paper describes the adaptation process to the European Credit Transfer System requirements of several subjects aiming at the Information and Communication Technologies (ICT) learning. Specifically, these subjects are sited at the Telecommunications Engineering studies lectured in the University of Valladolid. In a first step two first grade subjects have been established, while in a second and final step, coinciding with the new degrees beginning, it will be extended to five subjects placed in consecutive semesters.**

The global programming has been divided into several subprojects of growing complexity, developed into subjects sited in different and successive semesters of the degree, following a pathway leading to the development of a global project throughout four years. The whole learning process is ICT-supported, as tools for overcoming distance and scheduling barriers are offered. In particular, Moodle platform is used, which has been enhanced with self-evaluation and co-evaluation tools developed by the teaching group. Main innovation regarding to the classical approach consists of a computer programming subject focused on the student learning and based on the detailed specification of the activity the students have to perform in and out of the classroom in order to achieve the educational objectives of each of the subjects. The educational strategies used to accomplish these objectives are based on the cooperative learning, on the teamwork developing a programming project (Project Based Learning, PBL), and on the discovery learning.

Keywords: European Credit Transfer System; engineering subjects; Project Based Learning, Moodle platform.

I. Introduction

In the 50s, 60s, and 70s of the 20th century the idea about learning as a process of gaining knowledge is established. This process takes place when the student can permanently store new information in memory. In this model, the role of the student is to gain knowledge in a passive way, and the teacher's is to design environments where the student can receive a great deal of information [1].

As of 80s and 90s, the teaching idea is transformed into a concept of building up knowledge, which is performed when students directly participate in that building connecting new learning with the foreknowledge [4]. The teacher's task in this case is to design environments where important interactions among the students, the teacher, and the scholarly resources can be provided in order to let the student select, organize, and properly apply the new information.

The problem based learning, and its variant Project Based Learning (PBL), is a strategy which presents the students the challenge of "learning to learn" through the collaborative resolution of open problems, being guided by an enabler. That is, this methodology is based on a project or plan development following the project design approach. Activities are oriented to plan a solution of a complex problem. Work is performed in teams. The students have more autonomy than in a traditional class, they use different resources as the teacher is not the main source of information, he/she acts as an enabler providing resources and offering advice while they advance in their research. The students gather and analyze the information, make discoveries and report the obtained results. The teaching and facilitation are oriented by a wide range of explicit learning objectives; some of them can be precisely focused to the specific content of the theme. The students can achieve additional goals (no planned) as they explore complex themes along different lines; they learn to learn between them; they learn how to help their partners learning; they learn to peer-review and give constructive feedback both for them and their partners. Hence, the aim of the project based learning is to place the student in a realistic scenario, facing real-world issues, to initiate his/her learning process [6]. The PBL has been used in the university in general, and in the area of engineering in particular [5]. The project is the point which unleashes the learning process, and its development causes the knowledge structuring into modules grouping several traditional subjects. Therefore, this working practice depicts a consistent alternative with the teaching method needed for training professionals, especially technicians. This approach is also suitable, to a greater or lesser degree, in mostly every field of study.

II. BACKGROUNDS

In the 2005/06 school year we launched the adaptation process to the European credit system requirements in one of the subjects design for the Computer Programming learning – "*Fundamentos de Programación*"- undertaken at the Telecommunications and Electronic Engineering studies lectured in the University of Valladolid. Main innovation regarding to the classical approach consists of a computer programming subject focused on the student learning and based on the detailed specification of the activity the students have to perform in and out of the classroom in order to achieve the educational objectives of the subject. The educational strategies used to accomplish these objectives are based on the cooperative learning, formally structured by the puzzle technique, and on a teamwork development of a programming project of low-medium complexity level. This approach has been the result of the learning program adaptation of the Introduction to Computers subject –"*Introducción a los Ordenadores*"- undertaken at the Castelldefels Polytechnic School, a good standing center for its high quality teaching, for its wide experience in the subject adaptation to the European credit system requirements, and for being one of the pioneers in applying the cooperative project-based learning in Spain.

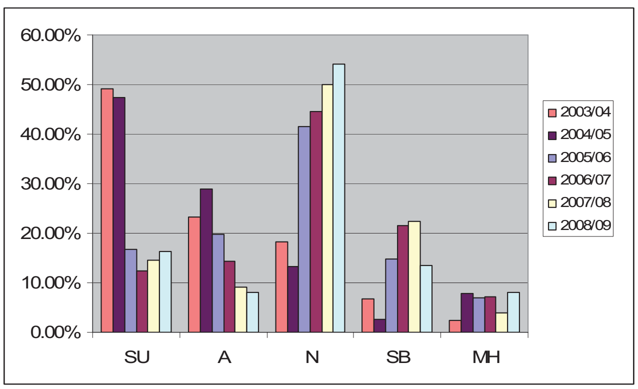

Figure 1. Data trend of the Computer Programming subject grades.

Results of this adaptation are shown in Figure 1. It can be observed failure rates ("SU") drop sharply since 2005/06, while pass rates ("A") decrease at the expense of higher rates ("N", "SB", and "MH"). Therefore, it can be inferred, using this student-centered new methodology, more students pass the subject and with better marks.

According to the promising results obtained in this trial experience over a single subject, last year this approach was extended to a new subject in the second semester, Programming of Multimedia Applications –"*Programación de Aplicaciones Multimedia*"-, thus incorporating a new element to this approach: a multidisciplinary project along a learning thread. Thereby, the project performed during the first semester in the Computer Programming subject is broaden, modified, and completed in the second semester during the Programming of Multimedia Applications subject.

III. MODEL-VIEW-CONTROLLER PROGRAMMING PARADIGM

After considering several organizational schemes, the model-view-controller (MVC) paradigm was considered the most appropriate to implement the steps comprising the proposed learning thread.

MVC was first described in 1979 by Trygve Reenskaug [3] , then working on Smalltalk at Xerox PARC. The original implementation is described in depth in the influential paper "Applications Programming in Smalltalk-80: How to use Model–View–Controller" [5]. There have been several derivatives of MVC. For example, Model View Presenter is used with the .NET Framework [7], and the XForms standard uses a "model-view-controller-connector architecture" [1].

At the heart of MVC, the idea that was the most influential to later frameworks, is what it is called Separated Presentation. The idea behind Separated Presentation is to make a clear division between domain objects that model our perception of the real world, and presentation objects that are the elements we see on the screen. Domain objects should be completely self contained and work without reference to the presentation; they should also be able to support multiple presentations, possibly simultaneously. In MVC, the domain element is referred to as the model. Model objects are completely ignorant of the user interface. The presentation part of MVC is made of the two remaining elements: view and controller. The controller's job is to take the user's input and figure out what to do with it. It is important to highlight that there is not just one view and controller. There is a view-controller pair for each element of the screen, each of the controls and the screen as a whole.

A very common issue for the programmers is code reusing and refactoring. Many times we have to solve a problem similar to another one previously resolved, to improve the interface of a program, to optimize the underlying algorithm, etc. These tasks can be simplified separating the code into parts which can be reused without any modifications. Based on these premises, in order to reuse a code for future software development, the model must be independent. Model classes (or functions and structures) should not access any class from another group. This way we can compile the model in an independent library reusable for similar developments. Furthermore, if the software is developed using C programming language and we change the platform used (from example, from Linux to Windows), it should be possible to recompile the C code with minor modifications. So the model should not include any concrete graphics, sockets or other library calls which are usually very different, even within the same platform, if we use a different environment (think, for example, in graphics with Visual C++ and with Borland C++, both under PC/Windows).

Besides, the controller can (and usually does) access model and view classes by reusing code. View is the more changing element, so we link it to the controller classes. If we change the controller, at least we will have to recompile the graphics interface.

To get all this operating, the main function has to instantiate the model, controller, and view classes. In case a new graphics interface has to be developed, we will work without modifying the previously developed model and controller. It will be enough modifying the creation/instantiation of the graphic interface to include the new developed version. Everything should work without even recompiling the model and the controller.

IV. ITINERARY OF THE LEARNING PROCESS IN THE ALREADY ESTABLISHED THREAD

In order to perform a reusable project, a learning thread shared between several subjects was proposed. In a first implementation, it included two subjects: Computer Programming and Programming of Multimedia Applications. Performing the project should mean meeting both the final goal and the associated objectives. Each subject has its own partial goal (subprojects SP1 and SP2). In Figure 2 it can be observed the final architecture of the proposed project integrating the contribution of both subjects.

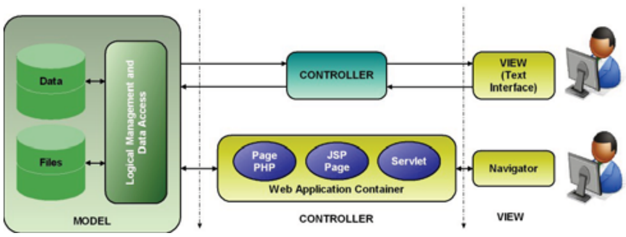

Figure 2. Architecture of the multidisplinary project to be developed in two subjects.

TABLE I. BREAKDOWN IN STAGES OF THE ESTABLISHED ITINERARY

Subject	Contribution to the thread	Result
Computer programming • 1st grade • 1st semester	Solving a complete problem using a high level programming language with a modular structure. Knowing how to specify and design modules and databases. Assembling a simple set of codes in a cooperative way using separate compilation units. Building a collection of function libraries.	SP1: A complete single-user application accessing to the application data following a model-view-controler (MVC) pattern. Text User Interface (TUI).
Programming of Multimedia Applications • 1st grade • 2nd semester	Solving same problem as previously presented with Web technologies. Developing a new graphic interface (view and controller) using HTML, CSS, JavaScript, and PHP programming language. Developing a new model if appropriate, or otherwise accessing to the previously developed model. Building new classes/modules (PHP) for accessing to the database (MySQL) into the model.	SP2: Adding to the application a new way of accessing, through Internet. User interface is a web site with dynamic pages. Controller are codified using a server language (PHP) and accessing to a database (MySQL).

MULTIDISCIPLINARY PROJECT: A TRAIN RIDE MANAGEMENT SYSTEM

As a specific example of a reusable project within the shared learning thread, we proposed last school year in the subjects Computer Programming and Programming of Multimedia Applications, a train ride management system. The project is divided into two different applications sharing same data. The first one, called *Management*, will be used by the travel agents to handle the information about train stations and rides. The second application, *TravelPlanning*, will be used by travel agents to provide the better travel plan to the clients according to their needs with the possibility to choose among the shortest, the fastest, and the cheapest travel. To compute the shortest path, the Dijkstra algorithm will be used.

A. Computer Programming

Students gain the abilities needed to solve a complete problem using a high level programming language with a modular structure, following the model-view-controller paradigm. They build a set of libraries in a cooperative way to perform mixed functions.

As a result, we obtain a complete single-user application (one process only) accessing to the application data by a hierarchical menu-based information retrieval system developed in a text user interface. Application execution is sequential and ruled by the main program controlling the evolution of the system states, particularly, the "dialogues" (input/output operations) which are always synchronous.

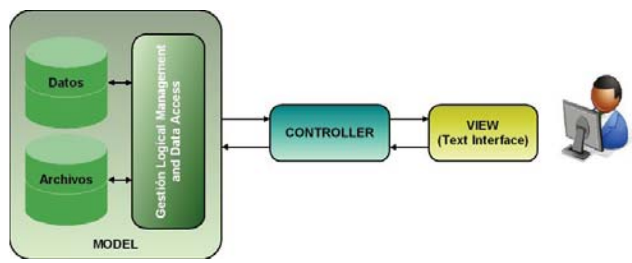

Figure 3. Architecture of the project to be developed in the Computer Programming subject.

MULTIDISCIPLINARY PROJECT RESULTS

In this first subject, the train routes planner problem is analyzed, designed, and implemented in two versions, using both C and C++ programming languages. In terms of the MVC paradigm, both applications use the same model and its view is a console application. In both versions, viewable result is exactly the same (see Figures 4 and 5).

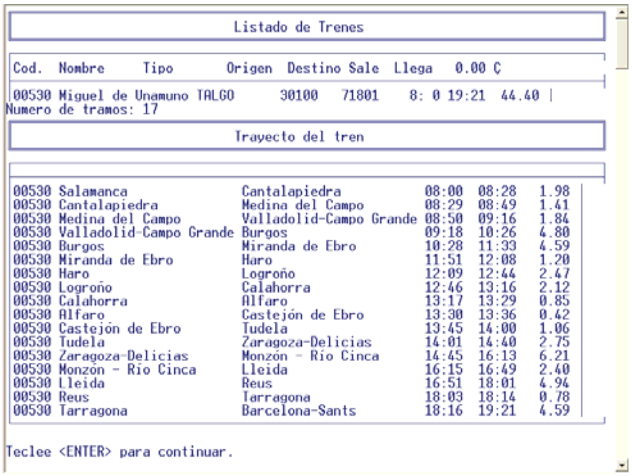

Figure 4. Screen shot of the *Management* application performed in the Computer Programming subject.

Figure 5. Screen shot of the *TravelPlanning* application performed in the Computer Programming subject.

B. *Programming of Multimedia Applications*

In this stage, the web technologies (HTML, CSS, JavaScript, PHP and SQL using MySQL DBMS) join to the learning thread. In this case, view will be a web page in a browser, which provides access from different platforms. Controller will be recoded using PHP and model (business logic) will be also recoded if necessary.

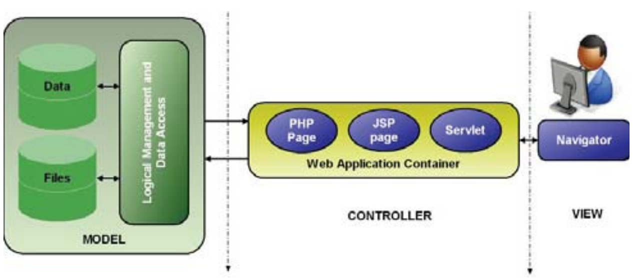

Figure 6. Architecture of the project to be developed in the Programming of Multimedia Applications subject.

As a result, we obtain a multi-user web application providing a user-friendly access from different platforms. This subject will disappear with the new grades, in its stead it will be lectured the subject Technologies of Web Applications ("Tecnologías de Aplicaciones Web"), where the web technologies can be widen.

MULTIDISCIPLINARY PROJECT RESULTS

The students start this subject using the first phase of the developed multidisciplinary project. The analysis and design steps have been previously done, so it is not necessary to prove abilities already evaluated in the Computer Programming subject. Within the MVC paradigm, the tasks to be performed to acquire the abilities covered by this subject are:

- Model: in the first version, data were stored in files. Now, a database will be added using MySQL.
- View: in the previous version, the user interacts with the system through a MS-DOS console. Now, a web site will be design to insert data and view the results obtained using the above-mentioned web technologies.
- Controller: the business logic was already designed and this design is language-independent. Now, the controller will be coded using the PHP language.

Therefore, the local application developed in the Computer Programming subject evolves into a network application with a graphic interface, more user-friendly than the console.

Figure 7. Screen shot of the *Management* application performed in the Programming of Multimedia Applications subject.

Figure 8. Screen shot of the *TravelPlanning* application performed in the Programming of Multimedia Applications subject.

V. ITINERARY OF THE LEARNING PROCESS IN THE THREAD PROPOSED

With the new grades starting, the Telecommunication Engineering degree will disappear while Telematic Grade will be established. Based on the gained experience and on the results obtained using the learning thread previously explained, a new learning thread is proposed with a multidisciplinary project along the four years of the Telematic degree. Hence, to better accomplish the final goal and the associated objectives, a five-step itinerary is proposed. Each step is tied to a subject, which has its own partial goal (subprojects SP1 to SP5). In the Figure 9 it can be observed the final architecture of the proposed project integrating the contribution of all the subjects.

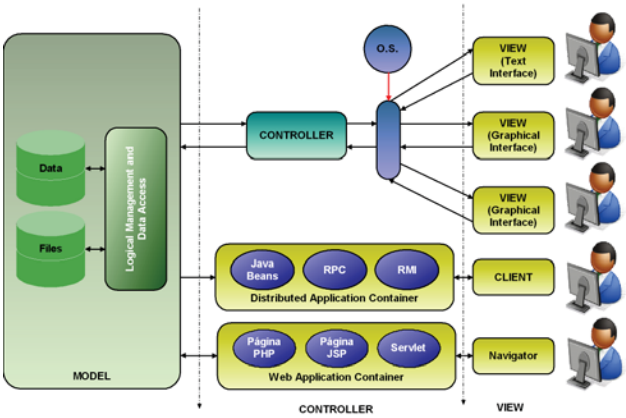

Figure 9. Architecture of the multidisplinary project to be developed along the degree.

TABLE II. BREAKDOWN IN STAGES OF THE ITINERARY PROPOSED

Subject	Contribution to the thread	Result
Computer programming • 1st grade • 1st semester	Solving a complete problem using a high level programming language with a modular structure. Knowing how to specify and design modules and databases. Assembling a simple set of codes in a cooperative way using separate compilation units. Building a collection of function libraries.	SP1: A single user complete application accessing to the application data following a model-view-controler (MVC) pattern. Text User Interface (TUI).
Computer Fundamentals and Operating Systems • 1st grade • 2nd semester	Incorporating concepts concerning to the operating systems to the project like the process planning, the process concurrency, and the communication between processes.	SP2: A complete multiuser application controlled by a dedicated operating system. The O.S. creates the semaphores and launches and controls the process controller and several view processes.
Software Systems Engineering • 2st grade • 2nd semester	Object-oriented programming. Software engineering. Event-oriented programming. Graphic interface.	SP3: Application is recoded using engineering software techniques. Controller is re-design using classes. A graphic interface is designed. *Database* access and management class library.
Architecture for Distributed Applications • 3st grade • 2nd semester	Client-server architectures. Sockets, middleware (RPC, RMI, EJB,…)	SP4: Adding to the application a new way of accessing: the remote access from other computer.
Technologies for Web Applications • 4th grade • 1st semester	Solving same problem as previously presented with Web technologies. Developing a new graphic interface (view and controller) using HTML, CSS, JavaSCript, and PHP programming language. Developing a new model if appropriate, otherwise accessing to the previously developed model. Building new classes/modules (PHP) for accessing to the database (MySQL) into the model.	SP5: Adding to the application a new way of accessing, through Internet. Use interface is a web site with dynamic pages. Controller are codified using a server language (PHP) and access to a database (MySQL).

Next, each subject contribution related to the learning thread will be explained. The contribution of the first and fifth subjects, already involved in the previous learning thread (Computer Programming and Technologies for Web Applications, earlier Programming of Multimedia Applications), are omitted as they were already explained.

A. *Computer Fundamentals and Operating Systems*

In this stage, new concepts over operating systems (O.S.), process planning, and communication among processes are built into the project.

The O.S. process of the application establishes the semaphores needed to control the concurrently access to the model of several clients and manages the communication between the controller and the view processes, applying different planning methods.

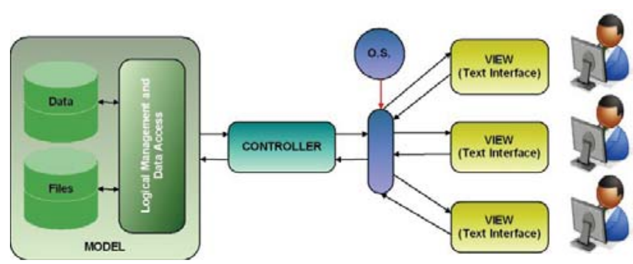

Figure 10. Architecture of the project to be developed in the Computer Fundamentals and Operating Systems subject.

As a result of the contribution of this stage, we obtain a complete multi-user and multi-process application managed by techniques used in real operating systems. In this stage communications among processes of the same computer are manage, which provides a background to the client-server architecture and the communications among process of different computers that will be study in next stages of the thread.

B. *Software Systems Engineering*

In this stage, methods from software engineering and application implementation are incorporated to the thread. The starting point is the analysis performed in the Computer Programming subject, then, the design of the required classes is performed. The model is encapsulated in a class library. The visual interface is designed following the event-oriented programming paradigm. Controller is also developed with classes.

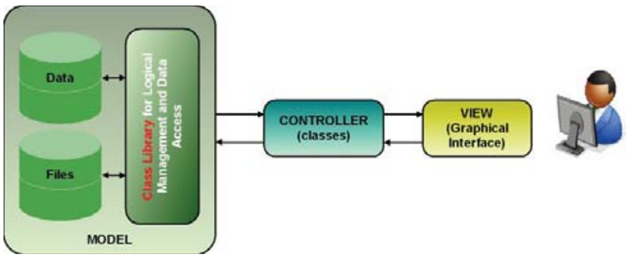

Figure 11. Architecture of the project to be developed in the Software Systems Engineering subject.

As a result of the contribution of this stage, we obtain a system completely implemented using classes, maintaining the model-view-controller scheme.

Including the result obtained in the Computer Fundamentals and Operating Systems subject, a system accessed from textual or graphic interfaces, or with the controller developed using structural or object-based programming language can be obtained. Furthermore, the function or the class library can be used, depending on the preferences or on the application to be developed.

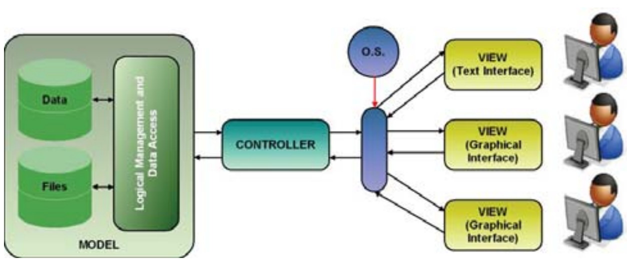

Figure 12. Architecture of the project to be developed in the Software Systems Engineering subject including the results obtained in the Computer Fundamentals and Operating Systems subject.

C. *Architecture for Distributed Applications*

In this stage, concepts related to remote communication among processes in distributed applications –sockets, middleware (PRC, RMI, EJB,…) are added, thus expanding the knowledge about communication among processes within the same computer provided in the Computer Fundamentals and Operating Systems subject.

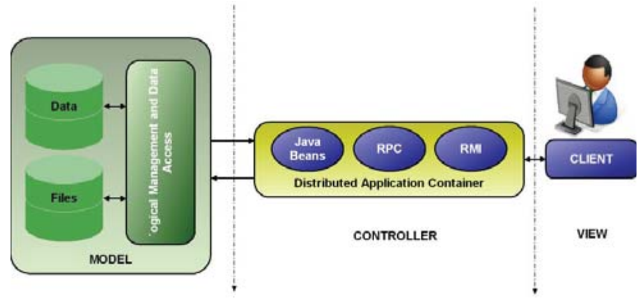

Figure 13. Architecture of the project to be developed in the Architecture for Distributed Applications subject.

As a result, an application is obtained keeping the model while controller is recoded, using specific technologies for distributed processing in different machines. View can be found in the same computer or in other.

VI. MOODLE: TOOL FOR LEARNING SUPPORTING

Some tools implemented as modules for the Moodle platform have been specifically designed to exploit the full potential of the PBL approach. A module called e-Liza is used for both a self-evaluation and a competitive evaluation of the gained knowledge. In e-Liza the questions are not only proposed by the teacher but also by the students. Of course, the last ones are supervised by the teacher accepting them or not, and assigning the difficulty level. Statistics of the individual or grouping play are shown to the students in order to keep them informed of their progress.

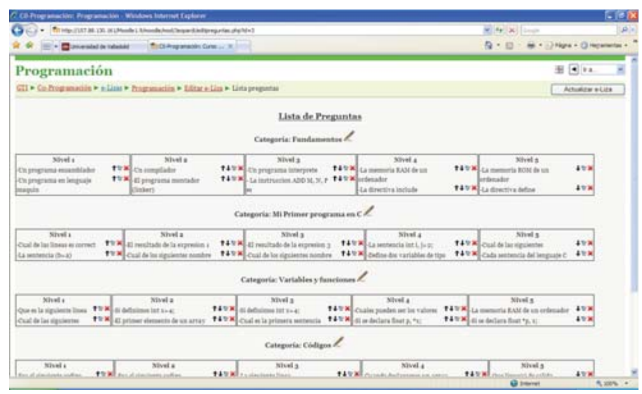

Figure 14. Screen shot of the module e-Liza, the section for entering the questions.

Another tool to perform questionnaires is used both for creating evaluation templates used in the peer-reviewing and for conducting surveys of the curriculum development. Students can also use other modules specially designed for each of the subjects, for example programming validators, also integrated in the Moodle platform. All these tools are very useful not only for the students making the learning process easier, but also for the teachers specially helping them in the classroom management, because this new approach adds more workload than the classical one, at least in their beginnings.

VII. Conclusions

In this paper a learning thread shared by several subjects of the Telecommunication Engineering degree related to application programming has been proposed. The goal is to place the student in a realistic scenario, facing real-world issues and following a pathway leading to the development of a global project throughout several years. Results obtained in the trials previously conducted are encouraging. Students get higher involved with the subjects and especially faster than without using this scheme. These facts provoke the students to get better marks, also decreasing the number of dropped out students.

As it has been explained, future work will consist of applying this methodology to a total of five subjects placed in consecutive semesters, coinciding with the new Telecommunication Engineering degrees beginning in the University of Valladolid.

Abstract— **This paper describes a research work that seeks to develop a pedagogical strategy to assist in programming learning, inspired by Mathew Lipman's strategy – conceived to help students maximize their learning through the conscious assessment of their self-efficacy level while they develop a programming study behaviour. We present the results of the preliminary tests on the formalization of the research methodology and the changes implied on the strategy to be tested.**

Programming learning; Research communities; Literary skills; Self-efficacy

I. INTRODUCTION

There seems to be a consensus among teachers and researchers that regards programming learning as a non-trivial activity, as it introduces a new series of cognitive requisites in students' routines, besides the technical requisites. This creates in students the need to change and adapt their way of thinking and manage time in college life to a different reality than the one lived through primary school and high-school. A change in a very short time frame. Among these requisites we may highlight:

1. Problems solving is above all a competence that involves cognitive processes - such as creativity and rationality - from a set of mental meta-abilities (abstraction, inference, deduction, etc), meta-abilities that sometimes come unnoticed and are supported on the exercise developed through their basic literacy skills (like reading and interpreting the description of a problem). Besides, in order that the student may start the aforementioned cognitive processes so that he can use his mental skills to build a solution, he needs to learn how to contextualize the acquired knowledge.
2. The whole understanding of a programming paradigm's requisites is not a trivial activity and implies an intrinsic natural difficulty level [1, 2]. However, the major difficulty in programming learning lies on the ability to abstract the acquired knowledge to solve problems. Abstraction and problem resolution abilities can only be obtained through individual effort and continuous practice. Having well-developed literacy abilities will be of extreme importance to ground the cognitive processes and to support the learning being created.
3. Although computer science is part of the students' daily life from an early age on, the transparency level intrinsic to the relationship user-computer leads them into a false sense of intelligent autonomy of informatics systems. Sometimes it is difficult to make them understand the difference between the notion of systems transparency and their responsibility in the relationship programmer-computer.

The abilities of abstraction and problem solving are underdeveloped among university newcomers from high-school. The lack of excellence in their development is further stressed by the superficiality of their literary skills [3, 4], crucial to a productive academic life and to develop the technical abilities proposed in the syllabi of university courses.

The major problem concerning programming teaching does not lie only on the difficulty students have to abstract and solve problems. There is still the difficulty in finding a way that motivates students to get involved in the course in spite of their handicaps and to not give up trying to overcome the natural barriers inherent to this learning [5]. It is vital to make them realise that the obstacles are surmountable and that the demanded skills may be developed and improved, encouraging them to develop and strengthen a set of essential academic competences so that they may better improve in their studies and in their future professional life.

II. TEACHING TO THINK

Access to education is an evident concern of today's society and of the global economy, with a strong commitment from governments of rich and developing countries in initiatives to improve and offer better conditions for learning in the different stages of the educational system: the enlargement of vacancies in the educational system, the evaluation of the quality of teaching, developing policies of social and digital inclusion, investment in the renovation of classrooms and laboratories with computing equipment and programmes to improve the qualification of teaching staff.

Nevertheless, those reforms have not yet been able to produce a system that can develop towards the "teaching to think" concept. There is nowadays a great number of students, from elementary to high school, who do not develop well enough the different abilities and competences necessary to evolve in a more productive way throughout university years, as shown in the results of the International Programmes of Teaching Evaluation [6].

The growing number of students in the university system has burdened the traditional academic model. In a short timeframe there was a growing demand that made the academia need to change their way of work and educational model, without a previous preparation to adequately respond to that demand.

Facing the urgency in finding ways to manage this situation, the academia often chooses processes that privilege administrative issues (classes format, resources allocation), which is not always the best solution under a didactic point of view. Although there is a need for a renovation in the academic life to better suit the new reality, it is a process that is under development and where the administrative reforms end up influencing the evolution of didactic processes.

A. Critical and Creative Thinknig

Matthew Lipman is an educational theorist who has called the attention from the North-American Academic Community in the seventies with his proposal of Teaching Philosophy to children, we called "Pedagogy of Judgment" (Philosophy for Children – P4C)[7]. It suggests to "teach to think" using the philosophical speeches, proposing teachers to readopt the Socratic teaching as a didactic approach.

His goal is to start in infancy a long term process of development of critical and creative thinking, joining literacy and language acquisition which will last throughout all the formal educational process that the child will live. In that proposal, at the same time the child begins to develop literacy skills, he/she also starts the continuous development of his/her abilities to think, going from the stimulus to the capacity of judging fairly.

To Lipman, issuing a judgment is a behavior that sets the basis for the qualitative development of the most relevant cognitive abilities for educational goals (research, reasoning, information organization and translation), thus making an elementary unit of thought. Judging is the basic cognitive unit for the development of critical and creative thinking, and it is influenced both by criteria (its rational element) and by individual values – the emotional element of its composition.

His proposal defines practical actions which converge with the thinking of John Dewey, Lev Vygotsky and Jerome Bruner, aiming at changing the wrong concept that childhood innocence impedes the child from learning to use reason as a learning tool. His work shows that the lack of motivation to learn must be understood more as a result of the evolution of non-reflective practice of the traditional educational model, rather than the "innate" lack of curiosity from the student [7].

This pedagogical strategy is implemented from a Lipman's redefinition of the concept of learning communities which he called "community of inquiry". Lipman's proposal is an appeal to teachers so that they focus their practices in guiding students in a search for knowledge: motivating them to learn how to consciously identify what they already know and what they need to know not only how to solve a problem but also to be able to think on and assess the quality of a solution.

B. Teaching to think in programming

There is an intense effort from researchers and teachers in trying to understand the reasons that make programming learning be seen as an obstacle for a growing number of students [8, 9].

In fact, the major problem is not language or the programming paradigm, but the difficulty to develop competences that make the student able to contextualize his/her knowledge in order to solve problems. It is important to make the student realise that programming is, above all, a conscious exercise of the mental abilities that are developed and offered in an appropriate context to support the development of several cognitive abilities [10,11].

Some researchers aim at a restructure of curricula [12], but that can only be implemented through the change in the way activities are proposed and to evaluate the progress of the student's learning [13, 14]. There are advances that can be obtained for instance with the regular practice of activities related with research and reflexion for problem solving, abstraction, modelling and the evaluation of the quality of algorithmic solutions [15, 16].

It would then be possible to understand programming learning as a situation that encompasses nuances similar to the context of language acquisition by children. Up to a certain extent, learning how to program requires a change in the way of thinking, according to the paradigm's precepts, just as when one learns a new language.

The relationship of mutual influence between language and thought is evident [17], and resembles to the relationship between language and the programming paradigm. That is why it is relevant to get close to Lipman's approach to programming learning.

Although the pure philosophical speech is not *per se* a natural approach to teaching practice in programming, the methodical and reflective thought that comes from the dialogue inspired in Science Philosophy is rather useful.

Literary skills may thus be reinforced together with programming teaching, as they will assist in the learning of the several stages of abstraction and modelling of an algorithmic solution and in the software development process. Furthermore, as one develops mental abilities, that usually influences the qualitative improvement of the several literary skills (reading, interpreting, summarizing, criticizing, etc), and vice-versa [7].

Thus, rather than just being able to define a methodology of teaching-learning for programming, it would be interesting to be able to establish a set of strategies that show students that solving programming problems is an activity that they are fully capable of accomplishing. It is important to value contexts and establish a dynamics in class that may motivate students to teamwork, giving evidence and making them aware that individual difficulties are surmountable so that they get ready to "learn to think" [18, 19]. This should lead to a higher student commitment to their learning, including behavioral changes that may improve their performance throughout the course.

III. MOTIVATION AND LEARNING

Motivation has a great impact on the individual's cognitive development and is a determinant factor for the individual success in a learning process. It is also among the most fascinating features of the human psyche, having one of its main research origins in Maslow's Motivation Hierarchy [20]. Understanding motivation to learn requires a deep analysis of the socio-cognitive components associated with personality (identification with the institution, Degree, career, accessibility to teaching and the analysis of school success) and the quality of relationships in coexistence environments (social identification and learning approaches) [21].

Along evolution in the formal learning process, from primary school, the student faces several tasks, contexts and learning methodologies. From those experiences the student develops his/her study behavior, finding a learning strategy and the method and activities that best fit his personality, his beliefs and values. Yet, it is not possible to underestimate the impact of the experienced learning methodology, as it influences greatly the type, quantity and quality of the abilities and competences that will be developed. This ends up merging within the study behavior of students of a whole generation.

Motivation presents itself as a domain of crucial impact on learning tools and learning [22], and several theories and instruments have already been described to classify measure, create and maintain students' motivation, especially among children and teenagers [23].

With the advance of research in Distance Education (DE), tools inspired in the John Keller's Motivation Model ARCS (Attention, Relevance, Confidence and Satisfaction) [24], have been widely used in course modelling and e-learning environments.

Formal tools to evaluate motivation measures (comfort, self-efficacy, satisfaction) such as the Inventory of Attitudes and Study Behaviours (IABS/IACHE) [25], are important and seek to assess features related with the students' learning strategies. The IASB is an independent, generic behavioral test with which it is possible to evaluate:

- If a didactic strategy may or may not satisfy a set of learning requisites in a given course;
- To point the existence of changes of attitude from the student regarding his/her academic performance
- To establish statistical parameters of a population, identifying the proportions of cognitive, motivational and behavioral dimensions.

The IACHE encompasses cognitive, motivational and behavioral dimensions, distributed in five sub-scales [25]:

- Comprehensive focus, using reflection and a deep content analysis, which implies for the student a greater effort and time in learning;
- Reproduce focus, a tendency to spend only a minimum effort on a superficial learning, based on memorization and contents reproduction;
- Involvement, or motivation, because this related essentially with requirements of intrinsic motivation
- Organization, it analyzes the indications of establishment some organization level on activities of study;
- Competence personal perception.

Other tools focus on more specific features, such as the case of the Course Interest Survey – CIS and the Instructional Materials Motivation Survey-IMMS) [26], two motivation evaluation tools, created in the framework of the ARCS model. CIS and IMMS may show the levels of attention, relevance, trust and satisfaction among students regarding a given course (pedagogical approach, classes rhythm, teaching practice, proposed activities) and the didactic materials used (textbook, handouts, worksheets).

The analysis of the study behavior through tools like IACHE may provide crucial information on the students' behavior, both individually and as a group, allowing to guide and/or to evaluate the selection of activities, methodologies approach and pedagogical practices for students with specific characteristics.

Although tools like IACHE and CIS have been proposed to measure motivation, there is the need to evaluate the level of acceptation and rejection of students to do the activities [27], as well to establish a motivation measure more closely associated with the aptitude of students to learn to program, which would also allow it to be measured with total independence from the other motivational models observed.

That motivation measure is self-efficacy [28], evaluated from scales directed associated with a self-analysis of the ability or inability of a student to perform a specific task. Self-efficacy scales for programming are a formal tool that may be independently and regularly used [29], and which can aid to maintain the student alert regarding the quality of his/her learning, offering another perspective of the assessment of his/her capacity, different from essays and exams' grades.Units

IV. PROPOSED PEDAGOGICAL STRATEGY

This pedagogical strategy aims at defining a theoretical framework that encompasses a set of recommendations regarding contexts and didactic activities, computational tools and motivational strategies that may assist the teacher in the definition of learning contexts for programming courses, as shown in figure 1. The goal is to try to identify the conditions that may make programming learning more stimulating, minimizing drop-out intentions and making the student learn more and better.

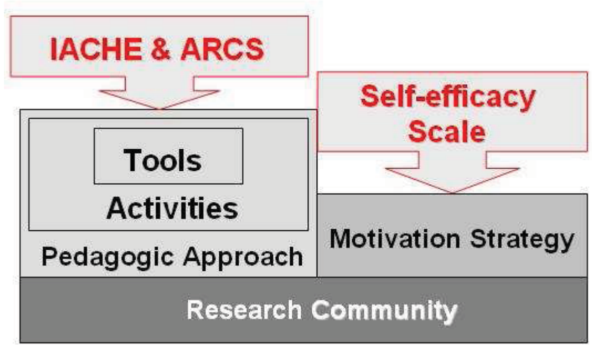

Figure 1. Theoretical scheme of the strategy.

This is a proposal developed under the perspective of learning communities, inspired by a metaphor of Mathew Lipmanp's research communities [7], considered to be a rather relevant abstraction for proposals involving the development of critical thinking [30] and literary skills, and also as a strategy to improve the capacity of solving programming problems among university students [31].

Learning communities are already a renowned perspective, both educational and technological, that allows the creation of contexts in which it is possible to reinforce learning through the association between collaboration activities and knowledge production [32]. Besides, that perspective favours the practice of several literary and mental abilities that will be necessary to students throughout their academic, social and professional lives.

The dynamics of Lipman's Research Communities for programming teaching defines a didactic approach that would allow the teacher to work in several different contexts: Problem Based Learning (PBL) [33], Just-in-Time Teaching (JiTT) [34], hands-on projects [35], games [36] and programming competitions [37] for example.

This is the first foundation of that proposal, i.e., the teacher should decide his/her didactic approach, being able to choose any of the suggested contexts to determine: how and which didactic activities will be developed, and which support tools he/she will use in the course. We suggest these contexts as they have appeared in the literature as well succeeded examples in programming learning.

When choosing the context the teacher should take into account some facts as class size, which can make certain contexts harder than others.

After choosing the context, the dynamics of Research Communities will be developed together with didactic activities planned to strengthen the student's involvement with the process of knowledge acquisition and development of competences to solve problems, through teamwork and the motivation to practice their literary skills in several ways:

- Research activities – which increase the research of content for the solution of problems, e.g.: research questions, evaluation simulations, exercises of discursive evaluation of the algorithmic quality of solutions, practical and/or programming challenges with different complexities, either individual or in group;
- Collaborative/cooperative knowledge production – adoption of methodologies and collaboration tools in reinforcement activities, peer review, motivation for the production of portfolios, webquests, seminars and participation in competitions;
- Distribution of work and tutoring – stimulating the use and recognition of voluntary tutoring between student-student and student-tutor;
- Continuous assessment – regular feedback tasks between teacher, tutors and students on the course evolution.

Programming learning demands the choice of technological tools that can support programming learning and collaborative work. We see as an advantage the use of algorithmic simulation tools and learning support programs adequate to the studied language and paradigm (RoboCod, Alice, BlueJ, o JavaTool e and SICAS, for instance). Competition and Test Platforms like TopCoder, Mooshak and Online-Judge are also welcome.

To stimulate extra-curricular activities and to support the monitoring and continuous assessment tasks, it is advisable that there is the support of a learning management support, such as the Moodle, Blackboard or AulaNet.

The second founding concerns the need to use a supporting strategy for the maintenance of good motivation levels for the students' learning during the community work. Regarding this, it is important that the teacher may be able to identify specific moments to intervene, advise and settle the students' frustrations concerning their performance [38]. The availability and sensitivity of the teacher are crucial to evaluate the students' progress and commitment, as well as to assist in the maintenance of their motivation levels.

Motivational measures such as the comfort level, self-efficacy, confidence, usefulness and satisfaction with the proposed activities should be checked regularly in order to be able to guide the work rhythm and to adequately direct the teacher's efforts for intervention actions, whether in the daily motivation or in the prevention of behaviors that may lead to students dropping out.

A. Methodology of Pedagogic Strategy Evaluation

The proposed strategy will use measurements of the usefulness of the proposed tasks along the course as well as some formal psychological tools to evaluate several cognitive aspects related with motivation: a survey on the features of study behaviour through the IACHE tool, an evaluation of the levels of satisfaction with formal aspects of the course development through ARCS, and a measurement of the students' levels of self-efficacy in relation with language and the studied paradigm.

The results of the IACHE test, as they are not *a priori* related to any course or degree, will be used to assess if the use of a certain learning approach has produced any changes in the study behaviour of a given population.

The motivational levels measured by the ARCS model will provide the evaluation of the evolution of the course (contexts, teaching assessment and used resources). For each proposed task there will be a survey to check those measurements at the end of the course.

Finally, a regular application of a self-efficacy scale in programming will be used [39], making the students aware of their competence level to carry out tasks with the studied language and paradigm. That awareness can better guide their studying efforts and stimulate the evolution of the necessary competences for programming learning, identifying the ones which are at an average or rudimentary level.

The evaluation scheme influences the application of CIS test in the middle of the course, and surveys will be made alongside the proposed tasks. Both the IACHE and the self-efficacy scale will be applied in the pre-tests and post-tests scheme, where the IACHE will take place at the beginning and end of the course. The self-efficacy scale will be applied in the middle and end of the course, preferably before the tests of knowledge evaluation.

V. AN EXPERIMENT WITH STUDENTS OF DESIGN AND MULTIMEDIA

Most programming courses of the Department of Infomatics Engineering usually present a high number of enrolled students - between 200 and 300- and a high level of heterogeneity among students in one course, from the several degrees offered in the Faculty of Sciences and Technology of the University of Coimbra (FCTUC), like Informatics Engineering, Industrial Engineering, and Design and Multimedia. The teaching model encompasses:

- Theoretical classes (2 hours): all students enrolled attend a lecture by a professor in a classroom;
- Practical classes (2 hours): students enrolled are divided into classes of up to 30 students to carry out practical lab activities with the same professor of the theoretical class or some other teacher, and:
- Lab practical classes (2 hours): support classes, remedial work or clarification of doubts, non mandatory, given by course tutors.

Applying an experimental strategy in this scenario would be risky and very time consuming. Any change in the pedagogical dynamics and work methodology within this kind of courses would not only imply a more laborious routine for the teacher, but would also raise the chances of failure of the proposed strategy.

Thus we chose to start with a small course, where management and changes control is much easier. The proposed strategy has started being developed in two stages, with students of the Programming course from the Masters Degree in Design and Multimedia (MDM): the first stage carried out from September to December 2008 and the second, still ongoing, started in September 2009. The aim of this course is to offer students a minimum programming knowledge that may allow them to participate in other courses of the degree that require previous programming knowledge.

The course's syllabus was developed according to the dynamics of the Research Communities, and the didactic approach was conducted to provide a practical learning. In the experiments carried out the following activities are used: individual seminars on artistic projects and applications developed with the supporting language, practical group work assignments, discursive evaluation of algorithmic quality from the peer code analysis, producing an artistic portfolio in programming , and continuous assessment.

The exercises and projects proposed involve a need for research, especially the review of algebra and mathematical knowledge, with monitoring from the teacher and motivation for regular qualitative assessment of the assignments accomplished in teamwork.

Bearing in mind the artistic background of the students participating in the experiment, we chose to use the programming language and IDE Processing programming language as a development tool. It was created at MIT by and for graphic designers [40], a tool that expands and facilitates the capacities to develop artistic works with JAVA language.

In the adopted strategy there is no distinction between theoretical, practical or lab practical classes. All classes are spaces for knowledge construction and practical experimentation, making up a total of 6 weekly hours of work. The course holds a class at the DEI's Moodle, where materials are available and some tasks are performed.

The size of MDM's classes made an almost one-to-one student monitoring possible. It has also maximised the opportunity for the teacher to know crucial characteristics of the students, changing the class dynamics to an eminently research approach during the practice of problem solving in groups.

A. First Stage

The first stage group included 11 students, mostly recent graduates from the BSc degrees in the areas of design (Multimedia, Industrial or Communication) and architecture. We chose to use the context of visual hands-on projects of growing complexity, as it would facilitate the students' involvement and interest in the creation of varied practical work.

In this stage the original idea was to verify the coherence of the desired approximation to Lipman's approach, for which a continuous assessment system was used, through the fulfillment of several proposed tasks. Moreover, the evaluation included to check: students' satisfaction with their own performance, tasks, materials and classes rhythm through biweekly reflection about the course evolution in the Moodle platform.

Among the positive aspects point out in the records we can highlight the following: research activities and code analysis, team work and class dynamics. Those activities are considered essential for the approach proposed by the Research Communities, enriching it as an interesting approach for programming teaching. Surprisingly, the peer evaluation tasks and the continuous assessment, as well as the artistic contexts proposed in group assignments, are positively evaluated although with a frequency way below expected.

Amid the most scored aspects in the evaluation of negative points, we highlight: the mathematical examples used during the arrays content, the first challenge of the course involving animation programming of a circumference mathematical model and the lack of individual commitment from students. Among the least scored negative points we underline: the delay in the teacher's feedback, classes' schedule, features of the Processing tool and OOP.

By the end of the course students answered an 8 questions interview related with the perspectives of the ARCS model, in which they presented their evaluation on the course, as well as aspects related with their school trajectory.

The most interesting answers were:

1. What do you consider to stimulate your interest in a course: the syllabus (25%), practical tasks (25%), your individual interest on the subject (25%), when you feel curious on the subject (18%). Only 7% consider the usefulness of the course as important;
2. Do you consider as positive the experience in courses where: there was a clear practical feature (25%), you liked the contents (21%), you felt inspired by the teacher (17%), you felt that the contents were interesting/useful (14%);
3. Do you consider as negative the experience in courses where: teachers were not motivated, with inconvenient, derogatory and/or authoritative attitudes (25%), the contents were not interesting to you (25%), there was a theoretical and expository prevalence (17%) you considered them useless (10%). Only 3% reported a failure in their own studying time management regarding studying.;
4. How do you manage your motivation to learn: in uninteresting activities you do not dedicate more than the minimum required (32%), you believe it is natural to feel unmotivated in certain periods (26%), you try to finish an uninteresting task as soon as possible (21%). Only 3% considered the options of: studying in advance to prevent accumulation of study material or to ask for help to study;
5. What grabs your attention: the usefulness of the task (19%), the teacher-student relationship (19%), the practical characteristics of the course (18%), the teacher's availability (16%), didactics (16%), your curiosity (7%);
6. You feel confident in a course when: you know something on the subject (40%), you trust on the teacher's knowledge (28%), you are interested and confident in the usefulness of the course's subject (12%), you trust the evaluation system used by the teacher (8%);
7. For a task to be interesting, it depends on: adopted context (30%), the clear relationship between theory and practice (26%), empathy with the teacher (26%). Nevertheless, 18% believe that some courses are naturally uninteresting, no matter what they propose;
8. The position of the Programming course in case a ranking concerning the interest on the course was organized: first place (25%), second place (33%), third and fourth place (18%) and fifth place (10%);

The result of the interviews corroborates with the aspects identified in the bi-weekly reflections analysis, with some pleasant surprises:

- Of the five courses attended by students in that semester, Programming and Internet Technologies were the ones that caused more negative expectations due to the frustrating experiences many say to have gone through during their BSc;
- The reports of good experiences with courses denoted the importance of the relationship between didactics and the teacher's posture. They have mentioned as positive experiences in courses where they did not feel attracted by the contents, while they felt inspired by the teacher;
- They have considered Programming a pleasant surprise among the courses they had attended, highlighting the way courses were conducted, the tool which was used and the evaluation process;

Only one student didn't manage to pass the course and the teacher was pleased not only with the results obtained but also with the dynamics of the strategy, and although he recognizes that there is an increase in work, he believes that the way to work is more prolific.

This experience was the first approximation accomplished for the definition of the strategy here described, and it is particularly important to clarify under which foundations it should evolve and which adjustments should be made. Both the feedback and the constant monitoring by the teacher have shown to be extremely important, as they have allowed a better evaluation of the quality and acceptability of the implemented activities.

It has also made possible to carry out on time actions that were adequate for the classes rhythm and the proposed tasks, to address issues of commitment and dispersion, and especially to be able to gain back students with major tendencies to drop out the course.

It also made clear the need to associate a motivation measure, self-efficacy –specifically connected with the language and the programming paradigm used, to support the process of keeping the students committed during the course. This also establishes a change in the evaluation of the experiment results, adopting formal instruments and parameters to evaluate the several components.

B. *Second stage*

There are 12 students in this group, one of them from stage one. Similar to the previous class, most students are recent graduates in the area of arts and design, and only two are student workers.

In this stage we analyse JiTT's potential, as it makes available a set of tasks that are tightly connected with the goals proposed by the Research Communities. On the second stage experimentation we choose to use once again the context of hands-on projects with the creation of a task inspired in JiTT challenges [41]. Although JiTT offers better opportunities for the development of research activities to a programming course [38], we bet on the positive context of hands-on projects received by first stage students.

The context based on hands-on projects and the tasks list accomplished in the first stage have been kept. One of the changes that were incorporated is a change in the organization and alignment of the syllabus' contents and in the evaluation method. There has been an effort so that the introduction of Object Oriented Programming (OOP) concepts is made earlier. Three new tasks have been introduced: individual programming challenges, mini-tests simulation and mini-tests.

Inspired in the JiTT proposal, small programming challenges have been planned in specific points of the course's syllabus, as a way to stimulate individual work, especially outside the classroom. These challenges include a self-evaluation component concerning the merit of the accomplished programming, making the student used to critical assessment and to the exercise of technical competences in software development.

The mini-test simulation is the only non-scored task and it was prepared so that the student may live the mini-test experience in less stressful conditions. The results are corrected and given back to students in a way they may understand their comprehension level of the course. Bad results will be presented in a way to motivate study outside the classroom. The inclusion of mini-tests does not imply a change in the rhythm or in the approach of the adopted didactics, and it is another opportunity to evaluate individually the level reached by students.

The evaluation methods included in the strategy have been are being put into practice in this second stage. In September we applied the IACHE pre-test, in October the Processing self-efficacy scale pre-test, due to academic events, the CIS test and surveys were postponed to November. The results of the pre-tests performed are presented and commented as follows:

a) *IACHE results*

The IACHE survey is divided into three parts, from which only the first one was considered for the analysis. It includes 44 statements. Groups of questions analyse each of the five cognitive dimensions whose answers vary in intensity from 1 (totally disagree) to 6 (totally agree). The score of each cognitive dimension is obtained by the sum of the answers to the questions for that dimension. The reference values and the average point for the comprehensive and organization focus are given by (1) and all other dimensions given by (2).

$$10 < \overline{X} < 60,\ with\ x_m = 35 \qquad (1)$$

$$8 < \overline{X} < 48,\ with\ x_m = 28 \qquad (2)$$

Figure 2. Summary of the descriptive statistic indicators of the IACHE pre-test

		comprehen-sive	reproduce	personal perception	involvement	organizing
N	Valid	12	12	12	12	12
	Missing	0	0	0	0	0
Mean		42,58	29,92	21,50	36,58	35,00
Median		42,50	29,50	23,00	36,00	33,50
Std. Deviation		4,078	4,999	4,462	4,621	6,495
Variance		16,629	24,992	19,909	21,356	42,182
Minimum		35	24	13	28	23
Maximum		49	39	30	44	47

At this point of the research the average values observed in the analysed cognitive dimensions, figure 2, show a rather high involvement level of students, who demonstrate a great predisposition for the accomplishment of the course's tasks. Surprisingly, the average of the comprehensive level was higher than the reproductive level, which can be a reflex of the organization sense shown by students. The low level of personal perception is a good indicator, but the great discrepancy between the maximum and minimum scores of the sample for that specific dimension warns the teacher on the aspects that involve self-efficacy for students who present a very high average value among this population.

There was another analysis carried out, assembling the groups of answers in the dimensions comprehensive focus, reproductive focus, motivation and organization in three intensity levels: low (answers 1 and 2), average (answers 3 and 4) and high (answers 5 and 6). That relationship was used to analyse all dimensions except the personal perception. For this dimension the analysis is carried out in the opposite way: low (answers 5 and 6) and high (answers 1 and 2).

The analysis by answer level in each dimension presented in table 1 endorses the analysis of the average value, i.e, this is an optimistic result in the sense that shows a predisposition of the group for learning, just 3% below the sample of the low level. Success expectations may be slightly larger than the apprehension of the course's contents. Although students do not show a very high sense of organization, there is evidence that many of them seek to develop study strategies directed to comprehension at a deep level. The low percentage shown by the low level of the comprehensive focus is rather significant.

Moreover, the fact that this population shows a high sense of capacities is positive, as students with low self-efficacy expectations tens to invest a lower effort in studying activities. Only 9% of the population is at the higher level of personal perception.

The most significant efforts of the proposal should be orientated towards the recovery of students who present more answers at the low level, and the improvement of those at the intermediate level.

TABLE I. IACHE DIMENSIONS INTENSITY LEVELS ANALISE

IACHE Dimension	Intensity Levels (%)		
	low	*average*	*high*
comprehensive	4	52	44
reproductive	20	47	34
personal perception	56	35	9
involvement	3	42	55
organization	23	59	18

The comparative analysis of scores and more specifically of the dimensions intensity level will only be possible after the conclusion of the post-test, at the end of the course.

b) Self-efficacy Scale in Processing

The scale used, translated and adapted from a scale for JAVA [42], includes 32 statements related with tasks concerning the tool, paradigm and problems solution, answered according to the intensity of the level of confidence: 1 is for totally unconfident and 7 for totally confident. The scale score is given by the sum of the answers.

$$32 < \overline{X} < 224, with\ x_m = 128 \quad (3)$$

The analysis of self-efficacy follows the same process adopted by the IACHE test, where the reference value and the average point for this population is presented in (3). The data of the descriptive statistics are presented, according to figure 3.

Score no teste

N	Valid	12
	Missing	0
Mean		114,00
Median		95,50
Std. Deviation		34,743
Variance		1207,091
Minimum		89
Maximum		192
Percentiles	25	93,25
	50	95,50
	75	133,25

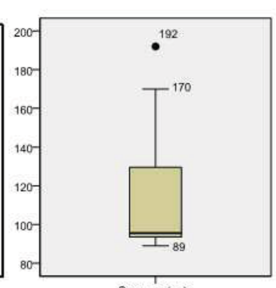

Figure 3. Results of the self-efficacy scale in processsing

The descriptive analysis of the average and the BoxPlot chart shows that there is a large number of individuals whose sense of self-efficacy is very low, since 50% of the population is concentrated on a small amplitude interval between the x_{min} (89) and the median (95,5). The third quarter is a value close to the expected average (128) and thus approximately 75% of the population presents a lower than or equal score to that reference value.

In spite of that statistics result, a more clear conclusion for the studying orientation goals is obtained from the analysis of the intensity level. This analysis reveals a less negative situation, since 63% of the population is concentrated on the average level of self-efficacy (answers 3, 4 and 5), while only 25% are at the low level (answers 1 and 2). Hence, we assume that only one quarter of the sample students consider themselves incapable of accomplishing minimum tasks with the tool, denoting a level of insecurity that makes is suspect that a bad future performance in the mini-tests may actually discourage the student up to the point of no longer doing any effort in the course.

Since self-efficacy is a type of confidence measure that only gives significant modification results when it is at the low level, the teacher's attention should be reinforced towards recovery of students with answers in the low level. Students in the average level may receive the results as an orientation on where to invest their studying efforts, encouraging a more positive expectation of their performance in mini-tests.

It is important to notice and check if the 12% of students who are at the upper level are not too optimistic with the level of their knowledge. In any case, one should not mistake the self-efficacy result with the enthusiasm to learn, checking if, in spite of the positive result, the student is not showing a low commitment with the tasks of the course. All in all, the teacher should adopt intervention measures for guidance and motivation of studying efforts, frustration management and commitment.

As happens with IACHE test, the comparative analysis of scores and more specifically of the dimensions intensity level will only be possible after the conclusion of the post-test, at the end of the course.

CONCLUSION

The general evaluation of the first experiment was considered positive either by students as well as by the course teacher, although there wasn't the full support of all formal cognitive evaluation instruments currently proposed by the strategy. Its accomplishment was particularly important to guide the necessary changes and to plan the second test stage experimentation. It has shown the need to use formal evaluation tools and not only interviews, to validate the strategy's results.

Part of the instruments and premises proposed by the described strategy are also being used to carry out voluntary work, offering programming support to all students of the Faculty of Sciences and Technology of the University of Coimbra (FCTUC), through the Computer Programming Supporting Class. This initiative was backed up by the Faculty's Supporting Office for Portuguese-Speaking Foreign Students, originally aimed at assisting students from Portuguese-speaking African Countries (PALOPs) to strengthen and develop their minimum competences in problem solving and programming. Having first taken place between February and June 2009, the goal is that these students may have better results in the programming courses of FCTUC. This initiative has currently broadened the access so that all FCTUC students interested in this kind of support may be included.

The changes proposed by the strategy also seek to sensitize faculty members and administrative staff of DEI and FCTUC, showing that there are changes which can be implemented in the organization of programming courses, with positive expectations for the quality of learning and more efficacy in the allocation of physical and human resources. In order to pass from reflection to action, it is important that the results of the proposed changes can be formally documented in a set of measures that have been previously tested in contexts as close as possible to the current reality.

ACKNOWLEDGMENT

The authors would like to thank the students enrolled in the Programming course of the Masters Degree in Design and Multimedia for their participation in the experiments.

Retaining electronic engineering students by project- and team-work from the first semester

Anna Friesel
Professor, Head of Section
Copenhagen University College of Engineering
Ballerup, Denmark
afr@ihk.dk

Abstract— **This paper describes the experience of teaching the basics of engineering: calculus and the basics of physics as part of a project-and team-work initiative in the department of Electronics and Information Technology, at Copenhagen University College of Engineering (CUCE) in Denmark. All the basics courses in the first and second semester have been taught as part of projects and involve teamwork. Modern engineering students are difficult to motivate in order to learn pure theoretical issues such as solving differential equations. Especially when we talk about undergraduate engineering students, who do not expect to continue their education higher than a Bachelor of Science in Engineering. At the same time, and for the same reason, the fail rate in mathematics is very high during the first two semesters. This was the reason we decided to change the structure of our education and incorporate the theory with practical projects. This paper describes some of the projects. The projects are the motivating factors to learn mathematics. The examination results show improved learning potential, when using this method of engineering education. The students' evaluations show a very positive effect on their experience with this "practical" way of learning theory. At the same time, the evaluation results have shown higher pass rates and higher grading.**

Keywords - Motivation, Project based learning, Teamwork

I. INTRODUCTION

The research confirms improvement of the learning outcomes in education when the theory is combined with practical training or projects [3,5,8,10,13,14]. Usually the project-based courses are introduced after the students have passed the first 2-3 semesters of the engineering basics, like calculus, physics and computer programming. Students who wish to work professionally with electronics, computers and telecommunication, and who do not wish to continue for Master Degree, are not motivated to use 2-3 semesters for pure theoretical studies [11,12]. These students usually have high fail rate in mathematics and physics in the first 1-2 semesters and, as a result, many of them stop. On the other hand we must introduce the theory in order to understand and work with a number of complex engineering disciplines. Considering the students' wish to work with real engineering projects and the requirements to master the basics of mathematics and physics, the message is clear: the students will be more likely "to stick with derivatives and integrals" [6] if we can offer them some evidence of how necessary these tools are in order to find solutions for engineering problems[1,2]. If we use this strategy from the first semester the students will experience that they already make progress towards completing engineering work/projects and the positive influence will be shown in an increased pass rate. There are different possibilities to include experimental work together with theory in engineering [7,9,17] like:

1. Using simulations programs involving graphics and animations in order to visualize mathematics and physics.
2. Mixing the theory classes with laboratory exercises.
3. Study-tours to industrial companies.
4. Inviting guests from industry for lectures.
5. Make students to work with engineering projects in teams.

In particular the engineering students benefit from new technologies [4], as they actively use both Internet and simulation programs [20,21]. Teaching theoretical mathematics today is a very challenging task, even more so when we talk about undergraduate, practical oriented engineering students. The engineering students' expectations for their study program are more practical and experimental activities, then the calculations of the theoretical problems with pen and paper. Many universities and engineering colleges have the opinion that pedagogical activities must actively involve the students in order to motivate them to learn basics of mathematics and physics [17]. Problem-based learning and working with projects has already been implemented in engineering educations in many different universities [1,3,9]. This paper presents how we implemented the calculus and the basics of physics in the curriculum for undergraduates, as a part of projects in the first two semesters.

II. STUDY STRUCTURE

Some years ago, we went through the process to renew the educational study structure in our department and we decided to change the study structure in CUCE towards more projects and teamwork. Similar changes were made for all semesters in our programs, involving the basic courses in mathematics and physics. Example of our program in electronics and information technology is shown in Table 1.

Project- based learning requires a high degree of concentration on particular topics, and in order to support this educational method we also changed the weekly time schedule. Students have only two modules/topics during one day, one from 8:30-12 and one from 12:30-16:00. Each module includes four lectures of approximately 45 minutes and some necessary breaks in between. The example of weekly schedule is shown in Figure 1. One module of tuition is usually related to a course of 5 ECTS credits, and one module of teacher tuition requires on average 4 hours of self-study for the student.

Mon	Tue	Wed	Thu	Fri
08:30-12:00	5 ECTS Credits

Figure 1. Weekly Schedule

III. FIRST-, SECOND- AND THIRD-SEMESTER MATHEMATICAL COURSES

The first semester mathematics course has the following content:

- Linear algebra, basics.
- Signals and systems.
- Complex numbers
- Number systems and number representation.
- Polynomials.
- Infinite series.
- Fourier series in continuous time.
- Differential equations, in project context
- MATLAB

The course has a value of 10 ECTS course with two modules per week. In connection with this course the students work in teams on projects connected to all the courses they have in the first semester. These projects give an additional 5 ECTS and are a mix of mathematics, digital signal processing, programming and digital hardware. Examples of first semester projects are:

- Development and implementation of the algorithm for Gauss elimination
- Development, programming and hardware implementation of the algorithm for an elevator's movement
- Apply differential equations in the description of a simple physical system and make a MATLAB simulation

During the semester, the students develop the following skills:

- how to work in teams,
- how to make a presentation for tutors and other teams on seminars,
- define and describe the fundamental problems and concepts introduced in the course – using proper mathematical notation,
- define and describe the fundamental methods for solution introduced in the course – using proper mathematical notation,
- define and describe a feasible algorithm based on a mathematical method for solution - allowing a subsequent implementation in MATLAB.

The second semester course in mathematics is a combination of Digital Signal Processing and discrete mathematics (DSM2). The content of this course is:

- discrete-time linear systems in the time-, frequency- and z-domains,
- design and implementation of digital filters on a digital signal processor including A/D and D/A converters,
- MATLAB used as simulation tool.

The projects connected to this course are concentrated on the following:

- set up specifications for the amplitude response of FIR and IIR filters,
- apply the design tools of MATLAB to calculate the filter coefficients,
- implement and test by measurements digital filters using a DSP evaluation kit.

The non-technical skills learned during the second semester's courses and projects are:

- how to work out written reports in connection to the course assignments and projects,
- how to collect information and acquire new information and knowledge,
- how to communicate technical problems in writing and speech,
- how to cooperate in teams.

The third semester courses combine mathematics, physics, and electromagnetism and circuit theory. Mathematical modeling is used as a tool to describe mechanics, electromagnetism and circuit theory involving differential equations.

The projects on third semester are more advanced, like:

- Specification, analysis and design of electronic scale. DC-project, (figure 2).
- Design of the metal detector, AC-project and filter design, (figure 3).
- Mathematical Modeling of the electronic scale, comparison between measurements and simulations (figure 4).

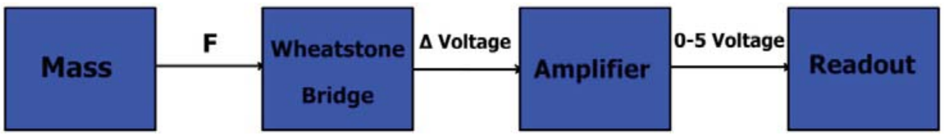

Figure 2. Block diagram of Electronic Scale, DC-project.

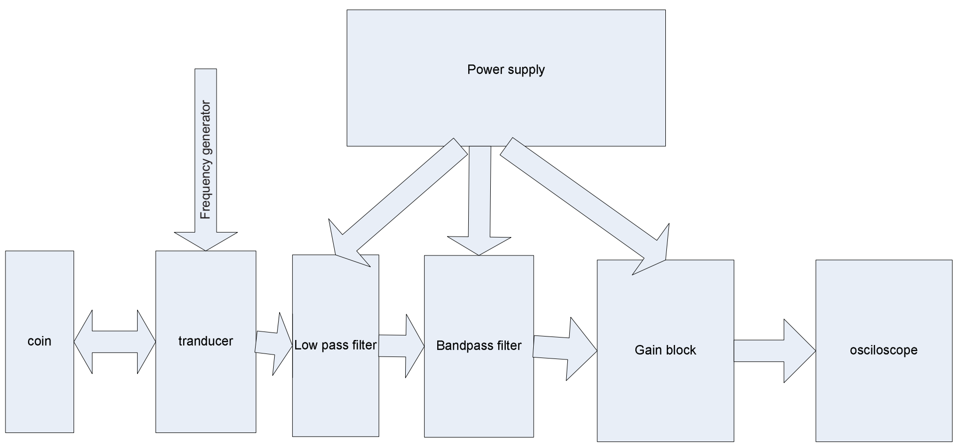

Figure 3. Block diagram of the metal Detector, AC-project

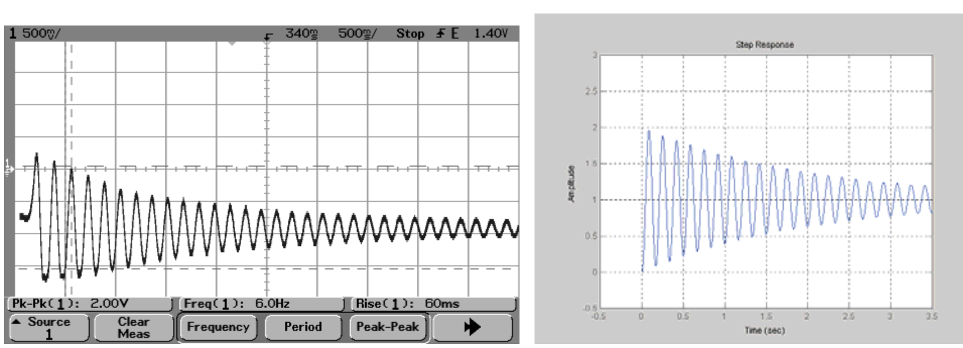

Figure 4. Electronic scale and simulation

The documentation of the practical design and experiments are described in the reports and give the basis for the evaluations of the projects on each semester. This is an advanced process of learning, where the students have the responsibility for combining the theory and practical electronics design [8, 9, 15]. The motivation to learn basics of mathematics and physics is improved, compared with traditional classical educational methods, where the students learn all the theory in pure theoretical courses during the first semesters of their education.

IV. THE EXAMINATION

The examination process in Denmark involves by law an external examiner certified by the Ministry of Education, for all examinations at the university level. For engineering departments the external examiner is very often a company manager. The role of external examiner, among other things, is to keep the engineering curriculum up to date. The external examiner has a great opportunity to discuss the contents of the engineering courses including: pedagogical methods, experimental work, and projects when he or she participates in the examination. The external examiner has to report his/her conclusions about the examination level, and the level of education to the chairman of the external examiners, who is approved by the Ministry of Education. This procedure gives the industry an influence on the engineering education in Denmark. The industry can easily have influence to change the engineering departments' curriculum according to the needs of the industry. On the other hand the students meet their future managers, and get the knowledge of the requirements in industrial companies at the same time.

The examination, for project related courses, is both group- and individual- examination, but the marking is always individual. The evaluation is based on a general impression of the level achieved by the student relative to the objective of the project based course. The examiners, teachers, and the external examiner have read the students' three reports in advance. The students present the results of their work, both as the oral presentation and as a practical demonstration of the hardware. The questioning, which is a part of individual examination, begins after their group presentations. After questioning, the students leave the examination room and the examiners discuss their presentations, as a group and as individuals. The marks are given individually, and the students, one by one are invited back into the examination room for the explanation of their marking. After the examination the students can evaluate the course anonymously on the Campusnet [18] (Figure 5). Campusnet is an intranet portal for students, teachers and university administration. It is also Course Management System, where all students can add and drop classes, view and print their schedule, manage their account, request transcripts, forward email, view grades, and more. Instructors and teachers can view their schedule, and view student information.

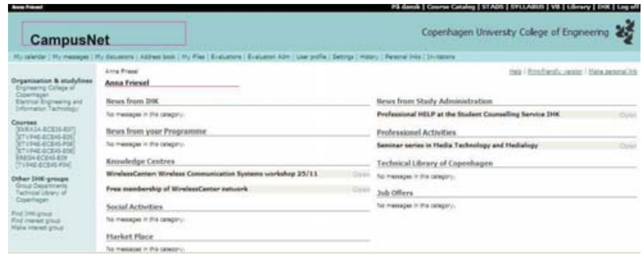

Figure 5. CampusNet at CUCE

V. STUDENTS' EVALUATIONS

Students make evaluation of theirs courses twice during the semester, in the middle of the semester and after the examination. The final evaluation, after the examination, is made on CampusNet and the results of this evaluation are available to the students participating in the course, the teachers and the head of the department. The evaluations include three parts: course evaluation, teacher's evaluation and general comments. The questionnaire is shown in Table II.

TABLE II. COURSE EVALUATION QUESTIONAIRE

Course evaluation
1. Target fulfillment:
To what degree has your learning measured up to the course description?
To a very high degree To a great degree To a suitable degree To a low degree To a very low degree
2. Your own performance
2.1 How much time do you estimate you have spent on the course compared with the expected time**?**
< 50% 50% - 70% 70% - 100% 100% - 130% > 130%
3. The relevance of the course:
To what degree do you consider the course relevant for your education?
To a very high degree To a great degree To a suitable degree To a low degree To a very low degree
4. The academic level of the course:
To what degree has the course challenged your academic abilities/competences?
To a very high degree To a great degree To a suitable degree

To a low degree To a very low degree
5. The study material:
To what degree has the study material supported your learning?
To a very high degree To a great degree To a suitable degree To a low degree To a very low degree
6. The teaching method:
To what degree has the teaching method supported your learning?
To a very high degree To a great degree To a suitable degree To a low degree To a very low degree
7. The test/examination method:
7.1 To what degree do you find that the examination method matched the method of teaching?
To a very high degree To a great degree To a suitable degree To a low degree To a very low degree
7.1 To what degree has your learning measured up to the course description?
To a very high degree To a great degree To a suitable degree To a low degree To a very low degree
7.2 To what degree do you find that the test/examination method is suitable for testing whether the objective of the course has been fulfilled?
To a very high degree To a great degree To a suitable degree To a low degree To a very low degree

Teacher's evaluation

1 The teacher's instruction in connection with the preparation of assignments:

1.1 How do you evaluate the quality of the academic instruction you received in connection with the preparation of assignments?

- Very good
- Good
- Satisfactory
- Poor
- Very poor

1.2 To what degree do you find the academic instruction you received, in connection with the preparation of assignments, to be sufficient?

- To a very high degree
- To a great degree
- To a suitable degree
- To a low degree
- To a very low degree

2 The teacher's instruction regarding teamwork, study methods etc.:

2.1 How do you evaluate the quality of the process instruction you received in connection with the preparation of assignments?

- Very good
- Good
- Satisfactory
- Poor
- Very poor

2.2 To what degree do you find the process instruction you received, in connection with the preparation of assignments, to be sufficient?

- To a very high degree
- To a great degree
- To a suitable degree
- To a low degree
- To a very low degree

3 The teacher's feedback on student work with assignments etc.:

3.1 How do you evaluate the quality of the feedback you received on questions, work with assignments etc.?

- Very good
- Good
- Satisfactory
- Poor
- Very poor

3.2 To what degree do you find the feedback on questions, work with assignments etc. to be sufficient?

- To a very high degree
- To a great degree
- To a suitable degree
- To a low degree
- To a very low degree

4 The teacher's presentation of the subject matter and ability to put into perspective:

4.1 To what degree did the teacher's presentation, summarizing and putting the new subject matter into perspective support your learning?

- To a very high degree
- To a great degree
- To a suitable degree
- To a low degree
- To a very low degree

4.2 To what degree do you find the feedback on questions, work with assignments etc. to be sufficient?

- To a very high degree
- To a great degree
- To a suitable degree
- To a low degree
- To a very low degree

General comments

1.1 What was good or worked well in the course?

1.2 What was bad or worked badly in the course?

1.3 What are your suggestions for improvements?

Table III shows the statistics of the first semester's evaluations. The results of this evaluation were as follows:

1. 68% of the students (who answered the questionnaire) were either very satisfied or satisfied.
2. 72% of the students felt that the teaching method supported their learning very well.
3. 84% of the students find that the test/examination method matched the method of teaching.

TABLE III. THE STATISTICS OF THE FIRST SEMESTER'S EVALUATIONS

1.Semester	Questionnaire	Total	Percent
ECD11	21	32	66%
ITD12	19	26	73%
ECD13	13	18	72%
ECE15	18	25	72%
ECE16	7	24	29%

VI. CONCLUSIONS

After several semesters of completed Project- and Team-Based basics courses in department of Electronics and Information Technology, we can make the conclusion, that the main objectives have been achieved. The students have got a better understanding of the mathematical tools in engineering. We have also observed much better understanding of more advanced engineering physics during the fourth semester of their education. The students' own evaluations show an increased motivation to learn mathematics and physics in this practical approach to the theory, especially for the students with previous practical experience. The examination results are shown in graph on Figure 6, it is clear that we have highly improved the pass rate for first and second semester students, and the overall dropout due to theoretical mathematics is much lower. The level of drop out after first and second semester is now below 20%.

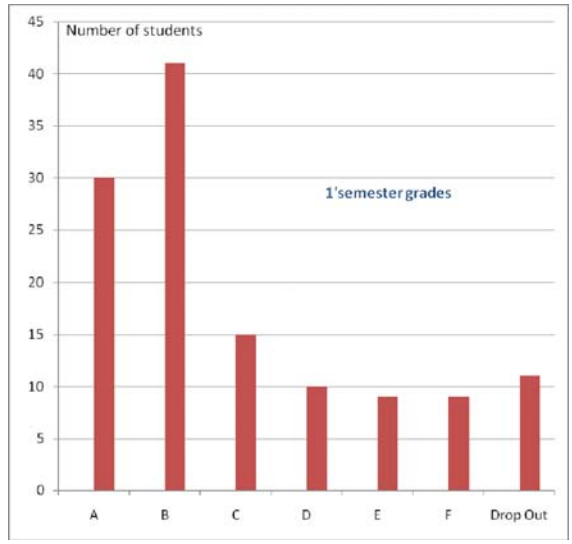

Figure 6. The examination results

VII. ACKNOWLEDGEMENT

I would like to thank my colleagues, the professors Agnethe Knudsen, Henning Haugaard, Lars Maack and Ib Lemvig Christoffersen at the Copenhagen University College of Engineering, for our good discussions and close cooperation during the process of implementing the new study-structure. Thanks to all the students for valuable discussions on future development of this course, and special thanks to all the students who contribute for the evaluation of the courses. Thanks to I.Stauning, H.Surkau and J.Greve for technical support in connection to the practical part of the projects.

Abstract—**This communication presents a collaborative experience between four Spanish centers: the School of Engineering (ETSE) and the Sports Services Area (SAF) both from the Universitat Autònoma de Barcelona (UAB) jointly with two centers of the Technical University of Catalonia, the high school from Vilanova i la Geltru (EPSEVG) and the high school in Terrassa (ETSEIAT). The idea behind this collaboration is to explore the possibility of role engineering education and project development for engineering students. The basic principle of such projects is the identification of the corresponding roles associated with the different parts that can be found on current social/industrial activity.**

Keywords-component; role-playing; project-based learning, effectiveness and satisfaction metrics

I. INTRODUCTION

The Role Playing is used in our work as a methodological tool to provide students an appreciation of the range of issues and problems associated with engineering requirements in a real framework [1]. The Role Playing strategy is a successful tool used, for example, in software engineering education. The Role Playing is used in our work as a methodological tool to provide students an appreciation of the range of issues and problems associated with engineering requirements in real settings [1], [2]. An integrated framework is developed in order to improve the relationship between the Role Playing strategies inside the educational theory of Technological Pedagogical Content Knowledgement [3]. One interesting approach is to establish a relationship between the use of the role playing approach and the realization of an engineering project.

Among all possible different engineering curricula that can be found around (see [4] for a few examples) it is recognized the value of hands-on experiments and realization of project courses. Effectively, the realization of a project, usually during the last year of the degree, allows the student to face with a somewhat large problem where he/she has to be able to tackle the analysis and design stages as well as considerations on technology for implementation. The motivation for this communication is to show how opportunities for real world control and automation applications can be found on the immediate student environment.

This paper presents the application of the Role Playing methodology in engineering classroom from the point of view of an industrial automation case study. Finally we will explain the feedback of the SAF staff and the effectiveness of this method with the aid of well defined usability metrics.

II. INDUSTRIAL-ACADEMIC COOPERATION

The "UAB" is a campus based university with more than 40.000 inhabitants (students, academics, staff, etc). In fact, this makes the University campus to behave like a city with some sort of facilities offered for their inhabitants. Among them, the Sports Service Area (SAF) is one of the largest and with more complex installations [5].

Due to the evidence for the need of introducing new control elements and to integrate the different subsystems to help the SAF management staff the collaboration between both entities (SAF and the Automation and Systems Engineering Group) has emerged (see Fig. 1). The interesting point is that we decided to develop the collaboration under the form of engineering projects for undergraduate students.

Each academic year, before summer, it is time to prepare the engineering projects to be developed during the next year. This way the students can look at the different offers and present their applications.

From the SAF management a list of automation and control problems is first elaborated. From this list (jointly elaborated with the academics), a subset of problems that are realizable as an undergraduate project is identified and offered to the students. From this point students should apply for one project by presenting their CV and explaining the motivation and reasons for doing such project. Once the selection is done, a first joint meeting between the customer (SAF management), Project Direction (Academic staff) and Project developers (the students) is done.

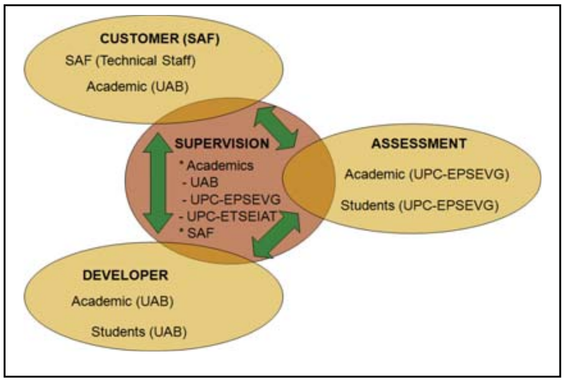

Figure 1. Identified roles and intercation between partners

From this point each student has a calendar of meetings (usually every 15 days) between him, the SAF management and the academics associated with the project. If any of the projects needs to collaborate with the work being developed on another project, there is a joint meeting where each one exposes their needs in order to find a joint solution.

Due to the evidence for the need of introducing new engineering system elements and to integrate the different subsystems to help the SAF management staff the collaboration between external entities has emerged. In this context, the SAF entity plays the customer role (maintenance functions), the ETSE member plays the software development role (monitoring and control interface), the ETSEIAT member provide us with the project-based learning approach and the EPSEVG member give us the human-centred automation approach [6]. The control engineering students from EPSEVG center have assigned the following roles: software developers (in order to build new supervisory control interfaces), designers (in order to apply ergonomics recommendations to display design), project management and usability engineers (in order to prepare usability testing and measure efficiency, effectiveness and satisfaction of the SAF human supervisors).

III. Engineering Students in the Role of Human Operators

From the framework described in the preceding section as the starting point, the experience is now driven one step forward and a third element is introduced: the external assessment role. The motivation for the introduction of this factor and force it to be developed on a different university (therefore geographically distributed and from a different educational framework/environment) is to create an atmosphere as similar as possible to the one the students will face within their professional life. The total interacting group is therefore constituted of three teams. Each team has a leading academic and a group of students. In addition, each team has associated specific roles corresponding to the professional activity they have to play. The development of such roles is mainly based on scientific and technological skills. These skills will be supervised and evaluated by the corresponding leading academic. In addition, other cooperation and interpersonal skills are to be considered. These skills (Table I) will be considered by a team that integrates the leading academic members of each team. The relevance of effective teamwork is very important in the successful operation of control room environments. According to this idea it's necessary to define a set of competencies [7].

TABLE I. Competencies Required For a Control Room Operator

Potencial competencies
Have a good knowledge of drills and procedures
Be able to operate control equipment accurately
Understand the theory andd application of the control process
Understand the safety aspects of control room operations
Be able to make appropiate decisions
Be able to assess a situation accurately
Be able to deal with stress and time pressure
Ensure that team goals, roles and responsibilities are understood
Be able to anticipate colleagues' requirements
Be able to pass the correct information to colleagues at the right time
Be able to notice overloaded colleagues and support them appropriately
Be able to think ahead and develop cintingencies
Ensure that colleagues maintains a shared understanding

The research in team training has been focused on training the members of a team together as a composite unit. The control engineering students from the EPSEVG center have the following roles: software developers (in order to build new supervisory control interfaces), designers (in order to apply ergonomics recommendations to display design), and usability engineers (in order to prepare usability testing and measure efficiency, effectiveness and satisfaction of the SAF human supervisors). At the EPSEVG center, a production systems laboratory that incorporates a Flexible Manufacturing System (FMS) is available. The control engineering students work in 2-people groups. Each group has a role inside the academic FMS and receives training about display design and systems maintenance.

This paper presents the application of the Role Playing method in engineering class from the point of view of an industrial automation case study in the following terms:

- One engineering student (Msc Automatic Control and Robotics from the Technical University of Catalonia) in the role of control room designer have been developing a new SAF layout in order to identify all the tasks (supervisory control, maintenance, display design and usability testing). This student made a meeting and a questionnaire with the SAF staff in order to obtain information about the physical and mental workload (see subsection A below).
- Some engineering students (MsC Engineeering in Automation and Industrial Electronics from technical school EPSEVG and ETSEIAT) have been using the display design ergonomics guideline (GEDIS guideline [8]) in order to improve the interface

quality. In these moments, one student is programming these changes in order to improve the quality of the SAF monitoring interface (see subsection B).

Finally we will present the feedback received from the SAF staff and the effectiveness of this method with the aid of well defined usability metrics as well as future steps [9].

A. Supervisory control task in the SAF Project

After a meeting among the SAF manager staff and the external assessment, it is necessary to show the SAF manager staff a set of important recommendations along the lines of the following:

- Train maintenance operators in supervisory control tasks (monitoring and alarm systems)
- Improvement of the feedback between the manager, the maintenance operators and the software developers
- Re-design the control center layout in order to define a control room (see Fig. 2). It is necessary just to establish the functionality for each room and translate the meetings inside a meeting room.
- Improve the display design quality, by using, for example, an ergonomic guideline

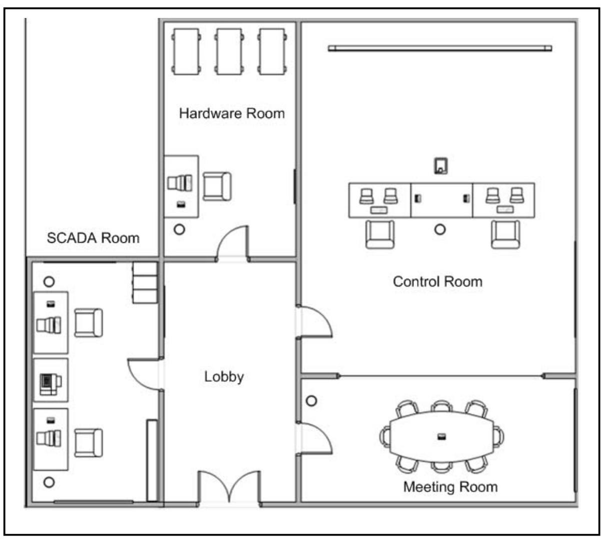

Figure 2. An engineering student (MsC Automatic Control and Robotics) in the role of control room designer: after a meeting and a questionnaire with the SAF staff, this is a possible SAF layout in order to differenciate all the tasks (supervisory control, maintenance, display design, usability testing)

B. SAF display evaluation

The experimental study is the evaluation of the SAF interface with the collaboration of control engineering students from Technical University of Catalonia. From Vilanova i la Geltrú city, twenty five students monitored the SAF interface for three weeks. The students assign a numeric value to each indicator of the GEDIS guideline [8] and propose interface improvement.

The GEDIS guide is a method that seeks to cover all the aspects of the interface design [9]. From the initial point of view of strategies for effective human-computer interaction applied to supervision tasks in industrial control room [10], [11].

The GEDIS guide offers design recommendations at the moment of creation of the interface as well as recommendations of improvement for already created interfaces.

The GEDIS guide is composed of two parts: description of ten indicators and measure of ten indicators. The indicators have been defined from extracted concepts of other generic human factors guidelines, and from aspects of human interface design in human computer interaction. As an example, included indicators are: architecture, navigation, alarm design, use of color and text, human operator inputs, etc.

TABLE II. GEDIS GUIDE INDICATORS (PART I)

Indicator name and Subindicator name	**Numeric/qualitative range and SAF numeric value**
Architecture	**1,7**
Map existence	[YES, NO] [5,0] 0
Number of levels le	[le<4, le>4] [5,0] 0
Division: plant, area, subarea, team	[a, m. na] [5,3,0] 5
Distribution	**3**
Model comparison	[a, m. na] [5,3,0] 3
Flow process	[clear, medium, no clear] [5.3,0] 3
Density	[a, m. na] [5,3,0] 3
Navigation	**3**
Relationship with architecture	[a, m. na] [5,3,0] 3
Navig. between screens	[a, m. na] [5,3,0] 3
Color	**5**
Absence of non appropriate combinations	[YES, NO] [5,0] 5
Color number c	[4<c<7, c>7] [5,0] 5
Blink absence (no alarm situation)	[YES, NO] [5,0] 5
Contrast screen versus graphical objects	[a, m. na] [5,3,0] 5
Relationship with text	[a, m. na] [5,3,0] 5
Text font	**3,2**
Font number f	[f<4, f>4] 5
Absence of small font (smaller 8)	[YES, NO] [5,0] 0
Absence of non appropriate combinations	[YES, NO] [5,0] 5
Abbreviation use	[a, m. na] [5,3,0] 3

TABLE III. GEDIS GUIDE INDICATORS (PART II)

Indicator name and Subindicator name	Numeric/qualitative range and SAF numeric value
Status of the devices	**4**
Uniform icons and symbols	[a, m. na] [5,3,0] 3
Status team representativeness	[YES, NO] [5,0] 5
Process values	**3**
Visibility	[a, m. na] [5,3,0] 3
Location	[a, m. na] [5,3,0] 3
Graphs and tables	**4**
Format	[a, m. na] [5,3,0] 3
Visibility	[a, m. na] [5,3,0] 3
Location	[a, m. na] [5,3,0] 5
Grouping	[a, m. na] [5,3,0] 5
Data-entry commands	**3**
Visibility	[a, m. na] [5,3,0] 3
Usability	[a, m. na] [5,3,0] 3
Feedback	[a, m. na] [5,3,0] 3
Alarms	**3,8**
Visibility of alarm window	[a, m. na] [5,3,0] 3
Location	[a, m. na] [5,3,0] 3
Situation awareness	[YES, NO] [5,0] 5
Alarms grouping	[a, m. na] [5,3,0] 5
Information to the operator	[a, m. na] [5,3,0] 3

Where a=appropriate, m=medium, na= no appropriate.

The method to continue for the application of the GEDIS guide is: to analyze the indicator, to measure the indicator, obtain the global evaluation index and, finally, offer recommendations of improvement. The computation of the GEDIS guide global evaluation index is done according to the following formula:

$$Global\_evaluation = \frac{\sum_{i=1}^{10} p_i ind_i}{\sum_{i=1}^{10} p_i} \quad (1)$$

In a first approach the mean value among the indicators expressed in (1) has been considered. That is to say, to each indicator an identical weight ($p_1 = p_2 \ldots = p_{10} = 1$) has been assigned, although this will allow, in future studies, to weight the importance of some indicators with respect to others. The global evaluation is expressed in a scale that ranges from 0 to 5.

For the correct use of the GEDIS guide it is necessary the collaboration between the control room technical team and the human factors technician, since in some cases to analyze the indicator it is necessary to consider the expert's opinion.

The SAF interface global evaluation GEDIS index is 3.4. So it is necessary to indicate the SAF designer a set of important recommendations for further improvement:

- Revise the relationship between architecture, distribution and navigation indicators
- Improve the feedback between interface and human operator in data-entry commands indicator
- Improve the location of alarm indicator

With the GEDIS guide it is also possible to indicate the SAF designer a set of important recommendations about graphical screen improvements. For example, the *Piscina ACS* screen can be improved with a set of changes in color and text font indicators. Fig. 3 shows the original *Piscina ACS* screen and Fig. 4 shows revisited *Piscina ACS* screen.

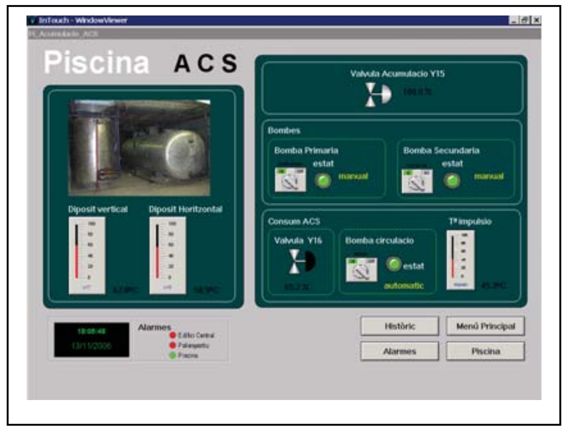

Figure 3. Original Piscina ACS screen (Catalan language)

Figure 4. Piscina ACS revisited with changes in color indicator (Catalan language)

In order to evaluate the effectiveness of the venture from the educational perspective, at the end of course 2008-2009 the students from *Integrated Production Systems* subject (IPS subject from the technical school EPSEVG) answer an adaptation of the Student Evaluation of Educational Quality Questionnaire (SEEQ):

- The students prefer dynamism in the class: more practical problems and less theoretical lessons.
- The students prefer to increase the number of laboratory sessions.
- The students think that the workload of the Msc Engineering in Automation and Industrial Electronics is high. Usually, these students work and don't have much time to do homework for their University Studies.
- The students are satisfied with the evaluation/assessment of the subject.

Fig. 5 shows one of the items related to the learning process.

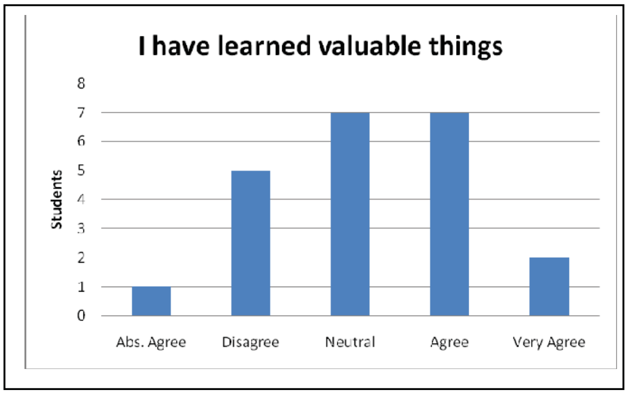

Figure 5. Inside the SEEQ "Learning" category (question two)

In order to evaluate the categories (Learning, Organization, Group Interaction, Examinations, and Assignments) the Table IV shows the comparison between some answers (only Good and Very Good answers) between the year 2006 and the year 2009. The questions are:

- Learning: A4 You have learned and understood the subject materials in this course
- Organization: C4 Practicum classes are useful and well prepared
- Group Interaction: D1 The own team and the other teams are a good tool to share ideas and knowledge
- Examinations: G2 Methods of evaluating student work are fair and appropriate
- Assignments: H3 Practicum tasks in the laboratory, contribute to appreciation and understanding of the subject

The Group Interaction assessment between the 2006 IPS Subject and the 2009 IPS Subject are similar. In the other categories, we can observe the increase in the 2009 subject students' assessment.

The next section shows a framework in order to introduce quality models concepts inside the engineering learning process.

TABLE IV. COMPARISON BETWEEN SOME ANSWERS

SEEQ Category	2006 IPS Subject	2009 IPS Subject
Learning		
A4	75%	80%
Organization		
C4	55%	80%
Group Interaction		
D1	78.9%	70%
Examinations		
G2	26,3%	60%
Assignments		
H3	36,3%	89%

IV. METRICS FOR EVALUATING HUMAN-AUTOMATION INTERACTION

An example of methodological framework is the Process Model of the Usability Engineering and the Accessibility MPIu+a developed by Toni Granollers [12] which gathers together all the cycle phases: requirements' analysis, design, implementation, launching, prototyping, evaluation and user,. The analysis of requirements is a necessary previous research work in order to establish the best relationship among the human, the interface, and the task. For example, which is the user's profile? A human in the role of maintenance staff or supervisory control operator or display designer.

In the evaluation phase, and for the usability measure, it is necessary to have the contribution of the experimental studies carried out in the usability laboratories. The problem is how to define common metrics for human-automation interaction because each task and each automation system has singular properties (chemical control processes, flexible manufacturing systems, oil control processes, etc.) [13]. another problem is: which is the best interface, from the point of view of the user's experience? Some interfaces are appropriate for a few users but not for all users.

In human-computer studies it is necessary to define qualitative and quantitative performance rates. Following some ideas of the experts in usability studies and field studies, the tasks presented in the previous section demand a high level of activity planning that involve reasoning and decision making. It is possible to follow different approaches: the *individual differences* approach, the *case study* approach and the *system characteristics* approach. In this paper we follow the first approach. The studies of user's differences have diverse goals:

- To find ways of predicting performance
- To find and characterize individual variability. To find not only differences in the degree to which users are able to reach the goals, but also differences in how they perform, i.e. decision making strategies and user satisfaction

From the point of view of usability engineering the proposed performance method can be summarized in three steps [14], [15]:

- Effectiveness measure
- Efficiency measure
- Users' satisfaction measure

Effectiveness is a measure of how well a human accomplishes the supervisory control task. For efficiency measures we find the ISO definition: "resources expended in relation to the accuracy and completeness with which users achieve goals" [16]. Effectiveness and efficiency measures are objective measures. For satisfaction measures we find user's questionnaire in order to achieve attitudes towards the use of the interface (how difficult is to learn the use of the interface, user's experience of discomfort in using the interface, etc.) [17].

Finally it is possible to define usability metrics. The number of attributes in usability engineering is three.

Attributes A = [Efficiency Effectiveness Satisfaction]

In the case of objective measures, it's possible to add these attributes inside (2)

$$Usability = \frac{\sum_{i=1}^{m} A_i}{m} \qquad (2)$$

The experimental session was carried out in the meeting room of the SAF enterprise at the Universitat Autónoma of Barcelona in December 2008, the two SAF staff members (maintenance head, computer science engineer) participated in an interview with a control engineering student playing the role of usability expert, they used the SAF display in a brief session in order to detect a possible device fault, and finally they answered a questionnaire about user interface satisfaction.

The questionnaire of the user interface satisfaction has been based on diverse classic references for this type of tools, for example the QUIS questionnaire [18]. The questionnaire has six questions related to the task where the user answers in concordance with the scale of Likert [19] with four answer options per question. Moreover, one more question has been added where the user assesses in a qualitative way the quality of the graphic display.

The six questions considered were:

- The task was difficult to understand
- The task has been long
- I have been confused, without having clear what it was necessary to do
- I needed to be very concentrated to carry out the task efficiently
- I have been pressured by the time
- I think that my performance has been correct

From the point of view of the maintenance head, the task is easy because he has great experience in process control and in fualt tolerant control. From the point of view of the computer science engineer the task is difficutl to understand for a novice user in process control and it's necessary to change some functionalities inside the screens in order to improve the quality of the supervisory control application (in example, the creation of an alarm system).

V. Conclusions

This paper has presented an experience that introduces a collaborative framework for undergraduate engineering project development. The idea presented here is based on representing the existing roles present in a professional framework with the additional value of integrating players from different universities and an industrial partner that provides services to the community. It is shown, among other points, how (i) the university itself can provide the customer points of view, (ii) promote collaborative work between different individual student projects within a global, large, project (iii) provide collaboration among different educational frameworks.

We will continue this work with usability testing in order to measure effectiveness, efficiency and satisfaction metrics over SAF supervisory operators. From the point of view of the authors, it's possible to apply the Cognitive Walkthrough method in order to obtain an analysis' task.

The SAF computer science engineer is assessing the use of the GEDIS guide in order to introduce changes and improve the quality of the graphical interface.

With the aid of well defined metrics and data collection it's possible to begin a statistical analysis as a future step of our work.

Finally, is necessary extend our approach in order to apply these methods to other subjects of the engineering curricula, study multiple roles, such as engineer-manager and find methods that help students to move from novice to expert.

Acknowledgment

Participation of the first and third authors is supported in part by an economical aid of the Technical University of Catalonia. Participation of the second author is supported in part by the Spanish CICYT program under contract DPI2007-63356. The authors thank Anton Gomà, head maintenance of the SAF system.

A Learning Approach Based on Robotics in Computer Science and Computer Engineering

Joan Oliver, Ricardo Toledo, Elena Valderrama
Universitat Autònoma Barcelona
Bellaterra (Spain)
Joan.Oliver@uab.es, Ricardo.Toledo@uab.es, Elena.Valderrama@uab.es

Abstract—**It is well known that the number of students that arrives to engineering studies decreases every year, due to the difficulty that these studies present, when compared to other studies, in a society that tends to be more social oriented than in the past.**

In order to increase the interest of the students this paper presents a Project Based Learning (PBL) that involves hardware and software using the robotics as the main object in computer studies. This educational project is being held in the Computer Science and Computer Engineering studies of the *Universitat Autònoma de Barcelona*.

Keywords-component: Project Based Learning (PBL), robotics in computer science/engineering.

I. State of the Art

The use of robotics for teaching purposes has motivated several generations of professors and students in computer studies. In 1994, Pattis et alt. presented *Karel the Robot* [1], a simulator to introduce programming techniques. From there up to now, several companies have introduced in the market excellent robot kits for education as Lego Mindstorms [2], Sony with Aibo [3], etc, based on robots that are programmed using specific tools. More recently, the Institute for Personal Robotics in Education and Microsoft presented the Myro robot [4] with an educational environment that has been extensively used to introduce students in engineering studies. Also, several authors [5] [6] have argued the use of robotics as a means in order to help the student in programming courses.

Until now robots have been extensively used in learning stages as a resource to improve teaching results, but rather limited to specific areas of knowledge. The robot, as a whole, is a powerful tool that can be used in transversal teaching processes. In this sense, engineering studies have a lot of transversal subjects that can be explored using the robot as a resource. Usually, the robot has only been used as a helping tool in the learning of programming techniques. The technological power that a robot presents has not been used as a whole in computer studies.

A. A PBL based in robotics in Computer Science

The paper shows a transversal experience that uses the technological power included in robots in a learning process in computer studies that includes hardware and software. Topics are introduced in a way such that students are confident with what computer studies imply despite the use of the robot. Robotics is only the "toy" for motivating the beginner students on the subject.

Of course, a PBL based in robotics in computer studies can include many topics comprising subjects from the first year to higher level courses. In the first year the robot can help to introduce basic topics taking as a basis the duality hardware/software (fundamentals of computer science, machine programming, programming techniques, programming languages, introduction to operating systems, etc.). At higher level courses, artificial vision, neural network and fuzzy programming, real time applications, human-computer interfaces, software engineering, etc. are typical subjects were robots are used as a resource. Robotics embraces all the computer engineering and computer science knowledge [7].

In this experience, the authors have used robotics in the first course as a resource to motivate the beginner students. In this sense, the robot has been used to introduce, hardware and software topics. The experience developed includes the subjects of fundamentals of computer engineering including low level programming (assembler), algorithms and high level programming and data structures.

The paper presents the experience that is being developed in our university. The explanation begins with a discussion in section two of the first course syllabus in computer studies and its adaptation to a robotic-based PBL. Section three introduces the scheduling of the reported experience. The setup and cost of the experience is discussed in section four. Section five describes the PBL application and results obtained and, in the end conclusions are presented.

The project has been granted by the 2009MQD00127 project and the *Escola d'Enginyeria* and the *Institut de Ciències de l'Educació* of the *Universitat Autònoma de Barcelona*.

II. A SYLLABUS FOR A ROBOT-BASED PBL IN COMPUTER STUDIES

A. *Syllabus in the first course of computer studies*

The experience developed in this paper is being hold in the first course of computer studies in the Universitat Autònoma de Barcelona. The subjects of the computer studies are defined in the student guide. Table 1 resumes the topics covered in the student guide during the first year of entrance in the university. The table shows that the main involved topics are software, hardware, mathematics and an introduction to electronics. In fact, this curriculum, with little changes, corresponds to a typical first course in computer engineering / computer science studies in Spain.

A first glance to this curriculum shows that it could be a tough course for students that arrive to the university. Near the half of the topics are related with computer studies but they are not strictly computer science topics. That is, a significant part of them are mathematics and electronics. Professors are aware that these topics are not really pleasant to first year students. Many of these students are used to work with computers only to chat with friends or to play games.

Furthermore, the decrease in the number of students that arrives to computer studies (and into engineering in general) worsens still more the panorama.

In this sense, the authors are aware that it is necessary to motivate first year students. A method to improve it is introducing new educational methods that help to improve the motivation in first year students as, for example, using a robot as a motivating resource in the studies.

TABLE I. COMPUTER ENGINEERING FIRST COURSE SUBJECTS

Programming languages & Algorithms (105 hours)	Programming languages Functions and procedures Pointers Files Algorithm analysis Search and ordering algorithms Recursive algorithms
Data structures (60 hours)	Object oriented languages (C, Python) Lineal data structures Non lineal data structures: trees Other non-lineal data structures
Computer fundamentals (90 hours)	Digital systems: information representation, Boolean algebra, combinational and sequential circuits CPU fundamentals: architecture, instruction set, address modes, assembler, interruptions CPU peripherals: memories and memory hierarchy, input/output, Communications
Electronics (120 hours)	Electrical circuit basic laws Permanent and transient analysis Semiconductors: diode, transistor, opamp Technology: bipolar and MOSFET Introduction to data acquisition
Algebra (105 hours)	Matrices, vectorial spaces, linear applications, rings, polynomial operations
Calculus (120 hours)	Differential calculus and differential equations, integration, Fourier fundamentals

B. *The robot for a PBL in computer studies*

The robot is a perfect tool to introduce and to motivate students into computer studies. The robot is a packed unit that contains all the components and structures to introduce students to computer fundamentals and computer programming in a first year course. All subjects can be exposed using the components and the structure of the robot.

Software is the first great subject students learn in a first course in computer studies. At this level, the robot can be used to model any behavioral conduct, programming it using a high level language. Typical languages used in computer studies (talking about the learning of algorithms or data structures) spread from the classical C to more actual languages, as Ruby or Python for example. The main routines can be programmed into the robot, or the robot can be a slave that performs accordingly to actions mastered by the computer. This later case implies that the computer request the robot its sensors state, make decisions and sends actions to the robot. In any case, an algorithm could be implemented in the robot and data structures must be used.

At the hardware level (the second great subject) the kernel of the robot can be exploited to introduce computer hardware fundamentals. Simple robots are based in known microcontrollers. Scribbler is based on a PIC microcontroller. RUAB1 (our own robot) is based on an Atmel microcontroller. Deep in the microcontroller there is a typical CPU core, memory and peripherals that can be used as examples when computer fundamentals are introduced. Of course, any of these robots can be used in a PBL in computer studies.

In the planning stage professors must be aware that not all the robots perform correctly with the competences and with the didactics established for the course. For example, in our first year application of the PBL we used the Scribbler robot. Scribbler showed to be a gentle robot when used in software problems/projects. But when we tried to use it in a mixed hardware/software PBL we had to solve some not evident problems because the robot lacks of facilities to incorporate hardware in its core. Furthermore, the robot architecture is based in a PIC microcontroller which internally interprets the pBasic, the language used to program the robot behavior. Furthermore, the PIC CPU core is a rather tough CPU to introduce students to computer hardware fundamentals.

The third topic involved in the first course is electronics. Electronics is the basic subject that is behind the functioning of any electrical device. The robot is a perfect example to introduce the subject. All (not mechanical) devices in the robot work accordingly to the electrical rules. Thus, electronic basics and devices are introduced using as examples the different components of the robot in case studies.

In the end, mathematics is a subject that covers an important part of the first course studies. Maths can be introduced in a PBL through calculus equations and modeling approaches. However, and due that maths are not fairly related with hardware and software subjects, in this first experience they has not been involved in it.

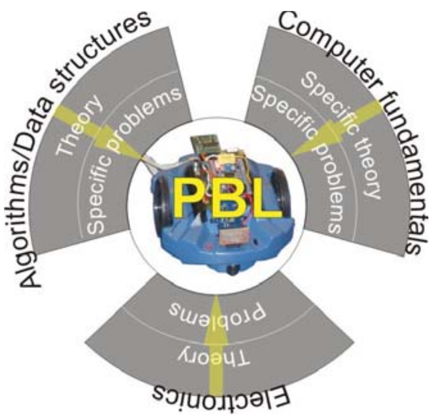

Figure 1. PBL scheduling

III. PBL SCHEDULING

A. Subject scheduling for a PBL in the first course of computer studies

The PBL approach is done in the first course studies of computer engineering in a subgroup of 20 students. In fact, this is a reduced set of the total number of students that enters in computer engineering studies, more than 100 students. The reason to do the experience with only a subgroup is that the cost that would imply to address to all students is not affordable neither recommendable in a first year experience.

So the project has been developed for a group of 20 students that voluntary decided to participate. The condition imposed to PBL instructors is that all the students of the course must acquire the same competences independently of the educational method carry out during the course. In order to achieve this, a planning of the course was made according to a study about the methodology used in each subject (Fig. 1) and the requirements imposed by the PBL:

- Theory is adapted in the subjects for the PBL students whenever it is necessary. This involves mainly the subject of computer fundamentals that needs to be reviewed in order to address the experience, and affects digital systems part as also the classical part of computer fundamentals. In what refers to digital systems topics, as they are not directly involved in the project, the subject is taken out of the PBL. So, this subject is given with the rest of the students. The more classical part of computer fundamentals (introduction of the CPU, memories, peripherals, etc.) is reviewed in order to fit the AVR architecture (the ATmega128 is used in the practical classes) in the computer fundamentals theory.
- Problems of each subject were adapted to the robot architecture in both hardware (except digital systems problems) and software. Problems are rearranged in order to fit with the PBL and with the devices that compound the robot.
- In the end, theory and problems focus towards a final project in which students must demonstrate the acquired skills in software and hardware. The hardware practical lessons were all reviewed in order to fit with the robot expertise that students must acquire. The software is more versatile and, with little changes practical lessons are adapted to control the robot. In the end, hardware and software are joined in a robot guiding problem/project. In it students must demonstrate that have developed the course skills in software and hardware.

B. Components of the PBL

The project to be developed by students comprises elements that address software and hardware subjects. This is accomplished using:

- A host to control the robot. In the host the students must implement high level algorithms to control the robot. Such algorithms are responsible of the robot behavior: line follower, light dependent tendencies, avoiding obstacles, guiding problems, etc.
- Fundamental computer hardware set on the robot. The student works on ATmega128 microcontroller in order to implement a low level hardware that fits with computer fundamentals subject. The objective to the final practice is that robot must send to the host the orientation of the robot. The task of the microcontroller is to send this message. The task of the student is to take expertise with the CPU and assembler language using this finality. So, a low level driver must run in the microcontroller and send data to the robot brain. To do this, in this first year experience students developed an orientation driver based on a compass sensor. In the end, the students must be confident with the microprocessor concepts introduced in computer fundamentals subjects.
- Introduction to elemental communication protocols can also be introduced in the PBL. In this case. The communication between the host and the robot is performed via RS232, a low level protocol easily understandable by first course students.
- At the software level students may introduce a high level conduct into the robot. In this case, the robot must run in a labyrinth with doors that have to be opened asking for a key.
- In the end, and though many good wishes always are expected, instructors were confident that the work in real time is difficult. In order to overcome it a setup based on a camera in the final practical lesson is prepared by authors in order to help the robot to follow the path.

IV. SETUP AND COST OF THE EXPERIENCE

If the aim of the experience is the motivation of students in a career, professors cannot expect to obtain it without investment. Of course, a teaching experience using robots has an important associated cost due to the need to work with robots. In this experience a robot is lend per group of students (2 persons per group). During the course students have the robot and can work with it at home. In the last class, students brings back the robots and in a plenary session must demonstrate the software and hardware knowledge and competences acquired by means of the evolution of the robot in a competition. Teachers think that this is a good strategy in order to increase the motivation of the students.

The market offers several robots that can be used in the experience. Scribbler is one of the last introduced educational robots. It is nowadays used in a lot of learning experiences. Associated with Scribbler useful software can be downloaded without any cost. We used Scribbler in this first year application of the learning approach, but we had to tune the robot in order to adequate it to our mixed hardware/software experience.

That is, Scribbler is adequate if the experience is to be held using only a software approach. The robot has enough devices (sensors and actuators) to create good software programming projects in order to achieve good learning skills in software. However, when the experience takes as a basis a PBL using hardware and software topics, the robot lacks for facilities for interfacing hardware elements on it.

In order to introduce computer fundamental topics additional hardware was built and mounted over Scribbler (see Fig. 2). Of course, this implies that (in addition to the hardware changes) several software changes are introduced in the Scribbler software kernel in order to work with the new hardware.

So, the cost of the experience is the sum of the costs of the robot plus all the elements introduced in order to realize the programmed PBL. It consists of:

- The robot. We used a Scribbler robot.
- Additional hardware mounted on the robot. It was necessary in order to introduce the computer fundamentals subject in the PBL experience. It is based in an ATmega processor, the compass sensor and related passive components.
- A serial-Bluetooth connection between the robot (that acts as a slave in our experience) and the host (a PC). So, the host and the robot can communicate via the simple UART port of the ATmega board and the PC in a wireless way.

Figure 2. Robot and tuning

Figure 3. Practical setup

- A setup based on a vision guided program introduced in the host in order to help robots in the final session.

The first three items correspond to the hardware that students take in a leasing form during the course. The fourth item is built for the setup of the PBL (see Fig. 3). In it students practice during the course and make the final examination.

And though it was not yet namely, surely, the more expensive item is the cost in people involved in the experience. During the PBL planning and developing, the people involved in the experience must foresee to spend a lot of hours trying to get along the hardware components in the robot and the projects to be done by students with the robots. It was rather cumbersome to get all the components working together because of:

- The physical connection at the hardware level. Scribbler only has a port that can get free in order to allow any hardware connection to it. It is the hacker port, used only to control three LEDs. In it we connected the ATmega microcontroller, responsible of two main tasks: to control the orientation behavior of the robot and to perform the communication with Scribbler.
- The software communication between the robot and the hardware just added. In order to work with the data sent by the ATmega that gives the orientation of the robot, communication between the low level language (assembler) of the board and the high level language (Python) in the host has to be established via the PBasic language interpreter running in the PIC.

V. PBL APPLICATION AND RESULTS

The PBL in robotics has been introduced in the Computer Science studies. During the school year students work with the different subjects with the finality to joint in the hardware and software learned topics in the final session demonstration. The qualifications of the subjects are composed of the theoretical qualifications, obtained in a written examination for each subject, and the practical qualification that is unique for all the subjects participating in the PBL.

Fig. 3 is a picture of the final class of the PBL in robotics. The main components of the PBL can be recognized in the picture:

- The robot is the kernel of the PBL. In this first year experience a tuned Scribble robot was used. On the robot there is a landmark to help tracking the pose of the robot with a camera
- The camera setup of the experience. A host follows the path of the robot via a camera in order to help the robot in its movement. We introduced this improvement once we realize that real time programming can be rather frustrating for novelty students.

In respect to the results of the PBL experience several comments can be stated:

- Academic results were rather good. Students acquired the established PBL skills (knowledge and competences) in software and hardware. Students get also aware that they get with the particular competences stated in each subject.
- Students get also self satisfied with the experience
- And several students commented to the instructors that their self regard had grown.
- However, students also said that the experience was hard.

VI. Conclusions

This paper resumes a robot-based PBL experience joining hardware and software subjects in the learning process. The experience has been done in the first course of computer engineering studies with the aim to motivate first year computer engineering students.

The conclusions of the experience are:

- The kernel of the experience is the unification of software and hardware topics in a project. The aim is the motivation of the students. The objective is achieved and also has been fruitful.
- The authors are satisfied with the expertise demonstrated by the students at the end of the experience. The main learning topics were introduced and the students passed with qualifications the course.
- A poll made to students reinforced that students were satisfied with the experience. Students were aware of the knowledge acquired during the course.
- The success of the experience has been demonstrated. But a lot of hours must be dedicated by professors in the setup of the whole experience.
- Perhaps the most critical part of the whole experience has been the need to work with different hardware resources. As introduced, a tuning of the robot had to be done in order to coordinate hardware and software practical classes. In order to improve this, the authors are developing this year the experience using RUAB1 a robot specially designed and built for the PBL activities. It is based in an ATmega microcontroller and for the PBL has a clear advantage: all the hardware and software topics can be done using a unique microprocessor.

Acknowledgments

The authors gratefully acknowledge the help of David Aldavert and Mònica Piñol of the Computer Science Department in the setup of the experience.

***Abstract* - Online hardware-based educational laboratories are increasingly being deployed in traditional on-campus as well as Web-based distance-learning courses around the world. An online laboratory generally will consist of several hardware-based remote experiments. However, one particular experiment can be performed at a time by an individual student or a group of students which require a careful scheduling of the experiments. For the proper implementation of an online laboratory an efficient laboratory management system (LMS) is thus essential. Also for an online laboratory, the students need to fully understand the experimental system setup and feel comfortable as in an actual laboratory environment which, however, can be effectively done by adding suitable videos and animations etc. Besides, the students should be able to run the remote experiments, extract, save and analyze the data and submit laboratory reports online. The front end of the laboratory management system should be made browser-based so that one can use the laboratory facility from anywhere. Also, for the teachers, the laboratory management system should include an online evaluation for the quiz/viva-voce, checking experimental data, grading of submitted laboratory reports and feedback for the students.**

In this paper, we describe the design and prototype implementation of an online laboratory management system (for use with shared hardware-based remote laboratory resources) which may be employed for running internet-based online laboratory courses for geographically dispersed Institutions.

Keywords - *Online experimentation, online laboratory, remote control, e-learning*

I. Introduction

E-LEARNING has been a topic of growing interest in recent years. It is a group effort, where content authors (educators), instructional designers, multimedia technicians, database administrators, and people from other areas of expertise come together to serve the community of learners.

Online Laboratory is a subgroup of these e-learning systems where the learner or the user interacts and operates the hardware from a remote location. Online laboratories must be operated with a laboratory management system (LMS) that make sure that the experiments being performed generate the desired results and also serve for the other requirements of each individual user.

The primary objective of the LMS is to manage the learners, keeping track of their progress and performance across various stages and types of training activities. The LMS should be able to manage and allocate resources such as registration, schedule instructor availability, serve instructional material fulfillment, online learning delivery, and authoring system. It should also provide an infrastructure that can be used to create, modify, and manage contents for a wide range of learning environment to satisfy the needs of rapidly changing laboratory education requirements.

The LMS also need to provide a scheduling system that makes sure that each user or a group can use the hardware without overlapping or disturbing the running of experiments of others. Also, there is a need for creating online laboratory facilities across multiple institutions through shared resources. By sharing resources (i.e., remote laboratories and corresponding curricula online) the high costs associated can be reduced. Currently, running an online measurement-based laboratory is an open challenge. Remote control of instruments and the execution of real experiments via the Internet are topics of interest for many researchers.

The LMS should also be able to save the experiment data, retrieve and evaluate and compare data on learner scores, navigation habits and use them to provide content managers (educators) the crucial information on the effectiveness of the content, if combined with specific instructional strategies, delivery technologies, and learner preferences. One such laboratory management system, NETLab, is being introduced in this paper. The system is in use in laboratory education. With LabVIEW for instrument control, the NETLab is being used for teaching microelectronic devices concepts in the courses EC29003 (Semiconductor Devices Laboratory) and EC29004 (VLSI Engineering Laboratory) at the Indian Institute of Technology, Kharagpur.

There have been a number of different approaches [1-4] proposed to develop laboratory management tools for online laboratories. Management of an online laboratory system requires at least the followings:

- Experiment scheduling
- Delivery of assignments
- Performing the remote experiment
- Publishing of the laboratory report
- Interactive session: students and teacher
- Evaluation (viva-voce) and assessment

Web Services are being proposed for distributed applications and have great potential for building online laboratory management system [5]. It needs to manage the local resources on the local area network (LAN) and the remote resources connected by the Internet. Among the other resources to be managed are the computational resources which are managed using Grid Service techniques. Experimental instruments are managed by Web Services. However, based on rather a simpler configuration, our proposed online remote laboratory is based on client-server architecture and uses off-the-shelf middleware for communication. Products from companies, such as National Instruments (for controlling) and Agilent (for measurement instrumentation) are chosen. Windows™ is the operating system for these instruments and the client side also needs to install proper software to operate the remote instruments.

II. SYSTEM DESIGN

The NETLab uses the following components:

i. Java server pages and Java servlets as the means to design web pages.
ii. The back end consists of Oracle 10g. The Oracle Database (commonly referred to as Oracle RDBMS or simply Oracle) is a relational database management system (RDBMS) produced and marketed by Oracle Corporation.
iii. This system uses JDBC connection to build a connection between the java interface and the database.
iv. The Sun GlassFish Enterprise Server v2.1 is used as the application server that generates the web pages according to the user inputs. The Sun GlassFish Enterprise Server is a comprehensive support offering for GlassFish, the leading open-source and open community platform for building and deploying next generation applications and services.
v. The front end is a computer with a JavaScript-enabled browser such as Internet explorer or Mozilla Firefox. JavaScript is an easy-to-use client side scripting language which loosely follows the Java syntax but its design principles are derived from the self-programming language. Currently all the major web browsers (Internet Explorer on Windows, Safari on Mac, Opera, all the Mozilla based browsers) support JavaScript. This assures that the application is OS and browser independent.

The NETLab system has a special interface that connects to the hardware through GPIB card. The overall system configuration is shown in Figure 1.

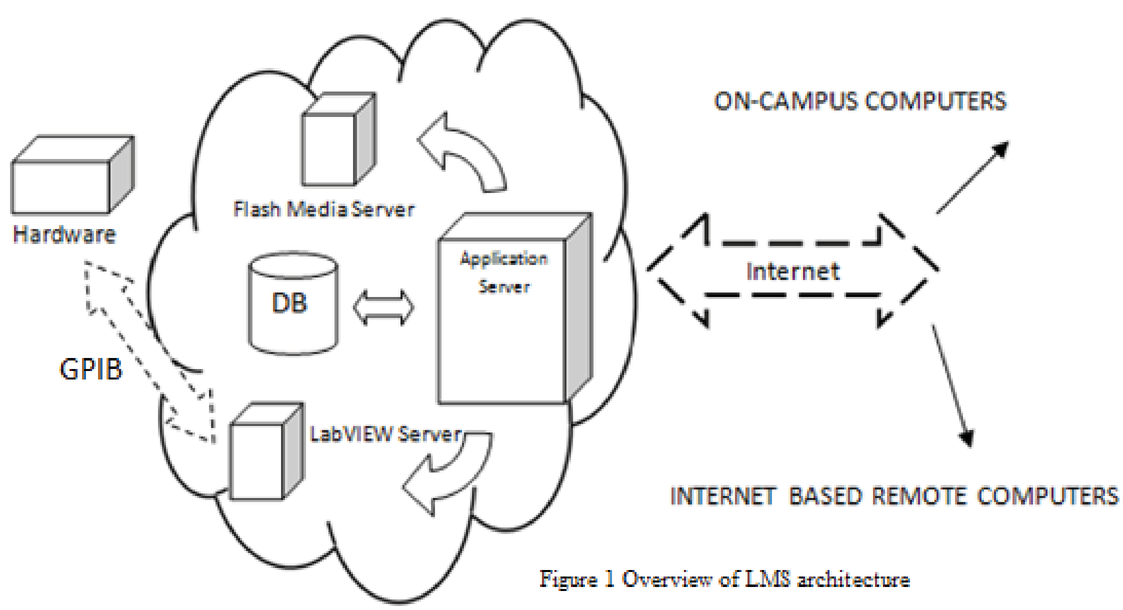

Figure 1 Overview of LMS architecture

These interfaces are built using the web development tool of NI LabVIEW 2009. The devices are connected and controlled by using the interface and their corresponding drivers.

Each user (student) need to register to get a username and a password (Figure 2). The students profile is also stored in the database. The user has to login and select a particular experiment and proceed. Each experiment has the following features: a laboratory manual, description of the experiment, experimental procedure, etc. As the system works in a batch mode, it distributes the time in slots and each user has to select and choose a particular time slot of his choice for performing the experiment. However, the experiment manuals and other functions are available at all times. Once the student logs on to the system, he has an access to the laboratory and gains full control of the laboratory hardware (experimental setup). The user can adjust experimental parameters or submit new commands in real time. When the allotted time for the experiment is over, the link is broken with a warning. However, the student gets a number of chances to book and perform the experiment till completion. This is done to optimize the use of the laboratory resources so that a large number of students can access the online laboratory.

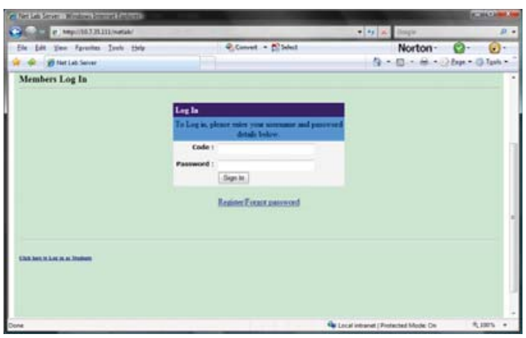

Figure 2 - Log In page.

After performing the experiment the student need to store the data, plot graphs and analyze the data for the preparation of the laboratory report. Then the student can upload the laboratory report and need to take part in a viva session for evaluation purposes. However, if a student cannot complete the above tasks in one session, he may perform the experiment again.

III. ON-LINE SCHEDULING SYSTEM FOR LABORATORY EXPERIMENTS

Online line laboratory consists of several experiments which the students have to perform in a semester. In the proposed LMS, only one student can choose an experiment at a time from the list of available experiments in the module. A student first needs to find an available time slot and then book the time for the experiment (Figure 3). As the time taken for different experiments are different, a typical runtime may be selected by the instructor and the pre-estimated runtime is provided for the particular experiment. The scheduling system for online experiments described here assumes that the students would be able to finish their experiments in the time slot provided, just like they would do in an on-site laboratory.

In NETLab each experiment is associated a given time slot which the administrator thinks is enough for running the experiment, keeping in view the speed of Internet and other network elements. Pre-experiment learning using laboratory manuals etc. and/or post-experiment data analyses etc. are not included in the experiment time slot for the optimized use of the hardware resources.

The workflow may be summarized as follows:

- The learner selects an experiment
- Then the learner opens the scheduling Web page link in the experiment page

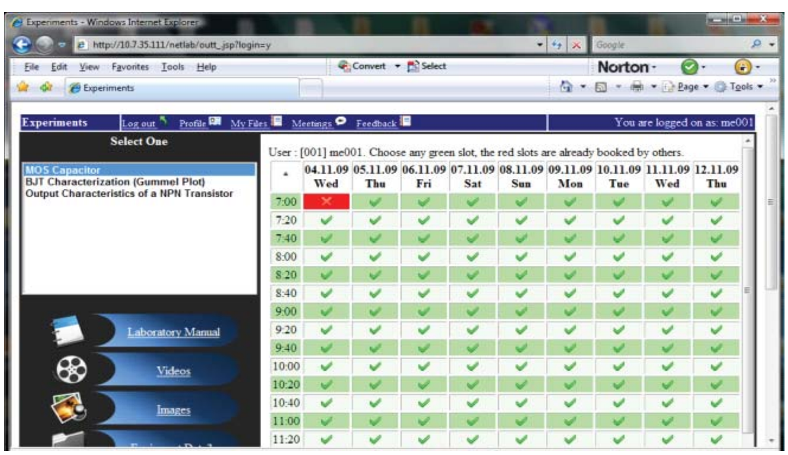

Figure 3 - Booking System.

- The system displays the scheduling interface for the next 15 days
- The system displays the available time slots for the selected experiment in green color and unavailable slots in red
- The learner then selects the date for carrying out the experiment in the scheduling interface
- The learner selects a desired time slot from the available time slots and submits the request
- The system saves the learner schedule information and updates the scheduling database
- The system displays a confirmation of the schedule to the learner

IV. LEARNING MANAGEMENT FUNCTIONS

Learning management function modules include authoring tools to generate laboratory tutorials, quiz, and data analyses. An embedded student management system manages the enrollment, marks/grades and progresses of students, and multiple collaboration tools, such as discussion forum, and chat rooms for students to communicate and work.

In the current version of the LMS the functions included are:

- Manuals (pre-laboratory and experiment) contain detailed information about the experiment (Figure 4). These are simple html pages that contain various type of information given in a usual on-site laboratory manual as well as the other detail needed for online interactions.

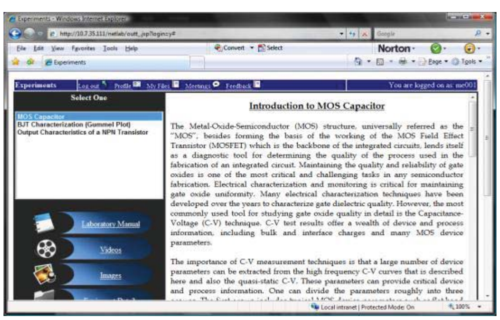

Figure 4 - Lab Manual.

- The video/image section contains videos and images about different aspects of the experiment (Figure 5). This helps the learners to have a clear concept about the real experiment would be like in a conventional in-campus laboratory. The video and image section is one of the most important parts of the LMS since there is little direct interaction between student and teacher and the actual experimental setup. The videos/images provide a vivid view of what the actual experiment would look like and build the confidence in the learner about he could do in an on-site laboratory.

Figure 5 - Video Gallery.

- Equipment details section that contains the information about the instruments used in a particular experiment (Figure 6). Every experiment requires a set of unique equipments and/or instruments. These equipments have unique control systems and also specifications. This section describes each of the instruments with both pictures and text which help the learners to be familiar with the necessary instruments. It is expected that the student will be able to perform the same experiment in a real laboratory without any difficulty.

Figure 6 - Equipment detail.

- Interactive Animation section includes animations that would simulate the setting up of the experiment (Figure 7). This is another very important aspect of the NETLab LMS where the learner follows a series of steps in form of an animation that helps the learner to understand the ways to setup the experiment. These animations are built using Adobe Flash CS4.

Figure 7 - Experimental setup (animation).

- Sections involving Question box and video chatting would provide ways to communicate with the instructor and also other students (Figure 8). This feature is very important for collaborative learning as needed in online laboratory education. The learner can use this feature to communicate online with the teacher and ask questions (in case of doubt) which teacher would respond to. In the LMS developed, provision has been made to display all the questions asked by the students and the answers provide by the instructor. Also, further provision has been made for a learner to request for a video conferencing with the teacher to discuss online on the experiment. During above scheduled video conferencing, other students can also join which would help in collaborative learning.

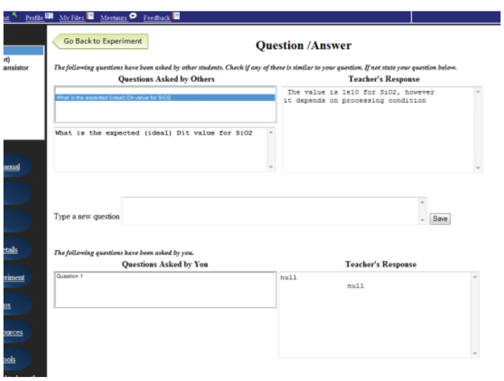

Figure 8 - Question/Answer (student feedback).

V. EVALUATION OF STUDENT PERFORMANCE

To aid teachers' online evaluation of student performance, provision has been made for keeping track of status at various stages of the experiment for each student and the evaluation is done. The process of evaluation is done in multiple steps as follows:

- Preliminary Quiz is conducted before the learner can access the actual experiment page (Figure 9). This is done online and consists of some random True/False type questions from the theory, manuals on the experiment and the instruments used. Only after checking that the learner has obtained 50% or above marks, the student is allowed to book the experiment time slot. This is done to optimize the use of the instruments and to make sure the students know about the instruments and also the experiment.

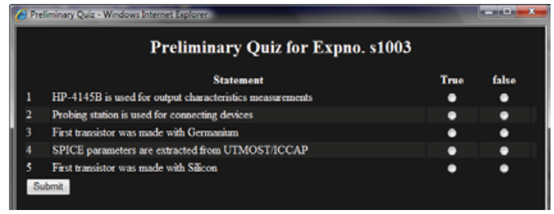

Figure 9 - Preliminary Quiz.

- After the Experiment has been performed successfully, the learner needs to save and plot graph etc., analyze data, interpret the results, and extract parameters, if applicable. Provision has also been made for online analysis using tools which may be supplied by the instructor. Once this is done, the student is now in a position to prepare the laboratory report for uploading (Figure 10). The laboratory report must contain the detail on the experiment done as well as the data obtained and results and discussions. However, the report file needs to be saved in a particular format. Once the laboratory report is submitted by a student, it is accessible only to the instructor who may check it manually and grade the student. If necessary, the instructor may send feedback on the experiment to the student and ask for resubmission. Laboratory reports of students are not accessible to others.

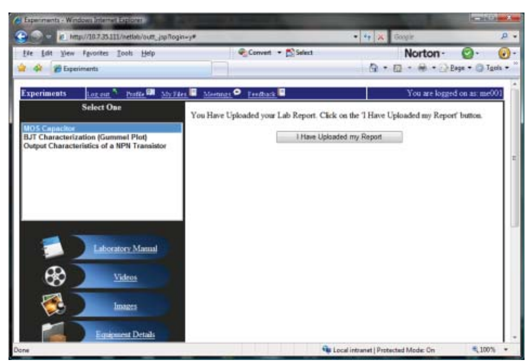

Figure 10 - Laboratory report.

- After submission of the laboratory report, the student needs take part in the online viva-voce examination (Figure 11). The viva-voce session requires answering of different types of questions set (already made available in the data base by the instructor). Both the viva-voce session and laboratory report are then graded and a final grade for the student is prepared and uploaded so that the student knows his grade.

Figure 11 - Viva Voce.

VI. EXPERIMENTAL SETUP

When students log on (during booked time) they can access the experiment pages. The html pages contains embedded object which are basically created using the LabVIEW Web development tool [5]. The html files are hosted and distributed by an in-built LabVIEW web Server. The interface in derived from the VI files created in the LabVIEW 2009. During the experiment, the students take over the control of all the equipments and can set the necessary experiment conditions from the user terminal (Figure 12). The measurements are made and the data are transferred to the client's PC. The html pages also contain learner information and display the time left during experimentation. Once this time is over a JavaScript function simply displays a warning alert and then closes the window. The student needs to place at least one screenshot of the html page in the laboratory report to prove that the experiment was done by him.

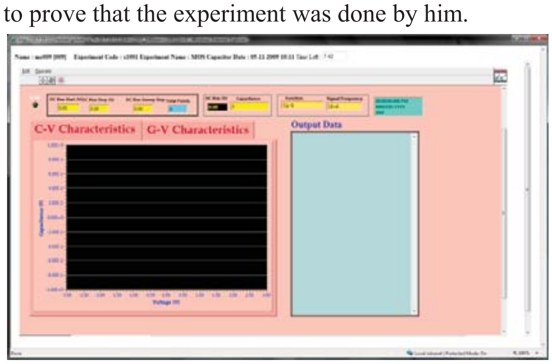

Figure 12 - Labview interface.

VII. ADMINISTRATION

The NETLab LMS contain an administrator section for the teachers and administrator to keep control and track of what is going on in the system (Logbook). The teachers can easily check the students' entry/exit records for information for future reference. The administrator can create new experiments by entering information about the experiments such as manuals, videos, images, animations etc. to update the laboratory module. Teachers are permitted to check the student's laboratory report and answer to the student questionnaire raised in the question box. The Logbook section displays information about the student progress, the grade obtained and the time and period when the students performed the experiment.

Following are the results of the students' and instructors activity profile (usage statistics) and opinion about NETLab as a learning tool. This study is based on a student population of about 40 in EC29003 Devices laboratory for the period January-April 2009. All the students used the same website http://203.110.240.33/netlab, which has the functionality such as choice of experiment, experimental procedure, laboratory manual, pre-laboratory theory etc. Interactive session with teachers and students, as well as an inquiry/feedback, formed the basis for the evaluation. Evaluation procedures consist of several criteria, such as, Very Poor (VP), Poor (P), Fair (F), Good (G) and Very Good (VG) as measures. Student Feedback Form were used regularly which helped in receiving online feedback regarding their laboratory exercises.

Laboratory Assessment Tools were used for evaluating the effectiveness of the Laboratory experiments in terms of pedagogical benefits, resource utilization and cost effectiveness on a regular basis. Analytical Tools were provided in each experiment to help in performing various analyses on the data collected during experiment. Following typical parameters were used for evaluation:

- Freedom of Access
- User Friendliness
- Unmanned Assistance
- Assessment Support
- Experiment's Effectiveness in Learning
- Freedom of Creative Experimentation
- Ease of Modifying experiment
- Skill Developed
- Operational Control
- Availability of Analytical Tools
- Performance Effectiveness

Survey for Devices Laboratory EC29003 was carried out at the end of the semester during Spring Semester 2009.The survey consisted of ten questions and its main objective was to measure the acceptance, usability and usefulness of the NETLab developed at IIT Kharagpur. The evaluation system has been chosen as: marks 6 and 8 are “very good”, 1 and 2 “poor” and 3 and 5 “good”. With this evaluation system, each student’s answers were evaluated. Further, the information obtained from the Logbook may be used for the evaluation of the LMS itself, for example, the weekly utilization information of the laboratory module is shown in Figure 13.

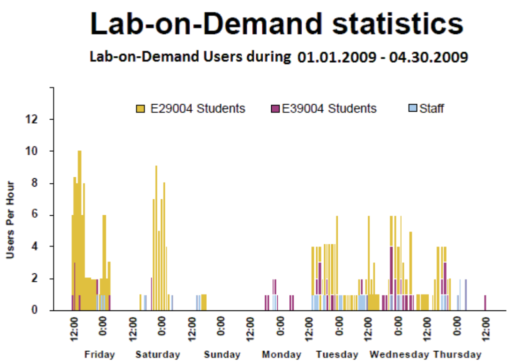

Figure 13 - Usage of NETLab showing preference in the weekend.

Table 1 - Survey response.

Question	Score
1. Has NETLab helped you with the Experiment?	8
2. Do you think it is a good idea to have an Internet remote laboratory?	7
3. Is it easy to use?	6
4. Did you feel at comfortable in changing the inputs?	7
5. Was the allotted time for experiment was sufficient?	8
6. What do you think about the inputs/outputs (in webpage) implemented?	6
7. Being not able to see the equipment, how you felt yourself to be in the instrument control?	5
8. What is your overall satisfaction with NETLab?	8
9. Have you ever faced with the server down?	1
10. Were the other available resources useful?	7

Table 1 shows that the opinion of the students and it is remarkable that the score of the questions related to suitability (Q1), time of experiment (Q5) and satisfaction (Q8) are high showing the effectiveness of online remote laboratory.

VIII. CONCLUSIONS

NETLab (Online Laboratory Management System) has been designed and installed for use in the undergraduate and postgraduate “Microelectronics and VLSI engineering Laboratory” at the Indian Institute of Technology (IIT), Kharagpur, India. The system described here currently uses manual teachers’ evaluation procedure. Attempts are underway to provide fully automatic online evaluation for both the laboratory reports and viva-voce examination.

Abstract— ***Technology plays a double role in Education: it can act as a facilitator in the teaching/learning process and it can be the very subject of that process in Science & Engineering courses. This is especially true when students perform laboratory activities where they interact with equipment and objects under experimentation. In this context, technology can also play a facilitator role if it allows students to perform experiments in a remote fashion, through the Internet, in a so-called weblab or remote laboratory. No doubt, the Internet has been revolutionizing the educational process in many aspects, and it can be stated that remote laboratories are just an angle of that on-going revolution. As any other educational tool or resource, the i) pedagogical approach and the ii) technology used in the development of a remote laboratory can dictate its general success or its ephemeral existence. By pedagogical approach we consider the way remote experiments address the process by which students acquire experimental skills and link experimental results to theoretical concepts. In respect to technology, we discuss different specification and implementation alternatives, to show the case where the adoption of a family of standards would positively contribute to a larger acceptance and utilization of remote laboratories, and also to a wider collaboration in their development.***

I. INTRODUCTION

The process of learning through technology is contributing to social changes. The size of available information for consulting has been imposing some pressure towards people, since they are now obliged to be constantly updated to avoid cultural and social isolation from the remaining society. Higher education has a big influence over this trend and must encompass current technological changes, so it may provide all means to satisfy people requirements by creating new educational resources. This has been happening since the 80's with the appearance of PCs and interactive CDs with multimedia contents. More recently, in current digital era, information circulates freely through internet and everyone have access to it, using PCs or mobile devices. This has been improving the learning process with the several educational tools developed, and technology is now viewed as fundamental to complement the traditional classroom. While at the beginning educational tools only covered traditional lectures, today the huge advances of internet services (larger bandwidth, many communication tools, etc.), have being promoting the adoption of learning technologies in the Sciences and Engineering (S&E) courses, namely in the laboratorial work, through the so-called weblabs.

This paper starts with some considerations about the problems and the added value that technologies are bringing to education. Focusing in the S&E courses, section III presents the relevance of experimental work, and section IV compares different laboratory environments. Section V describes the emergence and proliferation of weblabs, and the problems now faced by this educational technology. In this same section some infrastructural problems are pointed out and a reconfigurable weblab infrastructure, based on the IEEE1451 Std., is proposed.

II. TECHNOLOGY IN EDUCATION

In our present era, technology has been changing the way knowledge is acquired, facilitating students' access to information by lowering barriers once difficult to overcome due to social and economical restrictions. However, there are too many resources available, like books, journals, etc. that may contribute to information fragmentation, leading to an incoherent learning. This requires sense making to interpret, organize and link information to make it coherence. A critical attitude towards the learning process is fundamental, since not all the disseminated information is trustful (some are from specific entities, with credits in a specific area, and others are from individuals that can disseminate wrong information). A constructivist attitude is required, as students are building their knowledge based on information created by others.

Today skills are acquired not only inside a classroom but also outside, which requires an educational role based on two principles: i) traditional and ii) emergent. While traditional principles focus on pursuing ideals for influencing education to transform society with equality and democracy for all, following well defined theories and learning methods; emergent principles must defend a reaction of education to the technological trends, by adjusting theories and learning methods to influence students. This will be achieved by understanding students' needs and embracing their tools and skills, so it becomes possible to speak their languages and motivating them to learn, as already defended by theorists like Maslow or Herzberg's [1][2]. It is fundamental to look at education as a global process that may be improved through technologies. Spite the *Social Development Theory* presented by Vygotsky [3] focused on connections between people and the socio-cultural context in which they act and interact by sharing experiences, it does not pay attention to a social context characterized by the existence of social networks, which provides even more interactions between people and internet-based resources. Here, the *Communities of Practice* (CoP) described by Jean Lave and Etienne Wenger in 1991 [4] is still actual, because technologies facilitate more interaction, allowing students' collaboration by sharing ideas, strategies and practical experiences, through a global network. They are able to acquire skills more easily than ever, and influencing their attitude towards learning. This has been promoting changes in higher education, by shifting its focus from knowing, described by epistemology as a conjunction of truths and believes, to being, described by ontology as capacities and processes that allow a student to get and easily understand new information. Students' curricula should emphasize qualities and attributes for learning, rather than particular knowledge elements. The much information available requires students' capabilities to learn by their own, so know-what can be supplemented by know-where information can be found.

The today's common *Network Learning* concept defines a process of developing and maintaining connections with people and information to support one another's learning. As described by Siemens and Tittenberger [5] this network comprehends several nodes divided in three levels: i) neural - based on neuroscience studies where nodes are neurons; ii) conceptual - related to cognition, the nodes are seen as ideas or collections of ideas; and iii) external/social - supported by new web technologies that allow interconnecting students by social networks, blogs, wikis, forums, etc.. At this level, a node is a person or an information resource. These led to the appearance of a new paradigm named *Connectivism* [6] that classifies each piece of information or student/teacher as a node that interconnected with others, understood and classified as relevant/irrelevant and trusty/untrusty will create knowledge, promoting a coherent learning, as illustrated in figure 1.

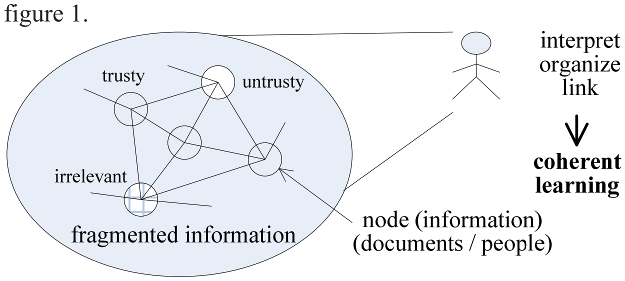

Figure 1. Coherent learning achieved through fragmented information.

As all nodes are interconnected in a network, each may influence all the knowledge already acquired. A resistance for learning and the *Cognitive Dissonance* [7], which describes a discomfort feeling when new information appears and tends to change previous beliefs, are no longer relevant, since information is constantly changing and students must be well prepared for changing their ideas supported by a critical attitude. However, the diversity of technological solutions and the amount of information available, namely in the internet, may lead to confusion in students' research, requiring a critical attitude and teacher's guidance through the whole learning process.

As presented in figure 2, the educational landscape has been changing since the 80's. If at the beginning the face-to-face instruction was the most preeminent method in education, the evolution of computers and the appearance of the internet, and its associated services and tools, incentivized students to learn (learning) instead of simple receiving information (instruction). Computers provided the use of simulations, interactive courses with multimedia contents, and other advanced resources, but the internet appearance brought the emergence of the e-learning concept providing the remote access to multimedia resources, the use of learning tools, the collaborative work using synchronous (e.g. videoconference) or asynchronous (e.g. e-mail) communication tools, etc.. Today, some of these tools are accessed through mobile devices (mobile phones, smart phones and PDAs) which provide the foundations of the m-learning concept. More recently appeared the web 2.0 allowing students and teachers to interact as a group (geographically dispersed) with web contents using blogs, wikis, etc., which allow to create and disseminate even more educational contents.

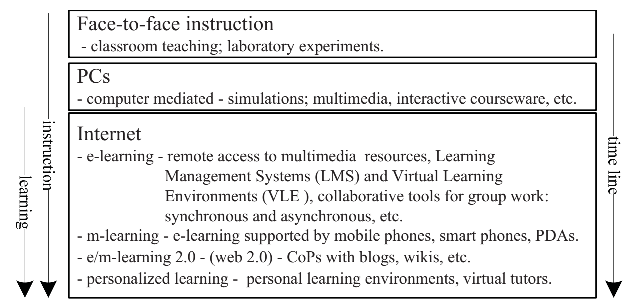

Figure 2. Educational landscape since the 80's.

Since the educational context is becoming more personalized, the spread of different tools and contents in the internet may create some confusion in a student's mind. To overcome this aspect, *Personal Learning Environments* (PLE) are appearing to support students' creation of their own environment (supported by a set of tools) so they can control and manage their own learning process.

Applying technology in educational contexts promotes changes in the traditional in-classroom learning that can be i) extended, ii) partly replaced, or iii) entirely replaced by its application. Extending the classroom with technology resources is very common and has been applied through computers and multimedia resources for fostering what students learn in the traditional classroom. More recently, solutions ii) and iii) have been spreading in the educational context, since internet and its associated services fulfill basic requirements encountered in traditional classrooms:

- dissemination - teachers/students can use websites and digital presentations with images and animations to disseminate their lectures/works, eventually supported by *Virtual Learning Environments* (VLEs), *Learning Management Systems* (LMS) and podcasts;

- discussion - there are several communication tools available; from synchronous (chats, videoconference, etc.) to asynchronous (e-mail, discussion forums, blogs, etc.), all contributing for the required teacher-student and/or student-student interaction that facilitates cooperative and group work activities;
- discovery - the internet provides access to several resources, allowing students and teachers to seek new information and tools;
- laboratory work - using the so-called remote experimentation concept, students/teachers may run or demonstrate real laboratory activities through the internet;
- assessment - while self assessment can be made through current VLEs (which comprehend several tools), traditional classroom assessment can use synchronous communication tools, so teachers can control students' assessments.

In spite of the basic requirements fulfilled by technology, it is important to be aware of the sense of isolation that students may have if the in-classroom learning is entirely replaced by technology. Some literature points this aspect as a drawback to entirely adopt technology in educational contexts, because this may lead to students' frustration, decreasing their motivation. Moreover, currently educational trends in higher education defend the adoption of the *Problem Based Learning* (PBL) theory where students' tasks focus on solving specific problems proposed by teachers. The teachers' task is restricted to supervision and guidance of students, so they can solve problems by researching and making decisions by their own, which may cause some isolation. In this context, adopting a methodology partially supported by in-classroom learning and partially using online resources will facilitate the adoption of the PBL theory overcoming the isolation drawback. As defended by the *Blended Learning* concept, nowadays the learning processes tend to be hybrid or mixed focusing on technologies tendencies to partially replace the in-classroom learning, providing students and teachers with more resources to improve education. This aspect is being applied in S&E courses, where the required experimental work is supported by educational tools.

III. Experimental Work

To apply the PBL theory in higher education, technology resources, like internet and its associated services, are fundamental, since they facilitate students' research, giving them the opportunity to learn by their own. It is important to understand how the new educational tools can be adopted in the particular case of S&E courses. As illustrated in figure 3, there are two important components for achieving learning: i) theoretical and ii) practical. While theoretical concerns transition of knowledge using the traditional pedagogical contents supported by documents, images and animations, describing specific theories; the practical component require students to be actively involved in the manipulation of variables and objects by doing experimental (or laboratory) work, researching, participating in group activities so they can understand, build, and verify theoretical concepts. In fact these are just some of the experimental skills that students should acquire in the laboratory environment, as reported by Feisel and Rosa in [8], which describes the role of the laboratory in engineering education.

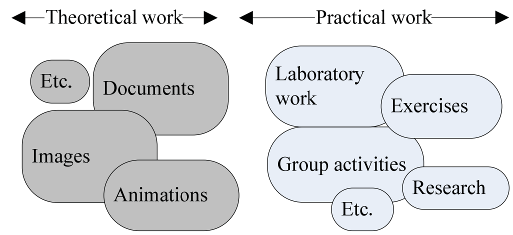

Figure 3. Theoretical and practical work.

Both theoretical and practical components are fundamental in every S&E course, since almost every theory concerns practical issues, and vice-versa. Besides, applying PBL theory requires well designed courses dividing practical work into: i) resolution of exercises, ii) laboratory work (either traditional or simulated), iii) research, and, iv) group activities, among others. The results obtained through these activities, for acquiring a specific skill, will contribute for an autonomous learning process, since students are able to compare the results obtained in each activity, gathering variables to analyze a specific phenomenon. Supported by results, students can justify the validity of a specific problem, enriching the learned theories. If those variables do not correspond to the expectations provided by theories, students are invited to reformulate them. The relation between theoretical and practical work can be viewed as a cycle with two dependent components that, if applied, will promote more consistence, autonomy and responsibility in the learning process. Moreover, motivation increases, since students have the possibility to interact with the described phenomena in a learning-by-doing scenario. The teacher should guide students to choose specific literature and tools so they can satisfy both theoretical and practical components.

Each activity has differences that must be analyzed in terms of their importance in S&E courses. While exercise solving and/or simulations provide results returned by theoretical models, i.e. students do not interact with real equipment; the traditional laboratory work gives students the possibility to work with real equipment where the results obtained can not be classified as non-real like in simulations or exercises.

Besides the importance of laboratory work for achieving good learning results, it is also fundamental to understand how students can be motivated to learn in S&E courses. Reporting the educational theorist Kolb [9], students have four different styles for perceiving and processing new information: feeling and thinking (perception), and watching and doing (processing). The analysis made in [10] based on the preferred learning styles of 49 S&E students indicates that most preferred doing and thinking (which are typically of laboratory work) rather than feeling and watching, as illustrated in figure 4. Moreover, the results obtained from a questionnaire made to those same students indicated laboratory work as the component that allows them to learn better, rather than lectures, reading or homework exercises.

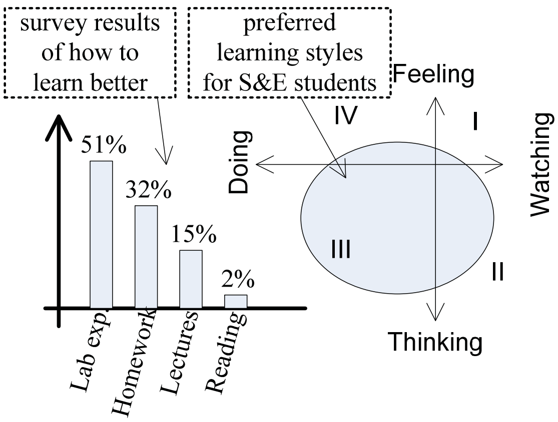

Figure 4. Survey results and preferred learning styles for learning in E&S courses (reported from [10]).

Supported by this analysis and reporting the research made by Ma and Nickerson [11], laboratory work is classified as one of the most important components of S&E courses, since students are able to acquire experimental skills which are fundamental in a practice oriented field such as engineering. This has been motivating the analysis of how can laboratory work be enhanced through technology, namely by providing different laboratory environments.

IV. Laboratory Environments

The proliferation of several technologies and services supported by internet allow creating several laboratory environments so students can conduct laboratory activities. As illustrated in figure 5, it is possible today to classify laboratories according to the access (remote or local) and resource (real or virtual) types, each one presenting specific characteristics:

- Traditional laboratories - represent the common laboratory already available before the appearance of the internet and associated services. In these laboratories students have contact with several instruments/modules (I&M) associated with an experiment and may or not may collect data through a computer. Student must physically be in the laboratory to conduct a specific experiment.
- Remote laboratories - represent a remote access to real experiments, using an internet connection. Students interact with real equipment like in traditional laboratories, however they are not required to be in the laboratory, since they can access it through a simple device (mobile or not). All actions should be carried out using the accessing device.
- Hybrid laboratories - these laboratory environments comprehend both kind of accesses and resources. Considering a remote access, students may use a simple device to access an experiment through the internet where, during the interaction with the I&M associated with the experiment, some parts can be real and others can be simulated by software. If the access is local, the laboratory comprehends some real I&M able to control locally like in traditional laboratories, but it has some simulated using a computer. Both are interconnected in the laboratory. This environment is still uncommon but it is important to consider it in occasions when the I&M are expensive and/or unavailable, and in situations where experimental variables are impossible to visualize (e.g. visualization of magnetic field lines) [12][13]. By using these hybrid laboratories, students may collect data using their accessing devices or the computer that simulates a specific I&M.
- Virtual laboratories - all the I&M are simulated using a computer. Although this solution comprehends the simulation of an experimental work, the interface provided for students must give them the sense that they are controlling real equipment. The access type can be either local or remote, as students can control a simulated laboratory by installing specific software on their devices or they can access a virtual laboratory through the internet. All data can be collected using the accessing device of each student.

The choice for a specific laboratory environment depends on educational contexts, comprehending the institutions, course requirements, and the type of students/teachers that will use the laboratory. Hence, a detailed analysis based in some parameters and costs is required.

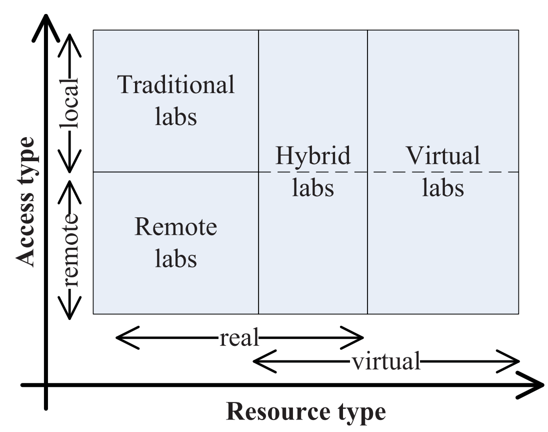

Figure 5. Types of laboratory enviroments.

The following parameters should be considered:

- Availability - a specific experiment should be available at all time. Since typically there is a lack of infrastructures and I&M to satisfy all students enrolled in a specific course, it is usual to schedule accesses, so experiments can be shared through time slots;

- Reliability - it is fundamental to analyze theoretical approaches using reliable data retrieved from a specific experience, so theoretical approaches can be proved or reformulated. Moreover, reliability also concerns the stability of the implemented laboratory, namely if it is able to work correctly during long periods of time without setup requirements or maintenance;
- Flexibility - the ideal laboratory environment should provide a platform (software and/or hardware) able to accommodate every kind of experiments, without changes;
- Reusability - a specific laboratory or experiment should be able of been used more than once, and the I&M should be able to be shared with other experiments available in the same institution.
- Motivation - the provided experiments must be well designed to motivate students' adoption. The setup and reconfigurability must be easily defined by the student (preferably without teacher or technician assistance) and the interactivity and realism should be high, so students can have real time access to equipments and data;
- Group activities - the ability to share experiences and ideas during laboratory work is fundamental to achieve good learning results. Hence, it is important to enable the conduction of experiments in groups, by allowing student-student and teacher-student communications. In an institutional level, sharing resources and I&M will improve laboratory work quality, since each institution has its specific skills in different areas enabling more quality in the provided experiences. The sense of isolation and solitude, pointed as a drawback for learning, must be overcome by this interaction.

Costs can be divided into two groups: infrastructure /equipment, and those involving actors (students/teachers + technicians):

- Infrastructure/equipment - if the local access is adopted, a laboratory experiment requires a physical space to accommodate both actors and equipment. If the remote access is adopted, an experiment does not require a large place for accommodation, since actors do not need to be in the laboratory place. Moreover, an analysis of the available equipment versus the cost of each unit together with the course requirements, in terms of how many laboratory experiments must be created, should be well analyzed. If the equipment is expensive and it is required several experiments, probably creating only one experiment able to share by several students is the best solution;
- Actors - the setup and the maintenance of a specific laboratory require at least one technician paid by the institution. Although not directly related with the institution, if the local access type is adopted rather than a remote access, students may have associated dislocation costs.

Reporting to all these parameters, table 1 provides a comparison among laboratory environments. Each parameter was classified following our acquired experience in previous international projects (PEARL [14] or ReXNet [15]) and has a mark from 0 (less favorable) to 5 (more favorable). They were analyzed focusing the use of software or hardware and on network requirements to access a specific experiment. The particular case of motivation was classified based on the adoption of technology and on the use of real or virtual I&M (i.e. higher motivation if students are using technology and real equipment).

TABLE I. COMPARISON AMONG LABORATORY ENVIRONMENTS

	Parameters						Costs		Sum	Weighted Sum
	Availability	Reliability	Flexibility	Reusability	Motivation	Group activities	Infrastructures /equipment	Actors + technician		
Traditional	2	5	3	3	4	5	2	2	26	**36**
Remote	3	4	3	4	5	4	4	5	**32**	**40**
Hybrid (remote)	3	2	4	4	3	4	3	5	28	32
Hybrid (local)	4	3	4	4	3	4	3	2	27	33
Virtual (remote)	4	1	5	5	2	5	5	5	**32**	34
Virtual (local)	5	2	4	4	2	5	5	2	29	33

Summing all lines, we may observe that virtual (remote) and remote laboratories environments have the highest mark (32), and probably should be the preferred choices to conduct laboratory work. However, from our experience, reliable results should be the most important parameter of analysis. Hence, by giving at least 3 times more importance to the reliability factor, the results will change, placing remote and traditional laboratories on top, with 40 and 36, respectively. This is inline with several theories that defend laboratory work environments should be provided by both solutions, placing remote laboratories as a complement for traditional laboratories, because both return reliable results.

While traditional laboratory environments are applied in education since the beginning, today, with the internet proliferation and the associated services, remote laboratory environments are becoming widely adopted. So, the use of these environments conduct to the appearance of weblabs that are becoming widely adopted in S&E courses.

V. WEBLABS

Weblabs are an important resource for complementing e-learning environments, as they provide the possibility to run remote experiments. Typically, weblabs are supported by VLE /LMS (e.g. Moodle) that provide all the pedagogical contents and resources that partly replace the traditional in-classroom activities. Remote experiments are accessible through simple

2D interfaces, and more recently, the use of 3D interfaces are being considered by the research community, since they provide an immersive environment where students can interact with the entire laboratory, approaching remote to traditional laboratory environments and increasing students' interest and motivation for laboratory work. Additionally, the recent technological evolution, which causes several instruments to be factory-equipped with Ethernet physical interfaces, is also promoting weblabs as important resources to improve laboratory work activities. This is proved by the increasing number of weblabs implemented at universities and schools [16] that give an added value to courses that usually only provide traditional laboratories, and to others courses that, due to a lack of resources (economical and/or technical), do not provide any laboratory work. This will facilitate changing the curriculum courses, giving students, spite of their social and economical conditions, access to real experiments and equipment, some expensive and others unavailable. There are no time constraints since students become more autonomous for conducting and repeating experiments at their own pace and they promote collaboration among different cultures and enable more "learn-by-doing", increasing students' motivation [17]. However, the implementation of weblab infrastructures comprehends some problems, which, in our view, may be overcome by adding reconfigurable capabilities to them.

A. *Weblabs' problems and new reconfigurable weblabs*

Spite of the large variety of weblabs available today, a large majority is focused in engineering courses [11][18][19][20] mainly because technical skills are required to create a weblab infrastructure. Moreover, each infrastructure is typically developed following specific and distinct technical implementations, with several hardware and software architectures that use different programming languages to remotely control the equipment [16][21][22]. The lack of a standard solution is hampering the wide-spreading of weblabs since it creates some problems:

- it does not promote large collaboration among institutions, because it is difficult to reuse and interface different instruments/modules used by a specific experiment;
- some institutions do not develop weblabs for supporting their courses, because they lack the required technical skills;
- costs may become high, since creating a weblab infrastructure requires a PC and associated software, together with several instruments;
- an architecture based on a single PC, poses constraints for running different experiments, and the required software layers usually create actualization problems due to non-compatibility issues between versions.

To overcome these problems, the use of reconfigurable weblabs based on boards with *Field Programmable Gate Arrays* (FPGA) that support a wide range of peripherals (A/D and D/A converters, interface ports, etc.) is a good solution [23], since they allow the accommodation of several I&M inside their memory blocks rather than using several independent instruments and a PC commonly adopted by traditional weblabs, as illustrated in figure 6. Furthermore, developing those I&M with open standard hardware description languages (VHDL/Verilog) and following a structure and an interface also defined by a standard, such as the IEEE 1451.0 Std., is a step in the direction of sharing and reusing the infrastructures and the I&M on other experiences and by other institutions. The IEEE 1451.0 Std. is a valid option because it defines a set of open, common, network-independent communication interfaces [24].

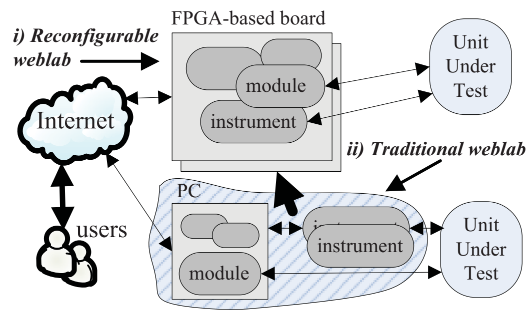

Figure 6. Traditional vs Reconfigurable weblabs architectures.

The added value of a solution based on standards for developing a weblab is large, but requires further analysis accounting for its educational requirements.

B. *Added value of reconfigurable weblabs*

Reconfigurable weblabs are more robust than traditional ones, since they do not use several software layers. A simple reconfiguration file using VHDL/Verilog description languages is sufficient to implement different infrastructures. Furthermore, there are no actualization problems, since this kind of languages are independent of any other software and FPGA manufacturer.

As reconfigurable weblabs are developed using FPGA-based boards and the IEEE 1451.0 Std., their implementation costs are lower than traditional weblabs that use PCs and several instruments, some with specific features eventually not necessary for a specific experiment. Reconfigurable weblabs adopt the same platform to accommodate several I&M able to be easily shared by several experiments that may (or may not) run in different institutions. Developing specific I&M using hardware description languages, allows easily sharing them by a simple download process from a specific web server to reconfigure the FPGA-based board, as illustrated in figure 7. To remotely control/monitor each I&M, a web interface should also be available. Hence, institutions may easily create their weblab without specific technical skills, since they become more reusable and flexible and the collaboration among institutions will increase, promoting the accomplishment of improved work group activities.

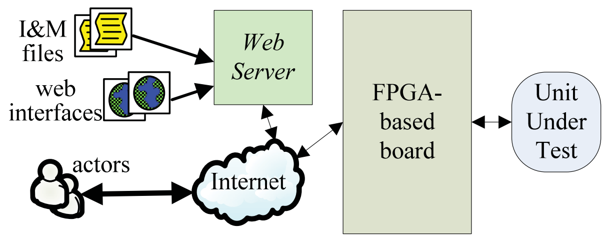

Figure 7. Distributed architecture proposed for FPGA-based weblabs.

Providing access to a laboratory requires scheduling, so several students may share a specific experiment. While in traditional laboratory environments scheduling classes is common, for weblabs two solutions are commonly applied: i) booking systems [25] and ii) running experiments in batch mode [26]. From an educational perspective, weblabs should provide students' feeling that they are interacting with real equipment as they do in a traditional laboratory environment. So, typically booking systems allows students to reserve a time slot so they can have total control over the weblab, like in the traditional laboratory. The adoption of reconfigurable weblabs provides an improvement to the traditional weblabs in this availability aspect, since FPGAs can be reconfigured with different I&M using two possible techniques: i) total reconfiguration or ii) partial (static/dynamic) reconfiguration. In total reconfiguration, using a new I&M requires reconfiguring all the FPGA by stopping its operation. This may be an uninteresting option for experiments using many I&M at the same time, since it requires stopping the weblab operation for changing them. Moreover, depending on the complexity of new I&M and on current FPGA configuration, this option typically requires more time to reconfigure the weblab than the second one [27]. Therefore, option ii) may be more appropriated if one needs many I&M to conduct an experiment, since it allows reconfiguring only part of the FPGA with one or more I&M, without changing the others inside. Two alternatives are available for partial reconfiguration: a) static or b) dynamic. Static reconfiguration requires stopping the FPGA, while in dynamic reconfiguration an experiment may keep running even if an I&M is changed. So, assuming one wants to change the reconfigurable weblab infrastructure when the logical space used inside the FPGA is totally occupied, only a fraction of it would be reconfigured, without affecting the rest of the FPGA. Eventually, that fraction could even be occupied by an I&M in operation in that instant.

Following on the FPGA reconfigurable capabilities, figure 8 presents a solution to solve typical scheduling problems encountered in traditional weblabs when 1 to N students wish to conduct 1 to N experiments. When there is only one experiment for a single student, there are no scheduling problems. However, when a single experiment is available and several students want to access it, a scheduling access is required. As previously referred, a typical solution to solve this situation is the adoption of a booking system where students can reserve time slots. At that slot time, no one else can access the experiment, which can decrease the availability of the weblab. By adopting the proposed reconfigurable weblab, the FPGA reconfiguration techniques will solve this problem, because it is possible to reconfigure several I&M, required for a specific experiment, in different FPGA's memory blocks. This allows student's transparent accesses to the experiments making them to believe that there are several available infrastructures. The only problem is the limited space available inside the FPGA that can also be solved using scheduling techniques or even the batch mode referred before. When one student wants to run different experiments, the reconfigurable infrastructure may provide different experiments running at the same time in different memory blocks or, in case of limited space, it is possible to change the experiments using one of the referred reconfiguration techniques. The most critical case appears if several students want to run different experiments. This requires the conjunction of both proposed solutions, i.e. the FPGA can be reconfigured with several experiments able to run at the same time for one specific student or, if several students want to run a specific experiment, it can be replicated in several memory blocks of the FPGA.

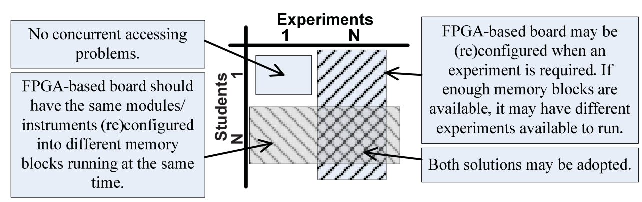

Figure 8. Solutions to run 1 to N experiments for 1 to N students on a single FPGA-based board.

C. *Security issues*

The reconfiguration capability provided by the proposed weblabs may cause some problems if students have access to the entire weblab infrastructure. It is fundamental to control the actions they are able to do, to avoid damaging the infrastructure and problematic situations when dangerous experiments are available. This situation was already present in the traditional weblabs, because some infrastructures and experiments may also be damaged by student's interaction. To overcome this situation, the usual solution is to restrict student's access to specific actions over experiments, by limiting the functions available in the web interface.

In reconfigurable weblab, besides interacting with a specific experiment, students/teachers can also interact with the weblab infrastructure by changing I&M. This freedom poses some security problems solvable through two alternatives: i) restrict the reconfiguration options of the laboratory to teacher and technicians; or ii) provide a web interface for each specific weblab infrastructure, limiting the reconfigurable options open to students. This last solution will decrease the weblab flexibility since it requires a specific interface for each infrastructure or experiment. Regardless of the adopted method, all I&M should also be well tested and checked for compliance with the IEEE 1451.0, so not to damage the infrastructure. A solution is to have a unique trustful website integrating those modules such as the www.opencores.org website, or, in alternative, providing a tool able to check if those I&M are in fact compliant with the standard.

VI. CONCLUSION

Failing to observe a standard has hindered a larger collaboration between the academic fellows and institutions that have been developing and promoting the use of weblabs. Although there are some large consortiums (e.g. iLab, and VISIR, among others) that follow and share a common architecture in their weblabs, the adoption of a widely accepted and open accessible standard, like the IEEE 1451.0 std., would definitely contribute to a larger consensus around this educational technology, much in the same line of reasoning that led to the adoption e-learning specifications like SCORM. If one regards weblabs as a contributing educational tool (or resource) to e-learning in S&E courses, then quite reasonably the idea of adopting a collection of standards, such as the IEEE 1451 family of standards, for the development of sharable remote experiments, with permutable I&M developed and made available by different institutions, will increasingly gain acceptance in the broad community devoted to Engineering Education. Besides the presented technological grounds, it is also important to evidence that the development of weblabs, namely their underlying infrastructure and I&M, is, in itself, a didactical engineering activity for many graduating students. If, in a general development effort, one certain student develops a specific I&M that can be easily downloaded and used by the entire weblabs' community then a real engineering development case will have been demonstrated to that particular student. Giving the large number of experiments done in the training phase of engineers (not mentioning their particular area, e.g. mechanics or chemistry, among others), then one can quickly foresee the huge potential for collaboration in the development and utilization of remote laboratories and experiments, if (and this should be clearly stressed) a universal standard is adopted. In our view, the IEEE 1451 std. is clearly an option in this direction, following the rational presented in this paper.

The Montegancedo Astronomical Observatory

The first free remote observatory for learning astronomy

Abstract—**This paper describes the first open robotic observatory available to the public on the Internet (http://om.fi.upm.es), interactive and completely free access through a Web 2.0 application, which lets users manage professional astronomical devices and collaborate with other amateur users through a web browser. Its main goal is to open the astronomy to the society and that people learn informally about the cosmos by means of experimenting with real remote devices.**

Its architecture is made up by common collaborative Web 2.0 tools (such picture gallery, wiki, forum, chat, voting and discussing systems, etc.) and services and policies to offer meritocratically the observatory and its observing time.

The paper presents an innovative approach which proposes a reputation system for sharing an online resource to encourage high-quality contributions, and the initial outcomes obtained since the observatory started in December 2008.

This paper also describes the first experience using the observatory for carrying out online practical assignments in an Educational Innovation Project within the Technical University of Madrid during academic year 2008-2009 and using it for three subjects of these different degrees: Computer Science, Industrial Engineering, and Topography.

Keywords - informal collaborative e-learning; meritocracy; social networks; web 2.0; web laboratories

I. Introduction

In 2004 the term Web 2.0 was coined by Tim O'Reilly [1], describing the trend in the use of WWW technology and web design that aims to enhance creativity, information sharing, and, most notably, collaboration among users. These concepts have led to the development and evolution of web-based communities and hosted services, such as social-networking sites, wikis, blogs and folksonomies [2]. Wikipedia, YouTube, Facebook, eBay, Flickr or MySpace are only some famous sites as a result of the Web 2.0 [3][4].

Society have new habits, people spend more time on the Internet and access more frequently than a short time before. It is obvious it is happening a revolution around the Internet, in all the fields [5]. E-democracy, e-goverment, e-science, e-learning or e-portfolio are a few new concepts appeared in few years. The Internet has grown to currently become one of the most important ways for voluntary collaboratorion. It was the way used to develop successful systems like the GNU/Linux operating system, Apache server and other meaningful contributions through the Free Software movement. Everyday, thousands of people participate in some site on the Internet, from a simple suggestion in a recommendation system like Amazon, to the classification of a galaxy in an astronomical website like GalaxyZoo [6]. Other people donate their computing power to scientific research projects, through platforms like BOINC [7]. These and other collaboration ways are only possible thanks to the Internet nowadays.

However, the Internet lacks online websites for real experimentation, like the web laboratories where people practise and control resources through a web browser. This issue and the idea of taking advantage of the knowledge of thousands of volunteers collaborating day by day, were the motivations for carrying out the project presented in this paper. The aim of the research was to design a new methodology for creating collaborative projects and citizen participation, focused on education and based on real experimentation. This was supposed a new approach to create open web applications for society to promote the informal learning, the social constructivism and the generation of knowledge through collaborative, self-organized and meritocratic systems.

For this reason, to prove these ideas, it was necessary to develop a concrete example to apply the methodology. Authors opted for the Astronomy because it is a science with a huge number of amateur people. This is the origin of the Montegancedo robotic astronomical observatory.

The Montegancedo observatory is an informal e-learning Web 2.0 platform whose aim is to open Astronomy to the society in order to people learn and collaborate creating and supervising astronomical knowledge through the Internet. This remote observatory pretends to be a way of real experimentation in Astronomy, collaborative learning and, in general, dissemination of Astronomy.

Nowadays, there are hundreds of robotic telescopes, with different sizes and purposes, working autonomously without an operator. Some of these telescopes offer services through the Internet, both an interactive and non interactive way. However, up to now, in the most of cases it is required to pay for using these systems or are available only for few organizations, like schools or associations. Also it is appreciated that there is low interest in using these scenarios for informal e-learning and citizen research. So, in opposite direction, Montegancedo observatory meant being the first open observatory to the

This project would not have been possible without the funding support from the following institutions: the Ministry of Science and Innovation (AYA2009-14000-C03-03); the Technical University of Madrid (IE08100184 and IE09100154); and the Community of Madrid (S-0505/ESP/000237).

public through the Internet, interactive and completely free access (http://om.fi.upm.es).

This paper describes the Montegancedo observatory and the experience gained through its teaching approach. The document is organized as follows: Section II describes globally the system. Section III presents some of the most relevant collaborative services. Sections IV shows the experience in higher education context. Section V describes results in the first months of working. And finally, sections VI and VII present the conclusions drawn and the direction and priorities of the future work of the project, respectively.

Figure 1. Location of the Montegancedo astronomical observatory. Campus of the Computer Science Faculty (Technical University of Madrid)

Figure 2. Montegancedo astronomical observatory

II. Description Of The System

Montegancedo observatory is located in Madrid, Spain, at the roof of one building of the Faculty of Computer Science, as shown Figs. 1 and 2. From December 2008 up to now, the first remote experiment through the Montegancedo observatory is running. This experiment lets users watch the Sun and control a high-quality professional camera for astrophotography, as will be detailed later.

Any Internet user has free access to this observatory from a browser. It is worth mentioning that, dated November 2009 (only eleven months running), its community is composed by a total of more than 600 users.

The observatory is controlled through a web application. As said above, an advantage is that anybody can access to an professional astronomical observatory from anywhere. Consequently, people learn to control the devices, from simple webcams to powerful astrophotography cameras and telescopes. The control software developed for remote observatories, called Ciclope Astro, is scalable and adaptable to a large number of devices. Also it includes the potential of Web 2.0 services [8], which promote and make the collaboration and communication between users easier.

Next the most characteristic aspects of the system are described. Mainly it is based on a social network of virtual anonymous users and includes a great number of collaborative services, such as wikis, photo galleries, news publishing systems, suggestions, discussion and voting systems, and folksonomy or collaborative tagging, among others.

Social meritocracy is another important feature of this system by means of a reputation/karma users system. Besides promoting user participation, this is an innovative approach which lets schedule observing time in an original way described later.

A. Architecture

The infrastructure is composed by a server software, end-user applications, content syndication formats, instant messaging and astronomical devices control protocols.

It requires a client/server architecture, summarized in the Fig. 3. It is worth mentioning that the system combine leading technologies, such as Google Web Toolkit framework to develop AJAX applications in the Java programming language, and the iBatis persistence framework with a MySQL database.

B. Astronomical experiments

The main component of the Montegancedo observatory, and which is really appealing to users, is the set of astronomical experiments that users can do online. An experiment is referred to a set of objects, actions, devices and guides for its execution. An experiment could consist on observing the Moon, moving the telescope around the Moon's surface, taking photographs and building a mosaic with the photographs taken. Another experiment could consist on observing the Sun and calculating the Wolf number, that is, counting sunspots.

There are specific interfaces depending on the experiments and also the user roles. Up to now, different interfaces have been designed, from a basic hand controller to an advanced replica of Autostar II hand controller, going through astronomical object catalogs. A control interface of the Montegancedo observatory is shown in Fig. 4.

From December 2008, the first solar experiment is running. The goal of this experiment is to observe the Sun in H-alpha and distinguish sunspots and solar protuberances, apart from learning to control an astrophotography camera and change its parameters in order to take excellent photos. The telescope and the dome track the Sun, so users only watch an interface with four four real-time cameras broadcasting the video. Two of those cameras are used to watch the status of the telescope and dome. The other two are connected to the finder and telescope to observe the celestial objects. The parameters of these cameras can be modified from the interface, e.g., exposure time, gain, brightness, gamma and region of interest, and let user learn basic knowledge about Astronomy.

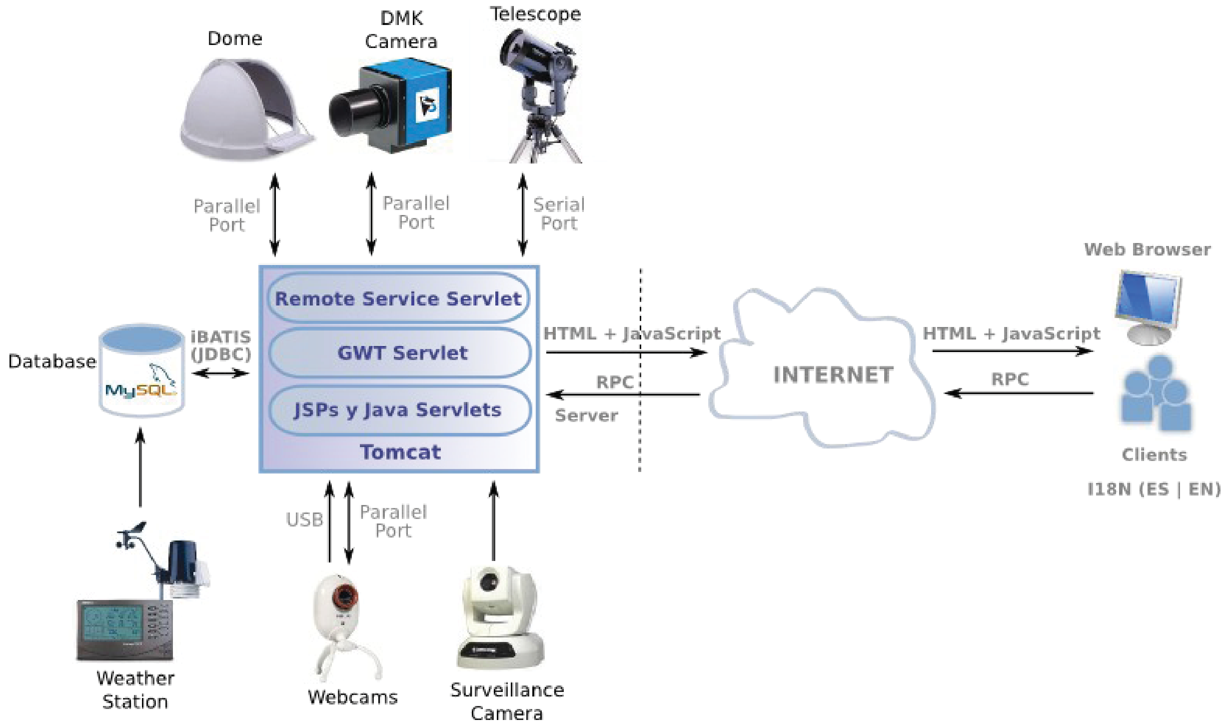

Figure 3. Montegancedo observatory's architecture

Another particular aspect is that to carry out each experiment there is a scheduling published on the website. In the case of the first experiment, each user has two intervals of ten minutes a day to control exclusively the observatory, as explained below. However, although an user has not the reservation or even is not registered, can observe what is happening during a session, since real-time cameras are broadcasting continuously through the web application. The drawback in this case is that the retransmission frequency is less than for the owner of the observing session, e.g., from twenty to one seconds.

C. *Observing Time Allocation*

In this subsection it is explained how observing time in this remote observatory is allocated innovatively.

First of all, user who wants to manage exclusively the observatory (telescope, dome and cameras) previously has to make a reservation in that interval. The web application publishes the reservations by means of a calendar, listing all the busy reservations made in a concrete day. A registered user has an interface in order to reserve the free intervals which are not reserved by other users. As said above, now in the solar experiment, the reservation policy only lets users reserve in the current day, from 00:00 AM. Website administrators are responsible of setting the timetable to carry out each experiment, the duration of each session, and the number of sessions a day per user. By default, the allocation policy is called FIFO (First Input First Output), that is, an user can reserve any free interval as they log in. However, these policies can be modified by the administrator according to behavior and feedback shown by the community.

Furthermore, there is implemented other policy based on a reputation system based on users' karma, that is, observing time per user is proportional to its karma. So, more karma, more observing time. This is a original way in order to compete for the available observing time using typical reputation technicals for Web 2.0. Basically, it is a manner of promoting and awarding to those most and best participative and collaborative users, and penalizing to damaging users for the community.

III. Web 2.0 Collaborative Services

One of the most important features of this system is the set of typical collaborative services for Web 2.0 incorporated in order to users participate creating and sharing knowledge, like collaborative edition through wikis, discussion threads or tagging through folksonomies. The synchronous communication by means of instant messaging also is fundamental to users exchange opinions, hobbies and knowledge. The social meritocracy is other of the most evident features of the Web 2.0. This methodology lets determine the karma of each user and other items within a remote laboratory based on the participation and acceptation of the rest of community. The fact of setting a user hierarchy is essential to encourage the motivation for competing for the use of online resources. And, in this sense, offering voting mechanisms is useful to organize the content of the collaborative systems. Next some of these services are described.

A. *Photo Gallery*

The photo gallery stores every astronomical photographs which are uploaded by the authors, both photos taken with own material and photos taken with the Montegancedo observatory.

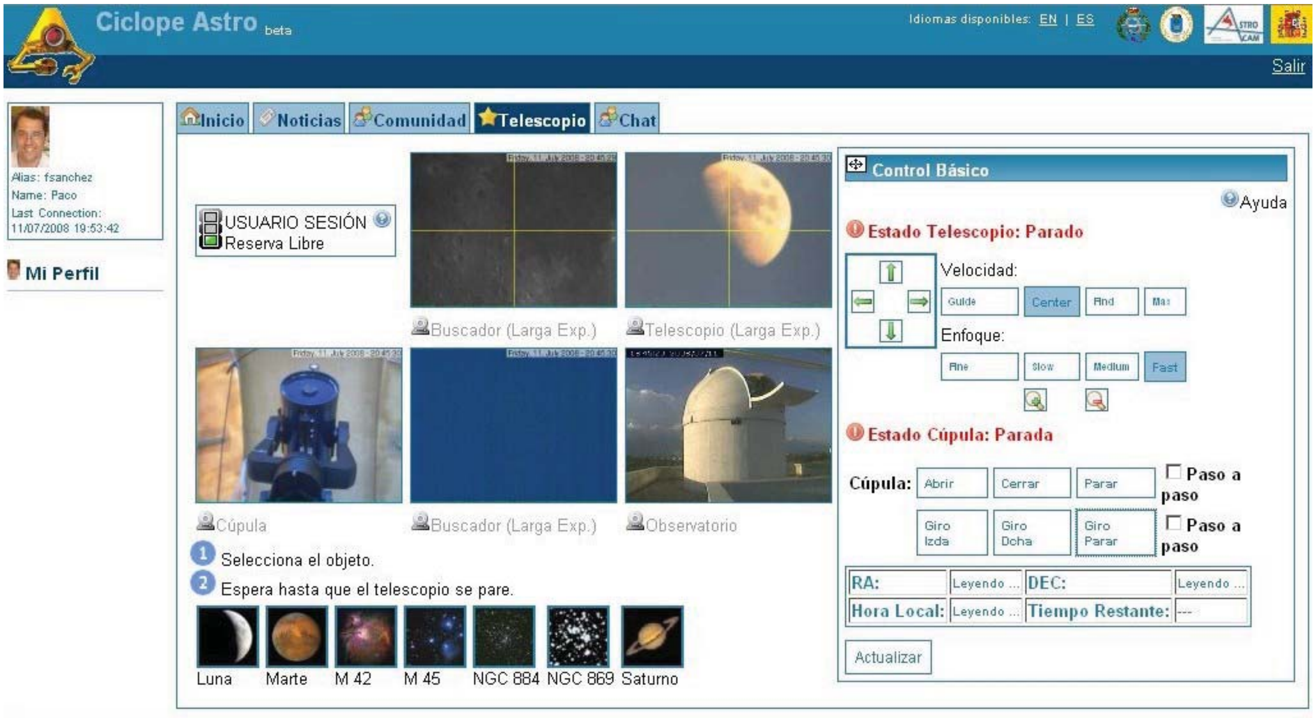

Figure 4. Control interface of the Montegancedo observatory: Observing the Moon

When an user uploads a photo, also has to fill a form indicating the title and the tags and, optionally, the rest of the fields regarding image processing, observing material, location, date and a free description about the photo. Each photo also has a karma associated and a global position which represents the importance and evaluation for the community.

B. *Meritocracy: Karma Reputation System*

Regarding to the meritocracy, karma is a parameter which measures the collaboration in Webs 2.0, a quantitative measurement of the user's effort within the community. The aim of the karma is to give more weight to the votes of those users who send the most and best contributions and best ability to determine the most valuable contents. As a result, content selection and hierarchy processes are accelerated.

All users obtain same karma value when they register in, but their karmas go up or down according a mathematical algorithm called PageRank, which is used by Google to order webs [9]. Essentially, users' karmas are calculated depending on quantity and quality of their contributions, votes sent and received, the attendance to live broadcasts (eclipse, occultation, etc.), that is, all set of own contributions.

Users are penalized if they carry out damaging actions for community, such as reserving observatory but not using, sending problematic photographs, etc.

C. *Suggestions*

Suggestions or proposals service lets users raise questions to the community. As far as community is concerned, they send suggestions and vote them. Users, anonymous or registered, vote proposals and, after deadline, close the process and award the winner proposal.

This service was used the first time to choose observatory name. In this case, name was chosen by means of democratic system where every vote has equal weight. The exhaustive survey process is described in Raquel Cedazo's doctoral thesis [10], besides the results obtained in comparison with a meritocratic system, where users have different voting weight.

D. *Wiki*

Its aim is that users edit collaboratively articles about Montegancedo observatory and Astronomy in general. Through this wiki, it is expected that users write astronomical articles which be useful to any Internet user, not only to observatory users. On the other hand, this wiki also is used for publishing terms and conditions regarding the use of observatory, press notes, related links, user guides for devices and functionalities, and results and statistics relating to experiments.

E. *Instant Messaging*

The observatory includes a synchronous communication as a virtual way communication among users. This instant messaging service is known as *chat*. It only can be used by registered users when logging in the application. It allows to open private conversation windows between two or up to five online users. Among main features, the chat allows to see any online user, set a own status message (busy, away, work, etc.), see online users' status messages and, finally, maintain a contact list. The chat divides connected users in two groups, those that are or are not on the contact list, so it is easier to locate favorite contacts.

IV. Experience In Higher Education

Montegancedo observatory was used in the 2008-2009 academic year for first time within the higher education context. Authors received a fund for an educational innovation project within the framework of the process of the establishment of the European Space of Higher Education and the improvement of the quality teaching. This project was entitled "Execution of collaborative remote practical assignments through Montegancedo robotic astronomical observatory. Applied to subjects: Geodetic Astronomy, Computer Vision, and Design for Web Applications ".

This project supposed to use Montegancedo observatory as a remote laboratory to carry out the practical assignments of three subjects of the three following Technical University of Madrid's centres: Computer Science, Industrial Engineering, and Topography. The target was to motivate students to put into practice the theoretical knowledge during lectures.

The three practical assignments were carried out by students after timetable through the Internet, and were focused on the solar experiment previously described.

Figure 5. Traditional methods to calculate the azimuth in practical assignments for Geodetic Astronomy subject (Topography)

The use of this system was specially benefit for Geodetic Astronomy subject, since practical assignments observing the Sun were canceled years ago because students were not safe running the risk of damaging their eyes by looking directly at the Sun, as shown Fig. 5. In this sense, Montegancedo observatory supposed to be a new opportunity to reincorporate it (118 students enrolled in 2008-2009 course), being out of danger and doing really comfortable for students, as shown Fig. 6.

This first year good experience [11] has caused that authors develop new experiments for 2009-2010 academic year. In this case, experiments are pretended to focus on calculating the azimuth, latitude, and longitude through observing stars at night.

V. Results

Data collected for analysis represents the collaboration of the users up to now. Statistical data are collected automatically into a database and analyzed subsequently. The experiment was successful in many aspects.

Dated 1st November 2009 and before one year running, there are satisfactory results: 609 registered users, almost 800 reservations, and a good participation and positive response: almost 150 photographs, 300 posts, 600 tags, more than 1000 votes, etc.

Furthermore, it is worth mentioning first results reflect that users access regularly, reserve the observatory, and take photographs. Even they use the other collaborative services, e.g., they upload and share their own astronomical photographs, edit wiki, send posts, votes, news, and suggestions, among others.

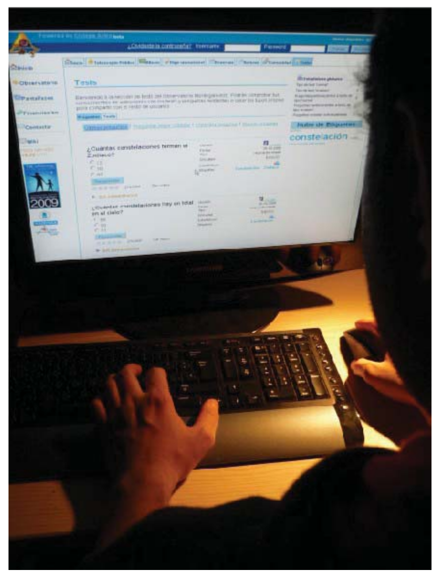

Figure 6. Montegancedo observatory' web controlled by a student from a computer

A. Social Network

Data analysis techniques are fundamental to understand how community works and its global behavior. The social network methods are particularly well suited for dealing with multiple levels of analysis and large communities [12] . Fig. 7 is an example of how visualization tools are useful to extract relevant information about the community [10]. So, it is possible to find out at first sight intrinsic aspects related to network structure or who are the most active users, the most influential ones, powerful, etc.

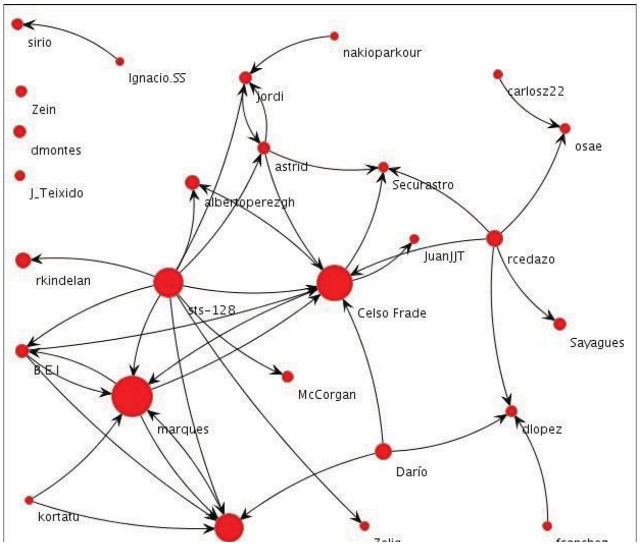

Figure 7. Graph which represents a observatory subnet and where it is possible to watch different sizes of the vertices to indicate the user karma. Links between vertices are votes

B. *Socio-demographic profile*

A users socio-demographic survey has been made in order to extract a pattern of the user profile. User data have been analyzed according to the age and gender, information required for the registration.

Regarding to active users, that is, those who have logged in at least once, gender statistics show that a high percentage of users are men (74.35%) in comparison to women (15.06%), as shown Fig. 8 and Tabla I. Meanwhile, the rest of the active users (10.59%) did not specify their gender since at the beginning these data were not compulsory.

With regard to age, Fig. 9 and Table II summarize that the predominant age corresponds from 20 to 44 years (73.64% over total).

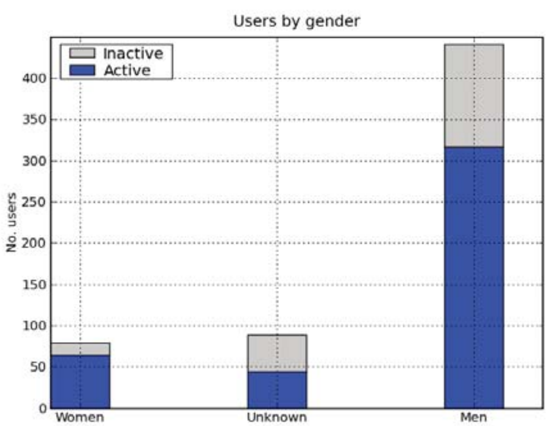

Figure 8. Statistics users: gender (5th November, 2009)

TABLE I. Users By Gender

Gender	Total	%Total	Active[a]	%Active
Female	79	12.97%	64	15.06%
Male	441	72.41%	316	74.35%
Unknown	89	14.62%	45	10.59%
Total	**609**		**425**	

a. Active users are who have logged in at least once

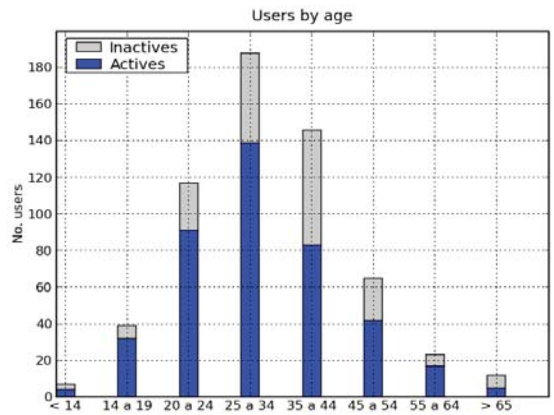

Figure 9. Statistics users: age (5th November, 2009)

TABLE II. Users By Age

Age	Total	%Total	Active[a]	%Active
< 14	7	1.15%	4	0.94%
14 to 19	39	6.41%	32	7.53%
20 to 24	117	19.21%	91	21.41%
25 to 34	188	30.87%	139	32.70%
35 to 44	146	23.97%	83	19.53%
45 to 54	65	10.67%	42	9.89%

Total	**609**		**425**	

a. Active users are who have logged in the system at least once
b. Invalid age refers to value less than 7

VI. Conclusions

As other authors have already proved, and as can also be observed from the Monteganceado project, the high potential of Web 2.0 tools allows to set up a large learning community, offering remote experimentation scenarios. Furthermore, one of the main features of this system is enhancing collaboration and participation through current well-known services on the Internet.

According to statistics collected, the experiment was successful in many aspects: high number of registered users; moderate number of reservations of the observatory; good quality content uploaded and written by users; and other collaborative tasks like writing, posting, voting, and tagging.

This paper has presented the experience using Montegancedo observatory to carry out practical assignments at the Technical University of Madrid. It has shown that this system offers huge opportunities for higher educational context.

Apart from being a project which could be used as a good example for designing new citizen science and e-learning projects in any other discipline, it will be a solution to face up to more and more data and to the insufficient number of experts needed for the review process of the astronomical tasks.

VII. Future work

One of the most ambitious objective is to build a network of free access remote observatories around the world, both hemispheres, to result in more observing time and more interesting experiments. Collaborations with amateur and professional astronomers will still be essential to design the remote experiments and to acquire the suitable material.

Gathering a large community that analyze data arrived from telescopes on this network is a socio-technical challenge and could be decisive to interpret astronomical phenomenons. Organizing this community and motiving them to collaborate in this initiative is a long-term objective.

Acknowledgment

This project would not have been possible without the funding support from the following institutions: the Ministry of Science and Innovation through "Collaborative Learning and Researching through an astronomical observatory controlled by the Internet" project (AYA2009-14000-C03-03); the Technical University of Madrid with two projects in Educational Innovation titled "Execution of remote collaborative practical assignments through Montegancedo Robotic Astronomical Observatory. Applied to the subjects: Geodetic Astronomy, Computer Vision, and Design for Web Applications" (IE08100184 and IE09100154); and the Community of Madrid through "ASTROCAM: Astrophysics Network of Madrid" project (S-0505/ESP/000237).

Abstract —**In Portugal, like in other European countries, people with strong professional competencies are encouraged to obtain higher education, no matter their age or their social condition. With their strong professional background and some theoretical aspects linked to scientific and technological domains, they become more helpful for the companies and for the society they belong. Considering these facts, the Portuguese Government developed specific legislation to attract new students for the technological higher education system. This legislation, intends to attract students older than 23, and also aims the improvement of technological education after the secondary school level. Pursuing this goal the Technological Specialization Courses (TSC) were created.**

The TSC are post-secondary, non superior training courses that will lead the students to obtain level 4 of professional training, according the 85/368/CEE decision of the European Union Council, published on the European Communities official journal. The TSC also allow people from different professional backgrounds to get technological training. The best students are allowed to access higher education in technological domains (basically in Engineering fields) and/or to the job market relied with the country's technological industries. Before the beginning of a TSC, the students are submitted to technological tests to determine their profile, which will be taken into account on the initial training, before the starting of the TSC.

In this paper, the success of TSC courses in Portuguese context is demonstrated, and the implementation of a successful partnership between University of Minho and the Technological Association for the Professional Education of Beira Interior (AFTEBI) is shown. The illustration of the successful partnership is done by presenting a case study of a TSC in Industrial Maintenance where the best students can pursue their studies in University of Minho, in the Mechanical Engineering Department in order to obtain a Mechanical Engineering Degree. The main role of UMinho (as Superior Education Institution) at different levels of this post-secondary (non superior) education is also discussed and highlighted.

Keywords: Engineering Education; Professional Training; Higher Education

I. INTRODUCTION

In the late seventies in Portugal the "Industrial Schools" have been extinct, under the assumption that equal opportunities meant a uniform non technical secondary level formative path for everybody. This transformation of the national education system under the Ministry of Education led to the rarefaction of the public offer of technical teaching, but also to the depreciation of the status of technical professions. To compensate the rarefaction or even lack of technicians with formal instruction to fulfill the available jobs, industry used to hire people that were initiated in the profession as apprentices, most of the time in situations that configure nowadays illegal infantile work [1].

From the information recently collected relative to professionals' availability resulted that maintenance and machinery operator positions presented a deficit of personal, both in quantity and quality [2]. It became evident that there were not enough Programmers/Operators of CNC Machines, Metalworkers, Turners, Welders, Mechanicals, Metrology and Quality Control Technicians, Product Development Technicians and other typical technical professions to fulfill market demand [3]. The main lacks in adequate professionals to fulfill industry needs occur in specific technical positions in those sectors, mostly technicians for undergraduate positions.

Also very few people respected eligibility criteria and the rules governing the quality certifications, safety and professional approval requirements of candidates' curricula, which turned the human resources scarce. The recent world wide economic slow down increased the difficulties for the less qualified, for they are less versatile to change profession, to perform new tasks or even to create new jobs.

By the beginning of the nineties the natural generation replacement led the shortage of skilled technical and technological intermediate level professionals in the industrial and business areas to a level that could no longer be ignored. Also the Portuguese Government inscribed competitiveness as one of the fundamental objectives for the Country in its Program, along with fomenting the social cohesion.

To achieve these objectives it is imperative that qualified people be available, for that is in fact the decisive factor for a sustainable long term progress, in particular in fast changing societies that are supported by knowledge and information.

Furthermore the installation of new technically demanding industries, and the competition for skilled people in Europe shortened even more the availability of skilled professionals in Portugal. The industry modernization in course and the challenges imposed by the fast changing reality demand that the new professionals be prepared not only to fulfill the present needs of the companies, but also to be prepared to permanently adaptation themselves to respond to emerging professions in areas that nowadays present already inadequate profiles.

In Portugal, because of remaining low education and professional qualification levels that still continue to characterize the great majority of the population in active age, in spite of the progresses already done in this domain in the last decades, this issue assumes special relevance.

It is then imperative to increase Portuguese skills and qualifications to create a potential for new opportunities and to promote both the people intrinsic development, and in consequence, the social, cultural and economical growth of the country. More qualified human resources generate larger competitiveness capability along with greater social cohesion. The educational system must be able to better qualify the youths, fighting in particular the high taxes of early school abandon (nowadays only half of the citizens aged between 20 and 24 has successfully finished the secondary education level). Also, to solve the inadequacy of the present skills of the work force to the emerging industrial opportunities, the formative offer must give new opportunities to adults, and promote school recovery and professional qualification, namely to those that are now facing unemployment because their jobs (even when skillful) vanished .

A careful analysis points to the development of solutions on technology learning under a solid technical teaching by trained professionals, to allow the graduates' integration in available work positions in present industrial companies, and to guarantee the adequate updating of the professionals already working, offering the possibility for the acquisition of new skills so making it easier their conversion and professional valorization.

In order to achieve the goals proposed in this work, the paper is structured as follows: section 1 is devoted to the presentation of the facing challenges; in section 2 the characteristics of the Portuguese Technological Specialization Courses (TSC), are presented; in section 3 is discussed the relationship between the University of Minho and the Technological Association for the Professional Education of Beira Interior (AFTEBI); followed by the presentation, in section 4, of the main characteristics of the successful TSC on Industrial Maintenance; in section 5 is discussed the success of this TSC and the impact on the caption of students for higher education; in section 6 is discussed the role of Superior Education Institutions on post-secondary (non-superior) education; finally, on section 7 are presented the conclusions achieved.

II. TECHNOLOGICAL SPECIALIZATION COURSES

The Portuguese Government assumed, in the "New opportunities" initiative, the minimum referential formation level goal to achieve 12 years for every youngster, having recently legislated the mandatory school frequency until finishing the secondary level or reaching 18 years old [4]. This goal was assumed in couple with the goal of increasing the rate of students attaining technological and professional courses at the secondary education level to at least half the younger population. The bet is not only that the new generations may reach higher education levels, but also that they get adequate professional qualification prior to enter the job market, namely by providing professional education oriented to professional profiles and skills that are in deficit and highly required.

Knowledge through professional teaching and formation must be conciliated with a qualified professional insertion component. Seeking the access to higher education and equal opportunities, and envisaging the engagement of more young and adults with the professional education and formation system, the Government assumed, in its program commitments, to enlarge the formation offer along the life to new publics. It was also decided to involve the higher education institutions in the expansion of the post-secondary formation, in order to grant the articulation between the secondary and superior teaching levels and the system's accreditation, for superior studies pursuit purposes, of the post-secondary formative courses specialization.

To materialize these commitments, the present law promotes a deep reorganization of the technological specialization courses at the levels of the entering access, the formation structure and the conditions to access higher education institutions for the graduates of this system.

Being aware of the Portuguese lack of skilled professionals, the Ministry supported the creation of a set of Technological Schools intending the promotion of initial formation in technological areas for youth, in a post secondary level. These courses later acquired the designation of Technological Specialization Courses (TSC), granting Level IV of professional qualification through Technological Specialization Diplomas (TSD). The TSC are especially encouraged in sectors or areas in which the companies are strongly lacking competent technicians, giving the youths a larger warranty of immediate employability, after the conclusion of the apprenticeship.

The technological specialization courses are post secondary non superior level grades, that seek the acquisition of the IV level of professional formation, as defined by the n. 85/368/CEE Decision, of the European Council, of July 16, that was published in the n. L 199 EC Official Newspaper, of July 31st, 1985.

Level IV of professional formation is obtained through the conjugation of a general or professional secondary level formation, with a post secondary technical formation and it is characterized by:

- Being a high level technical formation;
- The resulting qualification includes knowledge and abilities belonging to the superior level;
- Mastering the scientific foundations of the different studied areas is not demand, in general;
- The acquired knowledge and abilities in this level allow the assumption of autonomous responsibilities in conception, direction or management.

These courses aim to join the formation and learning components to the job market demand. The materialization of these objectives is done not only by the promotion of partnerships between formation schools, higher education institutions, but also by involving business responsibles and employers, seeking to direct learning activities to effective professional insertion, and to assure actual recognition of the subjects learned for higher education studies pursuit purposes.

In the analysis of the Idea Proposals for the creation of new Technological Schools under PEDIP II (II Programa Estratégico de Dinamização e Modernização da Indústria Portuguesa), the second Strategic Program for the Dynamization and Modernization of Portuguese Industry, a concern emerged to use already existent infrastructures in order to make the best use of the incentives that they had been attributed previously, namely under the preceding PEDIP program.

On the other hand, most schools are not supported in autonomous infrastructures, and so larger operation flexibility is possible, including the continuous access to new technologies, methods and formation methodologies, through the celebration of collaboration protocols between Institutions, so avoiding the duplication of investments in the same areas.

This Specialization Courses present advantages for the youth: with strong technological component are lectured by competent technicians. Now are offered under cross collaboration among Technological and Professional Associations, such as AFTEBI, with institutions of the Portuguese Superior Level System, such as the Universities of Beira Interior and Minho, and the Polytechnic Institutes of Guarda, Castelo Branco and Viseu [5].

III. PARTNERSHIP "UNIVERSITY OF MINHO / AFTEBI"

AFTEBI is an Association for Technological and Professional Formation, created in 1997 in the interior center of Portugal, with 12 years of experience in the formation of intermediate level professionals for the industry in various knowledge areas.

The University of Minho (UMinho), founded in 1973, is located in the Minho region of Northern Portugal, a region with a strong tradition of entrepreneurship, essentially of small and medium-sized businesses. The University of Minho was strategically planned with the surrounding socio-economic environment in mind, aiming to contribute to its development.

By 2001 AFTEBI made an invitation in to the University of Minho to enlarge the activity of AFTEBI to the North of the Country. This partnership is now translated in several cooperation forms, formalized through protocols to encompass the following objectives:

- To take advantage of the University human resources (namely in pedagogic coordination of the courses and lecturing) and infrastructures (pedagogic facilities and equipments);
- For Prosecution of studies of the AFTEBI graduates in the 1st cycle superior courses promoted by the University of Minho.

Due to the large spectrum of formative areas in which AFTEBI is acting, not all of the Technological Specialization Courses are running in the North of the Country, but all of them are validated by the UMinho not only for studies prosecution, but more importantly, for scientific approval of the knowledge domains lectured.

Actually the intervention of UMinho has grown significantly in recent years, not only by the enlargement of the formation areas, but also by the number of students that attend the formation courses, as it may be observed in Fig. 1. and Fig. 2. Additionally, the employability rate of AFTEBI students, graduated in partnership with University of Minho (Fig. 3.) is high.

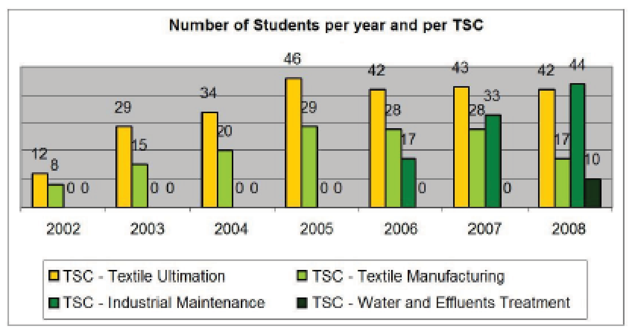

Figure 1. Number of Students per year and per TSC

A. Protocols

With the first graduates in 2003, a protocol of studies pursuit was signed, establishing the rules and molds for the graduates access the superior level courses promoted by the University of Minho. This protocol has been updated whenever any of the institutions introduced changes in their courses, the most recent update having happened in January 2008.

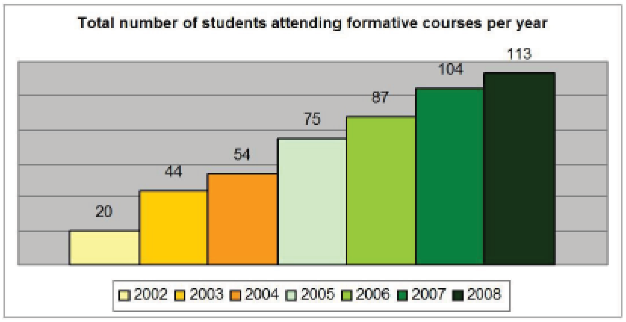

Figure 2. Total number of students attending formative courses per year.

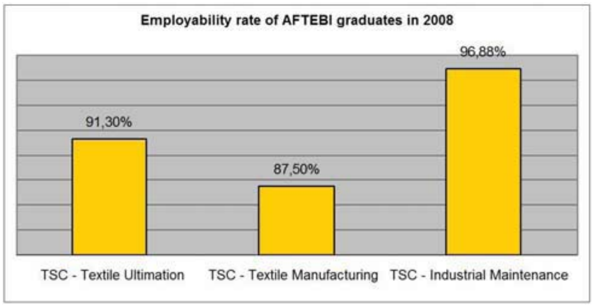

Figure 3. Employability rate of AFTEBI graduates in 2008

B. *Technological Specialization Courses*

In the year of 2009, the following Technological Specialization Courses were active:

- Textile Ultimation;
- Industrial Maintenance;
- Water and Effluents Treatment.

It is foreseen that the formation areas be kept in the outburst of the scholar year 2009/2010, with a probable replacement of the textile area by two possible courses to be promoted:

- Industrialization of Fashion Product;
- Fashion Commerce.

The decision will always be made in agreement with the expectations of the industrial area employers, because, besides the increasing youths' qualification and their pursuit of studies, one of the main objectives of this formation is the placement of intermediate professionals in the industry.

IV. Technological Specialization on Industrial Maintenance

A Specialist Technician in Industrial Maintenance is a professional that, autonomously or integrated in a team, makes the diagnose, prepares, plans out or accomplishes several tasks of corrective, preventive or "on condition" maintenance with the objective of guaranteeing the maximum readiness of the equipments and industrial facilities, for them to produce with quality and guaranteeing the execution of the production programs.

AFTEBI Technological Specialization Course professionals are graduated with a high level of technical specialization in the domain of the Industrial Maintenance (Fig. 4.) with a strong practical component in the areas of specialty of the mechanics, electricity, electronics and automation.

TOTAL		240	144	9	

Figure 4. Formative plan for Industrial Maintenance TSC.

The reinforcement of the technical capacity in these areas constitutes one of the fundamental objectives for the modernization of the industrial companies, and these graduates will be prepared to:

- analyze technical documentation of diverse nature (sketches, drawings, facilities' diagrams, manuals, manufacture catalogs, standards and procedures) relative to the equipments, systems or facilities of mechanical, electrical or electronic nature;
- execute outlines and drawings of facilities and connections electromechanical, electrical or electronic circuitry, as a support to the maintenance activity;
- prepare the tools, materials, components, and parts that are necessary for the development of the maintenance routines;
- execute the installation of equipments or systems of electromechanical, electrical or electronic nature;
- accomplish the operational, functional or officinal rehearsals in electromechanical, electrical or electronic equipments, systems or facilities, so assuring their conformity with the specifications of the project and quality standards;
- follow the performance of the equipments, systems or facilities of electro mechanical, electrical or electronic nature, in agreement with the established in the maintenance plan;
- propose modifications in equipments, systems or facilities of electro mechanical, electrical or electronic nature, taking in account the deviations between the rehearsal values and the pre-established parameters;

- execute interventions and to repair the equipments, systems or facilities of electromechanical, electrical or electronic nature in order to improve their operational characteristics;
- propose alterations to the layout of the systems, productive or operating equipment, with the objective of improving their performance;
- elaborate technical reports about the accomplished interventions;
- do maintenance plans, based in the historical reports of the equipments, systems or facilities of electromechanical, electrical or electronic nature;
- cooperate with the productive area, with the objective of optimize the resources and to reduce unproductive times;
- detect mistakes and technical deviations that may happen, to analyze them and to propose solutions;
- develop technical relationships with the suppliers of equipments, to analyze the adaptation needs of the technologies to the specificities of the company;
- analyze the equipment needs and provide their acquisition;
- promote and apply preventive maintenance practices.

By the conclusion of the TSC plan of formation, it is expected that the students possess a set of competences, not only at the level of the theoretical knowledge acquisition but also at the level of its practical implementation.

The TSC of Industrial Maintenance has the duration of 1560 hours 600 hours of which in industrial context. The formation has a strong practical component, 75% of the total hours of the course being supplied in laboratorial/officinal context. For this formation the facilities of the UMinho, of the Technological CITEVE (Centro Tecnológico para a indústria Têxtil e do Vestuário) – a Portuguese technological center for textile and clothing industry, and Industrial companies are used.

Students are stimulated to develop knowledge interests at the levels of know-how to do and know-how to be, seeking creativity and innovation. Also they are taught about industrial needs for workers with their profile in order to assure their own dynamic development, that collaborate by guaranteeing the apprenticeship of all the students that benefit in consequence of good job perspectives.

The Pedagogic Coordination of TSC of Industrial Maintenance, from the Department of Mechanical Engineering of the UMinho, is supported on a group of specialists and technicians of each area that come not only from educational system, but also from industrial origin. Program contents and methodologies are periodically checked and adjusted if needed with the objective of meeting the real needs of the industry. In Fig. 5 the part of the formation plan that corresponds to the Technological Formation is presented. In this map some notations are used, more precisely:

- in column (3) the total hours of work are indicated as defined in Portuguese Decree-Law n. 42/2005, from February the 22nd;
- In column (4) is indicated – among the total hours of work – the direct contact hours (with teacher), according the definition presented at point d) of the article 2nd of the Portuguese Decree-Law n. 88/2006, from May the 23rd;
- In column (5) is indicated – among the total hours of direct contact – how many hours are dedicated to practical applications, namely laboratory, workshops and/or Project according the point 2) of the article 15th of the Portuguese Decree-Law n. 88/2006, from May the 23rd;
- In column (6) is indicated the number of ECTS, complying with the European Credits Transfer System, according the Portuguese Decree-Law n. 42/2005, from February the 23rd.

Figure 5. Technological component plan for Industrial Maintenance TSC.

The main factor of success of this TSC is connected, fundamentally, with the vicinity of the industrial business and the correct detection of their need for intermediate technicians, and to the establishment of partnership protocols with Entities, Schools and Companies, that guarantee the high patterns of quality of the supplied formation.

The success of this TSC may be measured by these technicians' high demand in the industry being translated, consequently, in high employability rates.

V. DISCUSSION – TSC ON INDUSTRIAL MAINTENANCE

The industrial network of the north of Portugal is characterized by industrial companies of small or medium-size dedicated to the textile, mechanics, shoemaking and wood industry. These companies have been very active and versatile being competitive so far.

Nowadays, these industrial companies are object of profound changes due to the national and international situation, particularly related to globalization of the economy.

These companies are undergoing great transformations - from a situation where they based their competitiveness on non-skilled low cost labor – to a new reality where they must adopt a strategy to develop and produce innovative products with high level of added-value. In this context the technological formation of workers, more or less qualified, is the key for the success and especially the technological formation of well trained technicians for operating and maintaining the industrial equipments is crucial. These equipments are technologically sophisticated and allow the companies produce high added-value products. In this scenario, any technological formation course in Industrial Maintenance is, only by its existence, a guaranteed success.

The existence on a region like Minho (in the northwest of Portugal) of higher institutions (UMinho) and Professional Schools (ETT) and the cooperation work of those institutions for common objectives (improvement of the performance of the region's industry) based on their resources sharing (physical and human resources) is a strategic and useful service for the industrial companies, for the region's people and respective quality of life, and for the country.

The TSC on Industrial Maintenance of the ETT is coordinated, from the pedagogical point of view, by University of Minho. This fact brings the guarantee of the quality and success of the contents/programs of the curricular units that compose the formation plan. Also, some technological Curricular Units are assured by teachers from University of Minho. UMinho shares with ETT some teachers, highly qualified, for organizing and teaching some technological curricular units, related with key areas of Industrial maintenance field. This is, clearly, an added value for the TSC on Industrial Maintenance. Also, the knowledge of the industrial reality, by UMinho's teachers, is very important to adapt the pedagogical contents of the curricular units, directed to the real needs of the industrial companies. This solid knowledge of the industrial reality is the result of many years of cooperation between UMinho and industrial companies of the region.

Due to the teaching load, the TSC on Industrial Maintenance is specially focused on aspects linked with the practical application of the theoretical aspects of the studied maters. As these professionals are going to be – some of them – responsible for maintenance teams on their industrial companies, the theoretical aspects (even if 75% of the total hours of the course are supplied in laboratorial/officinal/industrial context) are carefully highlighted on their formation.

The aspects relied to Competence-Based Education [6] are highly considered during their formation. The concept of competence-based education may facilitate learning [7] in a society of rapid change and complexity. The solid theoretical formation and the posterior application on practice [8] gives, to these students after the conclusion of the TSC, strong skills on domains related with Industrial Maintenance.

Complementarily, on their formation, several areas like mechanics, electronics, informatics, automation and industrial robotics (Fig. 5) give, to these students, skills that are highly valuated and searched by the industrial companies. Commonly very good maintenance technicians may be found in the region, but their basic formation is on only one of the above mentioned areas. The fact that this TSC the formation has a solid and complete coverage, considering all the areas of the field of industrial maintenance, gives the trainees a basic formation with a high level added- value. Nowadays, more than in the past, the industrial equipments incorporate complex devices that interact between them, and any operator/maintenance technician that needs to interact/repair with these devices must have a complete and solid background at several and complementary fields related with Industrial Maintenance.

In the practical/training classes, as in the project developed in industrial companies, advanced teaching techniques are used [9], namely advanced formalisms and informatics tools in order to give the student a faster and more detailed description of the reality that they will find at work in real world. These tools are very important for level 4 technicians that are expected to assume, in a near future, responsibilities of leadership on their companies.

As a result of this reality, presented above, the students of the TSC on Industrial Maintenance are well accepted and searched by industrial companies and they reveal to have the necessary and adequate skills adapted to their needs.

But the real capabilities and skills of the technicians, that finish the TSC on Industrial Maintenance, are not only interesting for industrial companies. UMinho, too, is a possible choice for them, in order to continue their formation in the domain of Mechanical Engineering.

As a strategic University, UMinho intends to have the best students in all the domains. In the particular case of Mechanical Engineering - the possibility of having students with a practical background acquired and based on competence-based education concepts - highly focused on the Bologna declaration [10] becomes interesting to attract this students, namely the best ones of the TSC on Industrial Maintenance, for their graduation on Mechanical Engineering domain.

As a formalization of this idea the agreement signed between UMinho and AFTEBI considers this possibility and allows the access - to the Integrated Master on Mechanical Engineering of University of Minho - of the five best students of the TSC on Industrial Maintenance. This agreement respects and is in accord with the Portuguese Decree-Law n. 88/2006 of May the 23rd. This Decree-Law defines the rules for the TSCs and provides the possibility, for the students that finish their TSCs, of continuing studying on Higher Education Institutions.

The selection of the students, for accessing the Integrated Master on Mechanical Engineering of University of Minho, is done taking into account the average classification that they have obtained in the end of their TSC on Industrial Maintenance. Recognizing the previous quality formation of the students, it is, also, previewed the possibility of some equivalences of Curricular Units, when the students are admitted to the University. The actual decision any possible Curricular Unit equivalence belongs to the Director of the Integrated Master on Mechanical Engineering and it is regulated by the point 27th of the Portuguese Decree-Law n. 88/2006 of May the 23rd. This decision is taken, from an objective point of view, mainly based on the analysis of the students' curriculum. This possibility of equivalences is one important point to motivate the best students to pursuit their studies in the University.

In the scholar year 2008/2009 the five places available (for the Integrated Master on Mechanical Engineering of University of Minho) were completely taken and concurred, for these five places, twelve students. That shows the interest, of the students, for continuing their studies on the University and the utility of this strategy to attract different publics for Higher Education Institutions.

Being this year the first year that the experience is carried out, the first semester evaluations show that these students have had satisfactory results. A more complete evaluation, about the performance of these students, will be done in the final of the first year; until now, it was not possible because the first year is running. Moreover, the first conclusion that can be confirmed is that these students – because they have a basic background on several domains, related with mechanics, electronics, informatics, automation and industrial robotics – have more facility to understand some aspects and concepts related with the domain of Mechanical Engineering, when explained to them by the first time, and when compared with the other students that have not this basic background. It must not be forgotten that this students, despite having a basic background on several technological fields, are performing students too (they were the best of the TSC on Industrial Maintenance) and they can be an added value for the respective industrial units, after their graduation.

VI. The Role of University in the Post–Secondary (non superior) Level Teaching

The model so far presented is still in its earlier implementation days. Concerning the particular case of the UMinho/AFTEBI partnership in Industrial Maintenance, only two courses have been completed, and a third is going to finish this year. Anyway a discussion may start about the role that the High Education institutions are expected or should play in the definition and support of the post-secondary training/educational activities. Also it may be important to widen the look to the entire educational system, with particular emphasis in the developing technological subset that nowadays is growing under the umbrella and support of ministries other than the Education Ministry, like the Ministry of Labor or the Social Affairs, alongside with the conventional educational system, ruled by the Education Ministry.

In despite of the equal opportunities rhetoric of the late seventies that lead to technical formation disaster in Portugal, the technical courses made their way simple because they are a basic need in a developed society.

The experience reported above is only one case in the Portuguese reality nowadays. Different social and technical environmental realities must certainly be encompassed by different solutions, and the risk of wrong decisions is also diminished by the diversified offer that can be designed this way.

The University may act in diversified grounds in respect to the learning/teaching activities. As a matter of fact it must be stressed that the University is responsible for the scientific preparation of the bulk of the teachers of the system, but the research activities committed to the Universities in Portugal are also responsible to foster development, in particular in technical issues. Any discussion about technology, at any level, should involve the main actors in the country, either from the side of the end users of the skills (the companies), from the producers of knowledge (Universities and Polytechnic Schools) and also from the providers of trainees and ultimate beneficiaries of the system (the society).

According to IQF, (Institute for Quality in Formation) this learning model must be structured in a group of phases, processes and support instruments from the conception of programs, courses and pedagogic solutions, that can be explored and used in different ways, that is, as a function of the needs and readiness for the entities and professionals that intervene in the formation.

The formation including apprenticeship in context of work, guaranteed by the Schools through a Pedagogic Coordination of the courses that contacts and selects the housing companies, usually interested in the technicians under formation given is a guarantee not only to employment, but also to adequate choice of qualifications to be acquired.

The diploma obtained in the technical courses engaging the possibility of accessing Higher Education Studies, granted by written agreements between the institutions involved, allows an alternative via to access higher level. This alternative may lead in future to a more equilibrated choice at the lower levels, by defusing the anguish of a precocious decision.

As a potential receiver of the trainees that may want to proceed studying and taking in account that some formation credits acquired in the Technological Courses may be considered for prosecution proposes, the University must be involved in the actual design of the courses.

However limited nowadays, the number of student positions offered by the University may increase as the Courses become more consolidated and recognized by the society.

The issues linked to the evaluation, seem to be fundamental for the understanding of the effective role of the formation while instrument of development, according with Lima Santos and Pina Neves [11] . It assumes special importance in the materialization and regulation of the formation actions from the evaluation being a systematic dynamic and intrinsic process, to the formative process, contributing to the promotion of their global success

The formation must be conceived from the start considering the needs, to design the formative proposal, to organize the pedagogic sequences, in order to bring together the technical and pedagogic resources and to prepare support equipments.

In this context, Parry [12] referred that a formation activity performed well happened when "the right trainees (taking in account the process of selection made) develop the knowledge, the competences and the necessary attitudes (contents of the formation), through means, strategies and appropriate teachers (process), in a certain time and in a certain space (context), fulfilling the initial expectations (…) (objectives and expected results for the acting).”

VII. CONCLUSIONS

Among the reasons motivating the efforts of launching and supporting technological specialization courses, the most important is undoubtedly the high number of skilled people that is needed every year and that must undergo a training process.

It is well known that experience improves performance. Although the amount of experience needed to achieve a certain level of performance varies with the individual and personal characteristics, some experience is always desirable.

Creation, improvement and/or adaptation of methodologies that improve adequacy to the needs felt by the companies will not only improve the employment rates among youngsters, but also may allow to minimize or overcame the inadequacy of skills occurring due to technical knowledge change.

In this context, the TSCs provide some solutions:

- From the student's point of view, a better formation by the end of the secondary level is provided, enlarging the capacity to access the Job market;
- From the companies' point of view, the availability of new graduates enlarges the access to a more qualified work force;
- From the formation schools point of view, as for instance AFTEBI, the accomplishment of its mission results in a better and wider professional formation of a larger set of people;
- From the higher education Institutions (like the UMinho), the contribution to the quality improvement of the technological specialization courses of (through their pedagogic coordination) and by the attraction of its best students for continuation for superior studies in a very important area for any developed country, engineering;
- From the national point of view, the creation of conditions to improve the technological capacity of the country and also a sustainable development of the Portuguese society (either at the level of the companies by the availability of more specialized technicians, or by the fact that some of them may access higher education, that, otherwise, would not be possible).

The University must be involved with the forming entities and the companies in the definition of the global objectives to reach and activities to develop, and also in the assessment of the Courses, in order to assure the technical quality of the formative proposal, its coherence and robustness.

***Abstract*— Bioengineering, a relatively recent engineering branch, was launched 24 years ago in Argentina at our university (Universidad Nacional de Entre Ríos). The undergraduate program aims at providing solutions to health problems through the application of advanced technology. Consequently, a highly skillful professional is required. However, learning deficiencies and difficulties have been observed among first year students. Action Research was chosen as a research tool to generate new approaches to teaching mathematics in Bioengineering.**

Keywords: Biomedical Engineering Education – Action Research – Teaching/Learning Mathematics for Bioengineering Introduction.

I. Introduction

This paper accounts for the origins, objectives, methods and first results of an Action Research project concerning the teaching of mathematics to future bioengineers. The project is being carried out within the bioengineering undergraduate curriculum at the Faculty of Engineering (Universidad Nacional de Entre Ríos). Biomedical Engineering or Bioengineering is a recently developed Engineering branch. In our country it was launched 24 years ago at our University in order to provide solutions to health problems through the application of advanced technology. Consequently, a highly skillful professional is required with solid mathematical background, for example in the field of technology applied to imaging diagnostic systems such as computerized axial tomography (CAT) which relies on the inverse Radon transform. Mathematics also interacts with Computing and Biology in the modeling and simulation of human organs, computer assisted surgery, tumor growth and the immune system modeling, prostheses design and other health related areas. On the other hand, technological changes in all areas related to the engineering field occur at a great speed. In Latin American countries, both established and modern techniques are in use, so universities must offer courses of study designed to develop creative engineers capable not only of understanding the new technologies but also of adapting them to the true needs of society. Bioengineers should also be prepared to develop innovative systems and techniques while interacting with specialists from other disciplines without losing sight of the economic, social and environmental impact of their developments. There is general consensus, thus, that Engineering undergraduate teaching courses, especially Bioengineering ones, should provide the students not only with solid background knowledge, but also facilitate the development of cognitive, metacognitive, affective and social learning strategies to foster learner autonomy and critical thinking which will serve to evaluate information and lead to continuous learning. From this analysis, it is clear that the Mathematics courses in the Bioengineering curriculum (See Table I) must be planned in such a way not only to foster the acquisition of the necessary mathematical concepts, procedures and methods to cope with the subjects in senior years, but also to contribute towards the development of abstraction, and of critical and reflective thinking.

TABLE I.

Year	First Semester	Second Semester
First	Calculus	Linear Algebra and Analytic Geometry
Second	Vector Calculus	Differential Equations Statistics
Third	Functions of a Complex Variable	

a. Mathematics Courses in the Bioengineering Curriculum

As a result, a strong emphasis should be placed on learning to learn Mathematics This means that the student should be involved in a process of discovery about learning the general mathematical abilities so as to be sufficiently equipped to face the study of new areas of this discipline according to his/her needs and interests in the future. In furtherance of this, it is necessary to adopt a learner-centered approach to stimulate the development of such abilities. Far from being a passive subject, the student will have an active role in the teaching-learning process. Although the members of this research team agree with this point of view, designing and implementing new teaching and assessment tools is far from being an easy task for the Mathematics teacher in charge of the course corresponding to the first years of the Bioengineering curriculum. Generally, the groups are numerous and students come from different parts of the Entre Ríos province and from other provinces of our country. Consequently, the mathematics background after high school is diverse. However, this may be taken on as a challenging situation by the teachers.

II. MOTIVATION

Two opposing issues triggered this research project: on the one hand the demanding professional requirements imposed on bioengineers and the goals of the mathematics courses in the curriculum mentioned above and, on the other, the complex issues concerning students who enter our university program.

The difficulties that bioengineering students face during the first years of the course of study have been a cause for constant worry at our college. An analysis of withdrawals shows that different factors interact to influence this complex phenomenon: homesickness, vocation conflicts, socioeconomic problems, insufficient schemata, poor or bad study habits, among others. In the mathematics class, there is evidence of problem-solving, reading comprehension and academic writing problems that are then reflected in low marks. During the past five years, more than 55% of the students were bound to retake the course. This situation raised a series of questions that encouraged this research project: In our role as teachers in the Bioengineering curriculum, do we foster critical reflection on our students' learning strategies? Can we design and use didactic strategies in our classroom to enhance reflective reading and writing and to generate motivation, draw students' attention to the comprehension of concepts and encourage their active, reflective and critical participation during the mathematics teaching-learning process?

These worries were the starting point for the formation of an interdisciplinary group whose members study the above stated problems in a group of second-year students who are taking the subject Vector Calculus and Differential Equations.

III. METODOLOGY

Action Research was chosen as a research tool to carry out our project. The term "Action – Research" was first coined by Kurt Lewin, a social psychologist, in about 1947 [1]. Lewin's research method was not aimed specifically at education but at social practices in general. During the '70s, researchers from Great Britain and Australia put forward an alternative education research paradigm based on Lewin's model. Both John Elliot and Lawrence Stenhouse in Great Britain and Stephen Kemmis in Australia sought new ways of producing knowledge not only about the teaching-learning process but also about curriculum development and implementation [2], [3], [4]. In Latin America, the lines of enquiry developed by Paulo Freire, Orlando Fals Borda and Joao Bosco Pinto emphasize popular and informal environmental education [5], [6]. Currently, Action Research as a movement has gained strength in many countries such as Great Britain, Australia, the United States, Canada, Spain, Germany, Austria, Brazil, Colombia, El Salvador and Argentina, among others.

These lines of enquiry focus on different aspects. According to Elliott, Action Research explores situations in which teachers are involved, a sort of teacher initiated form of classroom based research aimed at improving practice. Wilfred Carr and Stephen Kemmis believe that the aim of Action Research is far from finding general pedagogic formula. Thus, it does not make any claims for universal relevance. Instead, its essential impetus is to change the system. And, as it is primarily situational, it is concerned with the solution to problems in a specific context. Action Research conforms to what is generally called active research related to the need of education quality enhancement in a specific context [7].

This is why active participation is a key element in Action Research as it offers a valuable opportunity for teachers to be involved in research which is felt to be relevant. Furthermore, as it is grounded in the social context of the classroom and the institution, it may focus directly on issues and concerns which are significant. From this point of view, every teacher is a researcher because this method is not so much something that can be done in addition to teaching but something that can be integrated into it. As a result, during the research process, teachers become involved in thinking about their own teaching which ensures continued professional development and enhances competence.

Action Research can be defined as the study of a situation in order to enhance action in the community. In this particular case, our community is formed by:

- Students in the second year of the Bioengineering curriculum who are taking Vector Calculus and Differential Equations.
- Teachers with different graduate and postgraduate professional formation (engineers from different fields: electronics, electricity, chemistry, bioengineering, with postgraduate studies in diverse areas including informatics, and mathematics teachers with postgraduate studies in education).
- Teachers who carry out Vocational Orientation and Pedagogic Counseling, a service that was created in 2004 as part of the Academic Department, and teachers from the Languages and Social Sciences Department. These members of the group are specialists in Education and Languages. They are or have been in contact with the second year students on occasion of the counseling workshops for freshers, the English as a Foreign Language courses, and other courses to develop Reading and Writing skills.
- Advanced students who cooperate with the mathematics teachers.

The first step the research group took was to discuss and establish the goals of the project:

- To reflect on our teaching practice aiming at introducing principled change to the teaching-learning process in our mathematics course as part of the Bioengineering curriculum.
- To identify needs concerning our professional formation, thus ensuring continued professional development and enhancing competence in topics related to mathematics and their specific application to Bioengineering.
- To plan our continued professional development in pedagogical aspects that will offer tools to analyze and interpret the professional situations in which we act and make informed decisions accordingly.

- To foster interdisciplinary work among scholars belonging to the Mathematics, the Social Sciences and Languages Departments and the Vocational Orientation and Pedagogic Counseling Service of our faculty.
- To encourage the active participation of the students in Vector Calculus and Differential Equations classes in order to stimulate the development of a responsible attitude towards the learning process which will, eventually, generate an atmosphere for meaningful learning.
- To plan and implement activities that contribute towards the development of learning strategies the student will use in a conscious, reflective and effective manner.

IV. Design and Implementation

Action Research is structured in spiral cycles which are divided into four classic developmental phases: the initial exploration phase, the planning phase, the action phase and the reflection phase which generates a new research cycle [2].

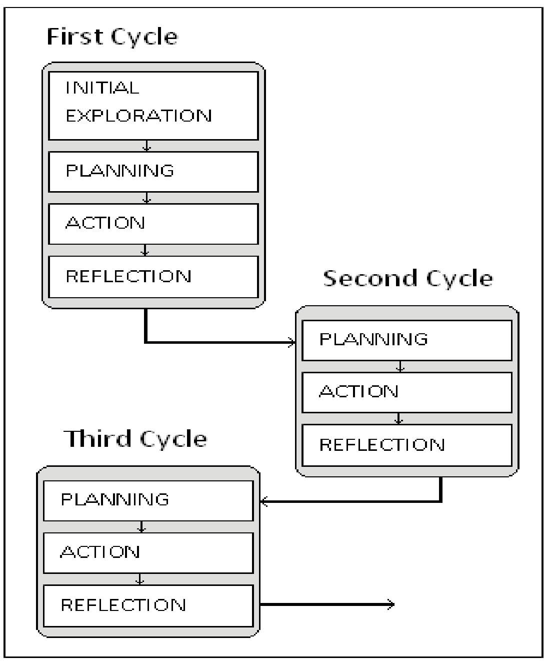

Figure 1. Action – Research Cycles

A. Initial exploration and conceptual frame of reference development.

The number of variables and circumstances that affect the teaching-learning process is significant. Thus, it is absolutely impossible to keep complete control over this complex whole. The first step in our project was to identify a problem and pose a specific question. We were confronted with the following dilemma: which aspects of the teaching-learning process are the most troublesome? We agreed that assessment is, doubtless, one of the burning issues in the process.

Traditionally, assessment in the Vector Calculus and Differential Equations courses has been carried out by means of term and final tests. The former have focused only on practical exercises while the latter deal with both practical and theoretical issues independently. The great number of students in our courses and Mathematics distinctive characteristics have led us to decide on administering written tests. Only on seldom occasions does the student sit an oral exam. We have noticed that students generally postpone study time to the last minute and the mistakes committed in the tests provide evidence of lack of conceptual and methodological comprehension. Furthermore, many students prepare for assessment solely through solving previous tests. This problem area led us to focus our enquiry on assessment.

Reflexion on our assessment techniques to brainstorm possible questions was the next step taken. Why do we assess this way? What do we assess? Which underlying rationale about teaching and learning Mathematics can be traced according to our assessment criteria? What other learning assessment criteria exist? Are there reports on recent research projects concerning these problems? These questions guided our research and helped to design a reference frame that served to redesign assessment.

According to Díaz Barriga an exam cannot improve the learning process by itself. The fundamental change must be carried out in the methodological strategies [8]. But those strategies cannot be designed without delving into the different principles that guide decision makers. The design of this conceptual frame was a long and complex process that brought about both agreement and disagreement among the members of the team with varied professional formation.

We finally agreed to synthesize criteria from Pedagogy, the didactics of Mathematics, and Cognitive Psychology that we have adopted as underlying principles that will inform the methodological changes and the redesign of learning assessment tools in our course:

- We adhere to a constructivist approach because it highlights the importance of understanding the knowledge construction process.
- In this particular context, our role changes from teachers to facilitators. That is, we do no longer merely transmit information to the class. Instead, the teacher must learn to act as a mediator that helps the student develop a set of cognitive skills that will enable the optimization of his / her reasoning skills (teaching to think) and favour mental strategies and processes awareness (metacogntion) in order to enhance learning (teaching about thinking) [9], [10], [11], [12]. Knowledge of metacognition was first developed in research on memory. Flavell (1971) first used the term metamemory, and later the term metacognition comprised metacognitive skills like monitoring and regulating cognitive processes [13] .
- We believe assessment is part of the teaching-learning process. It should promote learner autonomy and

responsibility. It is necessary to opt for assessment criteria that stimulate not only content learning, but also thinking processes and the development of metacognitive skills to assure students' awareness of the processes that have taken place, the mistakes committed, the learning strategies used and the difficulties encountered during the learning process [14]. In other words, our option is 'formative assessment' [15], [16], [17]. Moreover, apart from being a technical process, assessment is also a moral phenomenon and has an ideological and social component [18], [19].

B. Planning actions

From this point of view, we agree with Biggs in the sense that being a good teacher has much in common with being a good material designer. Good tasks should motivate the student and encourage him / her to reflect on his / her own learning process [20].

Once we had agreed upon our reference frame, without modifying neither the set amount of weekly face-to-face meetings for the courses (7 hours in the first semester and 8 hours in the second), nor the minimum contents for the subjects, the meetings took on a new whole meaning.

Traditionally, three weekly classroom activities were carried out in the following order: theoretical classes, discussion sessions, and practice sessions. The incorporation of assessment and metacognition activities was planned in the following way: The teacher presents the didactic unit in the theoretical classes by means of problematic situations to raise motivation among the students. Didactic questions are used to effectively diagnose the weak points concerning background knowledge.

When new concepts are presented, the teacher highlights the relationship between these and both prior knowledge and topics to be dealt with in future lessons or in other subjects in the curriculum. Definitions, properties and fundamental theorems are constructed collaboratively. A weekly study guide in which the goals of the unit are clearly set is presented to the students. It also includes a full bibliography and suggested readings[1], activities to be carried out during the discussion session and the weekly report to be discussed in the practice session.

During the discussion sessions some theoretical concepts presented in the theoretical class are dealt with more deeply by means of the analysis of selected demonstrations of formative value. This class aims at offering the student a space to carry out individual or group work using the suggested text and the weekly guide in order to clear up doubts and discuss mistakes while discussing demonstrations and examples. These activities also help to develop study strategies using Mathematics text books.

1 The texts used are: "Multivariable Calculus" by James Stewart, "Differential Equations with Boundary-Value Problems" by Dennis G. Zill and Michael R. Cullen.

This sequence of activities (see Table II) allows for a shift of the pendulum from a teacher-centered classroom to a more learner-centered one where students gain protagonism under the guidance of the teacher.

Classroom Activities	**Methodology**	**Assessment**
Theoretical Classes	Teacher presentation. Didactic interrogation.	Diagnostic assessment
Discussion Sessions	Group work with teacher participation. Discussion of demonstrations and examples. Integrative explanation carried out by the teacher.	Formative assessment Detection and correction of mistakes.
Practice Sessions	Students presentation of the weekly report. Integrative presentation carried out by the teacher.	Formative assessment. Self-assessment Peer-assessment

b. Activities.

The activities in the practice sessions are, thus, focused on the students. In furtherance of this, two types of activities are designed: the weekly report and the laboratory tasks.

What is the weekly report? In the theoretical class, the teacher presents the weekly guide in which the problems sections in the reference text are indicated. The sections correspond to the topics previously dealt with in the theoretical class and the discussion sessions. The selected exercises and problems are those that demand the application of different mathematical procedures and that are also related to other subject areas such as physics or biology. Between ten and fifteen problems are suggested, out of which five must be solved before each practice session using the text that was previously read in small groups and after having studied the corresponding theoretical background. A record of this activity must be kept in a weekly report in the following way: for each problem, the student must write the enunciation, the data provided, he / she must indicate its objective and explain the mathematical procedure(s) used to find the solution even if the attempt(s) failed.

At the end of each exercise, the student is asked to answer the following questionnaire: What new concepts or properties did I use? In what section and page of the textbook are they? Did I have to consult extra bibliography? What concepts from other subjects did I apply? Did I face any difficulties? Which ones? How did I try to solve them? Did I understand the concepts I used? Can I express them? What doubts do I still have?

The aim of this activity is to encourage a reflective attitude in the students, to promote the development of metacognition skills, to favour self-assessment habits and to promote learner autonomy. It enables us, teachers, to detect doubts and to act accordingly. As a result, the practice class is designed for students' full participation. They solve the problems presented in the weekly guide on the board, indicating the corresponding theoretical justification for each. If a student fails to solve any of the exercises, he / she is asked to mention the obstacles encountered. The teacher's task during this activity is to create an atmosphere of respect among students so that they can express their doubts without fear. This will favour both error correction and peer-correction, as well as making suggestions on the way the explanation was done. The teacher will do those exercises that present most difficulties to the group and will put forward others he / she considers appropriate for the students to solve in class individually or in groups in order to clarify concepts and methods.

The second activity is Computing Laboratory Tasks. Two integrative tasks are set for each semester. The teachers explain the rubrics of these tasks before presenting the corresponding topics. The students have the freedom to decide when to do them in a group of no more than three students. The only constraint is due date which coincides with the test corresponding to the same topic. In this way, carrying out the task will contribute towards learning the topics that will be assessed. These tasks also aim at taking advantage of software numeric, graphic, symbolic and calculus potentiality. To solve these, general mathematical procedures that contribute to the professional development of an engineer must be applied, i.e. modeling, graphic design, calculating, comparing, algorithmizing, solving, interpreting. Moreover, the student must apply definitions, formulate hypotheses, and refute linking theory to practice and to the applications proper to Bioengineering which are desirable in a second year student.

During the semester two integrative term tests that delve into theoretical and practical problems are carried out. One is administered mid-term and the other at the end of the semester. Vector Calculus and Differential Equations are courses whose accreditation is subject to the following conditions: a) presentation of 80 % of the reports carried out for the weekly practice session; b) marks corresponding to 80% (average) in the Laboratory Tasks; c) marks corresponding to 80% (average) in the term tests. Those students who fail to fulfill these requirements must sit a final exam (theory and practice).

C. Action

This planning was carried out for the first time during the development of Vector Calculus and Differential Equations courses in 2008. During the first semester, 66 students attended the course.

D. Reflection

To know the opinions of the students about the activities carried out during the course, the following survey was administered:

1) *Did you become engaged with this activity?* 85% of the students answered affirmatively.

2) *How much time during the week did you devote to the activity?* According to the answers, the average time devoted to carry out the activity was 4 hours (minimum 2 hours and maximum 10 hours).

3) *Have you formed a group to carry out and discuss the problems or do you prefer to work individually?* 36% of the students responded that they worked individually while 52% prefers to solve problems with a classmate.

4) *Have these activities helped you regulate your study time adequately? Yes?, No?, Explain.* 79% answered that the activities helped to "study the subject regularly which was positive when preparing for the term tests", "take advantage of the theoretical and practice classes", but some felt "it was an extra obligation to carry out the activities and assumed it as a burden". 21% explained that although they tried to complete the weekly activities at the beginning of the semester, they eventually could not sustain the rhythm. In some cases, they explicitly acknowledged that they needed to work at a slower pace than the one the subject syllabus imposes.

5) *How do you value this experience as a means to promote effective learning? Has it helped you detect and correct mistakes (conceptual and procedural ones)?* 85% of the students considered that the experience was useful and necessary because it helped them understand concepts and correct mistakes; 15% considered that is was not positive, especially because it did not respect individual rhythms as it is time consuming.

6) *Mention positive and negative aspects of this activity.* Some of the answers concerning positive aspects were: "I learnt how to study Mathematics better", "**we** worked more", "it helps to study day by day", "it helps to realize which are our doubts and clear them up in class", "it helped me realize that it's very advantageous to be constant", "it helps to study", "when we solved problems in previous years we were not obliged to think", "interesting and productive for the development of effective learning", "it helps me understand the topics", "it provided me with a way of studying". Students perceived the following pitfalls: "individual rhythms are not respected", "it's an extra burden", "it reduces time to study other subjects", "timetables to consult the teachers are insufficient", "there is no time to study a great variety of cases".

At the end of this first experience, the teachers in charge of the practice sessions expressed: "almost no students come to class without having tried to solve the problems", "the questions students ask are much more to the point", "gradual and continuous learning can be observed, some go deeper into the concepts studied in theoretical classes and discussion sessions". As regards the negative aspects and / or difficulties faced during the experience, some teachers said: "it is difficult to distribute time between monitoring individual work and group discussions to explain topics in which the whole group has problems", "the great amount of students per group makes personalized monitoring difficult".

Despite students' positive perception concerning the experience, we have noticed a strong resistance towards completing the questionnaire at the end of each weekly report problem. In many cases, this is due to the fact that many students believe it is "a waste of time", while others do not achieve to identify their difficulties. On occasions they say they have understood the concept, but the mistakes committed prove that it is quite the opposite. This is one of the aspects to be examined in future cycles of the project.

V. Results and Conclusions

The results of the 2008 academic year were good as only 11% of the 66 students who had enrolled in Vector Calculus had to retake the course, 30% passed the subject without sitting a final exam and 59% will sit the exam. At the end of the second semester (Differential Equations), 17% will have to retake the course, 43 % will sit a final exam, and 40% passed without having to sit it. As it was stated at the beginning of this paper, during the last five years 50% (average) of the students had to retake the course. This is why we consider that our project has brought about an opportunity for advancement. We should not forget, though, that both groups and context change year after year so it will be necessary to carry out adjustment cycle after cycle.

The analysis of the written material provided by the students and their weekly oral presentations are a source for obstacles detection. The lack of schemata to learn new topics is a constant problem. In many cases, the students themselves identify the topics that were not sufficiently dealt with in high school or during the first year of the university curriculum. Although some students offer resistance against completing the questionnaire in the weekly report, we still have the moment of the oral presentation or even a personal interview to complete that missing information.

We now have documented information which was regularly and systematically obtained that serves the purpose of working on different aspects of the teaching-learning process such as the articulation between the Mathematics Department chairs. As regards the Computing Laboratory tasks, students have responded with enthusiasm to these activities and the teachers have profited from the knowledge of other specialists teaching in the senior years such as the Biomechanics teacher who helped to find suitable and motivating problems for our students.

For the Mathematics teachers in the research team, it is an enriching experience to work together both with education professionals and Bioengineering specialists because their specific use of the language and their different points of view contribute towards our professional development. But this is only the beginning of a spiral process. New hypotheses have arisen to continue the process and to overcome the system's natural opposing forces

As we have tried to show in this paper, Action Research is a means for teachers to carry out both methodological and assessment changes to classroom practice according to the reference conceptual framework we designed and through which we can evaluate such modifications. In this sense, we consider it is a valuable tool for the professionalization of university undergraduate teaching.

Abstract—**Educators need to know how to motivate information-management (IM) students (i.e., future business practitioners) to learn and use project management, which can provide the practical skills necessary for IM professionals to analyze data and make decisions. This case designed a platform of game-based learning for IM students' studying based on course of project management. Using a sample of 54 sophomores in Taiwan, a modified TAM model, self-efficacy and flow experience in playfulness were examined using experimental design and causal analysis for learner's attitude and behavior. A knowledge test is conducted to inspect the learning performance with platform support. Test results present higher performance in posttest than in pretest. The empirical results show that self-efficacy has significant, positive effects on perceived usefulness; but not significance on perceived usefulness. Perceived ease of use is positive influence on perceived usefulness on flow experience. In addition, it was found that perceived usefulness and perceived ease of use, positively influence IM students' attitude to use game-based learning platform, and flow experience not significantly effect on attitude to use game-based learning platform, whereas attitude toward game-based learning platform has a significant, positive impact on behavioral intentions, and the behavioral intentions has positively significant impact on actual platform use based on course of project management. Both theoretical and practical implications are discussed in this paper.**

Keywords-game-based learning; project management; perceived usefulness; perceived ease of use; self-efficacy; flow experience

I. INTRODUCTION

One of the challenges of designing game for increasing the study interest is that of engaging IM students. Hosting a course should not just be about the individual teaching but also facilitating IM students' learning interest and experiences. Unfortunately, it seems that the individual teaching is used mainly as the information distribution channel that neglects the needs of IM students. To achieve IM students' attention, new ways to utilize game-based learning based on project program must be found. The use of technology alone does not motivate students that have lived in the midst of technology. Thus, learning situations and methods that engage learners must be created. One approach is to design the game-based learning platform based on project management in education. Computer games may create a new learning culture that corresponds better with undergraduate students' habits and interests.

Traditionally, games are equated with having fun. However, the fun factor is not the magic bullet in educational game design. The promise of educational games is to engage and motivate players through direct experiences with the game world. Games should provide possibilities for reflectively exploring phenomena, testing hypotheses and constructing objects. Games have been used in education primarily as tools for supporting the practice of factual information. The nature of action-based drill and practice games may lead to behavior, where players tend to try actions with no reflection on outcomes. In such games players may simply keep on experimenting with actions until the scores improve.

This paper emphasizes the need for integration of flow experience and self-efficacy, and modification of technology acceptance model (TAM) to be able to design meaningful and engaging educational games. These theories show that the self-efficacy, perceived usefulness, and perceived ease of use, flow experience, attitude, and behavior intention can predict students' behavior. The main purpose of this paper is to examine what perceived factors contribute to the game-based learning intention in order to generate an optimal learning experience for students maximize the impact of educational games.

II. LITERATURE REVIEW

Hasan [1] discussed extensions to previous research on computer self-efficacy (CSE) and systems acceptance by examining the impact of multilevel CSE on IS acceptance. Hus and Lu [2] applied the technology acceptance model (TAM) that incorporates social influences and flow experience as belief-related constructs to predict users' acceptance of on-line games. The results reveal that social norms, attitude, and flow experience explain about 80% of game playing. Kim [3] investigated the factors influencing the usage and acceptance of the mobile game in Korea, based on the extended version of TAM. Hasan [1] examined the effects of general and system-specific CSE on perceived ease of use, perceived usefulness, and behavioral intention to use a system based on TAM. Ha et al. [4] extended TAM to include an emotion variable and measured the moderating effects of gender, age, and prior experience on game adoption. Teo et al. [5] extends

This work was supported in part by the National Science Council of Republic of China under Contract No: NSC 98-2511-S-366-003 to Tsung-Li Wang.

TAM framework, with subjective norm and facilitating conditions acting as external variables and showed that perceived usefulness, perceived ease of use and subjective norm were significant determinants of pre-service computer attitudes. Hsu et al. [6] provided the practical skills necessary for giving the students' study motivation. The empirical results showed that both computer attitude and statistical software self-efficacy have significant, positive effects on perceived usefulness. Moreover, Liu et al. [7] integrated framework: TAM, flow theory, and media richness theory on e-learning. This study revealed that perceived ease of use was a predictor of perceived usefulness; both the perceived usefulness and the attitude of the user were predictors of intention to use.

TAM is an adaptation of the theory of reasoned action (TRA) from psychology specifically tailored to model user acceptance of information technology. To provide an explanation and prediction of the determinants of IT usage, Davis [8] used the cost-benefit paradigm and self-efficacy theory to propose two influential beliefs: perceived usefulness and perceived ease of use. Perceived usefulness is defined as ''the degree to which a person believes that using a particular system would enhance his or her job performance'', and perceived ease of use as ''the degree to which a person believes that using a particular system would be free of effort''. According to TAM, the system usage is determined by individuals' attitudes toward using the system and perceived usefulness. Meanwhile, attitude toward using the system is jointly determined by perceived usefulness, perceived ease of use, self-efficacy, and flow experience. Hence, the hypotheses are stated as follows:

H1a: Self-efficacy will have a positive effect on perceived ease-of-use of a game-based project management learning platform.

H1b: Self-efficacy will have a positive effect on perceived usefulness of a game-based project management learning platform.

H2: Perceived usefulness will have a positive effect on attitude to use game-based project management learning platform.

H3: Perceived ease-of-use will have a positive effect on perceived usefulness of a game-based project management learning platform.

H4: Perceived ease-of-use will have a positive effect on behavioral intention to use game-based project management learning platform.

H5: Perceived ease-of-use is positively related to flow experience of game-based project management learning platform.

H6. Flow experience is positively related to attitude toward game-based project management learning platform.

H7. Flow is positively related to intention to use game-based project management learning platform.

H8: Attitude has a positive effect on the intention to use game-based project management learning platform.

H9: An individual's intention to use game-based project management learning platform will have a positive effect on that actual usage behavior.

Among the latter is a study of learner acceptance of game-based project management learning platform among students. We thus reviewed the definition of existing theoretical determinants, presented new constructs affecting the TAM, and hypothesized. Based on the theoretical review, an amended technology acceptance model as shown in figure 1 will be tested.

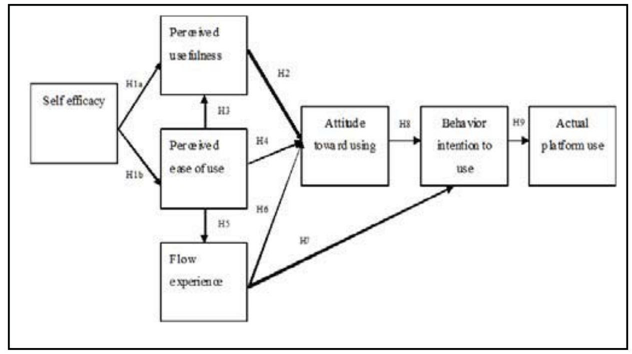

Figure 1. The Research Model of Game-based Project Management Learning Platform

III. RESEARCH METHODS

A. Course of Project Management

Project management based on challenging questions or problems is a complex task, through the student's design, problem solving, decision-making or action of research to give students a period of time engaged in self-related work, and the completion of a real product or report [9. 10]. Students in the project management can acquire new knowledge and skills through process of design, training courses and outcomes of products. As the number of aforementioned complex phases in project management, this study focuses the task of decision-making in project management as a lesson unit for teaching experiment.

B. Game-Based Project Management Learning Platform

In this study, game-based project management learning platform is to assist learners learning project management through the computer network game. The operational flow in the platform is divided into practice phase and exam phase. There are two game features were designed in two phases, including the reward / incentive mechanisms of practice phase and peer progress prompt of exam phase. In the practice phase, the more bonus points that learners earned from platform according to the earlier completion of their problem solving. Platform also popup message of encouragement to increase learner's confidence while they reply a wrong answer. In the exam phase, the platform announces the answer progress of each learner on other learner's screen to form a context to increase competitive play among learners. To contrast with the game-based project management learning platform, e-learning platform is usually not usually to emphasis on providing the functions like peer progress prompt, only to provide web-based materials learning.

C. Subjects

This study selected undergraduate students who initially to take the course of project management as the subjects. They all possess prior-knowledge of calculus and production management. They also attend the courses relating to the preliminary cost estimates, Calculus and Operation Management courses. In the teaching experiment, both pretest and posttest are conducted to verify the difference from learning platform use.

D. Procedure

It is a semester experiment. Subjects are first to take a pretest for getting attainment benchmark of learners in a classroom. An assistant then take the subjects into a laboratory for teaching experiment. Assistant first spends ten minutes to explain the purpose of lesson unit and practice way to the subjects. Next, they take forty minutes to practice exercises. During the practice, subjects are to use game-based project management learning platform to practice exercises. Finally, they take forty minutes to complete a knowledge test as posttest, and an attitude scaling are done for testing platform use.

E. Measurement

Measurement for self-efficacy was developed from the study of Compeau and Higgins [11] and Agarwal and Karahanna [12]. Measurements for perceived usefulness and perceived ease of use were adopted from the study of Hong et al. [13], with modifications of fit the game-based project management learning platform. Measurement for flow experience was built from the study of Novak et al [14]. Measurements for attitude and behavioral intention were adopted from Davis et al.'s study [15], and then measurement for actual system use was developed from the study of Venkatesh et al. [16]. The scales were slightly modified to suit the course of game-based project management. All items were measured using a 7-point-type scale with anchors from 'very strongly disagree' to 'very strongly agree'.

IV. RESULTS

In regard to the knowledge test, the posttest showed that subjects prevalently have a higher score than pretest. To test structural relationships, the hypothesized causal paths were estimated. The results of causal paths by structural modeling analysis are shown in the figure 2. Eight hypotheses were supported and two were rejected. The overall fit of the model is acceptable, since the goodness-of-fit statistics are satisfactory and acceptable. The results generally support the proposed model, illustrating the new roles of self-efficacy and flow experience in game-based project management learning platform. The specified relationship between perceived usefulness and perceived ease of use and self-efficacy was supported by the data, as indicated by a significant CR (critical ratio). The CR is a t-value obtained by dividing the estimate of the covariance by its standard error. According to Arbuckle [17], CR values larger than 1.96 and 2.32 are statistically significant at 0.05 and 0.01, respectively. Ease of use of game-based project management learning platform may be conducive to reaching a higher level of positive flow experience and user attitude. Flow experience was the most important determinant of user attitude and user intention for game-based project management learning platform. This reflects the significant effect of attitude on user intention. On the other hand, the effects of self-efficacy on perceived usefulness and flow experience on attitude were not supported by the results. There is a significant positive relationship between attitude and intention to use, and strong support for a positive relationship between intention to use and actual use behavior. The results imply that perceived usefulness/ease of use may influence attitude, which, in term, affects learners' use intention.

The model indicates that the variance in game-based project management learning platform explained, which is fairly high, given that numerous factors may affect acceptance of, and intention to use the game-based learning platform. The results show that the variance in individual intentions toward accepting the game-based project management learning platform can be explained by the experiment of self-efficacy, perceived ease of use, and flow experience, along with a relatively small control.

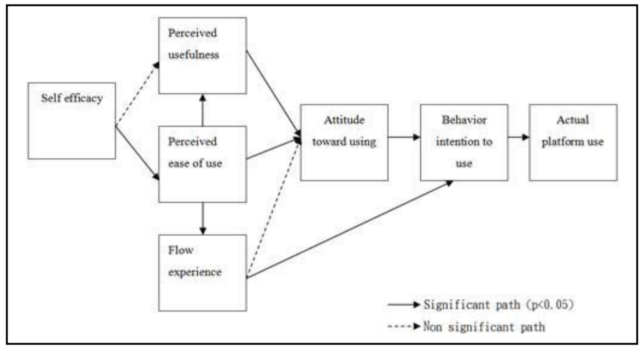

Figure 2. Results of structural modeling analysis

V. DISCUSSION AND CONCLUSION

The main purpose of this paper was to examine what factors would determine the learner acceptance of a game-based project management learning platform, an emerging innovative information system use the near future. We use the TAM to evaluate game-based learning usage based on project management. As prior research demonstrates, we find that self-efficacy is significant in using online game. The higher a person's self-efficacy, the less anxiety that person has in using a project management platform. As Compeau and Higgins [11] found, high self-efficacy can both relieve anxiety and increase positive influence in using a computer. Agarwal et al. [18] found that self-efficacy is more related to perceived ease of use than to perceived usefulness. Moreover, perceived ease of use on game-based project management learning platform, then, is now viewed as another determinant of flow experience, which in turn affects attitude and behavior intention to actual system use based on the course of project management [2].

The teachers who use this game-based project management learning platform should be aware of the importance of self-efficacy and flow experience applied on TAM. Interpersonal interaction among students creates a community in which education value can be created by improving learning interest and efficiency. When students use the game-based learning platform intensely, the interaction with other students will cause more to join in. Therefore, teachers should strive to attract opinion leaders or community builders to affect others to play this games-based project management learning platform through a normative effect. Moreover, through word-of-mouth communication or mass advertisements, teachers can accelerate network effects to achieve a perception of critical mass. The more students in this game-based learning, the more students-generated experience it is likely to exchange and thus the more users it will attract. This idea, called the dynamic loop, was found by Hagel and Armstrong [19] to yield increasing returns in a virtual community.

ACKNOWLEDGMENT

The authors would like to thank the National Science Council of the Republic of China for financially supporting this research under Contract No. NSC 98-2511-S-366-003.

***Abstract*—The Mentoring Program of the *Escuela Técnica Superior de Ingenieros de Telecomunicación (ETSIT)* is intended to establish a mechanism based on peer mentoring provided by upper-class students *(Mentors)* to provide help, support, and resources to incoming first-year students *(Mentees)*. This paper focuses on the experience gained in the creation and development of the ETSIT Mentoring Program during five years. The evolution of the results obtained from the evaluation of various aspects of the ETSIT Mentoring Program, is also presented.**

Keywords-engineering education; engineering student retention; peer mentoring;

I. INTRODUCTION

Nowadays, with the number of students entering engineering degrees programs declining, it is important to focus efforts not only on attraction, but also on student retention. In this sense, student support during the transition to University is one of the main influences on whether a student stays or leaves. The challenges for someone transitioning from high school to university can be significant. These challenges can be even greater when the student is entering into engineering. As a support mechanism, successful *peer mentoring* can impact students' desire to remain in engineering and at the University [1].

The term *mentoring* refers to a supportive relationship that is characterized by constructive role-modeling, encouragement towards raised aspirations, and by positive reinforcement for the achievement of goals. *Peer mentoring* at University typically involves the support and guidance for new students from more experienced students within the same discipline. *Peer mentoring* is an important strategy for assisting first year students during their transition to University in order to minimize the attrition rates that are typically high at engineering degrees [2]. The benefits of mentoring programs are both personal and professional, offering the satisfaction of helping peers and increasing the confidence of experienced students.

This paper focuses on the experience gained in the creation and development of a peer mentoring program at *ETSIT (Escuela Técnica Superior de Ingenieros de Telecomunicación)* from the *University of Las Palmas de Gran Canaria (ULPGC)* during five years, giving a detailed description of the program, the logistics involved in its implementation, or the modifications introduced throughout its successive editions to improve their key elements – including the selection and training of *Mentors*, the organization of the *Mentor* and *Mentee* meetings, or the content of the reports that the *Mentors* have to complete after each meeting–. The evolution of the results obtained from the *Mentor* and *Mentee* satisfaction evaluation of various aspects of the ETSIT Mentoring Program, are also presented.

II. THE ETSIT MENTORING PROGRAM

The ETSIT Mentoring Program is intended to establish a mechanism based on peer mentoring provided by *Mentors* to provide help, support, and resources to incoming first-year students throughout their first semester at the university on a range of academic, social and administrative issues, under the supervision of *Teaching Tutors*. This peer mentoring program has been in existence since the academic year 2004-2005 and has proven to be successful promoting student involvement and enabling success in *Mentees'* academic, social, and personal endeavors, as soon as developing in *Mentors* professional and transferable skills to take into engineering practice. For the academic year 2006-2007, improvements based on feedback from the participants in previous editions were introduced in the ETSIT Mentoring Program to its actual form.

A. Organizational structure

The organizational structure of the ETSIT Mentoring Program is shown in Fig. 1. *Mentors* are in charge of group of a maximum of 6 *Mentees*, reporting to their *Teaching Tutor*, who is an experienced lecturer preferably teaching on the first year course. Each *Teaching Tutor* provides guidance and supervision to the *Mentors*. *Teaching Tutors* and *Mentors* report to the *Coordinator*, who has oversight of the program and is responsible for the assessment, holding the training and weekly mentor meetings, …

This work was partially supported by the Spanish Ministry of Science and Innovation under project *Red de Mentoría en Entornos Universitarios Españoles (EA2008-0020).*

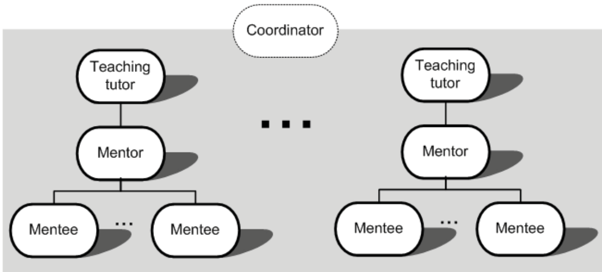

Figure 1. Organizational structure.

In addition, a technical committee coordinates the implementation of the different activities comprising the ETSIT Mentoring Program. This committee is composed by the Dean of the ETSIT, 3 lectures, and 2 undergraduate students. The *ETSIT Mentoring Program Technical Committee* meets at least two times throughout the duration of the program in order to select *Teaching Tutors* and *Mentors*, …

B. Recruiting and selection of Teaching Tutors & Mentors

The success of any mentoring program depends in large part on the skills of the *Mentors*. It is therefore important that care is taken when recruiting and selecting lecturers and students that will be involved in the mentoring program. The recruitment and selection of *Teaching Tutors* and *Mentors* commence at the end of the previous academic year, as *Mentors* need to be have been recruited and trained prior to the start of the academic year.

There are many strategies that can be used to make contact with the students whom *Mentors* will be selected. For the particular case of the ETSIT Mentoring Program, potential *Mentors* are contacted by publishing announcements on notice-boards, and by sending a mass email to students in later years of the degree. Potential *Teaching Tutors* are contacted by email.

Before agreeing to participate, potential *Mentors* are fully informed about the ETSIT Mentoring Program and about their role in it via an *information sheet* and an *information meeting*. The *information sheet* clearly identifies the aims, objectives and structure of the mentoring program, what will be expected from students who participate as *Mentors*, and especially how much time will be required of them. The *information sheet* also tells potential *Mentors* about the ongoing support they will receive. Finally, students are made aware of how their participation will be acknowledged. The *information meeting* is a session to which all students who have an interest in participating as *Mentors* are invited. The overriding purpose of such a meeting is to ensure that any student is fully informed about what is involved. The information meeting begins by welcoming and thanking all students for their interest in the mentoring program and having their attention drawn to the details that are provided on the *information sheet*.

Students who, having heard the detailed information, continue to believe they are able to make the necessary commitment, are asked to complete an application form. The application process consists of completing the application form with contact details, writing a short essay regarding the skills and experience they believe will enhance their ability to be effective *Mentors*, or the motivation for being involved in the mentoring program, and submitting a copy of their academic grades.

After the applications are received, the *ETSIT Mentoring Program Technical Committee* reviews the applications. The program faced several challenges when it began regarding how to organize the application and review process. Nowadays, students are selected mainly based on their academic progress and perceived interest in mentoring, since the importance of *Mentor'*s appreciation of the value of mentoring for the success of the program has been proved to be significant. In this sense, the technical committee members are familiar with most of the students who indicate that they would like to be *Mentors*, so it is not necessary asking them to attend any personal interview. The number of chosen *Mentors* depends on the available flexibility, that is, the number of applicants in relation to the number of *Mentors* required. *Teaching Tutors* are mainly selected based on their experience in mentoring, with special emphasis on the enrolment of lectures of first year subjects, since their participation in the ETSIT Mentoring Program has proven to be very important, as it allows closer links with lecturers and staff [3].

C. Training

Before meeting with the first year students, it is necessary to ensure that *Mentors* undergo appropriate training. The effectiveness of any mentoring program depends on the degree to which *Mentors* have the appropriate expertise, that is, both the skills and the knowledge. The greater their confidence in their skills and knowledge, the higher the likelihood that mentoring will be effective [4].

Training at the ETSIT Mentoring Program addresses issues related with the facilitation or conduct of the mentoring sessions, and others related to the content of the mentoring program. In this sense, *Mentors* have training in generic interpersonal communication skills, including building empathy, actively listening, or asking appropriate questions. Training identifies the strategies that *Mentors* might use for making their initial contact with their *Mentees*, for setting up the first meeting, and for running the first mentoring session. Interpersonal skills are put into practice in small group situations at the orientation and one-to-one in follow-up correspondence. In addition, *Mentors* are versed on campus resources, university activities, academic rules and resources, student associations, ETSIT organization, grants, exchange programs, …

D. Initial coordination session

The ETSIT Mentoring Program is established with a structure and relatively formal program to follow. The content of weekly mentoring sessions is agreed from *Coordinator*, *Teaching Tutors* and *Mentors* during an *initial coordination session* held before recruiting of *Mentees* and the start of the mentoring meetings. An outline of the topics that should be covered during the program of mentoring sessions is planned along with some suggestions for the week in which they must be addressed. This *initial coordination session* focuses on the content of the mentoring program, including the material, an identifying specific strategies and suggestive activities that might used for each of the topics or areas of material.

E. Recruiting of Mentees

One of the major challenges when the ETSIT Mentoring Program was implemented was how to inform incoming students about this opportunity. The chosen method is based on a flyer distributed during an announcement in a lecture in the first week of the course, ensuring that students are contacted early and in time for mentoring to begin from the second week of class. The flyer draws first year student's attention to the existence of the ETSIT Mentoring Program that is designed specifically for them. In addition, the information in the flyer includes the rationale for the mentoring program and its objectives, and briefly describes the expectations of participants in the mentoring program. Students are encouraged to attend a *welcoming session* during the second week of the course to learn more about the program and enroll in it.

F. Welcoming session

Before agreeing to participate, potential *Mentees* are fully informed about the ETSIT Mentoring Program, about what would be expected of them, and what they might hope to gain from being involved in it. The purpose of the *welcoming session* is mainly to ensure that any student interested in being a *Mentee* is fully informed about the mentoring program, and to mark off the start of the mentoring program for participants. The *welcoming meeting* begins with a welcome from the Dean of the ETSIT and covers a brief reiteration of the aims and objectives of the program, a comment about the efficacy of mentoring programs and the possible benefits of participating in mentoring, and a few remarks about being an effective *Mentee*.

Having provided students with the opportunity to ask questions about any aspects of the ETSIT Mentoring Program, those who decide to participate are asked to complete an application form. The form simply asks potential *Mentees* to record their contact details and about their permission that the information be provided to their *Mentor*, who will then make contact with them. Mentoring groups are formed just at the end of the *welcoming session*, providing the *Mentors* and *Mentees* with the opportunity to get to know each other before the start of the weekly mentoring sessions. *Mentors* are in charge of group of a maximum of 6 Mentees, with *Mentors* and *Mentees* being matched at random.

Figure 2. ETSIT Mentoring Program Portal.

G. Supporting tools

Once the mentoring program is underway –as soon as *Mentor* and *Mentees* groups are formed–, an intranet web-based portal is established by the *Coordinator*, shown in Fig. 2, as a supporting tool for *Teaching Tutors* and *Mentors*.

The ETSIT Mentoring Program Portal is exclusively available to the program participants and includes, among other, information related to the ETSIT Mentoring Program, a list of all the *Teaching Tutors*, *Mentors* and their *Mentees* with their contact details, and indicating the mentoring group to which they belong. In addition, a news forum is set up, so that there can be regular contact between the program *Coordinator* and all *Teaching Tutors* and *Mentors* who are involved in the program. Also, supporting information related to the topics proposed to be covered on the weekly mentoring sessions is provided. Finally, the web-based portal eases uploading and reviewing the reports being elaborated by the *Mentors* at the end of every weekly mentoring session.

H. Weekly mentoring sessions

The *Mentors* meet *Mentees* weekly during the first semester, beginning the second week of class. The first meeting typically lasts 45-50 minutes, with subsequent meetings typically lasting 30 minutes. At the first meeting, *Mentor* and *Mentees* get to know each other better and set up a weekly meeting time. It is important for the students to know they can terminate the relationship for any reason at any time.

Each week there are certain topics that *Mentors* will discuss with their *Mentees*, according to the planning agreed during the *initial coordination meeting*. These topics regard how to succeed in their first semester classes, being timed to provide the right information and support at the right time. With each meeting, *Mentees* gradually assume more responsibility for the weekly mentoring sessions. Main topics include academic rules, characteristics of subjects, structure of the first course, search for academic resources, student associations, ETSIT organization and services, … Other topics cover study habits, how to put a bad exam score in perspective, not repeating the same mistakes, organizational skills, dropping classes, exam survival, … *Mentors* discuss any issue of concern with the *Mentees*, not being limited to the topics to cover in any weekly mentoring session according to the planning agreed during the *initial coordination session*. In addition, *Mentees* complete three forms during the weekly sessions regarding previous knowledge of the degree and the motivation of the first year students for its election, their adaptation to the University, and the subjects covered on the first semester. The information obtained from these forms is used, i.e. to detect problems on the lectures of the subjects covered on the first semester of the degree. The second part of the first semester, *Mentees* have grown substantially, so topics cover some visits to research laboratories or telecommunication-related enterprises. Finally, the last meeting is held after the exams, in order for the *Mentors* to review the academic progress of the *Mentees*, being sensitive to students who appear to be at academic or personal risk.

In addition to weekly mentoring sessions, *Mentors* meet monthly to share experiences. Also, in order to involve *Teaching Tutors* with the *Mentor* and *Mentee*s weekly meetings, they are recommended to assist to some specific planned meetings covering critical topics for the first year students, allowing closer links with lecturers and supporting *Mentors*.

After each meeting with their *Mentees*, *Mentors* elaborate a report of the session and sends it to the *Coordinator* and their *Teaching Tutor*. This report is based on a template provided by the *Coordinator* of the mentoring program, including the meeting date and duration, along with the name of the assistants, the covered topics, and any comments or problems from the *Mentees*. Once fulfilled, *Mentors* upload each report using the web-based portal. Reports are available for the *Coordinator* and the *Teaching Tutors*.

III. ETSIT Mentoring Program Evaluation

The overriding objective of any evaluation process of a peer mentoring program is to determine the extent to which it has been effective [3]. The success of a mentoring program depends on how well it is able to assess its effectiveness, address any weakness and demonstrate that it is complaining established goals and objectives. However, evaluations of mentoring programs tend to exclusively assess *Mentees* satisfaction with a *Mentor*, with very few studies examining the impact of mentoring program on outcomes [5]. To ensure the quality and effectiveness of a mentoring program, it is necessary to develop a plan to measure program processes and expected outcomes, and create a process to reflect on and disseminate evaluation findings. To ensure the quality and effectiveness of a mentoring program, two different types of evaluation can be conducted depending on the purpose of the measurement [4]:

- *Process evaluations (formative evaluations)* focus on whether a program is being implemented as intended, how it is being experienced, and whether changes are needed to address any problems. Process evaluation is an ongoing data collection process that yields information about the successful activities and those needed to be determined. This information can help to improve the mentoring program. A well planned process evaluation is developed prior to the beginning of the mentoring program, and continues throughout the duration of the program.
- *Outcome evaluation (summative evaluations)* focus on what effects mentoring programs are having and help to determine objectively the benefits, costs, and necessary conditions to reach program objectives, and determine whether the mentoring program caused an improvement among the participants on certain aspects of interest.

Despite the importance of the information provided by the *Process evaluations* for self-monitoring and continuous improvement of program effectiveness, this paper will mainly focus on the issues and decisions involved in conducting an *Outcome evaluation* to assess the effectiveness of the ETSIT Mentoring Program in achieving pre-determined objectives. An *Outcome evaluation* implementation involves the specification of expected outcomes, the selection of appropriate instruments to measure outcomes, and the selection and implementation of an evaluation design.

A. Outcome evaluation

Outcome evaluation is a crucial part of any effective mentoring program as it provides information to increase its effectiveness through a feedback/continuous quality improvement process. *Outcome evaluations* of mentoring programs generally are of two major types [4]:

1) Single-group designs are the simplest and most common types of evaluation, since they are less intrusive and costly, and require less effort to complete. An example of a single-group evaluation is a survey completed by all participants at the completion of the program *(post test)* or before and after the program (*pre-post test*).

- *Post test.* Mentoring programs commonly use this design to determine how *Mentees* comply some aspects of interest at the completion of the mentoring program. *Post-test* evaluations can help determine whether the *Mentees* have achieved certain goals – according to the implicit or explicit objectives established during the planning of mentoring program–, or whether *Mentors* are satisfied with the mentoring program, among other issues.
- *Pre-post test.* Mentoring programs use this design to determine whether *Mentors* and *Mentees* actually improved during the mentoring program by comparing the results of a *pre test* and a *post test*. Even if *pre-post* evaluations can't indicate whether the mentoring program was responsible for the improvement, a *pre-post test* can be useful to detect differences within the group or to determine whether certain participant characteristics are related to achieving mentoring program goals.

2) *Comparison group designs* allow to determine whether the mentoring program is the cause of change in program participants, using controls to eliminate possible biases. An example of a comparison group evaluation is a *pre test* completed by all participants at the beginning of the program and a *post test* at the completion of the program to both the target mentoring group and a matched comparison group that does not receive mentoring. By including a comparison group it can be possible to isolate the effects of the program from the effecs of other plausible interpretation of change. However, this type of evaluation requires finding a comparison group that is sufficiently similar to the mentored group. In this sense, students who enlist in a mentoring program may differ –in terms of motivation, compliance, …– from those who do not enlist. Many mentoring programs are not willing to deliberately withhold their program from participants, mostly with the number of students entering engineering degrees programs declining.

The evaluation design adopted determines the confidence in the mentoring program to be the cause of improvements of potential in all participants. *Outcome Evaluation* of the ETSIT Mentoring Program is based on a *single-group* design with *post test*, since all first year students are invited to participate as potential *Mentees*. The outcomes are mainly measured using anonymous satisfaction surveys completed by *Teaching Tutors*, *Mentors* and *Mentees* after the fall meeting, as surveys of student perceptions provide just some information. These surveys have been elaborated as part of the activities of a mentoring network in university environments which includes most of the universities developing mentoring programs in Spain, including the University of Las Palmas de Gran Canaria (ULPGC) [6]. The elaboration of these common surveys has allowed the comparison of the results obtained from different universities on the same issues. The items on the survey cover different aspects of the ETSIT Mentoring Program, including *Personal Benefits*, *General Benefits*, *Development of the Program*, *Program Recommendation*, *Teaching Tutors/Mentors/Mentees evaluation*, and a *General Appraisal* of the mentoring program.

The results obtained for the 2008-2009 ETSIT Mentoring Program show that it is considered as helpful or very helpful by more than 90% of *Mentees*, 95% of *Mentors* and 88% of *Teaching Tutors*, with a general appraisal of 8.63, 9.12 and 9.37 (over 10), respectively. In addition, 70% of *Mentees* consider that ETSIT Mentoring Program has a positive influence on their academic, social, and personal endeavors, and more than 75% recommend to be enrolled in it, with an 83% willing to participate in the near future as *Mentors*.

However, as various issues covered through the implementation of mentoring programs are not directly used during the first semester at the university, and in many cases the incoming first-year students don't have an adequate temporal perspective to value all the aspects in which the mentoring program have influence, the ETSIT Mentoring Program also involves anonymous satisfaction surveys completed by *Mentees* after staying three years at the university in order to evaluate their perception about the effectiveness of the mentoring program on that period. Some of the results obtained from these surveys are shown in Fig. 3

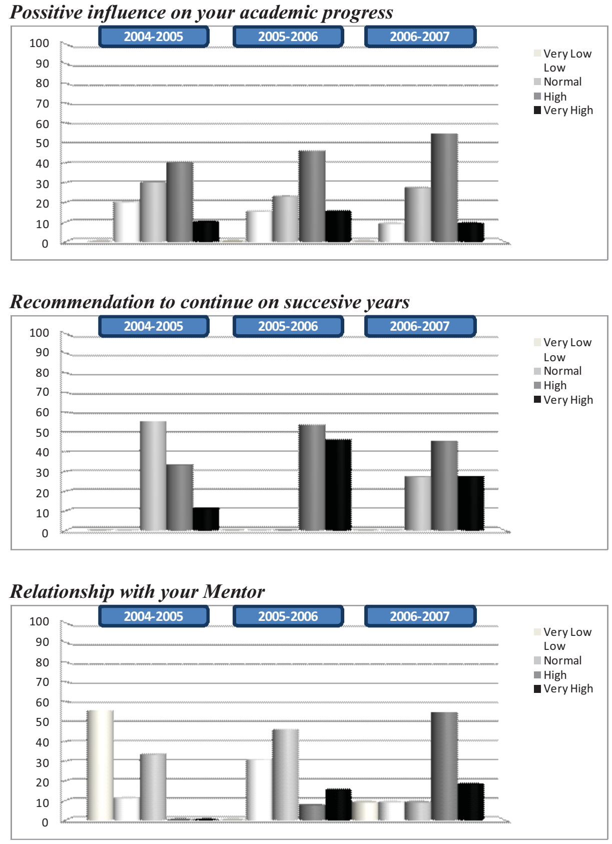

Figure 3. Results obtained from satisfaction surveys completed by *Mentees* after staying three years at the university.

for *Mentees* who participate in the ETSIT Mentoring Program along the academic years 2004-2005, 2005-2006 and 2006-2007, after staying three years at the university. From these results, 57% of students consider that ETSIT Mentoring Program had a high positive influence on their academic progress in mean, more than 72% highly recommend its continuity on successive years, and a 51% of students still continue the relationship with their *Mentors*.

However, satisfaction surveys often show that participants are at least somewhat satisfied, so results must be interpreted with some caution. High program satisfaction does not equal positive program outcomes, thus satisfaction surveys should be considered as just one part of an overall evaluation. In this sense, retention rate is tracked each academic year as a method of measuring retention of first-year students. In Table I, the overall first-year retention rates of *Mentees* for the last five academic years are shown. From these results, improvements introduced from the 2006-2007 academic year indicate that the ETSIT Mentoring Program successfully impacts retention.

TABLE I. OVERALL FIRST-YEAR RETENTION RATES OF MENTEES

Academic Year				
2004-2005	***2005-2006***	***2006-2007***	***2007-2008***	***2008-2009***
37%	32%	36%	56%	60%

In addition, a set of measurable indicators are being elaborated within the referred mentoring network in order to evaluate whether or not the mentoring program caused an improvement among the participants, including the degree to which the needs of the incoming first-year students are met, the skills gained by the *Mentors*, or the degree to which the university as a whole benefits from the mentoring program. These indicators will be used to improve *Outcome evaluation* of the ETSIT Mentoring Program at the current academic course 2009-2010, in order to verify the feasibility in collecting the required data and the relevancy of each indicator in determining the effectiveness of the mentoring program.

IV. CONCLUSIONS

The ETSIT Mentoring Program helps *Mentees* to develop an enhanced sense of student identity as an engineer, to become effectively integrated into the ETSIT, and to acquire the necessary skills to become independent. Regarding *Mentors*, the ETSIT Mentoring Program introduces them to skills in leadership, teamwork, problem solving, time-management, or communication, helping them get a leg up into professional practice. The effectiveness of this peer mentoring program can be attributed to several factors, including proper *Mentor* selection and training, weekly targeted meetings with *Mentees*, well timed information and mentee support, or the enrollment of lecturers teaching on the first year course.

***Abstract*— GILABVIR (Grup d'Interès en Laboratoris Virtuals I Remots) is a recently created Virtual and Remote Laboratory Group of Interest at the UPC (Universitat Politècnica de Catalunya) and it is integrated in a more general teaching innovation project: RIMA [1], [2]. RIMA has been developed to promote research on the use of innovative learning methodologies applied to engineering education and it was specially created to assess in the new European higher education adaptation process.**

Keywords- Generic skill, digital campus, software platform, laboratory experiment.

I. Introduction

The GILABVIR Group is formed by high education faculty members who are involved within different laboratory courses, all of them characterized by the use of real and simulated experiments accessed through the moodle based UPC digital campus platform (ATENEA). The experiments in the different laboratory courses usually follow the next three steps sequence: 1.- The student designs the experiment and configures the parameters on-line, either at distance or in the computer classroom. 2.- The experiment is executed. 3.- The different results (numerical, graphical, images, etc.) are displayed and optionally recorded at the student computer and are also optionally recorded at the ATENEA server.

Up the date, there are nine laboratories integrated in GILABVIR and they are used in courses corresponding to curricula of: Electrical Engineering, Telecommunications Engineering, Computing Engineering, Industrial Engineering and Civil Engineering. Technical and didactic aspects of them have been collected and classified. The two main goals of this group are to detect common needs of the technical solutions of the different laboratories and design new educational methodologies that use virtual and remote laboratory based teaching activities.

The first goal is related to the implementation of a software application to join all the virtual and remote laboratories the UPC digital campus (moodle platform) and allow students execute experiments and teachers propose monitor and evaluate these experiments, instead of spending a lot of time developing access and activity management applications. A dedicated software tool (Moodle_LAB) is being programmed in order to control and monitor the access and execution of an experiment. With this option, professors can enable or disable the access to each experiment offered in each course and can also obtain information, individually for each student, about the timing, the configuration parameters or the obtained results. These data are used to evaluate the students. For most of the virtual and remote laboratory based learning activities, professors can obtain automatically a list of numerical results and records.

The second goal aims to improve the students learning outcomes, taking into account the design of the learning activities in the context of the European Higher Education Area, EHEA, both in specific knowledge and especially in generic skills.

Paper Outline—The rest of the paper, is organized in five sections. After an introductory section I, section II is dedicated to define virtual laboratories and remote laboratories, emphasizing the differences and comparative features between them when they are used for learning activities. The virtual and remote GILABVIR laboratories are described. The design and functionalities of the monitoring tool: Moodle_LAB are described in section III. In section IV innovative teaching methodologies based on these laboratories are presented and related to a generic skill list. Finally, the conclusions are described in section V.

II. Virtual and Remote Laboratories

The university education environment is becoming more diversified and interdisciplinary in the type of activities offered to students. Virtual and remote laboratories have been developed by combining experimentation, homework and use of information and communication technologies. In this context, when a student executes an experiment at distance, two different modalities must be distinguished: Virtual Laboratories and Remote Laboratories.

A Virtual Laboratory is defined as an interactive environment for designing and conducting simulated experiments. The experiment execution consists in running a program loaded in a remote server machine. To start this program the user accesses the server through a user interface. A software monitoring platform starts the simulator program. The program models some real experiment behavior, producing output signals, graphs and/or data when a set of input parameters is configured by the user.

A Remote Laboratory is defined as an interactive environment designed to allow users to remotely control real laboratories. A monitoring platform is installed in a remote server machine. To start the experiment the user accesses the monitoring application through a user interface and configures an input parameter set. After the experiment, measured data or

The group is supported by the ICE (Institut de Ciències de l'Educació) UPC including a financial aid from the 2009 - Educational Projects Budget.

signals are obtained and returned to the user through the monitoring application.

As it can be deduced from previous definitions, virtual laboratories and remote laboratories are extremely similar in the sequence of steps to follow when a practice is executed. Teaching methodologies based on these two kinds of laboratories are also very similar.

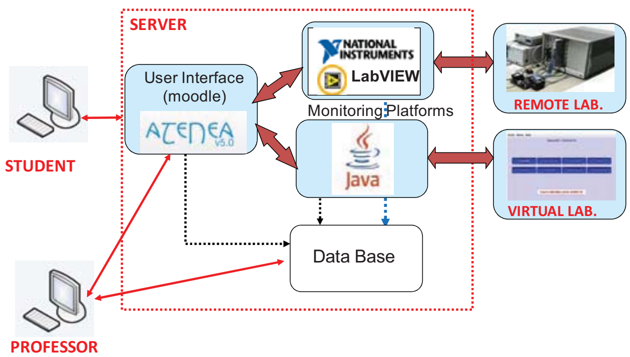

Figure 1. Remote laboratories and Virtual Laboratories are connected to the server through a software platform: Java or Labwiew. Atenea is the user interface (UPC Digital Campus).

Figure 1. shows a functional diagram including the elements that have a main role in this environment. Some advantages and disadvantages when comparing virtual and remote laboratories are displayed on table I.

TABLE I. ADVANTAGES AND DISADVANTAGES

Advantages	**Virtual**	**Remote**
Experimentation with real signals	NO	YES
Flexibility and configurability level	High	Medium
System registers user activity	YES	YES
Number of users simultaneously running the experiment.	Unlimited	1 user
Disadvantages	**Virtual**	**Remote**
Workstation booking system is necessary.	NO	YES
Software update is eventually necessary	YES	YES
Expensive	NO	YES

The GILABVIR group has been formed by faculty members who use virtual or remote laboratories in their teaching courses. Nine different projects directly related to nine different laboratories are currently grouped.

Virtual and remote laboratories that joined the GILABVIR initiative are described in the following list.

The group is supported by the ICE (Institut de Ciències de l'Educació) UPC including a financial aid from the 2009 - Educational Projects Budget.

A. Remote and virtual laboratories for mechatronics and enertronics students.

Different platforms have been designed to allow students to access the m re motely or virtua lly to complement the local laboratory sessions. The platforms are used in electrical engineering courses related to automation, mechatronics, motor control, renewable energy generation and power systems. Students program and supervise real systems as if they were working with real installations. This is done by using for example standard PLC (Programmable Logic Controller) programming software provided by the PLC manufacturers.

Remote laboratories include: Automation and motor control laboratory [5], Flexible manufacturing cell [6]. Power Quality laboratory, measurements of harmonics for different loads, power system laboratory, protection, fault detection and restoration of electrical power systems.

Virtual laboratories include: DC motor control laboratory, Hotel automation laboratory, Chemical process automation [7].

B. LAVICAD

The virtual laboratory of analog and digital communication systems is a useful tool to verify the performance of different communication systems and signal processing techniques, topics typically integrated in undergraduated courses of the curriculum of telecommunications engineering. The communication systems have been implemented and designed as Java applets and are free available. They can be run at the e-learning platform: comweb.upc.edu. The different communication systems present different levels of user interactivity and when students execute a system integrated in a comweb course, the obtained results can be supervised by the professor as an evaluation and assessment tool. From a pedagogical point of view, this laboratory has been created to facilitate the learning of certain matters, acting as a connection between the model of knowledge based on concepts and theories, and their practical understanding and experimentation.

C. Project: 62, an interactive tool to study discrete time signals and systems.

62 is an interactive tool written in JAVA that allows, first, to define discrete time signals and systems, and then to work with them. Signals, systems and operations are specified by means of menus or dialog windows without the need of knowledge of any programming language. One of these menus is devoted to specifying digital filters (FIR and IIR) both in the frequency and in time domains. The tool includes a graphic interface to show the sequences, their Fourier transform and the characterization of lineal invariant systems (frequency response, impulse response). The tool uses the A/D and D/A converters of the PC sound card. Thereby, the tool can generate and filter analogue signals in real time. 62 is part of the experimental framework designed for the students of discrete time signals and systems to carry out their practical training. This tool is freely available in [4].

D. iLabRS: Remote laboratory for Secondary Education.

iLabRS is built over a Modular platform to perform remote experiments in sensors and signal conditioning. It uses two experiment boards, which together with 3 additional boards allow doing currently 13 different practices. This remote Laboratory is aimed for Secondary Education students, to allow them to perform online real experiments, with remote access through Internet. The aim is triple: giving a tool to increase the experimentality in scientific and technological subjects, demonstrating the potential of the ICT's use and establishing a bridge between the secondary school and the university.

E. LEARN-SQL

LEARN-SQL is a system conforming to the IMS QTI specification that allows on-line learning and assessment of students on SQL and other database skills in an automatic, interactive, informative, scalable and extensible manner.

This tool facilitates the definition of virtual laboratories or remote questionnaires that are used by students of subjects to learn design and use of relational databases in the UPC.

LEARN-SQL is a tool whose main goal is helping in learning the use and design of relational databases in different subjects of schools of the UPC. More, specific goals are to:

- Provide the possibility to define virtual laboratories or remote questionnaires to be solved by the students at class or at home.
- Facilitate the participation of the students in its self-learning of database subjects.
- Provide students with valuable feedback, so that they can learn from their mistakes.
- Automatically evaluate the correctness of any SQL statement (queries, updates, stored procedures, triggers etc.) and other relational databases related exercises (Relational Algebra) with independence of the student solution.
- Help teachers define the questions or items in the remote questionnaires as well as allow them to review the solutions provided by the students.
- Adapt the subjects where it is used to the European Higher Education Area (EHEA) and to innovative education methodologies.

F. Circuit and Communications Systems Simulators

This virtual laboratory is still in construction.

The aim is to develop monitoring tools for homework based on running software simulators or remote laboratory experiments. The monitoring tool will automatically send a report to a moodle platform. It will be based in a Python module with functions to write ascii text, formatted text, results tables and figures in the report together with the answer to questions asked to the student.

This project is to be implemented in the following activities of the UPC "European Master of Research on Information and Communication Technologies":

Course: "Antennas for Communications" and "Waves and Systems". Activity: Modeling a WiFi system with intermediate repeater, including modulations and RF.

Course: "Electromagnetics Engineering". Activity: Analysis if a transmission line with impedance discontinuities using many different numerical methods in frequency or time domains. The results of different methods are compared in terms of accuracy and computational efficiency.

Course: "Design and Analysis of RF and Microwave Systems for Communication". Activity: Remote control of a network analyzer using the high-frequency circuit simulator ADS.

G. Modular platform to perform remote experiments in sensors and signal conditioning [8].

It is based on a custom acquisition board which includes a Ethernet capable microprocessor, so that every board has its own IP address. The connection of multiple boards to a switch allows the access to multiple experiments and/or to multiple replica of an experiment. Every board gives power supply and control signals to specific experiment boards that are connected to the control board in a sandwich structure. The signals are 4 A/D channels (16 bits), 2 D/A channels (14 bits), 8 control bits and a SPI bus. The experiment server runs specific applications made in LabView that control the experiments. Every application generates a remote panel that allows its use with a web browser. The link with the remote panel URL is placed among the course materials in the digital campus Atenea. This platform gives a certain degree of security, the user authentication and a basic record of the user activity. Four different experiment boards have been developed up to now, which allow performing 6 different laboratory activities around the sensor characterization and the set-up of conditioning and acquisition circuits. The use of the remote laboratory is focused as a complementary tool to add flexibility to the laboratory courses, mainly with the semi-distance students

H. VirtuaLab: remote workbench for instrumentation and sensors [9].

Remote laboratory based on a web server and a VXI modular instrumentation system connected to a circuit board with experiments and to a weather station. The access is made through a website (virtualab.upc.es) using a password. It only admits a single simultaneous user, who can use the resource during 20 minutes. Seven different laboratory activities can be carried out, from system identification and control, sensor calibration and remote control of instrumentation. In operation from 2003, the user interface was designed with the criterion of minimizing the data exchange and ensuring the system robustness. Because of this, the control applications in LabView that control the experiments are running in the server and they just exchange parameters and results with the user dialogues in the web pages.

I. rWLaB-Remote WaveLab

The goal of this laboratory is to convert an experimental setup (wave channel) into a platform for teaching, research and dissemination of knowledge using all the advantages offered by today's information technologies. Thus, we propose the creation of a knowledge portal based on experimentation with small-scale physical models with in the field of Maritime Engineering. The purpose of this portal will serve as the container of those remote and virtual laboratories that can be developed from this initiative. It is envisaged to provide the necessary content to the portal in order to, either through simulation, experimentation or study, achieve varying knowledge levels of methods and technologies employed in the experimental scale.

III. Connecting GILABVIR Projects to Moodle.

One of the main technical aims of the GILABVIR group is the connection of all the projects to the UPC digital campus. The UPC digital campus is a based moodle platform and it is called Atenea. In [3] some guidelines are proposed in order to connect virtual and remote laboratories to an educational platform.

Moodle_LAB is the application designed to connect all the at distance laboratories to the UPC digital campus. It is integrated by the connection module JLab and by the booking module.

A. Moodle Connection Module

The connection functionality allows the different at distance offered experiments can be run from a Moodle site. When an on-line experiment is invoked through the moodle platform there are some tasks that are identified to be performed in order to communicate the virtual and remote laboratories with the Moodle database to store practice results and then allow teachers view them.

The application that has been implemented is a new module for Moodle called JLab. JLab :

1. Centralize the management of the simulators that can be used in practices.

2. Allow laboratories to send the results to the server in order to be stored in the Moodle database.

3. Enable teachers to see the results of the practices from the portal and download them in Excel format.

The user enters in to the main portal using any browser. Then the user enters in a JLab practice of any of his courses.

On last page of this paper figure 3 shows the module operation process from the applet request to the results display. This is a communication protocol for a virtual java based laboratory, but the strategy is duplicated for any virtual or remote lab, using Java or Labview as software monitoring platforms.

1. The user enters in the main portal using any browser. Then the user enters in a JLab practice of any of his courses.
2. It shows the simulator applet using javascript embedded in view.php.
3. View.php obtains the id of the user connected, the id of the practice selected and a parameter that indicates if it is necessary to send the results to the server.
4. Applet is loaded.
5. Each stage of the applet, upon completion, generates an xml with the results.
6. This XML is sent to the server, the combeans.php file parses data and inserts them in the table mdl_jlab_results.
7. JLab also implements the report.php file which will show all users results of each practice.

Figure 2. shows the system architecture for at distance laboratories.

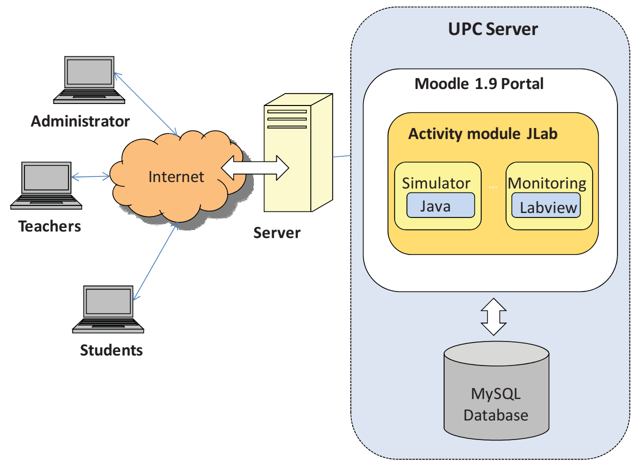

Figure 2. JLab – System Arquitecture.

Jlab module has been currently finished and it is being tested with a virtual laboratory (II.B) and with a remote laboratory (II.D). It is expected to connect all GILABVIR laboratories to Atenea campus on June 2010.

B. Moodle Booking Module

If the experiment is performed in a remote laboratory and the number of local workplaces is limited, a booking planning strategy becomes necessary. A dedicated moodle module is being designed to allow booking functionality and Jlab module coordinately work. The booking strategy defined for ours laboratories integrate:

- Students and teachers can book a workplace session some days in advance.
- A booked session can be modified or canceled
- The occupation time per session is configured by a laboratory administrator
- The dedicated moodle application assigns the workplaces to the booked sessions.
- A workplace inactivity detector releases the inactive workplaces and these are automatically available for other booked sessions.
- Teachers can supervise if a booked session is occupied by its owner.
- Laboratory responsible and teachers can periodically check the statistical books and the statistical use of the workplaces in the laboratory.

The Moodle booking module is currently being tested with a remote laboratory (II.D).

IV. ACADEMIC USE OF VIRTUAL AND REMOTE LABORATORIES

One of the main goals of the interest group is to share and improve the academic activities related with the use of virtual and remote laboratories. Two different aspects have been identified: the insertion strategies (how to use the virtual and remote labs within our subjects) and the learning methodology (what to do, evaluation, incidence in specific and generic skills, …).

After a survey within the group members, we can conclude that the virtual and remote labs are used both in classroom and remote activities. In addition to its remote use by the students, almost all labs are also used as demonstrators in classroom to support the teacher explanation and a half of them in laboratory sessions to enhance the in-situ activities. While one of the laboratories is used as an additional and independent activity and another as a substitutive of current laboratory activities, all others are used as complementary activities. Concerning the assessment, one half of the subjects including virtual or remote laboratories use them as voluntary issues while the other half specifies a given percentage of the mark. To perform the assessment, two of the involved subjects performed an automatic harvesting of results, a third one performed an automatic evaluation of the work and the remaining five performed a classical off-line gathering of reports.

Concerning the learning outcomes, the virtual and remote laboratories should contribute to improve the specific knowledge of the topics included in the respective subjects, but also to boost several generic skills. Among the mandatory skills defined by our University, the survey has shown that the use of virtual and remote laboratories can contribute to acquire the following skills: self-learning (8), effective use of learning resources (4), team work (3), innovation and entrepreneurship (1) and use of a foreign language (1). Additionally, the different schools can define other generic skills like "experimental behavior and instrumentation knowledge" or "engineering problems identification, modeling, formulation and solving". Most of them are also identified as targets of virtual and remote labs.

Several virtual and remote laboratories have born with a higher stress in their technical aspects than in their didactical aspects. An outcome of the Interest Group activity has been the recommendation of planning the virtual and remote laboratories as standard academic activities . That is, with a lifecycle that starts at the subject goals, defines a given learning activity, includes a deliverable that can be assessed and closes the cycle with an evaluation of the laboratory performance based on indicators. The learning activity should incorporate a form which, in addition to the technical content of the activity, gives information of all that aspects to the students. This includes the objectives and assessment criteria of the generic skills to be handled. As an example, table II describes the goals at three depth levels of the generic skill "engineering problems identification, modeling, formulation and solving". Each row in the table represents a different virtual or remote laboratory based activity that can be proposed to acquire the skill. Levels 1 and 2 are suitable for first and second years of an engineering degree and level 3 is proposed for third and fourth years. Goals at level 3 usually also serve to acquire more generic skills, as for instance "Cooperative Learning" and "Autonomous Learning".

V. CONCLUSIONS

The main aims of the GILABVIR group can be divided in two lines. As a result of detecting common needs of the technical solutions of the different laboratories, first line is related to the implementation of a software application to join all the virtual and remote laboratories the UPC digital campus Atenea moodle platform) and allow students execute experiments and teachers propose monitor and evaluate these experiments. The second main line is related to the design of new educational methodologies that use virtual and remote laboratory based teaching activities to improve the students learning outcomes both in specific knowledge and generic skills.

Concerning the learning effectiveness of web based experiments, in [10] a study is presented where their authors conclude that learning performance using dynamic media is significantly higher than those of the static textbook lesson, especially if the dynamic media can support learning when cognitive load and learners' mental representations. Furthermore, based on our experience, we can assure the learning effectiveness of dynamic resources doesn't depends on if they are offered by internet or in a laboratory classroom, but it is highly correlated with the teacher ability to choose the appropriate experiments to be made to work each subject or sequence of subjects in the program.

ACKNOWLEDGMENT

The authors wish to acknowledge all GILABVIR members for their aid and support provided throughout each activity and meeting, the enrolled students who have implemented most of platforms and applications and the RIMA management team for their institutional support.

Table II: goals of the activities that should develop the generic skill "engineering problems identification, modeling, formulation and solving"

	Goals		
Virtual and remote laboratory uses	**Level 1** To perform a guided activity	**Level 2** To perform an open solution activity which includes a partial system or sub-system design	**Level 3** Design and assessment of a complex system
As a complementary activity of a theoretical exercise	To solve a guided theoretical exercise with the aid of a virtual or remote lab as a verification tool. Their configuration parameters are given by the exercise statement	To solve a non-guided theoretical exercise and to verify it with the aid of the lab. The lab configuration parameters are given by the exercise solution	Design of a new subsystem that becomes necessary to solve a given, complex problem
As a complementary activity of a laboratory practice	Use of the virtual or remote lab to help knowing the instrumentation, preparing a given in-situ practice or confirming their results	Use of the virtual or remote lab to perform non-guided activities that reinforce the in-situ lab activities and help analyzing their results	Design of a system or sub-system with the help of a virtual or remote laboratory. Validation in the in-situ lab.
As an independent, remote activity (e.g. remote access to a singular resource)	To perform a guided activity using a virtual or remote laboratory as a demonstrator	To interacting with a virtual or remote laboratory with modification of parameters	Design of a new building block for a virtual or remote laboratory

Integration View of Web Labs and Learning Management Systems

***Abstract*—The integration of Learning Management Systems and specific learning support applications known as Web Labs (remote and virtual laboratories) are the target of a new wave of service-oriented applications devoted to improving on-line learning experiences.**

Nowadays these solution works in a separet way therefore the students teachers, administration must log in different systems, the are not reusing services, etc.

For these an other reasion in this paper we are focus in two topics. In one hand we describe a technique to present a web lab through a browser delivered by an LMS as a part of SCORM standard packaging. In other hand we describe a service-oriented architecture which allow integrating multiple LMSs (Moodle, .LRN, Claroline, etc.) with iLabs and multiples web an remote labs to supply the full functionality needed by educators

Keywords- e-learning; Learning management system; remote Labs, virtual labs, iLabarchitecture, e-learning standards; Web services.

I. Introduction

This paper discusses the need for merging several e-learning solutions into one. At present there are a great number of universities that are using blended learning or distance learning in parallel with traditional learning. In the case of distance learning, it is necessary to change and apply distance learning methods so that students achieve both theoretical and practical knowledge. To achieve this double goal, there are two new solutions particularly designed for distance learning [1]:

- A learning management system (LMS) is a software program that enables the display of theoretical content in an organized and controlled way. LMSs offer a set of features and services: user administration, e-learning standards (SCORM, IMS-QTI), content packing, etc.
- A web lab is a program that allows students to execute experiments remotely using a PC and an Internet connection. There are several ways to implement a web lab:
    - Software Lab. They are simulation programs and are executed locally on the student's computer. There is no collaborative work, and students do not work with real instruments or hardware.
    - Virtual Web Lab. These are simulation programs that use web resources. They permit students to collaborate during the execution of experiments.
    - Remote Lab. A remote lab allows the student to manipulate real instruments over the Internet during the run of an experiment.

Many universities are developing their own virtual and remote labs, but these efforts lack a unity of design, involve much custom development and present integration issues. There is little to no reuse of software between these efforts; each is developed from scratch. As one solution for this problem, the Massachusetts Institute of Technology has implemented the iLab Shared Architecture (ISA) [2-3] to facilitate the rapid development of new web labs and to provide a mechanism so that students from one university can use experiments and hardware instruments published from another.

While the ISA solves many problems, it does not offer the standard features supplied by learning management systems (e.g., chat, forums, learning modules). If you want these features in a current iLabs, you must program them into each lab's software. In this article we define a common architecture and middleware for adopting these typical LMS services as e-learning standards. We also illustrate the merger of theoretical and practical learning in a particular solution.

Thus, in this paper we will focus on two topics:

- We describe a technique to present a web lab through a browser delivered by an LMS as a part of SCORM standard packaging. The LMS will provide the web lab's communication, administration, and authentication tools. Of course, the lab can invoke the SCORM API so that the teacher can monitor the student's progress. When implemented as SCORM standard packages, web labs can be deployed in different LMSs such as Moodle, .LRN, Claroline, Sakai, etc.
- While the ISA provides an excellent management infrastructure for online labs, we argue that we need a service-oriented fusion of this architecture with general LMS services, compatible with multiple LMSs (Moodle, .LRN, Claroline, etc.) to supply the full functionality needed by educators.

II. LEARNING MANAGEMENT SYSTEMS (LMS)

A LMS is a software program that allows displaying theoretical content in an organized and controlled way. To do this, the most of LMS are designed using a common architecture, Fig. 1. that allows adding, deleting or modifying new functionalities.

The main elements in this architecture are:

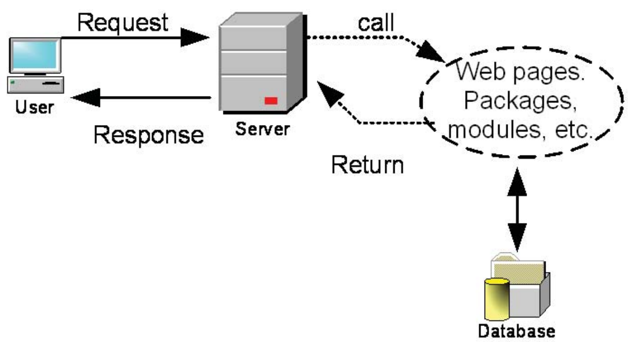

Figure 1. Architecture of a LMS.

- Database. This stores the information that the services are going to need and the information that will be displayed to user (administrators, teachers, students, etc.). Depend on the LMS that you are going to install and use, you will be able to work with mysql, oracle, postgres, etc.
- Modules, blocks, packages, etc. The structure of this modules or packages depends on the LMS. So how the programming language that you should use. For instance, if you are working in Moodle [4] you must use PHP to program. To sum up, these modules contain the logical of LMS services

  It is very important to mention that there are open source LMS as Moodle, DotLRN [5], Sakai [6], Claroline [7], etc. So that, a programmer could add new modules or modify standard services that are include in the standard installation of LMS.
- Web Server. All the LMS are installed along with a web server. This allows responding the user requests though Internet. Also, at the same that the others elements mentioned above, depending on the LMS with you are working, you have to install TOMCAT, APACHE, etc.

Once, we have known how a basic LMS architecture is. We are going to enumerate several of most important features and services that a LMS offers:

- Administration. It must be able to manage user registrations, roles, assign tutors, user payments, etc
- Content packing. It organizes the content in a hierarchical structure and sets up a mechanism to swap content between different learning management systems. To do it, it's usually used the specification IMS content packaging or the specification SCORM (Shareable Courseware Object Reference Model).
- Synchronous and asynchronous Communication Tools. It must allow collaborative work. So that they can share information, opinions and experiences.
- Knowledge evaluation. The tutors and teachers must be able to evaluate the student's progress. Also the students can do test where they can see their progress. To do it, it's possible to use the specification IMS QTI (Question and Test Interoperability).
- Tracking user. This feature should provide information user with teacher about that difficulties and problems have been found in the course by the students for the course term.

So, we have a tool that offers a set of features and services to display theoretical content in an organized and controlled way. As well as using e-learning standards like SCORM, IMS-QTI, etc.

III. SOFTWARE, WEB, REMOTE LAB AND ILAB

In many distance learning o blended learning courses, besides displaying theoretical knowledge by LMSs, is needed that the students acquire skills and practical knowledge. This and other reasons (the students are be able to carry out their experiment 24 hour by day and 365 day in a year, etc.) have given risen to design and create software, web and remote labs [8].

In this section we are going a brief description each one of these labs and one solution called iLab that was developed by the Massachusetts Institute of Technology to facilitate the rapid development of new web labs and to provide a mechanism so that students from one university can use experiments and hardware instruments published from another.

- Software Labs

  They are based on software programs that are being executed in the student's computer, Fig. 2.

  The student's computer must have the hardware and software requirements and an Internet connection it is not required.

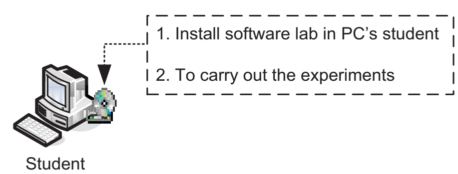

Figure 2. Software Lab.

Some of the main problems of theses labs are:

- Lack of collaborative tools
- Version problems, students have a lot of version of same labs. To solve it, the software labs allow the students to update the software using an Internet connection, Fig. 3.

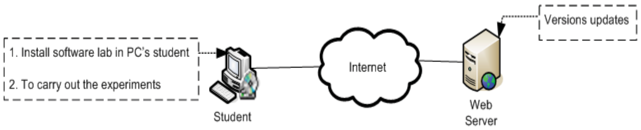

Figure 3. Software Lab with Internet Connection.

- Web Lab. These are simulation programs that use web resources. They permit students to collaborate during the execution of experiments, Fig. 4.

  The main problem is that students don´t manipulate real instruments to carry out his experiments.

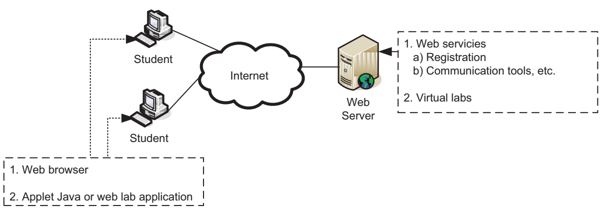

Figure 4. Web Lab.

- Remote Lab. These are simulation programs that use web resources. They permit students to collaborate during the execution of experiments, Fig 5.

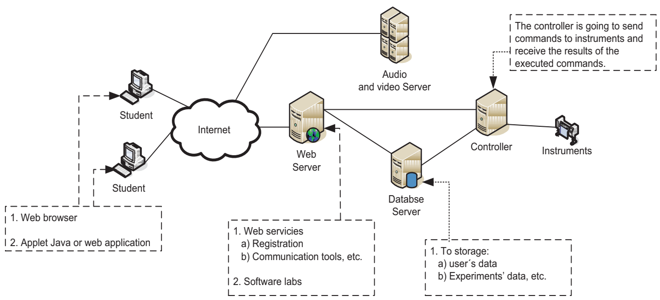

Figure 5. Web Lab.

Once we have described briefly what are software, web and remote labs. We are going to talk about the main problem that appeared. Many universities and organizations started developing their own virtual and remote labs, but these efforts lack a unity of design, involve much custom development and present integration issues. There is little to no reuse of software between these efforts; each is developed from scratch. For this reason, the Massachusetts Institute of Technology implemented iLab Shared Architecture (ISA) to facilitate the rapid development of new web labs and to provide a mechanism so that students from one university can use experiments and hardware instruments published from another.

To do this MIT divide the experiments according to the type interaction between user and lab. As a result of this, MIT has designed two architectures:

- Architecture based on batched experiments, Fig. 6.

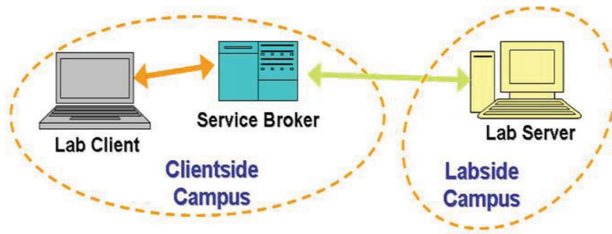

Figure 6. Topology of a batched experiment based on the iLab shared.

- Architecture based on interactive experiments where user and labs must establish a direct communication, Fig. 7.

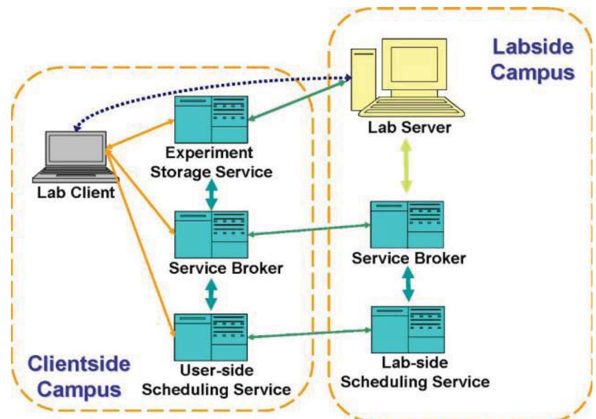

Figure 7. Topology of a interactive experiment based on the iLab shared.

So, ISA supports batch and interactive experiments. But, as well as, ISA allows being installed in every university or organization and therefore a student of one university could log in the system and using the web and remote labs from other universities.

While the ISA solves many problems, it does not offer the standard features supplied by learning management systems (e.g., chat, forums, learning modules). If you want these features in a current iLabs, you must program them into each lab's software.

So, imaging two universities, both of them want to create the same electronic remote laboratory and as well as theses universities want the laboratory provide one set of features, as: authentication, forums, chat, etc. To do this both of these universities must facing with the following challenges and disadvantages:

- Everyone should:
  - Defining and design one architecture. And probably the chosen architecture will be different.

- Programming and implementing the lab. Depend on the chosen architecture will be used different programming languages.

This provoked that the user from different universities needed different ways to log in and work with the system and therefore it is impossible to share labs. Due to this, appears ISA.

- Also, everyone should create the services that the laboratory needs as: forums, chats, storage area, etc. This is a problem, because by every lab we have to create, we must programme the same services one and other time. And therefore , the universities are wasting their time, personal and efforts in doing the same thing all the time, Fig 8.

To solve this and other problems as the integrating between both solutions (LMS and web, remote labs) we are defining and developing a common architecture and middleware for that the labs could use the LMS services and e-learning standards, Fig 9. And therefore, reuse services.

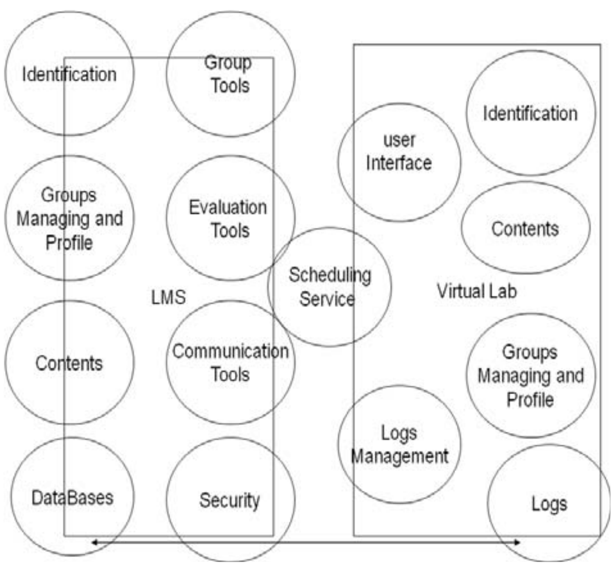

Figure 8. Duplicating services.

In the next sections also illustrate the merger of theoretical and practical learning in a particular solution. Thus, in this paper we will focus on two topics:

- We describe a technique to present a web lab through a browser delivered by an LMS as a part of SCORM standard packaging. The LMS will provide the web lab's communication, administration, and authentication tools. Of course, the lab can invoke the SCORM API so that the teacher can monitor the student's progress. When implemented as SCORM standard packages, web labs can be deployed in different LMSs such as Moodle, .LRN, Claroline, Sakai, etc.
- While the ISA provides an excellent management infrastructure for online labs, we argue that we need a service-oriented fusion of this architecture with general LMS services, compatible with multiple LMSs (Moodle, .LRN, Claroline, etc.) to supply the full functionality needed by educators.

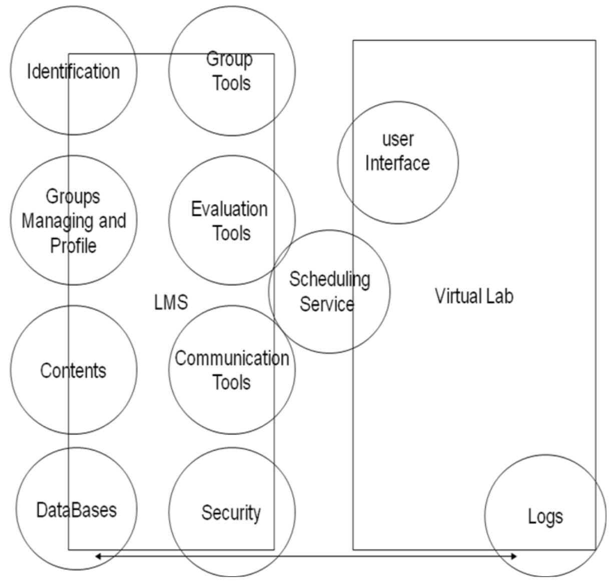

Figure 9. Reusing services.

IV. SCORM AND LMS

A Great number of Learning Management Systems support several e-learning standards as: IMS_QTI, IMS-LD, SCORM, etc. Every one of these has a different utility, for instance IMS-QTI is a specification for a metalanguage which enables the modeling of learning processes. In this section we are going to focus on e-learning standard called Sharable Content Object Reference Model (SCORM) [9-10].

SCORM content packaging provides a consistent form for describing content structures, learning content, the metadata that describes the various components of the content structures and sequencing and navigation rules.

This facilitates searching and discovering content packages and their resources.

How it is mentioned above SCORM documentation version 2004 describes a set of features of a content package as:

- Content Packaging: describes the SCORM components used to build a learning experience from learning resources. So, a package SCORM is composed of assets, sharable content objects (SCOs), activities, a content organization and content aggregations, Fig. 10.

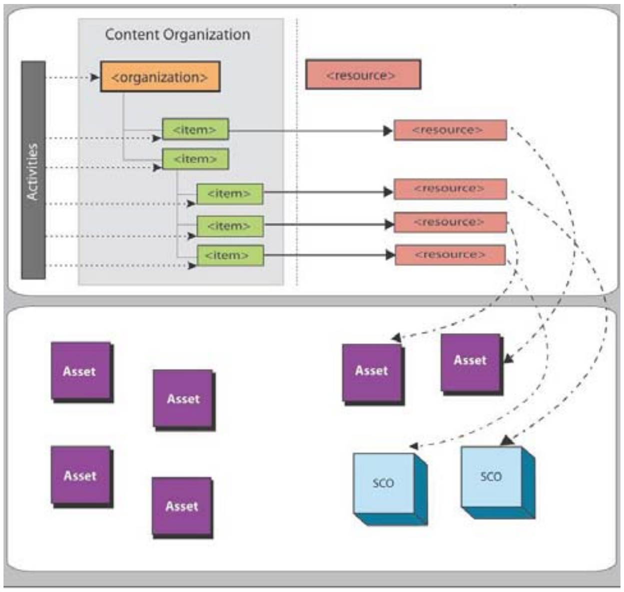

Figure 10. Content aggregation.

- Assets are an electronic representation of media, such as text, images, sound, assessment objects or any other piece of data that can be rendered by a Web client and presented to a learner.
- A SCO is a collection of one or more assets. The only difference between a SCO and an asset is that the SCO communicates with an LMS using the Institute for Electrical and Electronics Engineers (IEEE) ECMAScript.
- A learning activity may provide a learning resource (SCO or asset) to the learner or it may be composed of several sub-activities.
- A content organization is a representation or map that defines the intended use of the content through structured units of instruction (activities).
- Content aggregation can be used to describe the action or process of composing a set of functionally related content objects so that the set can be applied in a learning experience.

These packages are saved in a zip file. This file contains among other files, a description of package in XML, named imsmanifest.xml and the physical file of resources called

- The SCORM Run-Time Environment, Fig. 11. In this "book" is described:
  - Content launch process. LMS must load the SCORM when the user perform a request.
  - Standardized communication between content and LMSs. To do this, it uses an API
  - Standardized data model elements used for passing information relevant to the learner's experience with the content.

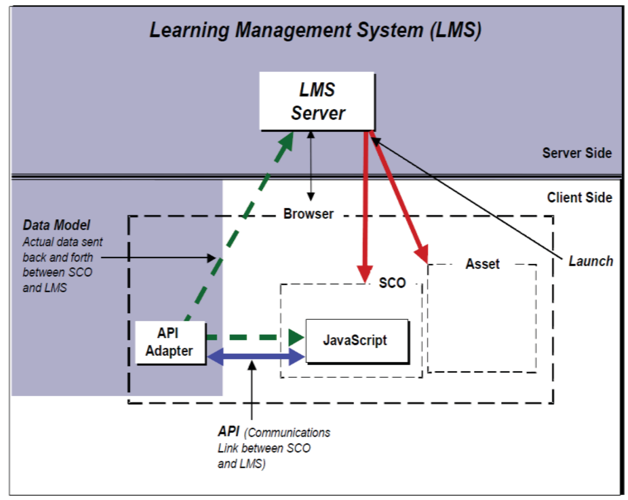

Figure 11. Scorm Run-time eviroment.

- Sequencing and Navigation: Descriptions and requirements for defining sequencing and navigation information.

  Nowadays there are several versions of SCORM v1.1, 1.2, 2004 and not all this version supports sequencing and navigation.

So, if a teacher or e-learning designer creates a SCORM package using these specifications then he could install it in all the LMS that support that SCORM version, reusing content and services.

V. PACKING WEB LAB IN SCORM

In the previous section we have read how a SCORM is composed and how we can communicate this SCORM with the LMS using an API. Now we are going to explain how we could use a web lab into a SCORM and therefore how we could reusing the LMS services and install this package in different LMS that are SCORM compliant.

Nowadays you don´t need program to create a SCORM package, only if you want to use the API for communicating LMS and SCORM. In this case you have to include in SCOs one o several javascript file, for instance:

- APIWrapper.js whose purpose is in wrapping the calls to the API is to provide a consistent means of finding the LMS API implementation within the window hierarchy and to validate that the data being exchanged via the API conforms to the defined CMI data types.
- SCOFunctions.js contains functions encapsulate actions that are taken when the user navigates between SCOs, or exits the Lesson.

Once you include these files in an html page or other SCO. You could use the functions that they have implemented to communicate with the API implemented in the LMS, Fig. 12.

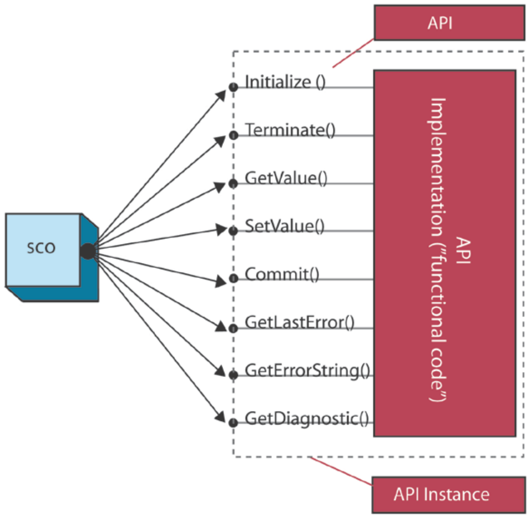

Figure 12. API.

It is very important to tell that when you create a web o remote labs you can use programming languages that don´t allow embedding JavaScript code, in this case we can integrate this lab in and *iframe* of a web page and in this page adds API functions to establish a communication with the LMS. The main problem is that the lab couldn´t communicate directly with the LMS. At this moment there are several projects to implement this API with web services.

So, the first thing that we have to do is to collect the resources that are going to composed the SCORM (html pages, images, etc.) and include the javascript files, that implement the API functions such as initializing the connection, exchanging information between SCO and LMS and finishing the connection, in the SCO that we want to communicate with the LMS. Later we have to establish an organization of every one of the resources to compose aggregation content.

Nowadays there is a great number of tools (free or commercial) allowing creating SCORM packages in a graphical way. So the teacher o learning designer, who don´t know about XML, can create their own SCORM packages without problems. Some of these free tools are:

- Reload, Reusable eLearning Object Authoring and Delivery.
- Couselab, is a free program but is not open source.
- eXe OPEN SOURCE SCORM Development Package

For this small example of weblab SCORM we have used Reload [11] and have include a web page named pag1.htm that include an *iframe* whit a URL of web lab in, Fig. 13. Of course you can include a web page hierarchy where you explain how the web lab works, the experiments that user can carry out, etc.

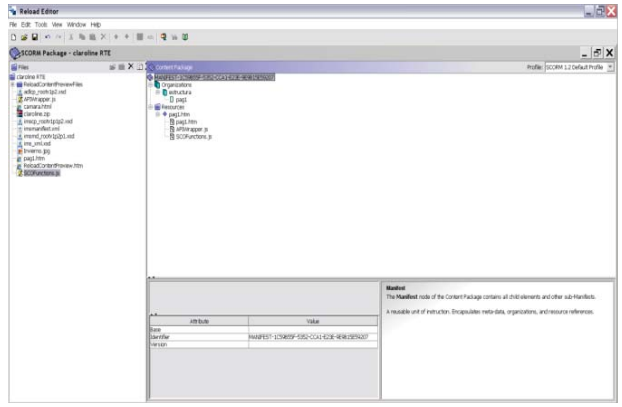

Figure 13. SCORM package created with Reload.

Once you save it, you could install this package in every e-learning platform that supports the same SCORM version that you have created. In the figure 14, we can see the result of installing this SCORM in Moodle.

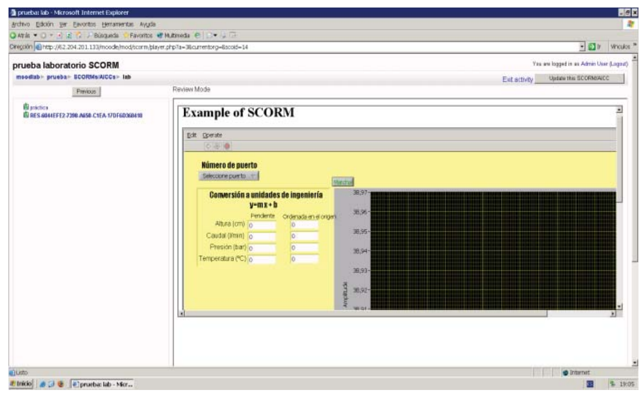

Figure 14. SCORM installed in Moodle.

Besides of creating an SCORM with a weblab, information about the experiment, etc and can use it in different LMSs (reusing). Also the user could use the LMS services as: Chats, Forums, Storage area, etc without having to be written a code line by lab programmer.

We have mentioned the problem in which code of web lab doesn´t allow embedding JavaScript and therefore there is no direct communication between web lab and LMS. To solve this and other problem as:

- What happen if the URL of web lab changes
- If we have several identical web labs and one this less busy than other (load balancing)
- If we simply want that web lab send information in a directly way
- Etc.

To solve this and other problems, we are working in a middleware for merging and managing both LMSs and web, remote labs in one.

VI. NEW MIDDLEWARE

In his section we are going to focus on a middleware and architecture to manage and integrate both solutions in one, Fig 15.

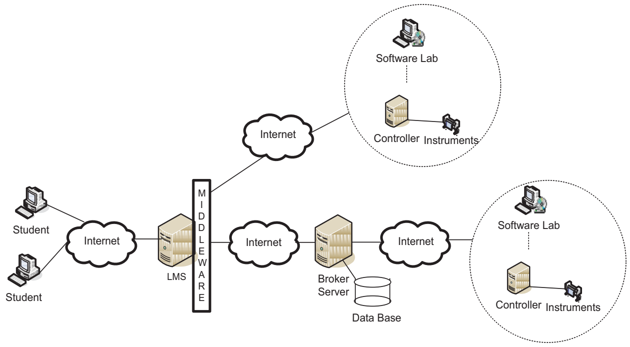

Figure 15. Integration LMS, iLabs and Virtual Labs.

To design this architecture we have to consider several ideas that have been mentioned in the previous sections:

1. The most of the LMS is composed by data base, a logical programming structure (modules, blocks, packages, etc.) and Web servers. So, we can design a module or package that use a database where is stored information about the laboratories, experiments, the pair lab-course, etc.

   Therefore if we design a module in an open source LMS as Moodle, this module could be installed in every server that contains an instance of Moodle. And the same if we create a package in .LRN or in other open source LMS as claroline, sakai, etc.
2. The iLab Shared Architecture (ISA) to facilitate the rapid development of new web labs and to provide a mechanism so that students from one university can use experiments and hardware instruments published from another.
3. There are other laboratories that only need be connected with a URL, with some information through of URL or other type of connection.
4. Both LMS as Web and remote labs need be displayed through Internet and by the way they use Web servers.

If we consider these ideas, the first thing that we should decide was what type of communication through Internet allows establishing a good communication among different systems and as well as provide several features as: scalability, loose coupling, etc. One of the best solutions that fulfil with these requirements is Service Oriented Architecture (SOA), Fig. 16.

As you can see in the figure 16, SOA [12-15]is based on services, to avoid the duplicating the services, the services providers publish information about the web service. The web service clients can search for the web services directory, if there are any web services that carry out the actions that the client need. If it is found the client bin and invoke the web service that is located in the provider.

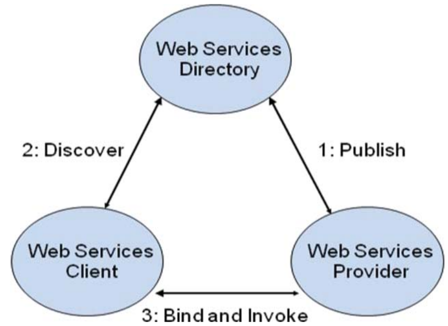

Figure 16. SOA.

All this process used several standards as:

- Web Services Description Language (WSDL) is an XML format for describing network services as a set of endpoints operating on messages containing either document-oriented or procedure-oriented information. The operations and messages are described abstractly, and then bound to a concrete network protocol and message format to define an endpoint.
- Discovery and Integration (UDDI) is a directory service where providers can register and clients search for Web services.
- Simple Object Access Protocol (SOAP) is a lightweight protocol for exchange of information in a decentralized, distributed environment. It is an XML based protocol that consists of three parts: an envelope that defines a framework for describing what is in a message and how to process it, a set of encoding rules for expressing instances of application-defined datatypes, and a convention for representing remote procedure calls and responses.

One part of SOA is the infrastructure that allows you to use services in a productive system. This is usually called the enterprise service bus (ESB), Fig. 17. The responsibilities of ESB involve:

- Providing connectivity
- Data transformation
- (intelligent) routing
- Dealing with security
- Dealing with reliability
- Service management
- Monitoring and logging

Therefore, this middleware establishes a way to communicate heterogeneous systems (such as old systems and new systems), provides a set of features as routing, security, etc. And it is based on Standards as WSDL [16], UDDI [17], SOAP [18], etc.

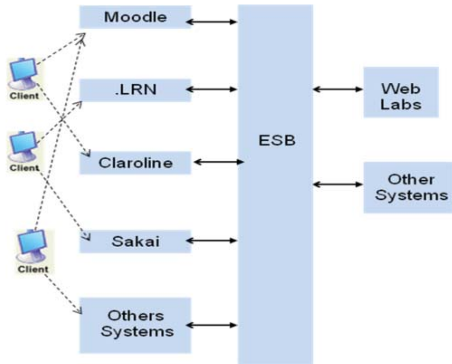

Figure 17. ESB.

VII. LMS (MODULE, PACKAGES BLOCKS, ETC.)

One of the first steps to define and design the architecture mentioned in the last section is to create LMS architecture. So, we have read that an open source LMS is composed by database, a logical programming structure (packages, modules, blocks, etc.) and web server. If we communicate and programme this element we can create an architecture based on services, Fig. 18.

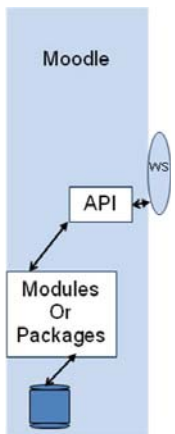

Figure 18. Middleware to connect a client with open source LMS as Moodle

At this point, we are talking about the creating of one .LRN package and a Moodle module to connect web and remote labs.

A. .LRN package:

We have defined and programmed a package for every .LRN administrator can create an area where connect a web or remote labs. To do this area we have created a package with the followed elements:

- A set of table associates to .LRN database (oracle or postgres) to store the created laboratory, the experiments that you are going to do, the way of connection between .LRN and web or remote lab, etc.
- A Logical programming (using Tool Command Language TCL) to exchange information between user and LMS, etc.
- And a user interface (ADP or HTML files).

Once the package has been installed in the .LRN the administrator could create all the areas that we need. This area is composed by, Fig. 19:

- A navigation menu where we can find services as:
  - Calendar
  - Asynchronous communication (forums, etc.)
  - Synchronous communication (chats, etc.)
  - Experiment area where are stored user manual, texts about the experiment, etc.
  - And area to display the remote labs and where the students can be work with it.

Figure 19. .LRN package.

B. Moodle Module:

To create a lab module in its first version we have carry out the next step:

1- We have created a set of table and have related them with Moodle database. To create this table we have used a XML file called intall.xml that uses Moddle to allow generating these tables with independence of the type of database that you install in Moodle (mysql, oracle, etc.).

2- We also modify the administration site for allowing that the administrator is able to add, modify and delete the labs or server broker (in case of iLab) and the way of connection of these, Fig. 20.

3- Later we have created te PHP file that provide of tle logical of module, as:

   a. Add a laboratory to a course.
   b. To Call connection services
   c. To store information in the tables of module
   d. Etc.

As a result of this a teacher could add every lab which has been inserted, using Administration site, in a course, Fig 21.

If we click on the created link then the students log in the web lab directly. Of course this is a first version so that we connect with web labs that require the username and password through URL. We are working in designing and implementation the web services into LMS.

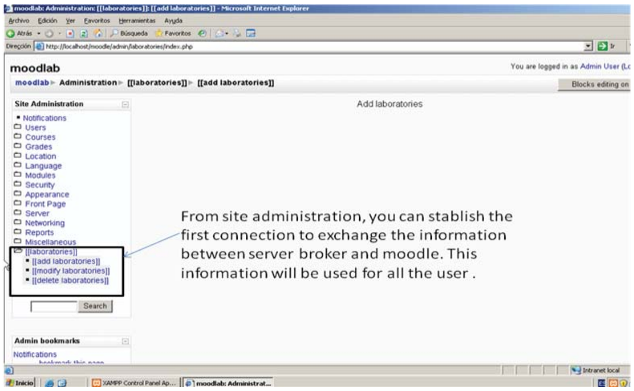

Figure 20. .Adding option to Administration site of Moodle.

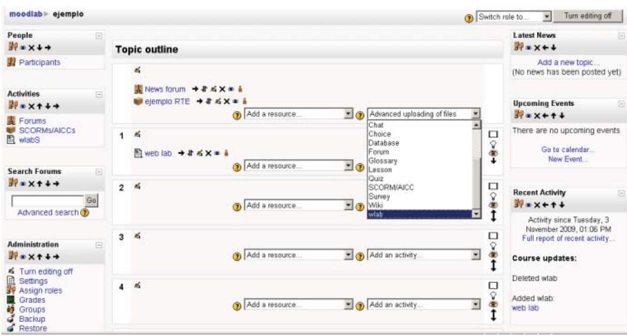

Figure 21. .Adding a web lab in a Moodle course.

VIII. Future works

This is a strong first step to connect LMS with iLabs and remote labs, and obtain shared labs, reuse of services and merge of these two solutions. But, of course we have to work in several important aspects:

- Design and implement web services in the open source LMS as Moodle or .LRN. For example scheduling service.
- Allowing LMSs and iLabs and web labs to use a single sign on
- Designing and implementing a enterprise service bus and the connector that systems need.
- Establish a common way to connect LMSs and iLabs and remote labs.
- Also we would like to work in the idea to describe web labs, so we can define an standard like WSDL or UDDI to search for web labs and bind with provider.

IX. Conclusions

We are working in a middleware and architecture that allow connect different systems and at the same time offer:

- Data transformation
- (intelligent) routing
- Dealing with security
- Dealing with reliability
- Service management
- Monitoring and logging

VirtuaLab, a Teaching/Learning System for 8 and 32 bits Microcontrollers

Juan Vázquez Martínez, Roberto Martínez Bejarano, Raúl Sánchez Reillo, Rodrigo Manzanares Bolea
Dpto. de Tecnología Electrónica
Escuela Politécnica Superior, Universidad Carlos III
Madrid, Spain
jvazquez@ing.uc3m.es

Abstract— **This paper describes the current state of the VirtuaLab facility at the Universidad Carlos III de Madrid. Under an authenticated access, the system allows to control a microcontroller based modular system, with visual feedback to the remote user through a web camera. VirtuaLab allows control through Internet of the same laboratory resources used on–site sessions from inside and from outside the campus area.**

Keywords-virtualab; e-learning; microcontroller; ARM7; 8051

I. INTRODUCTION

Microprocessor learning sometimes becomes a hard assimilation effort to students, requiring in addition a lot of attention to details in order to accomplish the mandatory practical laboratory sessions, [1].

Furthermore the necessarily limited time assigned to each session can be not enough, by the own difficulty of the exercise or because the student has the will to get a better insight of the full system working.

Although the market offers low cost evaluation microcontroller boards, buying one kit is not a common approach for a typical student, so the possibility to access a remote laboratory adds a useful complement to the traditional sessions into a laboratory with fixed training schedule.

This paper presents a modular system which can be used both into on–site sessions, and also from Internet using a software application which gets the total control of the PC based development platform, located into the real laboratory.

The developed platform is flexible enough to integrate available commercial evaluation boards, so avoiding microcontroller obsolescence and easing the migration to new models with low effort, [2, 3]. In this way, we use a project based learning approach, in the same path that other authors have followed before, [4, 5, 6].

Organization of the paper is as follows: section II explains the HW resources of the platform, while section III details the SW solution adopted in order to manage the access to system and to administrate the users Data Base; section IV describes some of the laboratory assignments to students. Finally, section V presents the evaluation results, and section VI summarizes the main conclusions reached during the life of the project.

II. HARDWARE DEVELOPMENT PLATFORM

A. Microcontroller board of 8 or 32 bits

The system can use any microcontroller of 8, 16 or 32 bit, usually included onto a commercial evaluation board, which makes the full system close to a real application. The actual system built use two completely different chips:

An 8-bit system, actually the evaluation kit C8051F226DK from Silicon Laboratories, a model derived from the original Intel 8x51 design.

A 32-bit system, the Keil MCB2100 kit that includes an evaluation board for the NXP-Philips LPC2148, based on an ARM7 CPU, a more complex and powerful model [2].

We have designed the board E/S MICROS in order to have control of different peripherals. The different interfaces use a specific I/O pins assignment and routing board for each one of the microcontrollers and, of course, requires its own software routines.

This special pin adapter board allows the connection of the concrete evaluation board used with the E/S MICROS one, using flat cable. The last one includes several input/output peripherals, which the user can freely combine.

Usually students program its assignment works on C and Assembler languages.

Actually, we are using IDE from Silicon Labs and µVision3 from Keil/ARM as development environments, which include tools that let to edit, assemble, compile and link programs, and then run and debug it when they are errors' free.

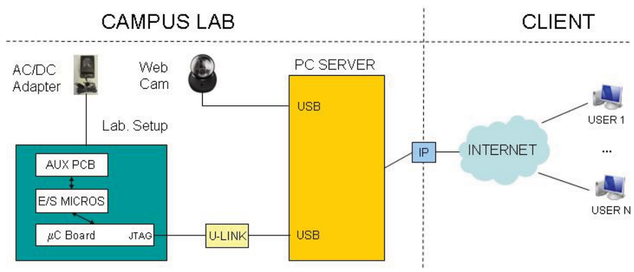
B. E/S MICROS peripheral board

This board includes a keyboard/keypad, an LCD liquid crystal display, a LED's matrix, an RS-232 serial port, an I^2C EEPROM and I^2C potentiometer, an infrared receiver, and a triac for AC phase control.

An expansion board adds to this E/S MICROS some peripherals, better placed outside of it because of space constraints: these are a little speaker, a power relay, a DC motor and a photo detector of the motor axis spin.

Keyboard: is has a 4x4 cross-matrix organization.

Figure 1. Schematic diagram of the complete system



LCD liquid crystal display: the character display module has two lines of 16 symbols. The HW interface is common to several models, making feasible to mount another one with a different number of lines or character, e.g. 4x20.

LED's matrix: this display has a 7x5 dots format to show the desired configuration. To reduce the number of pins, the microcontroller connect through the serial input of two 74HC595 shift registers, and its parallel outputs connected to ULN2003A drivers.

RS-232 serial port: this module includes a MAX233 level converter and a standard DE-9 connector.

I^2C devices: the board includes two devices with this type of interface: an EEPROM memory and a digital potentiometer. The 24LC16 memory has 16 Kbits but a higher capacity model can replace it. The DS1803 digital potentiometer, with 256 different output levels, controls the DC motor through an amplifier, and can connect to other devices.

IR receiver: With this device, it is possible to implement an infrared remote control that offers complete user isolation from AC powered devices, and allows controlling onboard peripherals through a remote wireless channel. It uses the Sharp IS1U60, an infrared receiver with a lens included.

AC phase controller: With this module, it is possible to manage up to 1 KW, through the triac phase control of an AC line. To get a safe operation, opto–isolators completely separate the power and control sections.

Speaker: a microcontroller output reaches an audio amplifier and this to a little speaker. A manual amplifier gain control, allows adjusting the volume of sound. By creating a memory table of frequencies associated to each musical note, it is possible to associate a different tone to each key or even play previously stored melodies.

Figure 2. View of E/S MICROS peripheral board

Figure 3. Platforms for ARM7 and 8051 VirtuaLab

Relay: it can switch on or off, signals of relatively high power, with galvanic isolation from control electronic.

DC motor: this type of motor finds typical application on micro-robots, toys etc. Its can be controlled directly with a variable DC voltage or through a PWM signal, which is the preferred technique. The module includes also a motor spin detector, based on the H21A phototransistor optical switch; to this end the motor mounts an X shaped piece fixed to the axis, which cuts the light path when spinning.

C. *Complete hardware platform*

Fig. 3 shows the two platforms, including the following components: microcontroller evaluation board, E/S MICROS board, expansion board, interconnecting cables and two supporting plastic sheets, the upper one of transparent polycarbonate.

Also included is a webcam of 640x480 pixels resolution and maximum rate of 30 fps and an auxiliary lamp. The visualization software is the AMCAP v1.00 bundled with the Trust Spyc@M100 camera model. In this application, we do not have special video bandwidth requirements, [7].

This constructive system based on independent modules, makes possible to protect effectively the HW of improper user handling. At the same time, it makes easy the substitution of modules by obsolescence, fault or upgrade, [8].

III. SUPPORTING SOFTWARE

The management and control software of VirtuaLab has been developed under Delphi. It uses the Windows Remote Desktop to access from Internet an on–site laboratory where a PC computer runs Silicon Labs IDE or Keil µVision3. The system authenticates the user to verify its access rights, and then he can work up to a maximum allowed time of 1 hour.

To get access, the PC requires a name and password fig. 4. When the system is busy, it denies the access, as VirtuaLab attends one user at time while working in non-stop mode.

A user is blocked after some failed access attempts but after a 24 hours lapse he is automatically restored. Five minutes before the session ends, the system sends a warning message to close opened files and save code changes, fig. 5.

Figure 4. Access screen to VirtuaLab

On the PC client side, the user needs a remote desktop connection, but a high-speed link is not required. Universidad Carlos III offers to its students several rooms with access to a large number of computers connected to Internet. By using these PC or a wireless notebook connected to the local Wi–Fi, it is possible to access VirtuaLab from inside the academic campus. The students also can access the system from outside, for example from the own home through Internet.

After login, the user execute the webcam and IDE programs from the start menu of the remote laboratory PC, and begins to work as if he were into the lab, near to the development platform.

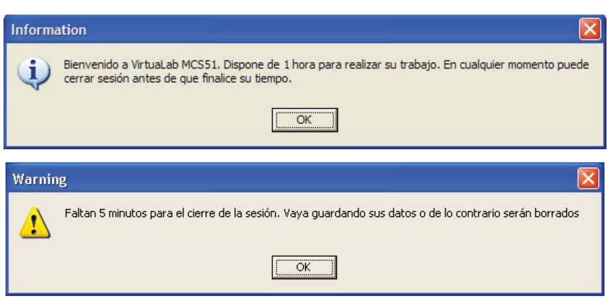
An obvious limitation of the system is that the input keypad is not physically accessible. In this case and when debugging an application, the user must use some technique equivalent to the keying action, e.g. changing a register or variable using a program breakpoint.

As a help to the instructor, it is possible to run an auto-test program, which allow verifying the integrity of any of the HW modules included in the system. This tool is useful to confirm that there is no hardware malfunction so a program module is incorrect and also to locate and repair a device fault.

The availability of a library of functions, which handle the full set of HW resources, offers the possibility of making some complex practices before the students have developed and debugged their own programs for all of the required modules.

Two library sets are available, one for each microcontroller model, in order to use, invoke and link without access to the source code. This feature has probed to be a strong advantage to learn the functionality of the full system.

Figure 5. VirtuaLab Welcome and Timeout warning screens



The Data Base includes a record of students, which can work with VirtuaLab, a timetable of its assigned slot time, and a historic register of accesses to system. If a student does not login the system within 15 minutes after the beginning of its time slot, any other user can gain access to it. This rule allows that anyone can use the system when it is idle.

Several security layers are included to avoid undue access to system. For example, to key the password the student uses a mouse over a virtual keypad onto the screen. As additional protection, we use an encrypted hard disk database, to avoid changes made by non-authorized persons.

The system administrator has its own special password to access database records, listings and control screens. In this mode, it is possible to get individual, group or global reports, selecting different fields of interest. Administrator can insert/delete users, manage blocked accounts, see access and time history, make searches by name or group, and define reports listing. Recording the number of access and consumed system time helps the evaluation of each student and group. The graphic interface has been refined along several years of use, in order to be intuitive and user friendly.

IV. Laboratory Projects

Let us shortly describe, some of the practical exercises proposed to students of different engineering degrees:

A. *Using 8051*

1. Speed control of a DC motor: the speed must change under keyboard command. The measured speed on rpm shows over the LCD. The program should use specific functions to develop. The user writes and debug in assembler and in a posterior session, he do it again using only C language.

2. LCD scrolling display: includes the use of keypad and LED's matrix; shows a 4-line message on a 2x16 LCD.

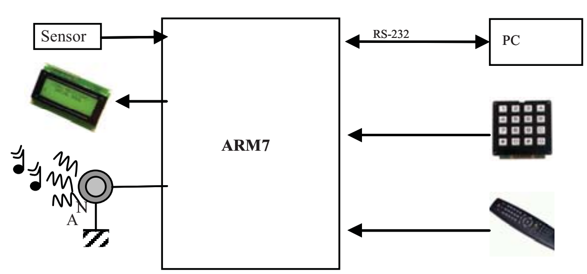
3. Serial link: communicates the microcontroller through a RS-232 interface with HyperTerminal running on the PC. LCD upper line shows data received from PC and the lower line show the data entered through keypad and sent to PC.

B. *Using ARM7*

4. The assignment is to build a complete alarm system, following a progressive process along several sessions, [9].

The alarm system detects presence with an analog sensor input, whose value must be higher than a certain level. In this case, the system generates an audio alarm and sends a message to a PC through the serial port.

Figure 6. Domestic alarm system based on VirtuaLab



The alarm system starts by entering its PIN number and silence by a command sent through the IR remote control. The system signals its state on the LCD, adding audible feedback to entered keys. It is possible also to activate the audio alarm from the PC sending a special message.

The last sessions are usually very instructive for the students, when the working team of each group must resolve some rather unexpected integration problems.

V. EXPERIENCE RESULTS

The Electronic Technology Department of Universidad Carlos III de Madrid UC3M, has 50 full kits for laboratory practices, including the I/O boards and the corresponding evaluation boards for microcontrollers of ARM7 and 8x51 families: Keil LPC2129/MCB2100 and Silicon Labs C8051F226.

Courses belonging to different three years engineering degrees at UC3M use this equipment kits at on–site labs. Actually, these second year courses belong to three different degrees:

- SED II, 8051 based. Degree ITI Electrónica Industrial (EI)
- SED, ARM7 based. Degree ITT Sistemas de Telecomunicación (ST)
- Microprocesadores, ARM7 based. Degree ITT Telemática (Tel)

A. Academic results

The following histograms summarize the results of several years and degrees. The X-axis shows reached marks from zero to ten, and Y-axis the annual percentage of students within a mark in that course.

For SED II we have 4 years data, from 2006 to 2009.

The data on SED covers from 2007 to 2009, and we only show the histogram for the three years average.

On Microprocesadores, we have data from 2006 to 2009 while fig. 7 shows the average histogram for these 4 years.

Figure 7. Four years academic results from SED II (EI)

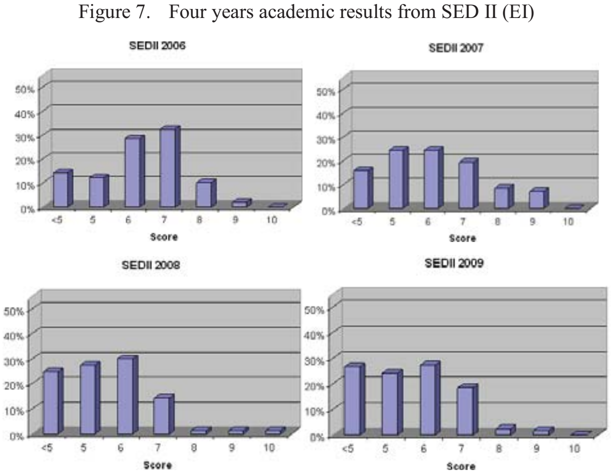


Figure 8. Academic results of SED (ST) and Microprocesadores (Tel)

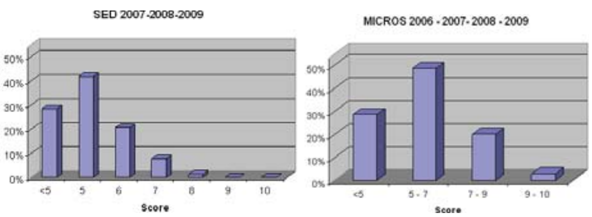

B. Student perception of results

We have carried some surveys on students the first two years after the introduction of the remote lab. Tables show the results for SED II on 2007, which agrees with other courses.

- General questions:

Q1: My topic interest has increased after the practices

Q2: I should like to study an advanced course on this topic

Q3: Practices are useful to understand the theory

Q4: Tell if the practices balance is right

- On–site Laboratory

Q1: Mark the usefulness of this type of practices

Q2: It promotes to work into a group

Q3: The number of exercises has been enough

- Remote Laboratory VirtuaLab

Q1: Mark the usefulness of this type of practices

Q2: It promotes an individual work

Q3: Working remotely with VirtuaLab has been easy

TABLE I. STUDENTS PERCEPTION AT SED II (EI)

General questions	Responses					
	1	*2*	*3*	*4*	*5*	*Av.*
Q1	1	3	2	10	9	3,9
Q2	2	2	9	9	8	3,6
Q3	0	1	3	15	11	4,2
Q4	3	2	4	11	10	3,8
On–site lab	**Responses**					
Q1	1	3	4	15	7	3,8
Q2	0	0	5	11	14	4,3
Q3	2	3	3	6	16	4,0
VirtuaLab	**Responses**					
	1	*2*	*3*	*4*	*5*	*Av.*
Q1	1	3	2	10	9	3,9
Q2	2	2	9	9	8	3,6
Q3	0	1	3	15	11	4,2

Marks qualifies from 1 (strongly disagree), to 5 (strongly agree)

In general, we think there is not a clear difference on the average academic results due to the introduction of the remote lab, although this is true for the more interested individuals, [10]. The student perception of VirtuaLab is good, but cannot be used to a fair comparison, because they have no experience of the same practices with and without a remote lab.

VI. Conclusions

The major perceived effect of access to VirtuaLab laboratory is an increase of the time students spend working with the microcontroller platform, because of some well-known real practical constraints, that up to now only this approach has probed to solve.

The remote lab is a complement to the conventional one, as it cannot completely replace it, although it is still possible to apply the transfer of training concept, [11].

Other studies as [1, 12, 13], have not detected any significant difference of results between remote and on–site labs of similar contents, in agreement with VirtuaLab findings.

Therefore, this additional time devoted to put in practice the concepts explained at classroom, is likely to increase the practical development skills of students, and as a consequence a better insight of the course topic.

From the point of view of instructors and school management, there are also significant gains in terms of time and resources assigned to classroom training, as more students can progress by auto learning, without close teacher attention.

VirtuaLab offers conceptual advantages from different points of view: a flexible HW platform able to use any microcontroller based on commercial evaluation boards, changing only a passive I/O pin routing adapter, and a mechanical design able to withstand heavy use, protecting effectively the platform of improper user handling. At the same time, it is easy to substitute any module by a fault or upgrade to a new microcontroller, [8].

From the SW side, it allows students a local and remote access to develop, download code into microcontroller flash memory, debug and run a program, while records its working data for teacher's control and management.

As a dedicated system, VirtuaLab allows the control of a broad range of peripherals, has flexibility to change easily the microcontroller board avoiding obsolescence, and to control the students working time, all of these maintaining the same HW platform used in an on–site lab.

However, as the market evolution brings cheaper boards and link dongles, the use of low cost individual trainers could become a real alternative to these dedicated types of systems.

***Abstract*-- A remote instrumentation model used to perform modern RF and digital communications experiments over the internet is presented. The setup allows for highly cost effective and pedagogically rigorous mechanism of instructions for students in situations where traditional laboratory equipment is either unavailable or at a premium cost. In the model, a switch matrix is used to eliminate the need for students to be present in the laboratory.**

Index—Remote, Analog, Digital, E-learning

I. Introduction

Rapid changes in the field of engineering technology have increased the need for universities to provide engineering and engineering technology students with meaningful and relevant practical experiences. However, limited available resources in the provision of laboratory hardware and infrastructure have been the principal impediment in achieving this objective. Such hardware limitations have been increasingly marginalizing the quality of engineering and engineering technology education. E-learning can be used to help universities and technical collages overcome this problem and one approach is to expand e-learning activities in programs with limited resources to take advantage of online computer-based technology. In this model, remote instrumentation technology and the internet are merged to interface students with the physical world. As such, remote laboratories allow students around the world to access a computer equipped with the suitable interface circuits, such as data acquisition systems connected to various sensors or communication modules, and perform real-time experiments. Each year, a growing body of work has appeared that has further validated both the technological viability of distance laboratories, and their effectiveness in delivering a worthwhile laboratory experience [1-4]. The quality of the architectures and designs has shown steady improvement, and there appears to be ample evidence that this form of experimentation delivers a valuable learning experience for students [5-9].

In this paper, a setup is proposed to perform modern RF and digital communications experiments remotely in a distance learning environment. The National Instrument Educational Remote Instrumentation Suite (NI ELVIS) and Emona Instrument's DATEx telecommunications trainer [10-11] were utilized in this setup. An amplitude-shift keying (ASK) experiment was performed online to demonstrate how students can easily carry out many tedeous tasks to perform the experiment; and hence focus on understanding the underlying principles of operation of the communication systems.

II. Remote Laboratories

Hands-on laboratories provide valuable experience in engineering and technology education. However, such trainers are not always necessarily available to students. Limitations on equipment access and funding further reduce the availability of laboratory resources in many institutions. Virtual laboratories are therefore a possible alternative to traditional laboratories, and they are already used in distance learning education in several universities. On the other hand, remote labs help alleviate these problem by increasing access and simultaneously reducing cost and a growing body of work has appeared that has validated both their technological viability and effectiveness in delivering a worthwhile laboratory experience. Over the past 10 years, two primary solutions have been implemented. Recently reported work continues to mirror this trend [12-17]. Some researchers have developed customized hardware and software that enables management and control of the process including data-based driven web pages with access scheduling. Others have chosen to employ commercial platforms, e.g. LabVIEW in combination with NI ELVIS. We decided on this latter approach since ongoing support, maintenance and design improvements would be readily available from the supplier network.

The NI ELVIS II can be used in many electrical engineering laboratories. In addition to its built-in instruments, it can be used to build LabVIEW-based remote instruments, a multifunction data acquisition device and a custom designed bench top workstation and prototyping board. The Main features on ELVIS II, shown in Fig. (1), are:

- Offering modern digital and analog experiments in a single board.

- Hands-on experiential system featuring a widely accepted block diagram modeling approach.
- Featuring a USB plug-and-play interface for flexible setup.
- Operation in both local manual mode and under fully integrated Lab VIEW software control.
- Out-of-the-box curriculum for telecommunications concepts.
- LabVIEW Programming and LabVIEW Signal Express software.

The Emona DATEx electronics training circuit board (ETCB) is a plug-in trainer board module that works in concert with and a personal computer to provide a solution for students who need to perform laboratory experiments, whether at a distance or on campus. It plugs into the NI ELVIS II as shown in Fig. (1). All essential hardware devices/blocks in the laboratory are housed in this single board which possesses the capabilities needed for implementing dozens of telecommunications experiment. It actually includes more than 20 circuit blocks for basic telecommunications operation such as adder, multiplier, mixer, signal generator and phase shifters, which can be effectively used in the construction of block diagrams by patching them together according to theoretical block diagrams. User management of this telecommunication bundle occurs in a PC-based control mode using LabVIEW and DATEx SFPs software to give the students the freedom to build communications systems hardware by joining together circuit blocks similar to those studied during the class.

Fig. (1): Emona DATEX Set-up for Use in Communications Labs.

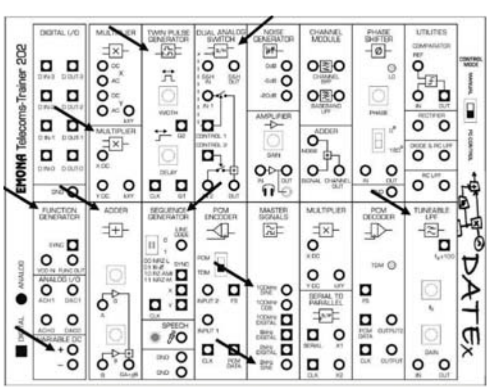

Fig. (2): Emona DATEx Front Panel.

The proposed architecture for this remote telecommunication lab is shown in Fig. (2). The main part in the lab is the ELVIS II-DATEx set-up. Experiments can then be setup up and conducted using this flexible platform where all programmable devices are controlled by digital signals, originating from the experiment server, through a multifunction data acquisition (DAQ) card. The user interface for a given application can also be created quickly and simply by LabVIEW, as this graphical development environment does not require any line of traditional text-based code to create such applications. LabVIEW subroutines, called virtual instruments (VIs), are composed and programmed to control the experiments. These VIs are hosted on the VI server as shown in Fig. (3). The programmer can use readymade VIs or compile and customize new ones that achieve the desired requirements. The remote experiment can be run from anywhere inside a local area network (LAN) or globally via the internet. The application is usually published with a web publishing tool, which converts the VI front panel into HTML format that can then be hosted by the web server. The client students can actually access the experiments with simple internet web browser in the same way a conventional website is accessed.

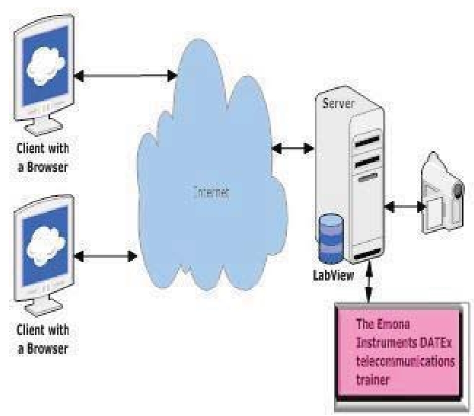

Fig. (3): Remote Communications Laboratory Based on the DATEx-ELVIS II Set-up.

In order to perform RF and digital communications experiments there is a need for eliminating the user interface needed to perform the required connections for modules. This setup has been prepared for students with only basic knowledge of mathematics and limited background in physics and electricity. The user interface can be controlled through a switch matrix that makes the lab setup accessible to the on-line community and obviates the necessity for physical presence of students in the lab to implement the necessary connection for the experiment being performed. Students can log in and generate their own AM/FM/BPSK signals, set up a bandwidth limited signal and explore its spectral composition. In addition to providing online laboratories, this remote laboratory may be a suitable way for on-line instrument evaluation.

III. SAMPLE ANALOG LAB: ADDING 2 SIGNALS

The Emona DATEx can model communications equations to bring them to life. This sample experiment will introduce you to modeling equations by using the Emona DATEx to implement two relatively simple equations. The steps needed to perform such an experiment using the standard ELVIS II-DATEx setup are as follows:

1. Launch the DATEx soft Front-panel and the NI ELVIS Oscilloscope Remote Instrument.
2. Locate the Adder module on the soft Front-panel and drag its G and g controls to about the middle of its travel.
3. The setup is implemented in the Front panel window by turning on the respective nodes.
4. The scopes time base control is tuned to view two or so cycles2khz sine output and measure the amplitude.
5. Now just disable the adder module's B input and activate the scope's channel B input by pressing the channel B controls on/off.
6. Adjust the Soft G control by using the tab key and arrow keys for fine adjustment.
7. Enable the B input then disable the A input and adjust the g control till the output voltage is same as the input voltage.
8. Enable the A input and you can implement:
9. Adder Module Output = Signal A + Signal B

This standard procedure may be followed by student in the lab in order to perform the experiment. This presence, however, can be eliminated when a computer-controlled RF switch matrix is used. These switch matrices are currently available from several manufacturers including National Instruments.

IV. SAMPLE DIGITAL LAB: AMPLITUDE SHIFT KEYING

Amplitude-shift keying (ASK) is a form of modulation that represents digital data as variations in the amplitude of a carrier wave. The amplitude of an analog carrier signal varies in accordance with the bit stream of the intelligence signal (modulating signal) keeping frequency and phase constant. The level of amplitude can be used to represent binary logic 0s and 1s. A carrier signal may be treated as an ON or OFF switch. In the modulated signal, logic 0 is represented by the absence of a carrier, thus giving OFF/ON keying operation. Fig. (4) shows the implementation of ASK modulation using the Emona 202 telecom trainer.

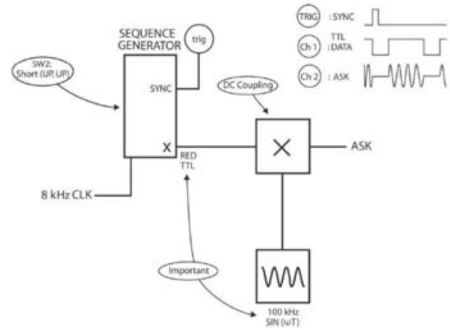

Fig. (4): Amplitude Shift Keying Set-up.

ASK modulation can be performed in a very easy way. The modules Sequence generator, Masters signals, Dual analog switch and oscilloscope are used for connections. The connections will be as follows:

1. Oscilloscope Ch 0->sequence generator X->Dual switch control2.
2. Oscilloscope Ch1->Dual switch out,trigger-> sequence generator sync,
3. Masters signals 2 KHz digital and 2 KHz sine -> sequence generator clk and dual switch IN2.
4. ASK signal's carrier and the sequence generator module's clock are the same frequency.

This experiment has been designed to make the ASK signal easy to monitor on the scope. Ideally, the frequency of the carrier signal should be much higher than the bit-rate of the digital signal supplied by the sequence generator module's clock frequency. The seuence generator module is used to model a digital signal and its sync. output is used to trigger the scope to provide a stable output, and the dual analog switch is used to generate the ASK signal.

Students do not have to perform many tedeous connnection tasks to perform the experiment; rather, they can focus on understanding the communication system and its components.

V. STUDENTS FEEDBACK ABOUT THE USE OF THE DATEX TRAINER / ELVIS II SET-UP

A survey was conducted to get students feedback about the use of the ELVIS II-DATEx communication trainer set-up in the lab. 20 students who used the set-up in their RF communications lab in the spring 2009 semester, and who are currently taking a data communication class and using the same set-up for the second semester.

The following questions about students experience in using the Emona-ELVIS set up in ECT352: Analog Communications (COMI) and ECT 361: Digital Communications (COMII) laboratories were used for the survey:

1- Do you feel comfortable using the Emona-ELVIS setup?

2- Where the Emona-ELVIS setup experiments clearly written?
3- Where the Emona-ELVIS setup experiments procedures easy to follow?
4- Does the use of the Emona-ELVIS setup increase your interest in the labs?
5- Did you have difficulties in configuring the Emona-ELVIS setup software?
6- Did you have difficulties in configuring the Emona-ELVIS setup hardware?
7- Was the Emona-ELVIS setup very valuable in terms of teaching and learning?
8- Overall, do you support the use of the Emona-ELVIS setup in the Communications labs?
9- Would you like to see test set-ups similar to the Emona-ELVIS setup integrated into other labs?

The survey was conducted for 16 students enrolled in two different lab sections, and the results of the survey are illustrated in Fig. (5). In this figure, the blue (light) bar represents a "YES" answer and the red (dark) bar represent a "NO" answer. The X-axis represents the question number, and the Y-axis represents the frequency of each answer.

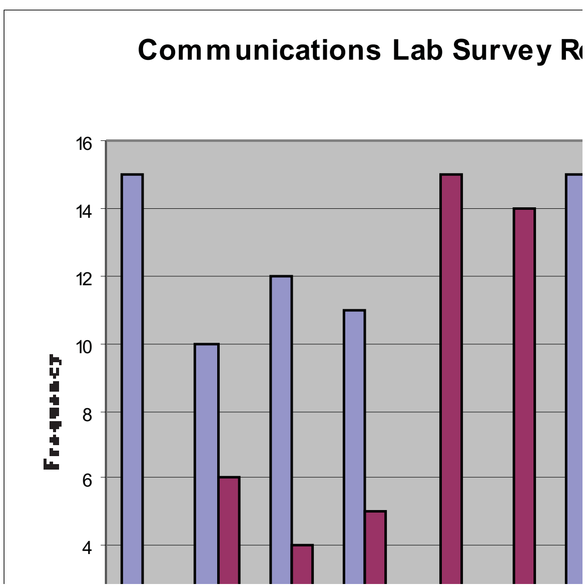

Fig. (5): Communications Lab Survey Results

From the results we see that there is a total agreement among students that they feel comfortable using the presented set-up. Only few students were not comfortable with the clarity of the experimental procedure for the labs. Students were comfortable using the LabVIEW software and the Emona-ELVIS II hardware set-up, and they overwhelmingly support the use of similar set-ups in other technical laboratories.

Conclusions

A laboratory design concept to perform RF and digital telecommunications experiments remotely in a distance learning environment is proposed based on an ELVIS II/DATEx trainer. In this model, a switch matrix is used to eliminate the need for students to be present in the lab. This setup allows for a highly cost effective and pedagogically rigorous mechanism of instructions for students in situations where traditional laboratory equipment is either unavailable or at a premium cost.

Assessments of the system show a strong interest of students on remote experimentation especially for those who cannot physically attend lab sessions to obtain hands-on experience. In addition, most of the class opined that it helped them to better understand syllabus topics and gain more applied knowledge. And the majority of students would certainly like to use remote labs in the future.

Abstract— **To successfully design and engineer solutions for today's and tomorrow's rapidly changing and expanding global contexts, in which people are confronted with new opportunities and challenges each day, engineering programs should be training their students to become broad based professionals, who are aware of the actual needs, values and behaviors of the people that use their solutions in their everyday life, work or play. This paper argues that in order to built such an awareness, engineering students should acquire direct, first-hand experiences of real people in real contexts. It presents a number of techniques that can be used to gain such experiences. Each technique is briefly described and illustrated with examples from our Industrial Design Engineering program. Knowledge, skills and attitude that are acquired through the use of the techniques are listed and reflected upon. Finally, our experiences with implementing the techniques into our program are discussed in view of their relevance for other engineering programs.**

Keywords-industrial design; user centered design; generative techniques

I. Introduction

Traditionally, engineering schools have been concentrated on instructing students in a certain technical discipline, teaching primarily knowledge, skills and attitude specifically relevant for that field. Technical, domain-specific knowledge has been mainly transferred in classroom settings, directly from professor to student, while skills used to manipulate this knowledge have been trained in laboratory exercises and case studies. Both knowledge and skills was then to be directed by the engineering student towards the fulfillment of certain goals, which were influenced by personal values, concerns and preferences, together making up his professional attitude. Several authors, however, have claimed that such traditional instructional methods will not be adequate enough to prepare students sufficiently for today's rapidly changing and expanding global context, in which people are confronted with more and more social and technological opportunities and challenges, for which appropriate solutions will have to be designed and engineered.

Developments such as the explosion of information resources, the social responsibility of new technologies, the blurring boundaries between disciplines and the ever increasing need for sustainable solutions, all would call for the education of 'The New Engineer' [1,2,3, 5] or "Renaissance Engineers' [4]. Such an engineer should be a broad based professional who is socially and environmentally responsible [1], who understands the context in which he or she will work [2] and can marry technical abilities with a broader understanding of the world [4]. Furthermore, he or she should understand concepts that go beyond their own discipline as well as be capable of communicating their ideas to other disciplines, in order to work in multidisciplinary teams [3]. Finally, they should be people-oriented [5]. This means that students should able to develop an understanding of how end users will interact with their designs and prototypes, and what their reasons and motivations are for doing so. In this way students become more aware of the needs, values and behaviors of the people that actually use their solutions.

In this paper we focus on the latter, arguing that this awareness should be an essential component of the engineer of today and tomorrow and that it therefore should already be initiated during the engineer's training. Since most engineers work in industry they tend not to interact one-on-one with the people who directly should benefit from their services or solutions. End users are often seen as abstract concepts rather than real people, if they play a role at all in the process. An engineering solution is traditionally considered to be successful if it is effective, efficient or innovative, not if it is usable, desirable or pleasurable. However, in today's complexity, where people are overwhelmed with technology that is more powerful and complex everyday, these latter aspects are becoming increasingly important. Future engineers can not limit themselves to focus on purely technical solutions anymore, they have to broaden their perspective to understand how these solutions will affect the everyday life of the people that they intent to serve.

In this paper we describe our experiences of bringing this everyday life of people into a design engineering curriculum. Adapting tools and techniques from ethnographic research, we have been training our students to tap into the deeper needs, values and dreams of potential users, going beyond the traditional focus on product functionalities and characteristics. We explain how these tools and techniques are implemented in our curriculum, show some of their results in courses and projects, and discuss their implications for engineering education in general.

II. Background

TU Delft's Industrial Design Engineering (IDE) program has been in existence for 40 years. With more than 4000 graduates and more than 300 freshmen every year, IDE has established itself as one of the leading design programs in the world. Its motto is “creating successful product that people love to use”, concentrating on designing and improving products which are used daily and intensively, at home or at work.

The Bachelor's program in Industrial Design Engineering lasts three years, in which design projects provide a thread of continuity throughout the program as a whole. These projects provide the opportunity to apply the knowledge and skills that have acquired from the various disciplines related to IDE, being engineering, ergonomics, design, marketing and consumer behavior, and sustainability.

After successfully completing the Bachelor's program, students can move on to one of the three two-year Master’s programs in IDE:

- Integrated Product Design, intended for those seeking professional mastery at the highest level in the field of product design. The program centers around mass produced consumer products and includes product service systems and products for professional applications.
- Strategic Product Design , which teaches students how to choose a strategic product direction based on insights from the external environment (market analysis, consumer and behavior research, trends and future scenarios, governmental policies, and new technologies and materials) and the wishes and possibilities of the company (product strategy, brand identity, mission/vision, resources).
- Design for Interaction, which teaches students how to design innovative and appropriate products and services by placing the key aspects of human-product interaction, which are use, understanding and experience, in the centre of the design process.

Over the years, new design approaches like “user-centered design” [6,7] and “user experience design” [8] have found their way into all programs. A key aspect of these approaches is that they put the user and not the product at the heart of the process. Initially this primarily meant that users were considered as ‘research subjects’ which were studied by expert researchers or designers, in order to generate product requirements or to validate design concepts. Typical techniques included *interviews, contextual inquiries* and *observations*.

More recently, however, approaches like “participatory design” [9], “co-design” or “co-creation” [10] have promoted a more active engagement of end users by having them participate in design-like activities that are traditionally considered to be the domain of professional designers or engineers. By giving ordinary people (i.e., people with no professional design or engineering background) tools and techniques, such as collages, diagrams or models, they are given the opportunity to articulate their experiences in ways that are more visual and expressive, and consequently, more accessible and understandable. It can be said that increasingly designers are taking on the role of researchers, while users are acting more and more like ‘designers’.

This development in both design research and education has been paralled by a growing need from industry for designers that have the skills to tap deeply into the context in which today’s and future products will be used, including the needs, values and motivations of the people that will use them. It is felt that because of the ever increasing complexity of this context a better understanding of it is needed to successfully design products or services that will have to ‘live and survive’ within this context.

Therefore, in several courses and on several occasions throughout the IDE program, students are stimulated to directly interact with end users by visiting the locations where people work, live or play, observing their behaviors, studying their moods and emotions, getting insights in their desires and wishes as well as generating ideas and concepts together etc. In the next paragraph we will discuss some of the techniques that we teach, illustrated with examples from various courses and projects.

III. TECHNIQUES

In general, all techniques have their base in ethnography, which is the branch of anthropology that deals with the scientific description of specific human cultures. A core principle of an ethnographic study is that data is collected through direct, first-hand experiences of daily life. In recent years this principle has been adopted in the development of several techniques that should support designers and engineers in acquiring such experiences. In this paper we will present and discuss three of those techniques: interviews /contextual inquiry, observations and generative sessions. The scheme in figure 1 [11] nicely shows how these three techniques are related to the type of knowledge they produce and the kind of insights that can be gained from them.

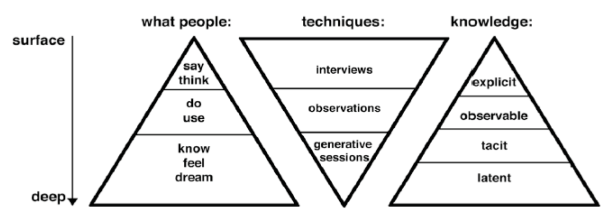

Figure 1. Relations between techniques, knowledge and insights [11] (used with permission.)

A. Interviews/Contextual Inquiry

Conducting interviews is a classical and often practiced technique to gather information from people. Typically an interview is a conversation between two or more people (the interviewer and the interviewee), where the interviewer asks questions to which the interviewee provides the answers. The style of the interview can vary from strict, where a predefined set of questions is closely followed, to more open, where the questions get adapted to the flow of the conversation. Interviews are particularly suited to acquire *explicit knowledge* on people’s current and past experiences. People are usually good at telling factual things, what they did or are doing now,

/

where they did it, when, etc. However, while this can provide designers and engineers with useful information, it is usually not rich and detailed enough to provide directions for the actual design process.

Therefore, in order to acquire data that is more grounded into the contexts of people's actual life or work, a technique called Contextual Inquiry [12] is often used in design projects. This is also a structured field interviewing technique, however, based on four core principles that differentiate it from the plain, journalistic type of interview.

- Principle of context: Visiting and absorbing the whole context in which the tool, product or system to be designed will be used, is considered essential. Thus the interviews should always take place at the location where the new design will be used.
- Principle of partnership: Users are seen as partners in the design process, they are considered to be experts of their personal situations. Interviewing during a contextual inquiry therefore usually does not include set, broadly worded questions. Instead, the partnership between the interviewer and interviewee is used to create a dialogue, where the interviewer not only can determine the user's opinions and experiences, but also his intentions and motivations.
- Principle of focus: Throughout the inquiry, the interviewer should be constantly be aware of his focus, being a combination of his own assumptions, beliefs and concerns of the particular situation. All that is seen and heard is filtered through this focus and the return of the inquiry therefore heavily depends on 'keeping focused'. Expressing this focus to the interviewee also makes forming a partnership easier.
- Principle of interpretation: After gathering the data, meaning has to be assigned to it through interpretation. Since design and engineering is nowadays commonly done in (multidisciplinary) teams, the goal of the interpretation is to build a shared understanding within the team. This is usually done in an open discussion, where the interviewer walks through the results of the inquiry, while the other teams members listen, ask questions, make comments etc.

In the course Interaction and Electronics, which is running in the second year of the Bachelor program, students are given the assignment to design the user interface of a Personal Shopping Assistant (PSA). This is a small computer device with a touch screen, which is mounted to a shopping cart. All products in the store are marked with an RFID-tag by means of an adhesive label, storing a special number known as the Electronic Product Code. Through this unique code detailed information, such as manufacturer, shipping date, price, weight, and best-before date etc. can be retrieved of each product. The interface of the PSA should thus provide the customers of the store with to a number of functions which should support their shopping process. For example, the device might give suggestions on special offers and show where these products are located in the store.

To gather requirements for their design, the students have to conduct a contextual inquiry, studying real users doing real tasks in real situations. For this students visit stores, conduct short interviews with customers, observe their behavior, map out the layout of the store etc. They are urged to take pictures or shoot videos (if permission is granted) or otherwise capture the actual context as rich as possible. Taking into consideration that their subjects are not designers and are therefore not trained to think of new functionalities, they have to look actively for opportunities in their subjects' behaviors, needs, preferences, social activities, daily routines etc.

Consequently, the results of their contextual inquiries need to drive their further design process. This means that emphasis was put on producing rich and inspiring visuals of a highly informative character instead of thick and wordy reports filled with demographics and statistics. Experience has shown that such a format is much better suited to communicate to others, mainly because of it's compact and attractive qualities. Figure 2 shows an example of such a presentation format.

Figure 2. Infographic showing the results of a contextual inquiry

Another, popular way of condensing the results is by creating a *persona*, which is a fictitious character that is created to represent a user type within a targeted demographic that might use the product, system or service to be designed [13]. Personas give a human face to otherwise abstract data about potential users, thus helping to better infer what a real person might need. Creating a believable persona involves coming up with a rich identity and a visually compelling character that gives much relevant information for the actual design stage.

Figure 3. Persona depicting characteristics of a possible future user.

/

Personas usually included a name, a photograph, a personal profile, interesting quotes, goals and motivators, etc. Again, by presenting the results of their study in such a way students are forced to stay close to the people they have interviewed, the situations that have encountered, the locations they have visited etc.

B. Observations

A technique that is often used in combination with or as integral part of a contextual inquiry, but can also be used independently, is observations. Carrying out accurate observations involves much more than just watching people doing things. It requires a sensitivity and alertness for the particular routines, behaviors and interactions people exhibit in certain situations. For this an open mind is as much needed as an open eye, since many of the things people do or how they behave in day-to-day situations, could easily be taken for granted. More than often there are conflicts in how people claim to behave and how they actually behave, without them being aware of it.

Good observation starts by deciding first what will be observed. Since many contexts are very rich, a clear focus is again essential not to get overwhelmed by all impressions. For this reason students are urged to come up with a plan before the actual observations are conducted. Being at the location, they are told to be as unobtrusive as possible in order to influence the context as less as possible. Camera's can be used to record interesting situations, but permission to use them should always be asked for. Things that can be looked for are certain routines as expressed through repeated activities, body postures or interactions. However, also extreme behavior should be recorded, since sometimes one 'strange' observation can trigger a whole range of possible solutions.

C. Generative sessions

While interviews, contextual inquiries and observations all can and will provide designers and engineers with valuable information about what people think, say, do or use, they tend to fall somewhat short when it comes to getting access to the deeper values, whishes and needs of people: what they know, feel and dream. In reaction to this, various method and techniques have therefore more recently emerged that try to address those latter type of information.

Within our IDE research program, substantial work has been done on the development of one of those technique, called *contextmapping* [14]. Building on the influential work of Sanders [15], contextmapping tries to create an overview of the context surrounding the use of a current or future product by gathering and analyzing personal experiences of real users regarding that particular context. Over last years the technique of contextmapping has been implemented in several IDE-courses [16].

The core of a typical contextmapping process is a so-called *generative session*, in which participants first create artifacts such as collages, diagrams or models, and then are asked to present and explain their creations. The premise is that through telling these often personal stories they are able to re-live previous experiences with a certain product, system or context more vividly and deeply. These stories are usually recorded on video and audio, and sometimes transcribed, for later analysis.

Preceding a generative session participants might receive a specially designed *sensitizing package* or *cultural probe* [17], which consists of small exercises or activities which are to be completed before the actual session. An often used format for such a probe is a workbook or diary, which contains smalls task for each day. The idea is that by doing these exercises the participants get triggered and motivated to explore the context of product use before the generative session.

After conducting a generative session the results are analyzed, usually by classifying quotes, observations, remarks etc. in meaningful categories. The conclusions are then to be communicated, again not in thick reports, but in ways that will enhance an understanding for and empathy with the users. Possible means for this are collages, card sets or diagrams. For an extensive description of the technique of contextmapping and generative sessions, the interested reader is referred to Sleeswijk Visser et.al.[11].

Exploring Interactions is a course in the Design for Interaction master's program. In this course students are required to formulate their own design project around a certain theme. The themes, for example Fear and Fearless, Power, or Trade, are quite broad and abstract, but so guide the students in their explorations and give them the opportunity to pick a topic they really like. The focus of the course is on analyzing and conceptualizing human-product interactions in relation to the physical, cultural, technological, and social contexts in which new product design(s) will be used. In other words, getting direct access to these contexts is a substantial part of this course.

Students are therefore encouraged to explore the context for which they intent to design. Observations and interviews are therefore extensively used, but considering the conceptual character of the course, many students also use contextmapping. Figure 4 shows an example of a workbook, used to sensitize possible participants of a generative session. The topic that is addressed here is shoes. The exercise on left asks people to describe or draw the shoes they are wearing on that particular day, while the exercise on the right is about visualizing one's appearance and the appearance of others.

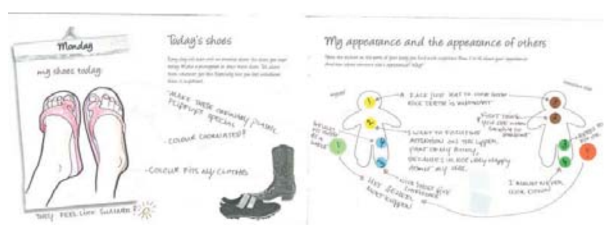

Figure 4. Example of a workbook, used to sensitize participants before a generative session.

The workbooks that are filled in by the participants, are subsequently used as input for the actual generative session, in which the topic, in this case living in a convalescent home or home for the elderly, is much deeper explored. Figure 5 shows a participant in an actual session, working on a collage that has to be presented and discussed later in the session. Sheets with inspirational images are given, but of course participants can also bring or create their own images, keywords etc.

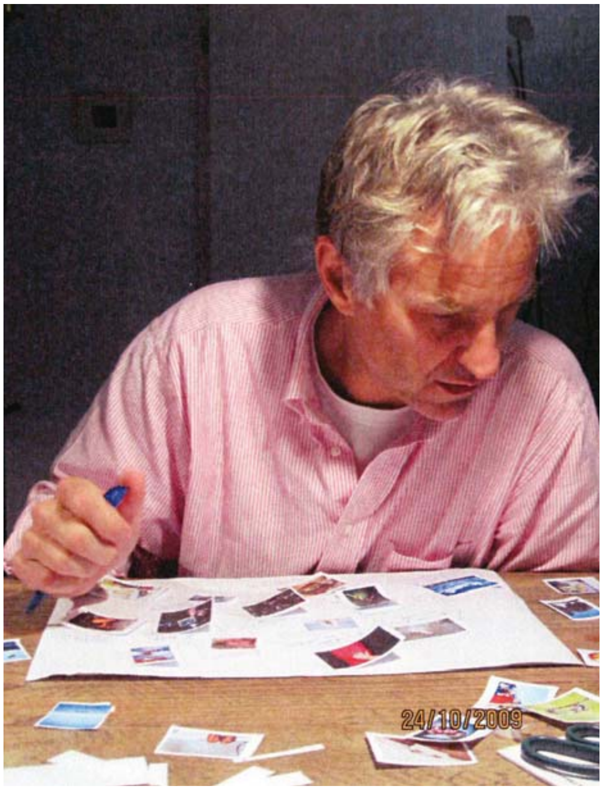

Figure 5. Participant creating a collage in a generative session.

IV. KNOWLEDGE, SKILLS AND ATTITUDE

Problem-based learning and realistic design projects are key in offering a rich and challenging learning environment; such realistic projects should be problem-based and should involve the activation of prior experience, the demonstration and application of skills, and the integration of these skills into real-world activities [18]. Throughout the IDE program, students work on several design projects, in which they apply their knowledge and skills, obtained in different courses, in an integrated manner to solve a real-life problem (similar to those they will encounter in their professional career). The integration of knowledge, skills and attitudes is at the origins of competency-based learning and is therefore increasingly being incorporated into university programs in general [19].

Central in all of the techniques described in the previous section is that they require students to leave the comfort zone of the classroom and take their presumptions, beliefs and ideas out into the real world. Through this they gain access to a different kind of knowledge, that is based on everyday life experiences instead of textbook examples. Furthermore, they get to train and sharpen their research and communication skills. Interestingly, we have noticed that the direct confrontation with real life situations and the interactions with ordinary people stimulates them to reflect on their personal attitude towards people, problems as well as their own role as designers and engineers.

A. Knowledge

Experiences from various courses and projects have shown that the techniques provide our students the means to tap into a rich and valuable body of *experiential knowledge*, which they could not have acquired in the classroom, from textbooks or from websites. While in education most situations get abstracted and simplified in order to demonstrate a certain principle or phenomenon, in real life such abstractions hardly exist. By studying the rich contexts of everyday life through direct interactions with the people who live, work or play in them, students are encouraged to put the mostly theoretical knowledge that they have acquired through their formal education into a different perspective.

This can lead to new discoveries and insights. More than once students reported how seemingly simple and ordinary situations turned out to be very rich and complex when researched carefully. They were often surprised to see what people actually do, how they use products in ways totally different from the instructions in the user manual, how they have developed certain routines to interact with other people, products or systems etc.

B. Skills

The specific nature of the techniques, with their emphasis on direct, first-hand experiences, on active collaboration and on visual, design-directed communication, also comes with a specific set of skills that is desired to successfully apply them.

First, the cooperative nature of the techniques requires students to practice their *communication skills* with people who have a different mindset, a different jargon and different set of needs and values. Contacting ordinary people, talking with them about their every experiences, listening to their wishes and concerns without prejudices, explaining goals and motives to them in non-technical terms, involving and stimulating them into design-like situations; these all require good 'soft' communication skills that are usually not engineers' greatest forte. With projects becoming more and more multi-disciplinary, such skills have an increasingly valuable quality.

In preparing the material, such as for the workbooks or the generative sessions, research questions or topics should be presented in an attractive way to stimulate participation. Furthermore, communicating the results of the techniques usually involves condensation and translation of the results in ways that should be easily understandable as well as highly informative. Therefore students are stimulated to create infographics, collages, moodboards or storyboards. We have learned that through their abstraction and attractiveness, these means communicate much better than thick, wordy reports. In addition, students' *presentation skills* are also heavily trained in conducting these techniques.

Finally, by interacting with people with different backgrounds, with different levels of education, coming from different cultures, students also train their *social skills*. By having to involve and motivate participants or having to facilitate and direct group sessions, students develop a better understanding of and feeling for how to deal with group dynamics, social or economic status and differences in personality. Again, such skills are very valuable for working in today's and tomorrow's complex, global society.

C. Attitude

All techniques that are discussed in this paper share the simple premise that first-hand experiences of the context to be designed or engineered for are essential when solving problems for this context. This requires from students that they step out of their comfort zones, not just on a physical level by leaving the classroom and going out on the streets, but even more so on a mental level, by leaving the comfortable, well-known environments and mindsets of design or engineering students and entering the everyday life of real people in real contexts.

From our experiences so far we can conclude that this change in perspective enabled our students to establish a much deeper and richer contact with their users, learning about ordinary situations, rituals and problems directly from the source. They have developed a greater *awareness* of basic human needs, values and limitations, which helps them to better assess the qualities of their own ideas and solutions. Furthermore, using the techniques and learning from their experiences most likely enhances their *sensitivity* for possible problems or opportunities in their own context.

Finally, from a learning perspective, the informal character that can be found in, for example, generative sessions, in which designer and user work side-by-side might even transform the learning process from a one-way knowledge transfer into an interactive, two-way dialogue in which both engineering student and potential user dynamically learn from each other.

V. Discussion

So far in this paper we have presented our view that students in engineering disciplines need to develop a better understanding of today's rich and complex contexts and the people who live in them, in order to design and engineer successful solutions, now and in the near future. We have argued that such an understanding can best be acquired through first-hand encounters and we have therefore presented our experiences with a number of techniques to tap into the everyday life of real people in real situations. We have explained each technique and illustrated it with examples. Finally, we have discussed how these techniques have contributed to the competences of our students.

It might be clear that we consider it essential for upcoming designers and engineers to acquire a thorough understanding of the user and the context of use. However, putting this into the curriculum does not automatically lead to applying these additional competences in practice. Learning by doing is crucial for obtaining a good understanding of these techniques. Moreover, not only a proper execution of the techniques need to be learnt, students also need to be able to select the right technique that fits the current research and design goal. This is not trivial. In their first practices students might start quite axiomatically 'we have to do the workbook now' and only after more design experience, their confidence and awareness on how the different techniques can be helpful in design projects increases.

Interestingly, the quality of data collected by teams that deliberately select a certain technique usually is much richer and better suitable for inspiring the design process, whereas teams that just execute some technique might get disappointed, as their data did not show something they did not know beforehand. In fact, starting with an attitude to get evidence for preconceived ideas often does not gain new insights as well. In sum, the techniques we presented here are meant for idea generation, they do not focus on validating results.

Furthermore, we would like to emphasize the value of qualitative data. High numbers do not automatically stress importance of a topic. Many remarks in the same direction might just be an indication of the obvious, while one peculiar quote could trigger a whole new design direction. Thus not only using the right techniques, but also the ability of analyzing and interpreting the data collection is important. Moreover, in order to use these insights to inform the remainder of the design process, the knowledge transfer of user insights and requirements should be carefully guided.

As said before, the learning by doing approach has been taken to emphasize the previously discussed knowledge, skills and attitudes in the curriculum. For this reason, a lot of studio work has been reserved in the curriculum. Although part of a learning-by-doing approach is self-study, it also requires an intense tutoring system to stimulate reflection and discussion, which is time-demanding for our teaching staff. Applying the techniques is also work-intensive for the students. Collecting data through observations and interviews, preparing sensitizing packages, conduction generative sessions, analyzing the data; communicating the results: these are activities that require considerable time, effort and dedication. The pay-off, however, is often a very rich set of possible design directions.

One might argue that our program is be much more design-oriented and human-centered than traditional engineering programs, such as mechanical or electrical engineering, and that therefore the presented techniques are much more suited for our students than for 'hard-core' engineering students. Design students would have to have a profound understanding of the everyday needs and wishes of prospective users, since consumer products that are unwanted, unusable or undesirable would simply be rejected by the market.

While this might be true, it is strongly believed that these techniques could be of value to more traditional engineering disciplines as well. After all, even very technical and professional products or systems have end users too. Real people with various backgrounds, that have to service, maintain, monitor or operate increasingly complex machines and devices in increasingly complex contexts and situations. Shouldn't these people have the right to work with products and systems that are usable, pleasurable or even desirable too? And isn't it the obligation of the engineer, most likely in collaboration with other disciplines, to provide them with products and systems that have those qualities?

VI. CONCLUSIONS

Good engineering today requires more than technical problem solving skills, a profound knowledge of mathematics and dynamics or an excellent understanding of material behavior or software algorithms. It also calls for a deeper understanding of and a greater sensitivity for the day-to-day situations and contexts in which technological solutions and innovations have to assimilate, and of the people who will use them to live, work or play. If so, then why not go out and explore these contexts and situations, observe those people, talk to them, invite them for design sessions, involve them into the development process etc.

Although contact with the actual end-user might not be so obvious for all engineering disciplines, due to the increased multidisciplinary character of design projects all kinds of engineers have to communicate across different disciplines, and thus have contact with either internal or external users. The techniques presented and discussed in this paper, with some modifications here and there to make them better suited for a specific discipline, could be used as a framework for exploring and investigating the everyday life of these users. Thus it is our strong belief that these techniques and the knowledge, skills and attitude that they bring with them, could be of considerable value to any engineering program.

Abstract— **This paper shows the results of a survey performed in Spain about the different functionalities of e-learning platforms. This survey was filled in by a group of teachers, experts in Engineering Education along all Spain, through the Spanish Chapter of the IEEE Education Society. The paper shows the opinion on several aspects about the e-learning functionalities, such as knowledge level, usage level, usefulness, etc., as well as the most used platforms. One of the objectives of this work is to create a reflexive debate in the international community about the e-Learning platform use.**

Keywords-component: e-learning platforms, e-learning functionalities

I. Introduction

During the last years E-Learning platforms (Learning Management Systems) have been a new component that have increased their use in Higher Education (as well as in small, middle and large companies) and proliferate in number in the learning applications scenario. The Engineering Education domain has been aware of this tendency and their application in on-line, distance and traditional university education.

An e-learning platform is a software application installed in a web server, which is used to administer, distribute, and supervise the educational activities of an organization or institution. Its main functions are to manage users, resources, and educational materials and activities, to control the access, to supervise the learning process and progress, to make evaluations, etc.

This year 2009, a survey [1] about different aspects on the use of e-learning platforms in the Engineering Education was filled out by the CESEI (acronym in Spanish of the IEEE-ES-Spanish Chapter) group [2]. This group is promoted by the IEEE-ES Spanish Chapter [3] and currently is composed by more than a hundred teachers of 40 universities along Spain, all of them deeply related with the Engineering Education.

This paper shows the most used e-learning platforms in Spain, the main functionalities of e-learning platforms, and the results of a survey about several aspects on these main functionalities, such as (i) Knowledge Level, (ii) Training, (iii) Usage, (iv) Perception of training proficiency, (v) Usefulness, and (vi) Preparation Effort.

Finally, the paper ends with some conclusions and reflections about the results, and the future actions that could be made.

II. E-Learning Platforms and Functionalities

The first group of e-learning platforms considered for the survey were Moodle [4], Ilias[5], Dokeos [6], .LRN [7], Sakai [8], Claroline [9] and WebCT/Blackboard [10]. They were selected according to previous studies, such as [11] and a previous reduced survey on a selected group of users.

The questions on the survey were focused on the usage level of each e-learning platform on each university grade, and on the presential or on-line characteristic of its usage.

With respect to functionalities, they were selected mainly from the Edutools Site [12], works [13][14] and the analysis of functionalities of the previous e-learning platforms.

As a consequence, the following functionalities were selected:

- Content Delivery: It is the most usual functionality, and permits to deliver contents to students.
- e-mail: Internal email is electronic mail that can be read or sent from inside an online course.
- Tasks-Exercises: They usually consist of some kind of material that students have to upload to platform in response to some required activity.
- Forums: Discussion forum is a threaded online text conversation between participants.
- Mailing lists: They allow to send mails to different users in a joint fashion.
- Exams: the typical exams to evaluate the work of students.
- Self-assessment: This kind of tools enables students to assess his/her progress and knowledge level on a specific subject.
- Surveys: This functionality enables the possibility of perform surveys to students on different topics.
- Groupwork: Group Work is the capacity to organize a class into groups and provide group work space that enables the instructor to assign specific tasks or projects.

- Chat: Real-time chat is a conversation between people over the Internet that involves exchanging messages back and forth at virtually the same time.
- Calendar: it enables students to document their plans for a course and the associated assignments in a course.
- FAQs: It is the typical Frequented Asked Questions service.
- Wikis: It is a service that allows the easy creation and editing of any number of web pages, using a simplified text editor.
- Blogs: A blog (a contraction of the term "web log") is a type of functionality that permits an individual to show regular entries of commentary, descriptions of events, or other material, usually in chronological order.
- Glossaries: This functionality allows a way to present definitions that can be looked up by the students.
- Videoconference: It allows two or more locations to interact via two-way video and audio transmissions simultaneously.
- Notebook: It enables students to make notes in a personal or private book. The personal notes can be shared with another students and/or teachers, but private notes can not be shared.
- Whiteboard: Whiteboard tools include an electronic version of a dry-erase board used by instructors and learners in a virtual classroom (also called a smartboard or electronic whiteboard) and other synchronous services such as application sharing, group browsing, and voice chat.
- Learning Paths. This functionality, also called lessons, allows teacher to add entire lessons that guide the student based on the student's answers. It might be helpful to think of a lesson as a kind of flowchart.
- Student Portfolio: Student Portfolios are areas where students can showcase their work in a course, display their personal photo, and list demographic information.
- Podcast: It is a series of audio files that can be downloaded from the e-learning platforms.
- Student Tracking: Student Tracking is the ability to track the usage of course materials by students, and to perform additional analysis and reporting both of aggregate and individual usage.
- Vodcast: It is a series of video files that can be downloaded from the e-learning platforms.

After a period of reflection and discussion, and based on the experience of the working team, we agreed that the questions about these functionalities were: (i) Knowledge Level, (ii) Training, (iii) Usage, (iv) Perception of training proficiency, (v) Usefulness, and (vi) Preparation Effort. We thought that these topics would help us to understand and improve the use of e-learning platforms in teaching/learning processes.

III. RESULTS

The survey was realized during the last days of May and first days of June, 2009. Finally the survey was completed by 162 teachers, where a 79% was male and a 21% was female. The results shown us that only the 13% of the teachers did not use e-learning platforms, and the rest (87%) did use them.

The characteristics of the teachers can be seen in figures 1, 2 and 3. Figure 1 shows the distribution of teachers according to their age. It can be shown that there practically all ages are represented, and that the most of them are in 36-50 range (63%). Figure 2 shows that the 45% of teachers has more than 20 years of teaching experience, and that more than the 50% has more than 15 years of teaching experience. Finally, figure 3 shows that more than the 60% of teachers who use e-learning platform has at most 5 years of experience in such platforms.

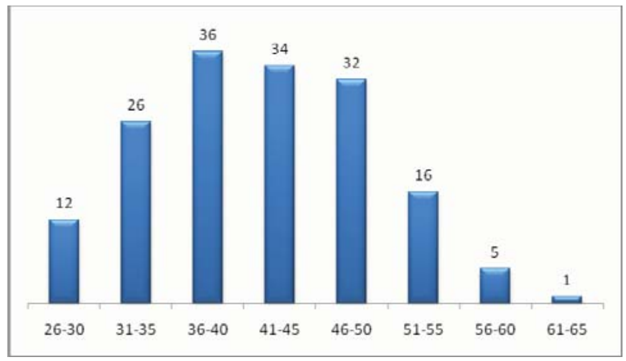

Figure 1. Distribution of teachers according to their age.

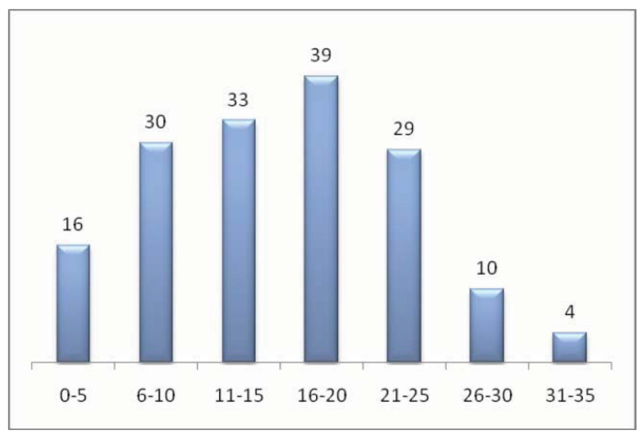

Figure 2. Distribution of teachers according to their teaching experience in years.

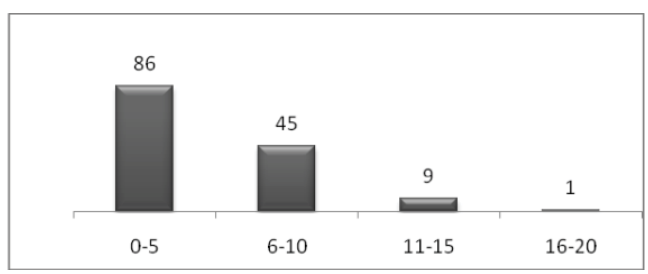

Figure 3. Distribution of teachers according to their e-learning tools experience in years.

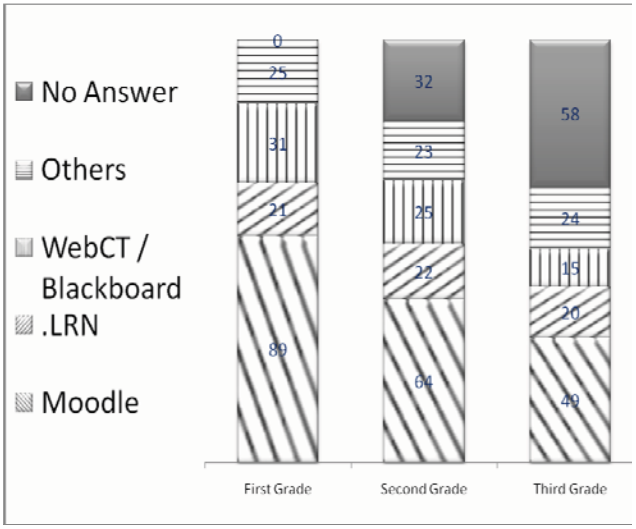

Figure 4. Distribution of e-learning platforms according to grade.

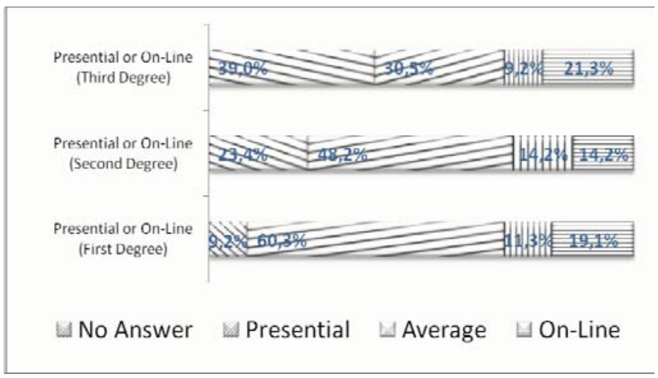

Figure 5. Presential versus on-line use of e-learning platforms.

In the figures 4 and 5 we can see the most used e-learning platforms in Spain according with the university grade (first grade or diplomate studies, second grade or graduate studies and third grade or doctoral studies), and the presential vs. on-line use in each grade. Notice that Moodle [4] is clearly the first used e-learning platform in all grades, and that WebCT [10] and .LRN [7] are both quasi-equal in the second place. Among the others e-learning platforms used in Spain are proper university platforms (6 cases), Aula Global (3), Aula Web (2), ACME (1), eKASI (1), ecampus (1), SIFO (1), ADI (1), SWAD (1), MIT (1), GEN (1) and Drupal (1).

With respect to the use on-line or presential, we can emphasize that the character on-line is between 14% and 21% in the three grades, and the character blended learning (mixture of on-line and presential) is between 9% and 14% in the three grades. However, the character presential significantly decreases with the grade, from the 60,3% in first grade, to 48.2% in second grade and finally to 30,5% in third grade. It is also significant that a greater grade, the greater the teachers who do not answer to this question.

In figures 6, 7, 8, 9, 10 and 11 (last pages of the paper), the results for each one of the topics and functionalities selected in this paper are shown:

i. With respect to the Knowledge Level of these functionalities, we can see that there exists a group of functionalities with a high degree of knowledge (greater than 50%): Content Delivery, e-mail, Task-Exercises, Mailing Lists, GroupWork, Surveys, Exams, Self-assessment and forums. On the other hand, there exists a group of bad-known functionalities (low or no knowledge greater than 50%): Podcast, Vodcast, Whiteboard, Notebook, Student Portfolio, Learning Paths, and Student Tracking.

ii. With respect to the Training received for each one of the functionalities, we can remark that in general it was scarce: there is no functionality with a high level of training greater than 25%. This is one of the more interesting results of the survey: the missing training.

iii. Figure 8 shows the Usage Level, and we can see that Contents Delivery, e-mail, forums and task-exercises are the most outstanding functionalities (high level greater than 50%), while whiteboard, videoconference, student portfolio, learning paths, podcast and student tracking are the less used (not used). If we add mailing lists, Groupwork, surveys and exams to the most outstanding functionalities, the rest of functionalities are rarely used.

iv. Figure 9 shows the perception of training proficiency for each one of the functionalities, and confirms the results of topic ii. There is a general perception of lack of training.

v. Figure 10 shows the perception of usefulness of the different functionalities. The most outstanding (with a high level of usefulness, greater than 50%) are Content Delivery, e-mail, mailing-lists, Groupwork, Surveys, Tasks-exercises, exams, self-assessment, and Forums. On the other hand, the less useful (denoting no or low useful with a level greater than 50%) have been Student tracking (the only functionality with a level of no useful greater than 50%), Podcast, Vodcast, Notebook, Student Portfolio, and Learning Paths.

vi. Figure 11 shows the preparation effort for each functionality. This topic must be considered with care, and taking into account the results of the other topics, specially the usage level. If one functionality is not used, obviously its level of preparation effort should be null. Therefore, it can be shown how the results for the less used functionalities are also the lowest in this topic, and the most used functionalities have a relative high preparation effort level, such as content delivery and task-exercises. However other most used functionalities such as e-mail and forums have not a relative high degree of preparation effort.

IV. CONCLUSSION

In this paper we have showed the results of a survey realized in Spain about the e-learning platforms functionalities.

In short, there are two main conclusions: (a) first of all, the most used e-learning platform in Spain is clearly Moodle[4]. And in second place, and in our opinion the main conclusion of this survey, (b) it is the lack of training in the different functionalities. Therefore, it is apparent that there is a need for training on the different e-learning functionalities. If we compare the set of functionalities where the teachers have less level of knowledge (topic i), of usage (iii) and perception of usefulness (v), then we have always the following functionalities: Podcast, Vodcast, Student Portfolio, Learning Paths, and Student Tracking.

We think that the different Spanish universities have to increase the training of university teachers not only on these functionalities but also on the different methodologies linked with them, in order to obtain the best use of all of them.

ACKNOWLEDGMENT

This work has been funded by the Spanish "Ministerio de Ciencia e Innovación" (Science and Innovation Ministry) under grant EA2008-0120. Our sincerely acknowledgment to all people who has collaborated with this survey [15][16].

Active Learning in Power Electronics

From classroom to laboratory

Jose-Maria Flores-Arias, A. Moreno-Munoz, F. J. Bellido and M. Linan
Department of Computers Architecture, Electronics and Electronic Technology
University of Cordoba,
Cordoba, Spain
jmflores@uco.es

Abstract— **Changing the paradigm from lecture teaching to student learning an experience has been successfully carried out in a 3rd course in the degree: there will not be lecture sessions or lab sessions any more. Students go directly to laboratory and the sessions take place on guided experiments about each analyzed topology in the syllabus. So theoretical analysis, modeling and simulation and experimental results of power electronics topologies are carried out together by students in an active learning methodology. The facilities have been disposed in a suitable way in order to become it flexible and have got a wide set of equipment that allows to perform lecture sessions, modeling and simulation skills, web based activities or lab experiments. Moreover, a professional power systems simulation tool with limited license is offered to each student in order to support his learning process at home same as that in classroom.**

Keywords- laboratory, methodology, Power Electronics.

I. Introduction

The University of Cordoba (UCO) and its Higher Technical College (HTC) have carried out many experiences along the last seven years with the aim of adapting teaching methodologies, guides and subject programs to the European Higher Education Area (EHEA), and more specifically, to the European Credit Transfer System (ECTS).

The University of Cordoba has supported methodological innovation and improvement by means of its own Teaching Innovation and Improvement Projects Program for the last ten years [1]. This program supports financially the purchase of the needed media, materials and equipments to develop all the approved activities and provides experienced supporting personnel to help us meanwhile them are carried out.

Four years ago, one of these projects (related to a non compulsory subject on Power Electronics) included a partnership contract with Powersys Ltd. in order to obtain the needed student licenses to help the Electronic Power Systems learning [2] [3]. As a consequence, all of our students are provided with a license of PSIM® for their scholar life. This professional power systems modeling and simulation tool is one of the basis of self-learning procedures carried out in the subject referred at this paper. It is used both for explaining the power systems function and for making simulation experiments both at university facilities and at home. Even this simulation tool is able to be used in many other engineering subjects in the degree.

Once financial problems (the major nemesis on any change action) have been solved, methodologies and teaching paradigm have to be revised and updated to self learning procedures and experience based learning.

II. Active learning principles

Active learning focuses the responsibility of learning on learners and comprises a wide set of methodological activities and experiences. Active learning activities include, for example [3]:

- Think-pair-share activities. Learners ponder a previous lesson, later to discuss it a little group of their mates, finally to share it with the class in a formal discussion. The instructor should clarify misconceptions during this last stage. However students need a background in the subject matter to converse in a meaningful way. So, this exercise is useful in situations where learners can identify and relate what they know to others
- The learning cell gets a pair of students together to study and learn. First they read the assignment and write down questions that they have about the reading, after students alternate asking and answering questions on commonly read materials during the learning process. At the next class meeting, the teacher will merge new pairs randomly and the students will asked their own questions to each other alternatively. During this time, the teacher is going around the class from group to group giving feedback and answering questions.
- Class discussions that may be held in person or in an online environment. This environment allows for instructor guidance.
- Short written exercises are a good way to review materials, the better if they are proposed as worked-examples.
- Teaching the new contents to each other at class at a studying or working group or by means of a forum or a wikiplace. Anyway students have to be closely guided by teachers.

In our opinion, the first activities related are more formal than the last ones and requires a more structured teaching procedure. So they are more complex to be carried out. Discussions, short exercises (guided or proposed), and peer teaching are in fact more flexible and allows the teacher to adapt the learning flow to learners. Anyway, as seen in the aforementioned activities, in order to ensure efficient instructional strategy teacher guidance must be an essential part of active learning. Moreover, practice after initial learning is of vital importance in student's education. Its importance lies on the fact that students who practice discovery learning are more likely to recall information.

Many activities described before are able to be applied to experiences in a discovery learning way. Learners work in pairs during lab sessions, discuss materials while role-playing, debate, engage in case study, take part in cooperative learning, or produce short written exercises, etc. As can be seen, the whole set of activities related to active learning are used meanwhile lab experiences are carried out.

The reinforcement of learning lies on practice, discovery activities and application problems. But this last one is not always suggested specially if the matter is their first approach to a subject in the syllabus. Guided or worked-examples could then be the best choice.

III. DESCRIPTION OF THE EXPERIENCE

Some previous experiences on active learning in Electronics are almost exclusively focused on simulation [4], multimedia [5], remote labs [6] or CAD tools [7]. However, other active learning education experiences include a wide variety of activities that fit with the aforementioned principles, as in [8]. The work described in this paper matches this profile. The experience is carried out in a noncompulsory subject in the 3rd (currently the last) course in the degree of Industrial Technical Engineering, specialty in Electricity. Traditional methodology of lecture sessions and laboratory or simulation sessions has been suppressed and they have been joined in a holistic learning process [3].

A. Facilities

Students work in laboratory facilities in which lab places are distributed likewise a lecture room. The advantages of both teaching methodologies are then focuses together to improve learning. Each place in the lab is equipped with a desktop PC connected to the Internet, adequate electronic instrumentation, 3-phase 24/42/230/400 V_{rms} and DC supplies and a set of power converters adapted to educational purposes. A lab overview can be seen at Figure 1. Figure 2 shows a detailed a pair of sights of the specialized equipment in a lab place. Thus, students have means enough to a classic lecture session, to model and simulate a power system, to experiment with the lab modules, to access to the internet and the learning resources sited there or to cooperate each other.

On the other hand, teacher's place is provided by an interactive smart screen. The teacher has access to every lab place personal computer from his place. So any situation that can occur can be shown to the classmates who can give their opinion and discuss the posed problems.

Figure 1. Laboratory overview

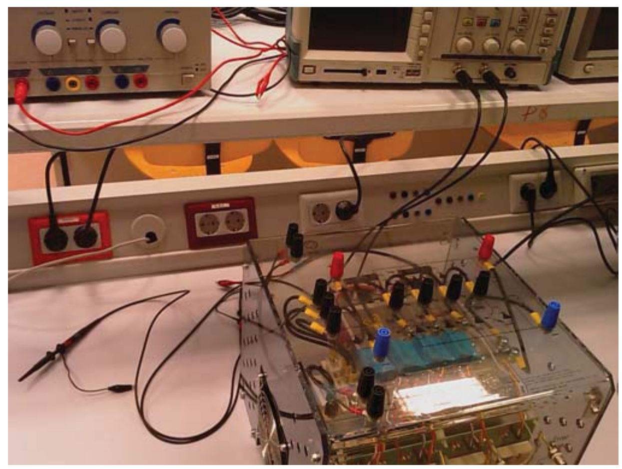

Figure 2. Lab places in detail

B. Learning Virtual Platform

Theoretical principles are at students' disposal by means of the e-learning platform UCOMoodle®. UCOMoodle® is an evolution of Moodle® developed at our University. Figure 3 shows the subject main page. Links to java applet simulations, data sheets of electronic devices, slides, presentations, etc. are also offered in all studied cases. So, the materials disposed give the source of knowledge background needed to active learning activities.

Figure 3. Subject main page at UCOMoodle

C. Modeling and simulation tool

Powersys Ltd. and the University of Cordoba have a partnership contract since 2005. As a consequence an unlimited number of student licenses of PSIM® software. So, All the students fro the UCO can request a student license for their scholar life due to a partnership contract between Powersys Ltd. and our University. This professional tool is able to be used for modeling and simulating power electronic systems and control, function and programmed blocks, electrical machinery, instruments and sensors and a wide variety of loads as well. It is a helpful resource both for explaining the power systems function and for making simulation experiments both at university facilities and at home.

In the presented experience, its use is restricted to analyze the behavior of the most common used power electronics topologies and to model the basis of their control modes. It also can be used in order to prepare the sessions, check the results of analyses or prepare for solving non guided cases at their convenience.

Figure 4 shows one of the analyzed topologies: A DC motor drive fed by a Buck converter with a speed control loop

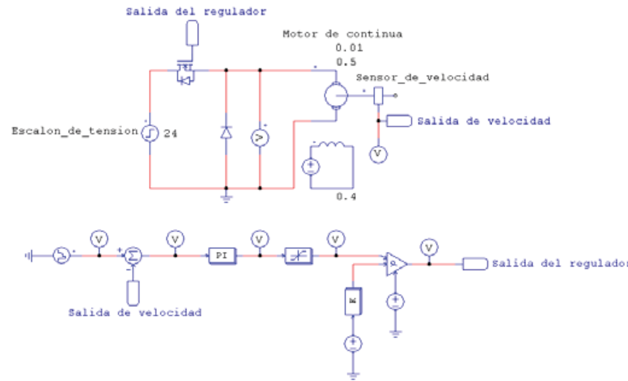

Figure 4. An example of the analyzed power systems

D. Working at classroom and homeworking

The class process starts with a brief introduction on a focused matter. Principles of operation of the about power topology and its basic control techniques are then explained and some worked-examples are discussed and developed for students as a class exercise or homework. Question and answers flow to each others after a think-pair-share activity or like a class discussion way. This takes place first at classroom and at a discussion forum guided by the teacher at UCOMoodle® later.

Students have to analyze and solve more complex problems after the exampled are done. They calculate the appropriate parameters of the topologies studied, model the circuits and simulate then using PSIM®. This autonomous work is done in a kind of learning cells. Another forum site at UCOMoodle is offered for sharing experiences, problems and solutions during this job.

All the collaborative activities of learning by teaching strategies at the virtual learning framework are supervised and valued by the teacher and its marks included at student studio assessment.

A set of lab sessions are done along the semester once theoretical behavior are know and operation modes have been analyzed. During its implementation a form about the experience has to be filled in and some short written exercises related with experiment functionality and lab procedures are done.

The evaluation of the acquired knowledge and competences includes a summary of the labs exercises done and a more complex analysis case than included in the syllabus. Students have to expose their work too and answer any question asked by the teacher or their classmates at the examination session.

IV. Results

This methodology has been carried out in several non compulsory power electronics subjects in the syllabus by the group of teachers aforementioned at authors' field. An average of twelve students (between six and twenty students) has been attended in these subjects. Lab facilities can be employed by up to twenty four students at the same time.

Presence rates have been improved in all cases up to almost the 100% across the last four years. The success rate didn't change significantly but marks have grown for all the students.

Satisfaction surveys within our quality control system show an important approval of the adopted methodology. Unfortunately we are not authorized to show any of these quality index data.

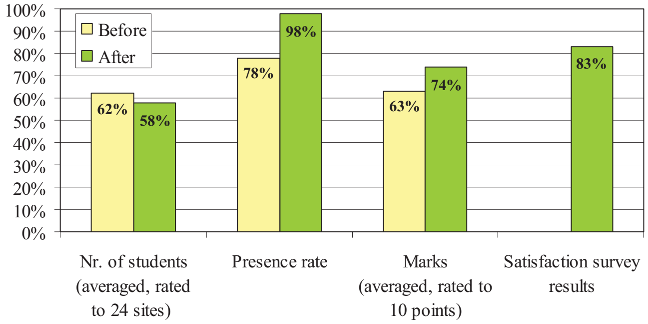

Figure 5. Comparison overall rates before and after adopting the presented methodology

V. CONCLUSSIONS

An active learning methodology has been planned and successfully carried out, including a wide set of proposed activities. Lecture sessions, simulation exercises and lab experiments are able to be given at the same place and at the same time without any break in continuity. Students have welcomed the experience for the last five courses and their marks have significantly improved. Absenteeism is negligible.

ACKNOWLEDGMENT

Authors thank the UCO for its supporting program that aims to methodological improvement.

Authors also thank Powersys Ltd. for keeping the aforementioned partnership contract for the last four years.

Abstract— **Even though active learning is not a new trend in engineering education, different schemes based in "learning by doing" are being proposed every day in the engineering education community. Considering "teaching" a topic to be a learning activity it can provide profound learning outcomes. A course previously adapted into an active learning environment has been reshaped to let the teaching experience to take place as a learning situation.**

Keywords-active learning; learning by teching; engineering education.

I. INTRODUCTION

The arrival of the European Higher Education Area and the re-design of University degrees have become a big challenge. The new degrees will start their implementation in September 2010 at the University of Alicante. Even though there are experiences in which competences-based education is a reality, the uncertainty feeling is inevitable. In this environment, engineering teaching-learning strategies are immersed in a constant evolution worldwide. The case of European Universities is especially noticeable due to this convergence process. The main goal of our task as educators is to provide with students an environment in which learning may happen. The active role of students is now a must to reach the new quality standards. Even though active learning is not a new trend in engineering education, different schemes based in "learning by doing" are being proposed every day in the engineering education community. There is no doubt about the benefits of "doing" as an effective learning tool applied to engineering training. Nevertheless, by itself, doing can not ensure effective learning to take place. A further reflection of what and why has been done is compulsory to transform the information into knowledge. In fact, there are several "doing situations" in which learning appear to be more exhaustive. Let us think, for instance, in the learning outcomes derive from our own teaching experience.

Teaching a new topic, or course, for the very first time is a profound learning situation. Any educator will agree considering her or his first classes as a high-level learning situation. Besides, within this teaching environment, assessment provides a valuable generation of feedback and reflection. Making students be involved in such an environment (peer-teaching and peer-assessing) will let them into a favorable and very effective learning opportunity for both trainer and trainee.

With these principles in mind, a course previously adapted into an active learning environment has been reshaped to let the teaching experience take place as a learning situation. Course activities try to persuade that some of the students will act, at certain moments, as trainers of a group of colleagues being trainees. Roles will change at different activity stages so that all students will have to be the trainer sometime.

Regarding the assessment, students will have the opportunity of getting feedback and high level reflection about the concerning subjects by means of peer and self assessment.

Besides, working in a particular course designed into an active learning environment, including learning by teaching will get not only academic but transversal skills improvement. Issues as group working, communication skills or liability are managed as good as engineering or scientific skills.

After a five-year process of adaptation of the learning model concerning the courses "Video Engineering" and "Video Laboratory" from conventional to active style, a considerable set of activities have been generated. Both courses present high realistic engineering contents, making them an interesting environment of professional-like engineering training experience.

Although Video Engineering and Video Laboratory are third year courses in Telecommunication Technical Engineering (BSC), single or sequences of activities have been exported to other compulsory and optional courses inside both Telecommunication and Computer Science degrees. The possibility of exporting any particular activity or sequence of activities to other disciplines will provide a wider range of benefits, promoting improvement in these other courses. This process has been carried out to provide other professors an easy way to adapt one particular activity or a sequence of activities focused in Video Engineering to their own disciplines. One of the main outcomes of the project was the interchange of activities between courses trying to make extensive the application of the methodologies designed.

II. TEACHING SITUATIONS

Video Engineering is a third year course in Telecommunication Technical Engineering (BSC), with sound and image speciality. It is a compulsory course included in two of the three program branches considered at the syllabus. The duration of the course, as established at the curriculum, is six theory credits and three practical ones, with one credit considered as ten hours attending class. Video engineering is a discipline with a high degree of engineering based development. The course main goal is formulated by one general objective: to train engineering work characteristics by means of studying video systems. Some of the competences explicitly presented include group working, communication skills and complex problem analysis. For that reason, it can be suitable for using problem based learning (PBL) [1] boarding the different aspects as if the students were the engineers trying to find the answer of a particular technology problem. This will be the approach of all activities performed along the course, taking into account the constraint of slowly increase their level of complexity. Besides, a series of short research projects is included within the course, resulting in a methodology combining project [2] and problem based learning. A more comprehensive course description can be read in [3].

Summarizing, the course is structured into an active learning scheme. Nevertheless, if students' degree of motivation is not high enough it is not easy to maintain the required working level to success in the course. An interesting strategy to let students reach a high level of motivation can be found in the "ripples model" presented in [4]. This model states the main factors and their relationships underpinning true learning situations. These five factors can be declared as: 1. wanting to learn, 2. needing to learn, 3. learning by doing, 4. learning through feedback and 5. making sense of what have been learned. Teaching a new subject is, among others, an experience in which all five factors are present, so it can be assumed to be a true learning situation.

The adaptation of Video Engineering course into an active learning scheme began in 2003 with a pilot test. Since that time a continuous evolution have been carried on, introducing changes in course structure, contents, methodology and assessment. From 2005 the course can be considered to be fully implemented into an active learning scheme based on cooperative learning, problem based learning and project based learning. Students are organised in small working groups, performing a sequence of activities preceded by short introductions and followed by discussion facilitated by the professor. With this starting point, it is not difficult to reshape some of the activities with the aim of making teaching a conscious part of the course.

The project hypothesis can be stated as: "making students play teacher's role puts them actively in a "wanting and needing to learn" situation based on a high degree of motivation". Some measurable results of this motivation are expected in terms of improvement of the academic results and reduction of the number of drop-outs, as these two items are widely considered as some intrinsic problems in engineering education [5]. Even though Learning by Teaching is not a new trend in education, it has been basically used in language learning [6], [7]. The goal of this work is not to get an adaptation of previous learning by teaching schemes to engineering education, but to emphasize teaching opportunities in an engineering course adapted following active learning models.

It is important to state that all the referred teaching situations are preceded by a working stage following the designed sequence of activities. We are not making students just to explain part of the syllabus to the others. All the teaching situations follow a previous reflection stage ensuring the expected learning outcomes.

The following sub-sections will describe some of the learning situations generated in the course. The goal is not to make a comprehensive description, but to present the basic ideas supporting the teaching-related activities.

A. Course goals statement

If one wants students to feel responsible of their learning process, they really have to be responsible. The first designed activity of the course is performed to let students to state course goals. If students are working what and how they want to, motivation is guaranteed.

B. Explaining contents

Group working activities lead easily to explaining-related situations. Taking into account some basic rules of cooperative learning will ensure that, at specific moments, all group members will have to act as teachers explaining their group-mates part of the course contents.

Besides, the project based sections of the course facilitates a major challenge, making students to explain their research results to the remainder of the group (Fig. 1).

Figure 1. Student presenting research results to the remainder of the group.

C. Tutorizing laboratory work

Laboratory work in video engineering is not easy to organize. The laboratory is equipped with broadcast-quality video production elements representing realistic professional working configurations. Due to the high cost of the laboratory equipment, there is only one working station of each configuration, so each cooperative group is working in a different station. Every week, each group has to be able to become familiar with a different, new and unknown working station. Having up to 12 groups trying to figure out how a new, and different for each group, system works can be difficult to manage. To avoid this situation to become chaotic, some students act as tutors of any configuration (Fig. 2). Each group has had extra time at the beginning of the semester to become experts of one of the available working stations. This system generates benefits in two ways. Not only students are teaching mutually, but the problems of the groups can be solved more eficently.

The system is implemented so all the students will have to play tutor's role during course semester.

Figure 2. Student playing the role of peer-tutor.

D. Assessing

Possibly, the activity demanding a higher level of responsibility is the assessment. Having to assess some other's work implies a profound knowing of the matter and a serious stage of the "learning by feedback" and "making sense" ripples presented earlier in this section. Students will have to perform peer and self assessment activities at different course stages.

III. RESULTS

Course design results are measured using both quantitative and qualitative indicators. Quantitative indicators are the students' academic results summarized in their final marks and the analysis of the number of passing and abandoning students through the course. Qualitative analysis is based upon questionnaires designed to get students' opinion regarding different course aspects.

Fig. 3 presents the evolution of the average final mark of the whole group from 2002 since 2008 and its standard deviation.

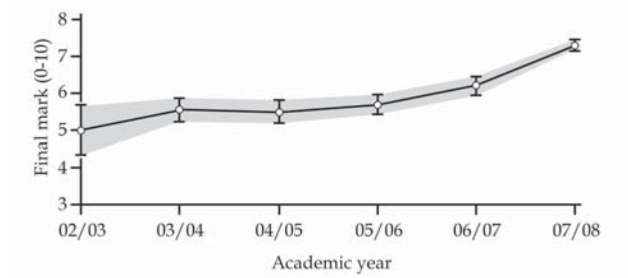

Figure 3. Evolution of the average final mark in a 0-10 scale and the standard deviation between 2002 and 2008.

As the course methodology has been changing, assessment has been evolving as well. The assessment is actually performed as a combination of several evaluation activities combining self, group and peer assessment and a final exam. A more detailed description of the assessment procedure can be found in [8].

This analysis period has been chosen as in 2002 the course was still implemented in a conventional methodology based on lectures, laboratory and problem solving sessions. The first pilot experience of active learning approach was carried out in 2003, and the teaching-based activities were introduced in 2007.

The results derived from Fig. 3 are quite interesting, as they show a clear ascent tendency, from 5 to 6.9 points in a 0-10 scale. It is also significant that the standard deviation decreases as the average value increases, meaning not only an improvement on the academic results but also a more coherence between students.

There is no direct indicator to measure if the introduction of teaching activities has impact in the motivation of students. Nevertheless, thinking of motivation as an effect of the "wanting to learn" and "needing to learn" ripples, a relationship can be assumed to be between the presence of that ripples and the number of students abandoning the course. An increase of the degree of "needing" and "wanting" ripples will cause a decrease of the drop-outs. Fig. 4 presents the evolution of the number of abandoning and passing students in the analyzed period. It is remarkable the difference in figures between the first year (traditional teaching scheme) and the other ones. In 2002 the number of abandons was near to 50% of the students. On following years this figure clearly drops below 20%, surprisingly arriving to 0% on 2007.

Moreover, the conclusive data about drop-outs is followed by an ascent slope passing students curve, going from 60% to more than 85%.

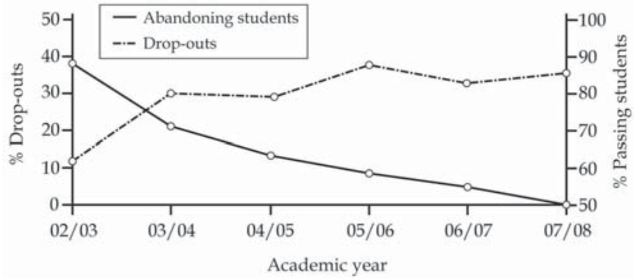

Figure 4. Evolution of number of drop-outs (left axis) and nunber of passing students (right axis) between 2002 and 2008.

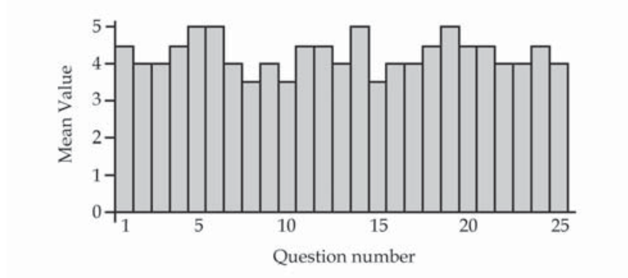

Figure 6. Mean value of the answers to the course evaluation questionnaire regarding 2007/2008 course.

Besides the numerical results, some qualitative data have been obtained using custom designed questionnaires. The aim of such questionnaires is to get students' opinion concerning particular aspects of course structure, such us contents, general methodology, group working tasks, and so on.

The questionnaire is composed of a set of sentences that students have to mark their degree of acceptance. The answer is coded in a 0-5 scale, in which 0 means "absolutely in disagreement" and 5 "absolutely in agreement". One of these sentences that students may (or not) agree with states "I have the impression of being learning", relating to the self awareness of the learning process. Fig. 5 shows the mean value of the answers to this sentence in the 0-5 scale previously presented. The degree of agreement with this sentence is especially significant, as it relates, not only with students' responsibility towards learning, but with being actively conscious of the learning outcomes derived from a particular set of activities.

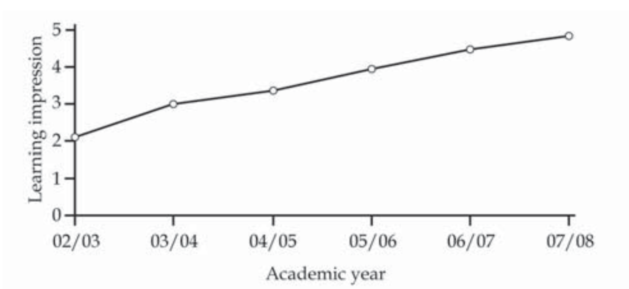

Figure 5. Evolution of the mean value about "I have the impression of being learniong" sentence between 2002 and 2008.

The full questionnaire consists in 25 coded questions plus five more open answer questions to let students freely express their opinion about the course. Fig. 6 presents the mean value of the 25 questions, rounded in 0.5 steps, regarding 2007/2008 course.

The topics included in the questionnaire are both general and specific ones about different course aspects (goals, contents, methodology, assessment…). Without pretending to perform a highly detailed analysis of the results, it is clear that students' general opinion about the course is quite positive. As the questionnaire has been designed just for Video Engineering course, it is not possible to compare results with other courses. Notwithstanding, it can be said that the general results have been improving following course evolution.

Considered as another interesting outcome, the possibility of exporting any particular activity or sequence of activities to other disciplines will provide a wider range of benefits, promoting improvement in these other courses. The methodology adaptation process carried out in the Video Engineering course during the last four years has generated a considerable amount of single activity and sequences of activities. Up to date, the activity migration process takes place unidirectionally, from Video Engineering to other courses. This fact is due to having in mind the possibility of migration as one of the design basis. The courses actually using activities from Video Engineering are Digital Electronics (firs year compulsory course in Telecommunication Technical Engineering), Broadcast and Cable Television (third year optional course in Telecommunication Technical Engineering) and Multimedia Techniques (third year optional course in Computer Science).

In addition, as a final quality indicator, a test was performed by the end of the first semester in the 2007/2008 academic year in a randomly selected last year course of the degree. The random aspect was included to unlink the answer of the test with any particular course. Students were asked to write down the two courses in which they had the impression of being learned more. There were two most rated courses selected clearly among the others, with similar marks. One of these courses was Video Engineering, while the other is one of the courses actually adapting some of the sets of activities designed for video engineering.

IV. CONCLUSION AND FUTURE WORK

Active learning schemes are widely considered as suitable methods to be used in engineering education. Nevertheless, it is possible to improve the results of the learning process going further than just "making students to do things". Complementing the "doing" factor with elements ensuring that students are conscious of their own learning process (they have evidences of how they are learning) improves course outcomes. One of these factors is the promotion of teaching experiences to students.

Teaching related activities are well shaped to provide the wanting and needing to learn ripples that will generate a high level of motivation and self awareness of learning in students.

From the basis of a course designed following an active learning scheme, it is simple to introduce small changes allowing teaching opportunities to take place explicitly.

The analysis of quantitative figures obtained from students marks and qualitative data obtained by questionnaires, are coherent with the expected results. The presented scheme clearly improves motivation and promotes students to be conscious of being learning.

There is one more indicator not still implemented to analyze the impact of course design concerning professional skills demanded by audiovisual industry. A set of contacts have been done with selected professionals actually enrolled in several TV and video production facilities. They will be asked about their opinion concerning the relevance of the skills obtained by students related with real industry needs of the video engineer position.

ACKNOWLEDGMENT

The authors would like to thank Dr. J. D. Ballester-Berman for his continuous and stimulating support and critical review of this work.

The authors would also like to thank anonymous reviewers for their contribution to the improvement of the article.

Abstract—**The field of Computer Networks has evolved quickly during the last years. In this paper we consider different aspects of those changes that condition the design of a subject in Networking; specifically, we discuss social, technological and economic aspects. Additionally, the changes proposed in the University studies for the European Higher Education Area condition the design of any current subject. Altogether, these changes condition the design and implementation of a subject on Computer Networks.**

Considering the presented changes we sketch the design of an introductory subject on Computer Networking. The subject is part of a pre-Bologna course, but is designed with the transition on mind. On the paper, we sketch the implementation of the course, designed to simplify the transition to conform the recommendations of the European Higher Education Area. We detail what contents were part of the theoretical or lab sessions, and how we managed to make most lab sessions with mid-class real hardware, introducing relatively complex concepts such as Quality of Service.

Keywords-computer networks; revolution; Bologna process; course design; lab exercises;

I. INTRODUCTION (HEADING 1)

Computer Networks are in a constant evolution. We consider that such evolution during the last decade is not only technical, but also comprises social and economical aspects. These are aspects that should altogether determine the composition of a Computer Networks subject.

The changes in the Computer Networks field themselves are accompanied with a regulatory change in the Education System in Europe. The Bologna process pretends to unify the higher education in Europe, making programs in Universities from different countries compatible with each other. Such change requires a rethinking of each course aspect.

We have considered such the design of an introductory course in Computer Networks before the change to the Bologna requirements, to provide for a smooth transition once a Bologna "grade" course has to be implemented. We describe the course design and how some of our lab courses aim to teach the most interesting and applicable capabilities of networking devices, using friendly exercises.

The main contributions of this paper are:

- A study of the evolution of the area of Computer Networks, focused on how recent changes affect the organization of an introductory University course.
- A rationale about the design of such introductory course on Computer Networks, including concerns about the division of theoretical vs. laboratory sessions, studying outdated technology or not, using simulation tools or real hardware, etc.
- A presentation of some lab sessions, intended to teach advanced concepts (such as QoS capabilities) using affordable mid-range real hardware and multimedia tools.

Specifically, note that this paper is not about converting a Computer Network subject to the requirements of the Bologna process, although we will refer to them in Section III.

The organization of the paper is as follows. Section II studies the changes in the field of Computer Networks during the last decade. Section III considers the changes required by the Bologna process, specifically in what concerns to our country. Section IV presents a rationale of our course design and the contents covered, including an example of our laboratory sessions. Section V presents our experience with such organization and pending issues. Finally, Section VI concludes the paper.

II. REVOLUTION IN EDUCATION ON COMPUTER NETWORKS

The field of computer networks has evolved quickly in the last years. We will focus in the evolution during the last decade (1999-2009, at the time of writing). Such a timescale is sufficiently small to consider that any field with fundamental changes has suffered a `revolution´.

We identify below the three main aspects of Computer Networks that, in our opinion, have suffered a significant evolution during the last ten years. We will first focus on the social aspects: computer networks have become a commodity nowadays, while access to them was uncommon ten years ago. Next, we will study the technical aspects, arguing how the performance evolution (not only in network speed, but with many new capabilities) has introduced new features and outdated others. Finally, we will discuss the economical aspect that limits the implementation of a certain lab exercises. Given the cost reduction of network equipments, new laboratory exercises can be considered with only a limited budget.

Considering the revolution occurred, based on the following three pillars, we believe that many aspects of any subject on Computer Networks should be reconsidered.

A. Ubiquity of Computer Networks – Social aspects

Ten years ago, the access to Computer Networks was not widely extended, and broadband access was in its earlier stage. Specifically in the case of Spain, in 1999 less than 8% of the population had access to Internet, and there were less than 4000 ADSL broadband accesses [1]. Additionally, many computer equipments were not equipped with networking technology (such as a modem or a LAN card). Therefore, most students had no previous knowledge of Computing Networks, not even from the user's perspective.

Nowadays, thanks to the globalization of Internet as a communication channel, students are familiar with both network-based applications and network management. According to the Spanish regulatory organism [2], there are almost 9.5 millions of broadband accesses, with an overall population of 46 million people. While Spain has been traditionally delayed in the penetration of Internet access, these figures are representative of the radical change. Similar figures can be found for other countries.

Of course, these data differ from one country to another. Spain is in an average position in the European Union. In the United States, studies from the U.S. Census Bureau show that the percent of homes with Internet access rose from 26.2% in 1998 to 61.7% in 2007. In 2007, the most recent year with Census data, 50.8% of the householders had broadband access, and 10.7% had dial-up connections [3].

All of our students are nowadays familiar with email, web and distributed applications. Specifically, they are also familiar with the problems of multimedia applications, such as VoIP, videoconference systems, or real-time gaming. These services require special QoS capabilities from the network and suffer when multiple applications make use of the network simultaneously. Regarding network management, surveys carried at the beginning of the course report that about 80% of the students could deploy a local area network, wired or wireless, although they could miss the internal details. For example, they were used to configure NAT on their networks for P2P systems, but most of them did not know how such protocol worked internally.

B. Evolution of Networking Equipment – Technical aspects

Ten years ago contention-based Ethernet or Fast-Ethernet hardware was the norm. Nowadays students are used to low-cost switched gigabit networks and ubiquitous flexible wireless accesses. But the evolution of the technology does not come only from the network speed. The Ethernet standard (802.3, [4]) has undergone multiple revisions increasing its performance and functionality.

Contention-based hardware (CSMA/CD Ethernet hubs) was common ten years ago. Nowadays it has been completely replaced by switches (following the 802.3x standard) that do not present collision problems. Apart from the performance benefit, this makes the Medium Access Control mechanism less important, since now the media is no longer shared. However, the Medium Access Control problem still plays a significant role in wireless networks, were it is impossible to provide a switched mechanism.

Besides the advance in contention management, multiple technologies have been developed and integrated to base and mid-range network products. Among them, we can cite the following:

- Optical links, providing more reliable links between network devices with a high speed and a low error rate.
- Virtual LANs (VLANs, 802.1Q), that allow for multiple users from separate networks to share the same physical network switch without interfering or even noticing each other.
- Traffic prioritization for multimedia applications (802.1P). Such prioritization implements a classification of the traffic (which packets should be prioritized, and which not) and a segregation among multiple hardware queues in the network devices. Different priority policies are assigned to each queue so the most important traffic is cursed first, and it does not suffer from network contention and variable delays.
- Link aggregation (802.3ad), that allows increasing the effective bandwidth between two devices by grouping together two or more physical links and sending traffic using all of them.

All of these technologies are present in today's equipments, and will likely be in future products. Besides, simplified management using web interfaces hides the complexity of the internal design and the requirement to learn commands specific to a single device or vendor.

Of course, we are not the only ones to consider that networking advances should affect the courses. Let us consider the case of Cisco. Cisco is one of the main manufacturers of networking equipments. It also provides certifications [5] about networking, using their own hardware for the examinations. There are different levels of certification, with different contents on each level. The base level has been traditionally the CCNA examination (Cisco Certified Network Associate, [6]). However, in the last years the evolution in computer networks has increased the contents in that examination. Considering the increased difficulties of the additional contents, the lowest level has been divided in two, the CCEnt (Cisco Certified Entry Networking Technician, [7]) and the CCNA levels, with the first one covering the simplest contents.

Finally, this technical evolution has outdated many technologies that were important ten years ago. The list is huge, and includes technologies at different levels, for example: Access to modems using RS-232 serial cables and Hayes commands; network technologies such as Token Ring for LAN or X.25 for WAN; or network protocols such as Novel Netware (IPX/SPX). In our opinion, the inclusion of such outdated technologies in a Computer Networks course should be avoided, unless they have some historical or educational interest.

C. Networking Equipment Cost – Economic aspects

Despite the increases in performance and capabilities presented in the previous section, the cost of network equipments has been constantly decreasing during the last decade, similarly to what happened with most types of computer equipments.

As presented in section *B*, a decade ago a medium-range LAN equipment could be a contention-based hub with some basic management capabilities. A single of those hubs could cost more than 3000€, according to our University IT stuff.

Nowadays, networking systems are much cheaper and more flexible. This allows for flexible mid-range devices to be acquired with a limited budget. In our case, we acquired five switches 3Com Baseline 2916-SFP [8] with optical transmitter modules for less than 5,000€ in 2008. These equipments are suitable for multiple lab sessions, since they have interesting properties such as web-based management, VLAN support, configurable QoS queues, link aggregation, etc.

Fig. 1 shows the basic relations between these three areas. We believe that all the three areas are somehow related with each other. Social aspects are driven by the decrease in the cost of networking products and the increased performance and capabilities. The economic aspects are driven by the advance in technology and the increased market derived by the augmented usage. Finally, technological evolution is driven by the social demand and the market requirements. Altogether, these three aspects should modify the contents of a Computer Network course.

III. THE CHANGES IN THE BOLOGNA PROCESS

The Bologna process intends to provide a uniform framework for University studies across the different countries in the European Union. The current course is currently given in the Spanish "Superior Engineering", equivalent to a Bachelor + Master (a 5-years degree including specialization). However, the Bologna process aims to provide a uniform framework across Europe, similar to the American style, with 3 or 4-years generic "grades" and 1 or 2-years specific "masters".

When designing the subject, we considered that, while the course is still part of a "Superior Engineering" degree, we should focus on the *applied* aspects of the subject, especially considering the changes listed in Section II. Therefore, we insisted on the *useful* aspects (such as configuring network devices, QoS or VLANs) and gave less importance to other aspects that have been outdated by the technology (such as CSMA/CD in contention-based Ethernet networks) or are too specific (such as network dimensioning, which is left for further subjects). Such design aims to simplify the transition to a *less specific* grade course.

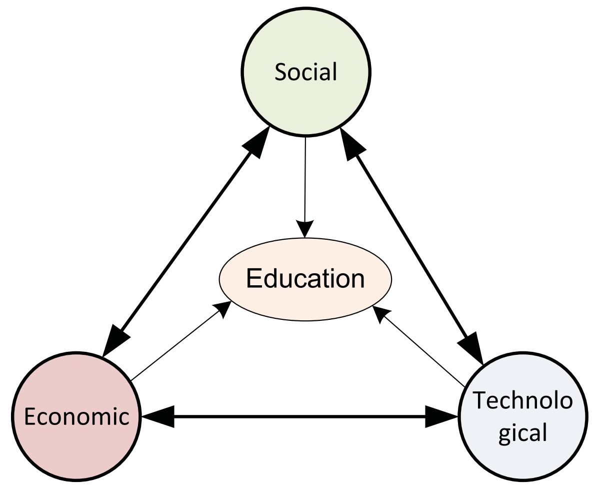

Figure 1. Interaction of the different aspects of the Revolution in Computer Networks that affect Education

Finally, the Bologna system also introduces the explicit idea of competences, divided into specific and transversal competences. While this course, prior to the establishment of the new system, does not need to consider them, we made sure that the proposed model would fit correctly. The core competences are clear, dependant on the course contents. Besides, core competences should be defined concurrently with other courses in the same group. The proposed model, which will be described next, will cover some transversal competences which are commonly discussed in our University: Some lab sessions require the cooperation between the students, exercising the team work; the use of a large amount of proposed problems deals with the autonomous work of the student and his planning of the work. While sketched, all of these competences are left for a future implementation of a grade course.

IV. COURSE DESIGN

In this section we will detail how we have selected the contents of our course, considering the revolution presented in Section II. We present a rationale of different design alternatives. Later, we detail will two advanced lab exercises that show how we exploit some of the switches capabilities: VLAN deployment and a videoconference system with QoS guarantees.

A. Background

The imparted course is part of the "Engineer in Computer Science" degree in the University of Cantabria. It is imparted in the third academic course, out of a total of 5 years in the degree. As observed, current Engineering degrees in Spain are equivalent to a BS & MS in most other countries.

The degree in the University of Cantabria is relatively new; it started in 2005 before any Bologna changes were taken into effect. However, the first time the course was imparted was in 2007, and the European Higher Education Area requirements were already a concern for any course design.

Therefore, the authors considered from the first point the possibility of providing a smooth transition to a Bologna Grade course.

B. *Theory vs. laboratory sessions*

The course contained as many hours of theory lectures as laboratory sessions. There are two basic approaches:

- Use the laboratory sessions to verify experimentally the theory introduced previously in the class, or
- Use the laboratory sessions to introduce complementary contents that are not necessarily studied in the class.

We decided that we should not restrict to the first case if some contents are more suited for the laboratory rather than the class. This allows us to cover a broader content in the course, since the laboratory exercises are complementary to the class lessons.

C. *Bleeding-edge vs. outdated technologies*

While many technologies build on previous standards, in many cases it is useless to teach them. We believe that this occurs when the following circumstances concur:

- The technology is no longer in the Market (so it is never employed in new installations or its products can not be bought).
- The technology does not have a significant installed base that still requires maintenance and management. This is more difficult to know since it requires a deep knowledge on the status of the market and how different companies have adopted new technologies.
- The technology is not part of a subsequent technology. For example, ISDN lines are still in the market, but their penetration is really low and they have been surpassed by other technologies, such as ADSL Internet accesses. However, ISDN switching technologies constitute the base for existent second-generation mobile networks, so it makes sense to know the former before studying the latter.

The first point is clear; for example, it is impossible to find Token Ring products in the Market nowadays. The second point is more difficult to check. In the example of Token Ring products, we could still find some companies maintaining old networks based on this technology. However, a quick search on the Internet (if no other resource is available) will show that such cases are really minor, so they do not justify the study of the technology.

Finally, the third point is the more complex to determine. Despite a given technology can be out of the market (such as Token Ring), its basic mechanisms can be worth studying. For example, the token passing mechanism in Token Ring prevents the problems of collisions when accessing a shared medium. Then, specific parts of a technology can be presented in detail, without the requirement to know the complete system.

In a case such the last one (outdated technology with interesting properties) our approach was the following: First, make a generic study of the possible implementations (in this example, medium access mechanism). Then, discuss the implementation in current technologies.

D. *Course expectations*

An important point for us was the expected knowledgement that a student should get taking our course. Typically, two opposite positions can be considered:

- The student should be able to *invent, design* or *build* a new networking system from scratch, by deeply knowing the involved principles and design parameters.
- The student should know be ready for the day-to-day work, knowing the current technologies in detail and what is currently demanded by the companies.

The first position is the most theoretical one, while the second is the most applied. Both approaches have flaws, since the first case gives no knowledge of the real work, and the second case does not teach the basic concepts in which technology relies.

Of course, we considered that none of these extreme positions gives the best result. In our course, we pretended to mix both approaches. In general, the lab sessions were more focused to the 'real world' approach, while the theoretical lessons would be useful to introduce many of the basic concepts. We further discuss this scheduling in the following subsections.

E. *Simulation vs. real-world practices*

Simulation tools are widely used to teach the main concepts of Computer Networks. Simulation provides multiple benefits, among them:

- The possibility to deploy a network much larger than what is permitted by our real hardware.
- Faster deployment.
- More data are available after the simulation to understand the behavior of the simulated model
- It allows the students to analyze the implementation of a protocol to better understand the behavior of the system.
- Cheap! Most educational simulators are free.

However, simulation also implies some limitations that we cite next:

- Many network simulators are based on traffic models that can differ from what is found in a real application.
- Simulators present a very simple view of the real system, hiding many characteristics that will affect the performance or behavior in the real world.

- The learning cost of the simulation tool could be used to learn some other, more applicable, idea.

Considering the cited limitations and the studied economic aspects, we decided that in general we would try to stitch to the real hardware to give our students a real view of the technology they would find outside of the University. We would restrict to simulation tools when they can be used to better understand a mechanism or protocol without introducing a significant complexity to the students.

Multiple simulation tools exist. We cite some of them next. C.S. McDonald presented his Cnet simulator in [9]. It is an educational tool mainly oriented to studying link level protocols, allowing the users to implement their own protocol. We use this simulation tool in one of our lab sessions. Comnet III [10] is a commercial simulator oriented to network dimensioning. Domínguez Dorado et al. implemented a detailed simulator for MPLS traffic [11]. It can also simulate QoS capabilities. However, MPLS was out of the scope of our course. Goyal et al. propose [12] a graphical simulation tool to evaluate network performance. However, many of their proposed lab sessions are out of the scope of our subject, and others concern outdated technology such as Token Ring. Surma [13] proposes a set of activities to understand the behavior of some network protocols. While such active learning games are excellent to motivate students, we prefer them being able to study the detailed code in a simulation tool such as Cnet. Finally, virtualization is being widely used in many laboratories as a tool for the student to work with one or multiple computers at the same time. While this could be interesting in other fields, it does not fit with our course since, essentially, it removes all of the networking issues that we study in the course.

F. Course schedule

Our introductory course on Computer Networks belongs to the third year of the degree on Computer Science Engineering. It is followed by a subsequent course in the fourth year. These two courses are complementary: Our course focuses on the main principles of networking (data coding, transmission protocols, multiplexing, etc.) and the first two levels of the network hierarchy: physical and Network access. The subsequent course in the fourth year deals with network layers 3 and 4 (TCP/IP).

The course is divided into three sections. First, theoretical lessons are used to present the contents to the students. Second, we provided a wide collection of problems with the final solution, so the students can apply the theoretical contents. Finally, we developed several complementary laboratory sessions, mostly using real hardware, to complement the other areas.

Theoretical lessons are organized in 9 sections. As commented before, we introduce basic networking mechanism and the two lowest architectural levels, based on the organization in [14]:

1. Introduction
2. Protocol architectures, showing both the OSI and the TCP/IP models
3. Data transmission, including aspects about digitalization of analog data (such as audio or video.
4. The physical layer, detailing multiple transmission medium, data codification mechanisms and signal propagation. Also, we introduce the concepts of structured cabling and ISO 11801.
5. Link layer mechanisms, including flow control and error control mechanisms.
6. Multiplexing mechanisms.
7. Circuit and packet switching.
8. Local area networks
9. Wireless networks

Obviously, the last two sections are the most important ones, but they rely on the contents of the previous ones. Each of these sections, except for the Introduction, is accompanied with a set of problems with a final solution provided, so the student can work autonomously. Problem discussion is derived to a forum on the course website.

We designed 9 laboratory sessions, oriented to complement the theoretical ones, 2 hours each:

1. **Ethernet cable fabrication.** The students have to make a cat5e cable with the proper connections, and validate its correctness. Two tools are used for validation: a naïve pin checker (that checks electrical connectivity) and a Fluke cable certifier used in real installations. This device was borrowed from the University IT service, since we could not afford it, and the high expense was not worth for a single session.
2. **Serial cable fabrication** using DB-9 connectors. While this cable has been outdated, it is still in use in many current devices. Also, it introduces the concept of flow control in a simple manner.
3. **Flow control simulation.** We used Cnet [9] for the study of simple stop&wait flow control protocols. The students have to study and understand the performance of the protocols, and modify the existent code to add new functionality, such as introducing negative acknowledgements. We selected a simulation tool for this session since flow control protocols are difficult to study using real hardware.
4. **Introduction to LAN networks.** The students had to set up a wired LAN network using both hubs and switches. Wireshark [15] is used to analyze the traffic in the network and observe, with multiple PCs connected to the same device, the difference between hubs and switches. The hubs had been also donated by the IT staff, retired from our University, and are used in this session to show contention-based access control.

5. **Switch management and fiber links.** We introduce the web-based management interface for the switches, shown in Fig. 2. The students use it to configure the speed and duplex properties of their own links, and configure a larger network using fiber links.

6. **Security aspects.** It introduces the MAC address learning mechanism and MAC filtering mechanisms to provide security in the network.

7. **Virtual LANs (VLANs) and link aggregation.** The idea of virtual LANs is studied by configuring multiple VLANs in their own switches, and configuring a network comprised of multiple switches with several VLANs, using tagging to propagate the VLAN information. Link aggregation is also introduced, as a way to increase the capability of an individual connection by using two parallel links.

8. **Traffic prioritization.** It studies the prioritization of traffic between multiple flows in a single link. This session is shown with more detail later.

9. **Wireless LAN.** 802.11 wireless networks are introduced. Students configure multiple networks in the lab, and study the available throughput on each case (between wired or wireless clients, in the same channel or a different one).

It can be observed that sessions 5 to 8 use the advanced capabilities of the switches discussed in Section 2, while other sessions are more basic. We detail next two interesting sessions that make use of the advanced capabilities of the switches.

G. *Virtual-LAN lab session*

This advanced lab session explores the work in groups. The idea is that the students must build a single network in the laboratory, but comprising different virtual LANs. Each VLAN is seen as a separate LAN for the users connected to it, although all of them use the same network equipments to lower the implementation costs.

Fig. 3 shows an example case. Our desired implementation contains two networks, one for management operations, and another one for the students. The equipments in different networks should not access each other, so the simplest

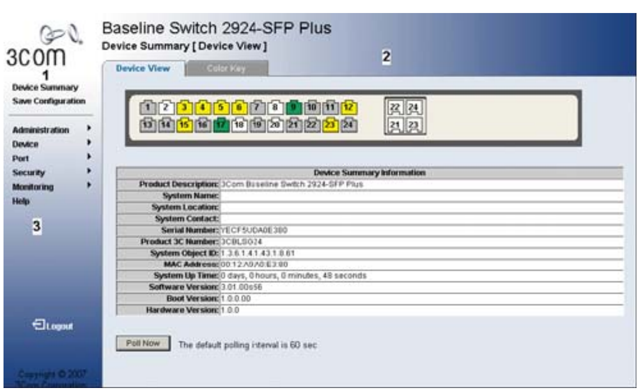

Figure 2. Web-based management intefarce of the laboratory switches.

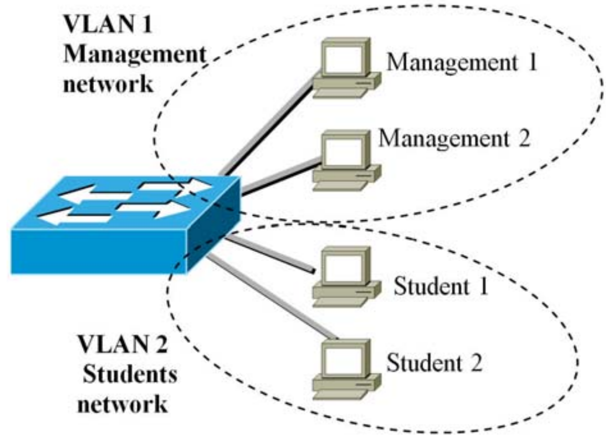

Figure 3. Two VLAN networks in a single switch.

configuration would be to use two physically separated switches. However, a single switch with two VLANs configured, as presented in the figure, gives the same service.

The interesting configuration problem arises when equipments in the same VLAN are connected to different switches. In this case, the connection link between the switches must be configured to transfer VLAN information with each frame. This is a distributed configuration, what forces each group of students to collaborate with the others in the configuration, validation and problem solving phases of the work. Similar problems are faced in the second part of the session, in which multiple links are laid between each pair of switches to aggregate their speeds and provide more performance.

H. *Traffic prioritization lab session*

We will detail now a session of our laboratory that uses multimedia, switch management and group work to study the effect of network congestion and how to solve it with prioritization at OSI level 2. As discussed in Section 2, the effects of congestion are familiar to the students, since it affects multimedia (VoIP, videoconference, video on demand) and network gaming, among others.

We configured a 10 Mbps link between two switches to model a congested WAN access, as presented in Fig. 4. Multiple PCs used FTP to transfer large files (sustained transfer) across the shared link. Simultaneously, the PCs on port 1 of each switch had webcams that would transfer video between each other. We used the VLC player [16] to encode, transfer and receive video at 4.5 Mbps using MPEG-2. This emulates a videoconference system that runs on the same link as the remaining traffic from the FTP transfers.

Without any prioritization, the video would show clear transmission artifacts, as presented in Fig. 5a. The lack of sufficient throughput and variable network delays affect the quality of the transmitted video. The image shows macroblocking and false colors artifacts.

The laboratory switches provide four hardware queues per port. Traffic flows can be inserted to one or another depending on their input port or their priority tags (CoS at layer-2 or ToS

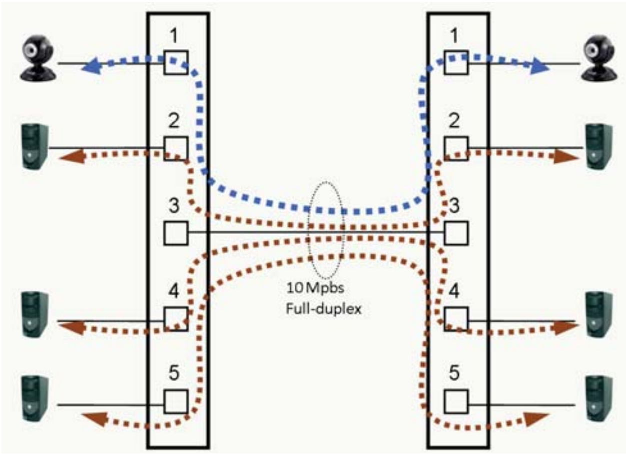

Figure 4. Schema used to obtain congestion in a network link. Both switches are connected trough port 3. The computers on port 1 of each switch make a videoconference enconded with 4.5 Mbps. The other computers transfer files on both senses.

at layer-3). Different hardware queues have different priorities (strict priority or weighted round-robin) when they compete to transmit on the same link, in our case, on the link between ports 3 in both switches. By configuring the video in the strict priority queue and the remaining traffic in one of the remaining ones, the students guarantee that the video transmission does not suffer from the concurrent file transfers on the same link. The result when the proper prioritization mechanisms are employed is presented in Fig. 5b, where the concurrent transmission of 3 files does not affect the video quality.

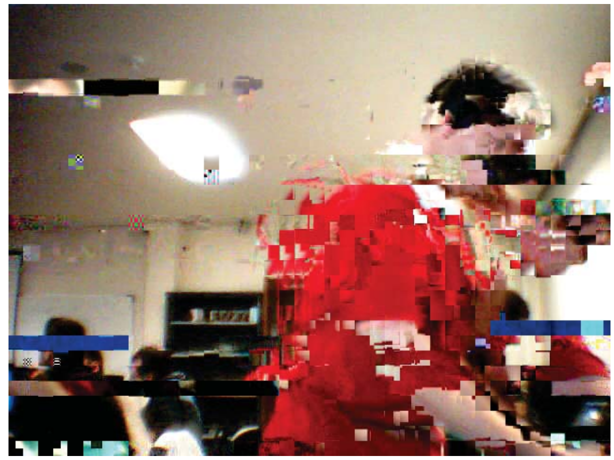
Other approaches study quality of service with a quantitative approach [11]. By contrast, our practical approach is highly qualitative. We believe that this simple and visual approach, with familiar problems (such as video pixelation) that are solved with prioritization, are better suited for the introduction of the problem and associated solutions to the students, leaving detailed studies of the quantitative performance for further courses.

V. Experience and Open Issues

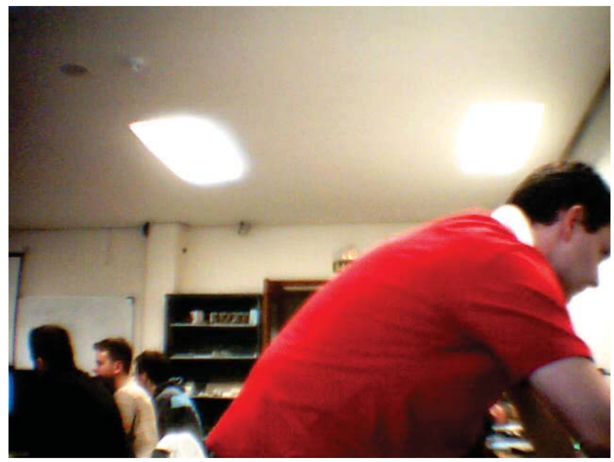
The proposed organization is now running for the second year. We have observed that the students understand the contents presented and can follow the course without major problems.

One of the main issues with the lab sessions is that many of them introduce relatively advanced concepts. Therefore, we have determined two concerns:

1. Special care has to be taken with the synchronization of theory and lab sessions. The start of the lab sessions could be delayed a few weeks until the necessary background has been presented. When the lab sessions refer to contents not yet introduced in the theoretical class, the lab instructions must be accompanied with the necessary contents.
2. It is required for the students to read the instructions before the lab session so they are familiar with the exercise and the involved technology. Otherwise, the 2 hour limit is not enough to finish the proposed exercise. We observed that in many cases the students would omit this step, and would have problems in the session. While we have not done so yet, we are considering the idea of adding a quick test about the instructions at the beginning of each session. Such a test, with a low impact on the final grade, would incite the students to prepare the lab sessions thoroughly.



a) No prioritization mechanism, no QoS



b) With proper prioritization on the shared link

Figure 5. Example of video received when multiple traffic flows share the same link. Case a) shows the result in the default case (without any priorization mechanism) where packet loss is observed in the form picture errors and macroblock patter showing. Case b) shows the result when the port queues are properly configured.

We also noticed that the effort required to prepare the setup of each lab session (prepare switches, cabling, configuring equipments) was relatively high. This is a cost to be paid for the advantage of lab sessions with real hardware.

Our main concern for the future is the adoption of this course to the Bologna requirements once the new 'grade' is working. However, we believe that our practical approach is well-suited for the change.

VI. CONCLUSIONS

We have argued that the evolution in Computer Networks, not only in the technological aspect, must condition the way that corresponding University courses are designed. Specifically in the current context, the technology, economic aspects and students' background allows for relatively advanced contents to be taught without requiring a large effort. We believe that similar discussions should apply to most technological courses.

Based on the previous discussion, we have presented the organization of our course and detailed the laboratory sessions using affordable mid-range hardware. Our experience shows that this approach is affordable for the students and provides better results than using exclusively simulation-only tools.

ACKNOWLEDGMENT

We thank J. Miguel-Alonso, for his help in the initial setup of the course. We also thank the generous equipment donations and loans from the IT service from the University of Cantabria, required for our lab sessions.

Integrating People and Technology *By Design*

Design-First Instruction for Introductory Students in Information Technology

Mary Beth Rosson and John M. Carroll (IEEE Fellow)
Center for Human-Computer Interaction and College of Information Sciences and Technology
The Pennsylvania State University
University Park, Pennsylvania 16802 USA
mrosson@psu.edu

Abstract— **In the design and implementation of interactive systems, teams typically consider and debate multiple perspectives, for instance exploring objects comprising a problem domain, the user population, and current technologies that might be useful. In this paper we report a field trial of our approach to using analysis and design activities as an integrating framework for introducing introductory students to the dependencies among information, people, and technology in information systems development. In this course, students work individually and in teams to 1) analyze structured information; 2) understand relationships implicit in online information; and 3) design technology concepts. We describe the activities we have developed and a preliminary evaluation of student outcomes, including a discussion of the mediating influence of students' technology background.**

Keywords - design-based learning, interdisciplinary education, team projects

I. Introduction

In response to the information explosion in society – and the corresponding need for interactive systems to store, access, manipulate, and present information – the iSchool concept has surfaced as an interdisciplinary paradigm for university education in computer and information science [1]. An *iSchool* is a college, school or other university program concerned with the social, cultural, and technical issues surrounding the design and use of information systems. A defining feature is a focus on *information*: what information is; how it is gathered and used; how it is transformed and stored; and its risks, benefits, and other consequences for a multitude of stakeholders. iSchool researchers seek to understand information in a contextualized fashion, which leads to an interdisciplinary research community; for example our own program integrates computer science, psychology, cognitive science, sociology, business, education, law, geography, and medical informatics. Another focus point is *design*, by which we mean the materialization of information to support human activity, through a sociotechnical process that interleaves theory, sociocultural and psychological studies, and technology innovation and implementation [2].

Shared visions of iSchool education are still evolving. There is not yet a standard curriculum such as exists for computer science or engineering [3]; indeed many iSchools focus primarily on research and graduate studies. Our four-year baccalaureate program combines sociocultural and human-computer analysis with technology fundamentals like databases and networking. Although our undergraduate students are exposed to modern programming languages (e.g., Java), most do not develop strong software skills, limiting their capability for innovative systems design work. In this paper we describe steps we are taking to inject hands-on *design* experience into the program's introductory course, conveying basic analysis and design skills that would provide a solid foundation for more advanced system design courses and projects.

In brief, we enhanced our college's introductory course with design-oriented activities to reinforce the course's general learning objective to introduce an integrative view of information, people, and technology. The enhancements comprise several active learning modules that mix homework assignments with three phases of a semester-long team project. In the balance of the paper we present the motivation for and design of these activities, the results of our initial implementation in two large sections, and the broader implications concerning design as an integrative concept for technology education.

A. Design as an Authentic Integrating Activity

We propose that design can serve as a powerful integrating activity for students who are being introduced to the subtle and complex interacting influences of information, people, and technology in society. Through their design activities, students are led to articulate, confront and resolve tradeoffs, while at the same time experiencing the empowerment and reward that comes from creative work [4].

A particularly attractive aspect of design as an integrating concept is its *authenticity*. iSchools span the information disciplines to comprehensively address issues ranging from image processing to social policy. In this vast spectrum, design is a fulcrum. One cannot talk about information processing, storage and retrieval, information behavior, the use of information in groups, organizations, or in society, or information policy and regulation without making strong and substantive assumptions about the specific ways that information can be presented to and manipulated by people [2].

The information explosion on the web is at once a driving factor for the emergence and refinement of the iSchool vision and a resource for exploratory learning of design concepts and skills. A broad array of public information is available to any web-active user who seeks it, for example social networks, weather updates, stock information, news, sports, along with many others [5]. This web information and services can be used for authentic learning about information systems design

[6]. One defining feature of authentic learning is that students become immersed in real world problem settings, so that the understandings and connections they form are general and reusable in future settings [7] [8] - the web provides ready access to such settings.

Learning by design is authentic due to the open-ended yet goal-directed process that designers follow. Design is not puzzle solving; there is never a "right" answer [9]. But clearly design is motivated by goals; these goals are translated into more and more concrete specifications as they are better understood and mapped to possible solutions [4]. The authenticity of learning by design can be enhanced even more if it takes place in a team setting, with peers brainstorming and negotiating to construct shared design ideas. A shared process such as this allows students to experience the collaboration, tool manipulation, domain-specific goals and heuristics, problem solving, and reflection-in-action typical of professional work [10] [11].

B. *Leveraging the Web for Learning by Design*

The phrase "Web 2.0" has emerged as a label for web technologies that allow users to take an increasingly active role in their use of online information and services [12]. In other work, we have been investigating the opportunities and challenges in making these web technologies more useful and usable to end users [5,13]. For example, we are studying modern university students, young adults we call "web-active end users" – they engage in many ways and for may purposes with web information and services (e.g., media sharing, online news and discussions, social networking), but they have no programming background or skills to apply to these activities.

In addition to providing information in many forms, the internet hosts a rich selection of tools to visualize and make sense of information. Figure 1 shows a typical example from Digg Labs, the BigSpy visualization of , a visualization using timing, color, font size and numeric annotations to convey real-time newsreading patterns. Our studies of web-active end users indicate that they already understand and expect to work with dynamic web services like these. Thus we decided see if we can use web information systems of this sort to engage students' curiosity and motivate a deeper understanding of online information and its design implications.

Figure 1. Screenshot from digglabs.com "BigSpy" visualization.

We organized students' exploration of web information system designs into three phases. First we emphasized the *structure* of the underlying information, so that students would begin to think of a stream of real-time web data as comprised of an organized sequence of information elements. Next we shifted attention to the *uses* of information – how to think about users' needs and preferences, with a focus on information analysis as a pervasive human activity. Third, we introduced simple technologies for *programming* with online information, leveraging emerging tools for web mashups [5]. We turn now to a more detailed presentation of the learning activities and student experiences.

II. COURSE ACTIVITIES

Historically, our introductory course introduces students to three facets of information-intensive systems: information, people, and technology. Table I summarizes the overall plan for the course, showing how the general concepts and concerns of information systems design recur across facets (e.g., layers, sociotechnical analysis, information organization); at the same time different elements within this pool of constructs come into focus within different facets (e.g., data concepts are primary in the first facet and usage concepts in the second). This general organization formed a background for the three activities focused on web information systems: we integrated the data analysis module into the first facet, information usage into the second, and web programming into the third.

TABLE I. OVERVIEW OF THREE-PHASE COURSE PLAN

1) INFORMATION: Understanding sources, types, roles, and management of information in digital society • Data basics: What is data, how do we store it? • Spreadsheets and databases: How do we create efficient and reusable information repositories? • Information sources: the Web, input and output, multimedia. • Information applications: What makes information relevant, how is it used to address problems, issues, or needs. • The future: Where are we headed?
2) PEOPLE AND ORGANIZATIONS: Understanding the mutual influences of people, organizations, society on information technologies • Human-computer interaction: Analyzing and designing information systems to respond to human needs and preferences. • Situated use: Representing and studying both explicit and tacit aspects of a usage context. • Groups and organizations: How the roles and relationships of groups and organizations affect information systems • Socio-technical analysis: interleaved evolution and adaptation of social systems and the technology in use. • The digital society: Use and design of IT in our world
3) TECHNOLOGY: Understanding the infrastructures, protocols, and tools for accessing and manipulating information • The Internet and Web: History, evolution, how it works. • Networks: Technology, protocols, media, methodologies for creating, maintaining, and debugging networks. • Layered systems development: Introducing the basic architecture of information-intensive systems analysis and design. • Quality attributes: Usability, reliability, maintainability, reusability • Emerging technologies: Artificial intelligence, multimedia, ubiquitous computing

Each module consists of an individual homework assignment and a phase of a semester-long team project. For example, the first module was focused on information, and students worked on a structured information analysis of a simple domain (an animal shelter) while their group brainstormed, identified, and analyzed the information domain that would be the focus for their semester project. We hoped that in their individual work students would gain basic concepts and skills, and through collaborations withteam members they would apply these skills to projects that are larger in scope. summarizes specific objectives for each module and the following sections describe each in more detail. A complete set of course materials can be obtained from the first author, but we provide a summary description here.

A. Module 1: Analyzing Structured Information

In the class sessions associated with first module, students were introduced to simple abstractions for thinking about the structure of online information. For instance, we visited the BigSpy website illustrated in Figure 1 and discussed the information attributes that might be used to create such a visualization. We talked about the use of tags for describing such structures, and visited RSS news feeds in browsers, using the "View Source" option to see the specialized tag set used to describe RSS data streams. We also talked about databases in general terms, using simple SQL expressions to show how logical expressions can be used to retrieve specific records or fields in a structured data set. In the individual homework, students analyzed a familiar object (the class itself) using a simple data tree that they then converted to a set of tags, illustrating the tags through some sample markup.

The Phase I project assignment was for each team brainstorm, identify and analyze an information domain that would form the basis of their semester project; they were encouraged to work with information domains for which members already were familiar with or had interest in researching. They produced a concept map (using the collaborative Mindmeister tool, mindmeister.com), investigated activities and information objects making up the domain, and defined and exemplified a set of XML tags for a central information object in the domain. Topics were diverse, for example: coaching college football, getting a record deal, using a university library, military communication, and online shopping. The major challenge during this phase was scoping the topic enough to guide their analysis of information used in the domain, and in particular to select an information object for detailed analysis. Examples of objects that teams analyzed and represented using XML tags included electronic patient records, schedules of varying sorts, a security audit, product inventory, and contracts of varying sorts.

B. Module 2: Visualizing Social and Organization Structures

In the second module, course content shifted to the human side of information technology in use. This included a basic introduction to human-computer interaction concerns and guidelines, as well as central concepts from collaborative work and socio-technical studies of organizations. A central issue was the many consequences that technology can have in different usage contexts, where context is defined and analyzed at multiple levels (individual, informal collaborations, project team, organization).

In the individual assignment, students were introduced to the Motion Chart tool that is part of Google Docs spreadsheets (this tool is a simple variant of the GapMinder tool introduced and popularized by Hans Rosling for analysis of world health data). Using Motion Chart, students can create simple time-based animations of data sets entered in a prescribed spreadsheet format. The spreadsheets must conform to an expected structure with respect to year information and other columns, but other than this the tool can visualize anything that includes numeric data as an "outcome variable" associated with a mix of either categorical or numeric "independent variables". In the tool the outcome variables are graphed and can be viewed as they change over time as a function of the other specified variables.

The data set provided to students was a randomized list of hypothetical company records. Each record had data about complaints to management for a given year, and the companies varied according to their adoption of computer-mediated communication tools (CMC), their size, and their industry orientation. Students were told to create a visualization that might explain the variation in complaints submitted. In this case there was an obvious correct answer, where companies that were smaller (thus benefiting more from the social distancing expected from CMC) and more competitive (thus provoking more complaints in general) were influenced to a greater extent by increases in CMC. Once they worked out how to use the tool, students had little trouble discovering and explaining this relationship based on our class discussions. Figure 2 contains a sample visualization shown at two different points in time.

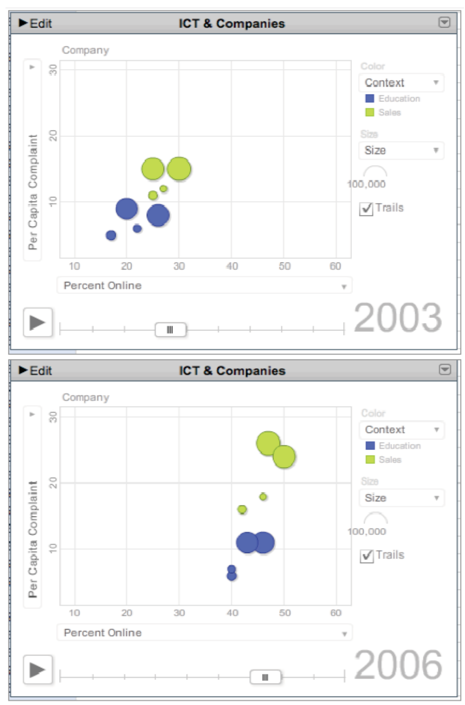

Figure 2. A sample Google Motion Chart at two points in time

In this module, the teams were assigned to continue their work from Phase I, but shifting attention to the stakeholders and potential uses of the information they had analyzed earlier, with particular focus on the information object they had investigated and represented in more detail. The teams produced a table of usage situations with associated stakeholders, a stakeholder diagram that illustrated concerns associated with different levels of analysis, and persons (user descriptions) that conveyed typical characteristics of individuals drawn from across the proposed usage situations. For example, one team working in the problem domain of movie production considered use situations like researching actors and marketing movies; stakeholders that included cast members, director, production crew, unions, movie theaters; and person variables like personality, technology experience, and gender.

C. *Module 3: Designing Information Technology Solutions*

The final module was focused on the technology used in information systems. In class we discussed the technology from a systems perspective (e.g., network architectures with associated performance and security implications) as well as an end-user perspective (e.g., typical and more emerging input and output techniques, including multi-touch displays, augmented and virtual reality, and ubiquitous computing). We also discussed simple "programming" concepts, focusing on end-user techniques like faceted search, keyboard macros and web mashups.

The individual assignment was to experiment with an example mashup that had been created in advance. We used the Yahoo! Pipes tool (pipes.yahoo.com), as our ongoing research has indicated that its visual programming language is reasonably accessible to nonprogrammers [13] and it is robust enough for experimentation by unsophisticated users. The sample mashup was chosen as one that might be attractive to college undergraduates (college football enthusiasm was at its height then), and involved selection from and integration of two sports feeds. Students were required to explain how the mashup is working, and to carry out two different experiments to enrich its output – in one they simply changed the selection criteria, and in the other they integrated a third image feed. Figure 3 shows an example of the second experiment.

The team assignment in this module required production of both a written report and a final design deliverable in the form of a concept video. Because the students had not been taught programming skills, we instead taught them to use a range of techniques for mocking up design concepts (e.g., paper prototypes, animation of simulated workstation screens). They used these techniques to illustrate their design concepts that were then conveyed as part of a video. The video enacted one or more task situations associated with their information domain, with the appropriate mockups (e.g., a data visualization) inserted and "used" at relevant points. For instance, a team working on a library concept videotapes several cases where a student used a mobile phone mock-up (build with paper overlays) to access useful information that would help him locate and retrieve library resources while in the library. Sample videos can be obtained on request from the first author.

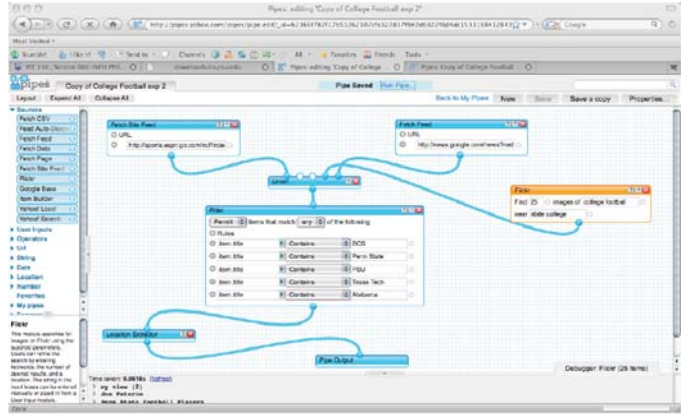

Figure 3. Sample output from Yahoo Pipes assignment.

TABLE II. SUMMARY RESULTS FOR HOMEWORKS AND TEAM PROJECTS

Individual Homework	**Phases of Team Project**
Information Structure Average score: 10.4 Max 12, range 3-12	*Information Domain Analysis* Average score: 23.8 Max 25, range 20-25
Visualizing Social Structures Average score: 14.2 Max 15, range 2-15	*Stakeholder and Usage Analysis* Average score: 33.0 Max 35, range 24-35
Web Information Mashup Average score: 17.4 Max 18, range 6-18	*Design Concepts Video* Average score: 33.0 Max 35, range 27-35

III. CLASSROOM EXPERIENCES AND OUTCOMES

The field trial of the three-phase curriculum took place in two large-enrollment sections of the course that was taught in Fall 2008 (one section had 137 students, the other had 126). Although the activities were assigned to all students, only data from students who gave informed consent to be research participants is summarized in this paper. Across the two sections, 158 students gave such consent, but because of missing data, some of the summary values reported here are based on a partial data set. Of the 143 students who indicated their major program of study, 91 (58%) were pursuing a major in this college; other students had not yet decided on major (13%) or were enrolled in some other program (e.g., Finance, Telecommunications, Psychology, Supply Chain). Because this introductory course can be used to meet a university-wide requirement for social science education, it tends to attract quite a diverse population of students. Among the 144 students who reported their gender, 22% were female and 78% male.

With respect to the design-focused learning activities, performance was generally high, as summarized in Table II. Although some students failed to submit one or more individual assignments, those who did tended to meet expectations; summing across all potential homework points (45), the average was 39.6 (88%). Performance on the team assignments was even stronger: out of 95 possible points, the average was 89.9 (95%). The high scores for team assignments are typical for classes of this sort, as evaluation of shared deliverables primarily focuses on whether the team followed the specification. Not surprisingly, both individual performance and team performance were related to students' final course grades (r=.79 and r=.49 respectively), with participation and quiz grades also playing important roles (r=.78 and r=.74 respectively. The overall class average was 87.8%, ranging 55.6% to 99.2%.

IV. Perceived Self-Efficacy

In addition to the grade-related outcomes, we collected 33 self-efficacy ratings before the course began, with repeated assessment at the end of class. Self-efficacy refers to one's belief about specific capacities in a proscribed context or situation (e.g., a task; see Bandura [14]); items assessing self-efficacy are often used as surrogates for achievement as they tend to be highly correlated with other outcome measures. Our items were designed to assess capacities related to skills taught in this particular class; students responded on a scale from 1 to 7, where 1=Strongly Disagree and 7=Strongly Agree. The majority (24) of the items had been in use for several years by other instructors to assess learning objectives for this course. Nine items were developed for this project and focused on more specific capacities related to analyzing the structure of information and working with web information. A complete copy of the self-efficacy items can be obtained from the author.

TABLE III. Sample Self-Efficacy Items from Four Subscales

Identification with the baccalaureate program (Program) • In the course of applying for an internship, I could describe at least three distinctive features of an IST education to the interviewer. • Despite my limited experience, I can make a convincing argument that problem-based learning is the best way to get a degree in IST.
Computer and Information Technology (Inf Tech) • If I were writing a show called "Computer World," I could create dialogue for characters such as data, memory, central processing unit, and motherboard. • In the checkout line at Wal-Mart a woman asks, "Why don't they just use a cash register? Why do they need bar codes?" I could explain barcodes to her and tell her how they reduce costs.
Web 2.0 Applications(Web 2.0) • If I were demonstrating the use of Flickr to my mother, I could describe several attributes of photos that it tracks to calculate social networks. • If my boss asked me to "mashup" the highlights from a presidential campaign, I could locate, combine, and visualize several online information feeds.
Structured Data Models (Data Model) • Although I am not a sales professional, I could predict 5-10 database fields that would be needed as part of an online grocery store. • Despite my limited experience with computer programming languages, I could use a mark-up language like XML to describe the people in my family tree

Rather than examine self-efficacy as a single construct, we used data reduction techniques to develop several subscales that assessed different aspects of students' beliefs about their capacities at the start and end of the course. Factor analysis of self-efficacy data from earlier instances of this course had revealed two stable factors, one interpretable as ability to appreciate and succeed at the baccalaureate *Program*, and another capturing general skills in *Information Technology*. Factor analysis of the new items developed suggested the presence of two additional factors that we identified as *Web 2.0* and skill in analyzing or building *Data Models*.

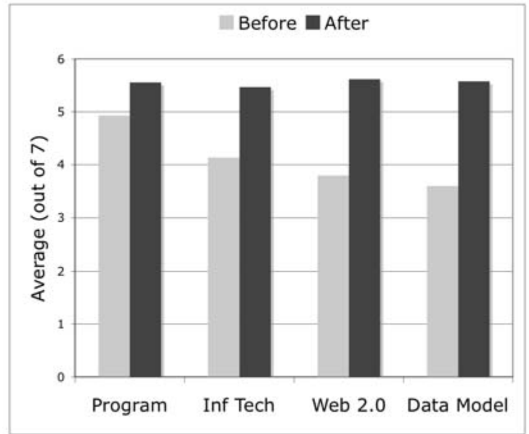

Figure 4. Self-efficacy scores at start and end of course.

To generate the indices we aggregated items loading most strongly on each of the four factors; the four constructs with examples of items loading strongly on each appear in Table III. Not surprisingly, average self-efficacy scores for these four capacities varied at the start of the semester, ranging from a mean of 4.94 for Program, 4.14 for Inf Tech, 3.80 for Web 2.0, and 3.60 for Data Models (F[1,142]=51.66, p<.0001). That is, these introductory students began their course with relatively more confidence about succeeding in the baccalaureate program, but relatively less confidence that they could design web systems or construct data models.

After creating the four indices and ensuring their reliability, we constructed isomorphic indices from the post-course survey. The resulting contrast of self-efficacy ratings before and after taking the course are graphed in Figure 4. As the graph suggests, students reported higher self-efficacy for all four indices after the class was over (t(106)=5.61 for Program; t(107)=9.73 for Inf Tech; t(106)=12.54 for Web 2.0; and t(106)=13.68 for Data Model; all significant at p<.0001).

We were particularly pleased to see the relatively greater self-efficacy increases for Web 2.0 and Data Model. At the start of the course, these ratings were lower than those for Program and Inf Tech (F(3,426)=58.72, p<.0001). At the end however, the ratings for all four subscales were about the same, suggesting that the perceived gains for specific capacities relating to Web 2.0 and Data Model were more substantial than the other two subscales. A one-way ANOVA that analyzed self-efficacy *gains* confirmed that this was true (F(3,318)=41.53, p<.0001). These survey results are promising, in that they suggest that students felt most impact in the specific capacities we had targeted with the new learning activities.

Because the student population in this class was quite diverse, and because a general goal for this course is to provide a broad introduction to information, people, and technology, we conducted an exploratory analysis of the possible relationship between students' starting background and their success in the class. We had included four expertise-related scales in the background survey: experience rated on 5-point scales for traditional programming languages, web authoring, working with digital media, and use of wiki/blogs. These four items were correlated, with an inter-item reliability of .71, so we created a single Tech Expert index by averaging the four items. The resulting index ranged from 1.0 to 5.0, with an average of 2.22.

Interestingly, students' technology background seemed to be unrelated to their overall performance in this introductory course: the correlation of Tech Expert with final course grade was -0.02, ns. It may be that the learning activities – including significant emphasis on team activities that might include peers with greater expertise – were enough to erase any advantage the more expert students had at the start. Not surprisingly, Tech Expert was closely related to all aspects of initial self-efficacy ($r=.28$ for Program; $r=.49$ for Inf Tech; $r=.52$ for Web 2.0; $r=.60$ for Data Model; all significant at $p<.001$). Informal comments from students after the syllabus was previewed on the first day reinforced this relationship, with many of the less sophisticated students voicing concerns about their chances of success in the course.

When we explored the relationship of students' technology background with *gains* in self-efficacy we found a striking pattern. For simplicity, we grouped students into low and Tech Expert groups using a median split. We found that although Low Tech Expert students reported lower self-efficacy for every subscale at the start of class, these differences were gone by the end of the semester. In other words, all students increased in self-efficacy, but those who began with the *least* technology background had the greatest gains. The differential gains for these less expert students were largest for the Web 2.0 and Data Model subscales ($F(3,103)= 2.82$, $p<.05$), again emphasizing their gains in knowledge and skills that are most "technical" and specific to this course. Figure 5 graphs these results emphasizing the relatively greater semester gains for Lo Tech Expert students in these two self-perception areas.

Although we hesitate to place too much emphasis on the results of these exploratory analyses, one interpretation of this pattern of results is that the three modules (and indeed the course in general) were of most use to students who had relatively little background with programming or online tools. This is a positive outcome for the more inexperienced students, but raises a question about the learning benefits of the new activities for students who arrive with a strong technical background. This issue of course is one that faces any educator who offers an introductory course to a diverse student population that includes many variations in prior knowledge and skills.

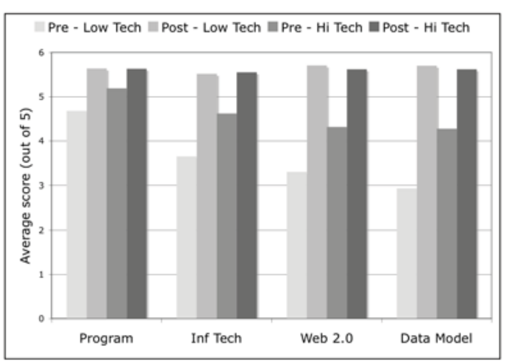

Figure 5. Self-efficacy scores at start and end of course.

At the end of the post-course survey, we asked students to reflect on whether the emphasis on design was useful to them. 95 students answered this question, and of these, most (83%) agreed that the emphasis on design was useful; the remaining students were either neutral (8.5%) or negative (8.5%). The rationale for these opinions was as one would expect – many of the positive responses cited the integrative effects of design thinking, or that it leads you to view problems from multiple perspectives. Of course these reflections were quite consistent with the rationale provided along the way as the project and homework activities were introduced, so to some extent the students are likely just "parroting back" what their instructor has told them. Some students (24%) made more specific comments, for example saying taking an information systems design perspective made them feel more connected to the real world, or that it made them feel better prepared them to work with real world problems. The neutral or negative comments tended to have less explanation, but seemed to come from students who felt they never "got it", or who complained that they already knew how to do everything presented in the class.

V. Discussion

We have described a design-based approach to promoting an interdisciplinary view of computer and information science, with an emphasis on introductory students who are first encountering and considering the challenges of the field. We experimented with several learning activities that focused first on data structure, second on discovery of implicit social and organizational relationships, and finally on innovative design concepts. We found that students were able to complete the activities, and that perceived self-efficacy for data modeling and web 2.0 application design increased. Finally, we found that these benefits were most apparent for the students with least technology background on entering the course.

While clearly still in its early stages, this educational development effort makes several contributions. At a practical level, we have developed and evaluated several specific learning activities suitable for an introductory class in the interdisciplinary information science programs that are emerging as part of the iSchool trend; these activities as well as our assessment instruments can be obtained by request to the first author. More generally, we have taken a step toward understanding whether and how design analysis and thinking can help novice information professionals learn to consider and integrate a range of different perspectives in solving information technology problems. Finally, we have documented the impacts of technology background, raising questions as to whether the activities should include more advanced learning options.

Taking a larger perspective, an introductory class such as we have described fits well within broader discussion of computer and information science curricula. For instance, there has been an ongoing discussion about whether and how to introduce more of a design (versus programming) emphasis early in an information technology curriculum. The materials and activities presented here offer one mechanism for introducing a more pronounced design emphasis prior to requiring a solid foundation in software development skills.

Although the activities prototyped in this class were successful, there is much to do. The individual and team assignments overlapped in broad terms, but our long-term pedagogical goal is to connect them more tightly. For example, we hope to decompose the work needed for the team project into individual components that each team member "practices" on the way to collaborating with his or her team. If we can do this, we may be able to reduce the tendency to distribute group work among people according to their starting levels of expertise – which of course counters much of the cooperative learning that we as educators hope to promote in group activities. We have found that the final team assignment – in which design concepts are mocked up in a video – is engaging, but we need more convenient and accessible tools for prototyping and video construction, so that the final design concepts can be expressed in a more realistic fashion. The more authentic the design outcomes can be, the better prepared the students will be for tackling interdisciplinary projects in the real world.

Abstract—**In this paper we describe how we have integrated several techniques of the "Design thinking" (DT) into the User Center Design (UCD) methodology in the process of development of project as a learning activity. The experimental activity has been carried out with students of the Human Computer Interaction's subject, corresponding to the 3º course of the School of Computer Science of the University of La Laguna.**

Keywords: Design Thinking, UCD, HCI, elearning

I. Introduction

The Human Computer Interaction is a subject corresponding to the 3º year of the Computer Science Engineering of the University of La Laguna. This subject include the contents relating with usability, accessibility, design for all and User Centered Design (UCD) methodology. Since 2004, we have been using a learning methodology based on projects and collaborative work and the blended learning model supported by Moodle. During the first course, several activities of Computer Support Collaborative Learning (CSCL) has developed [1]. Among these activities, we can highlight the creation of wikis (inter & extra groups) with a clear specification of roles and distribution of tasks. In the successive courses, this work group and based on projects' methodology has continued, changing the type of activities and experiences carried out to the laboratory. So, we have worked since the integration of multi player video games with Moodle, analyzing the motivational factors in learning process [2], to the creation of collaborative conceptual maps to support the User Centered Design (UCD) methodology.

Moreover, we have used several methods from the Design Thinking (DT) methodology into the phases of DCU methodology, in order to promote the creativity and empathy in the thinking of our further software developers. Then, during the 2009 we have integrated techniques from the creativity area with techniques of the design of interfaces from the Human-Computer Interaction (HCI) area. So, from the creativity area, we used the DT [3,4,5,6,7] as a creative process based around the "building up" of idea. However, from the HCI area, we used the UCD methodology as a design philosophy, in which needs, wants, and limitations of the end user of an interface take special attention at each stage of the design process [8,9, 10, 11, 12]. This last learning activity was carried out in the design and development of the projects selected by students with the objective to increase the significant learning.

This paper is organized as follows: first of all we will present both methodological approaches, DT and DCU, then we will show how we have integrated the methodologies into an learning activity carried out with students of Human Computer Interaction subject of the Computer Science Engineering.

II. Design Thinking (DT) methodology

DT can be described as a discipline that uses the designer's sensibility and methods to match people's needs with what is technologically feasible. It is based on the idea of the designers has a singular way to confront the innovation: "a protocol to solve problems and to discover new opportunities". So, the principles and tools used to design objects could be applied to "design" services or new solutions to complex problems. However, DT is not related with how to "design" products, on the contrary, is about how to "apply a methodology" of design and about certain skills that designers has to solve complex problems that need a creative more than analytic thinking.

This human-centric methodology integrates expertise from design, social sciences, business and engineering. High performance project teams are capable of simultaneously applying these different points of view. It creates a vibrant interaction environment that promotes iterative learning cycles driven by rapid conceptual prototyping.

However, DT is supported on the following principles:

1.*Empathy*: a deep, empathic and multidisciplinary observation about the user's needs, including their emotions.

2.*Imagination*: the optimistic search of solutions, thinking more in "the desirable" than "the possible".

3.*Experimentation*: the visualization of the possible alternatives through the experimentation, the game and the construction of visual stories (storytelling) in cooperation with users.

4.*Collaborative prototyping*: the application of techniques of collaborative prototyping to create models that help to visualize alternatives and to validate in group.

5.*Integrative thinking*: the capability of integration and synthesis of factors that influences the user's experience.

6.*Iterative learning*: the iteration of observation-creation-prototyping-validation process the time what it would be necessary until to find the best solution.

This methodology is based not only in the “usability”, but it is based in the “meaning” that people give to their context and the interaction with the product. In consequence, DT allows us to have a more complete vision of the user experience: emotional, cultural, cognitive, social, etc.

In addition, DT is a model of a creative thinking that could be applied in every area, following several stages:

1.To define the problem

2.To create and to take into account many options

3.To refine and to iterate with the selected options

4.To select the best option and to execute it.

We can summarized the DT in three large phases: 1) Understanding and observation, 2) Creation and prototyping, and 3) Testing and learning.

Tim Brown, the manager of innovation and design firm IDEO [13], defines the DT how a process centered in humans, and remarks the “human sight” of the designers. Moreover, he says that to know how the product is used is more important than the product does. It is applied a “activity-based approach” instead of based on the product. This way to see the context and the activity as a whole helps to discover new and innovative solutions beyond than the product.

On the other hand, the designers “learning by doing” into a laboratory where they can experiment in teams with several prototypes, putting in practice many creative techniques, such as: drawing, modeling, video recording, speed prototyping, storytelling (verbal and visual), photography and other techniques.

III. User-centered design (UCD) methodology

User-centered design, is a comprehensive software development methodology driven by a clearly specified, task-oriented business objectives and a recognition of user needs, limitations, and preferences. Information collected using UCD analysis is scientifically applied in the design, testing, and implementation of products and services.

There are several standards that define how to design and evaluate software products with the human-centered process approach, such as: ISO 13407 (explains the activities required for user centered design), ISO 16982 (outlines the types of methods that can be used), ISO/IEC 14598 (gives a general framework for the evaluation of software products using the model in ISO/IEC 9126-1).

Based on the principles of ISO 13407, we cited ten methods that are recommended when developing software for interactive systems:

0. Assessment of needs

1. A stakeholder meeting

2. Context of use

3. Task scenarios

4. Evaluating an existing systems

5. Usability requirements

6. Paper prototyping

7. Style guide

8. Evaluation of prototypes

9 Usability testing

10.Collection feedback from users after release to inform any redesign.

Moreover, UCD is an iterative process where we have to develop several techniques in different phases:

a) User Analysis: A user analysis is generally conducted before project planning has begun, or during the early stages of a project. In cases where no formal project has been established, a user analysis may be conducted before project planning to provide business management with an understanding of the workplace that can help to determine if there is a need for systems development. For projects that are just beginning, the workplace evaluation may be used to help define the project scope and determine the project approach.

b) Task Analysis: Task analysis should be conducted during project planning to help define the project scope and determine the project approach. However, the task analysis cannot be conducted until after the business objectives have been defined. The task analysis may be continued through the early stages of requirements analysis.

c) Information Architecture and Initial User Interface Design: The information architecture and initial user interface design can be completed at a number of different points in the design process.

d) User Interface (UI) Prototype: The UI design is generally refined and the UI prototype completed as requirements definition is finished and system design begins.

e) Usability Testing: Usability testing can be conducted as soon as a working UI mockup or prototype is available. The earlier usability testing is done, the more effectively problems found in the testing can be addressed.

f) User Interface Specification: Generally, the UI specification is a living document that is begun as soon as the first UI concepts are created, and is completed once the final UI design is finished.

As we showed above, we can observe that both methodological approaches match not only in the conceptual part besides in the methods, techniques and phases. For this reason, we propose an integration of both, focused on which techniques from the creativity area of the DT could be useful in the UCD phases.

IV. Integration of techniques: creativity in design

In order to start to work with the DCU methodology, students has to build a conceptual map of a project selected by themselves. The conceptual map given initially by the tutor, has the hole information about the methods, techniques of DCU and usability, organized in phases. This conceptual map will be building collaboratively in group under the supervision of the tutor. Each phase of the conceptual maps has one or more deliverables and the techniques applied must be selected adequately in each case, depending on the project of each group.

Regarding to the integration of the DT methods into the DCU methodology, specifically we have integrated the following in the phase of the design: a) Creative exploration (to look for quantity, ideas), b) Building and hands thinking (prototypes) and c) Simulation and role playing (interactive situations).

The "building games" using the game thinking based on building and where the learning is a sub product of the game. In this kind of games, the ideas are explored through prototypes, both in the design and with the physical objects, allowing the experimentation in the design [Fig. 1].

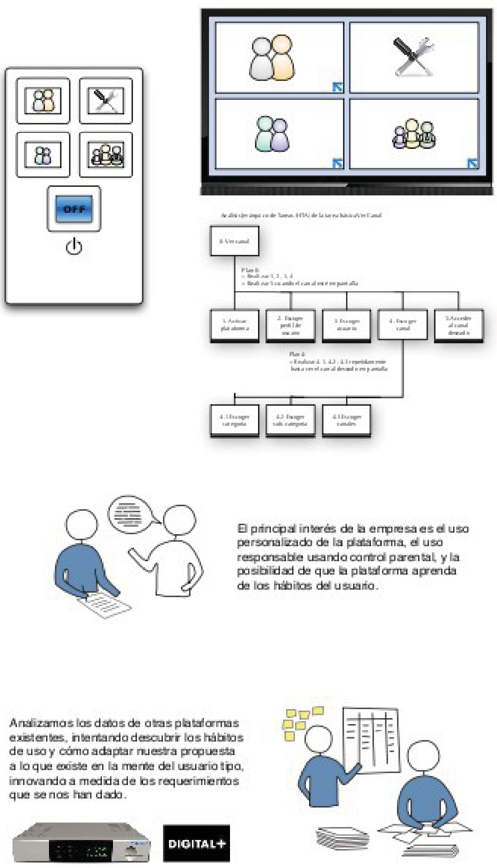

Figure 1. Example of a group proposal -DCU methodology.

In the case of the designers, this "building games" is denominated "to think with the hands" and it is achieved with "low cost and quality prototypes". This game allows to find solutions through prototypes and to carry out the designer's thinking to the real world quickly.

On the other hand, when we talk about to design something that is not a physical object but it is a system of interactions, we can use the "role playing" [14,15]. The role playing is very useful to think in experiences, to put us into the situation that we are designing and to project us in this situation. We can said that through the role playing we can achieve the "empathy of the designer", because the designer can put himself in the place of users of its designs and can imagine the situations where the designs will be used. It is so important in the instruction of further designers, because they must try the proposed solutions and the "role playing games" are very useful as "prototypes of situations" [Fig. 2].

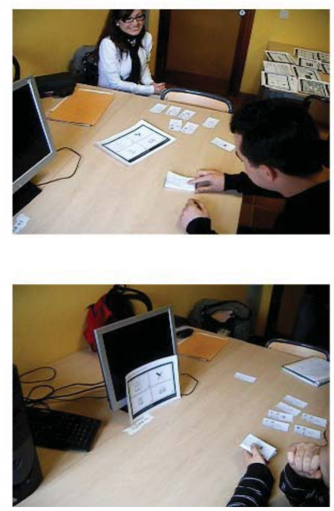

Figure 2. Testing prototypes in the laboratory.

V. Conclusions

In this paper we have presented an learning activity to teaching DCU methodology using some techniques from the DT methodological approach. Through this kind of activities we also provided an overview of the main HCI techniques and methods illustrating that the user target and the methods used affect the end design. Our main objective with this kind of activities were to promote the creativity and empathy in the further designers of software, showing the key steps of a UCD process in an enjoyable and informal setting. We are absolutely convinced that we need to increase the creativity thinking of our students in order to improve their capabilities to produce innovative solutions and to create products and services adapted to real needs of users.

Toy Design Experience:

Improving Students' Motivation and Results in a Final Year Subject

***Abstract*— In recent years educational gaming has been progressively perceived as a very effective tool for improving teaching-learning activities in higher education. The use of such play-based methodologies for engineering education can promote several practical and communication skills of great value for students' future professional development. At the same time it greatly helps to motivate students and make them more aware of their own capabilities and the learning process.**

This paper details the application of a play-based methodology for improving students' results and motivation in the subject "Development of Plastic Products". The active learning strategy consists in assigning student groups different toy development tasks, so that they can apply the design concepts learned and present their results in public. It is thereby hoped to promote a set of abilities that are ever increasingly valued in the industrial and business world, such as teamwork, creativity and communications skills.

Results have been compared with experiences from previous years, linked to the development of conventional products. The results show that carrying out a monographic experience on "Toy - Design" has promoted students' satisfaction, motivation and results. Some ideas for future improvements, mainly based on students' opinions, are also discussed.

Keywords: Learning through play, Active learning, Motivating students, CAD-CAM-CAE Tools, Rapid Prototyping Technologies.

I. Introduction

The subject "Design and Manufacture with Plastic Materials", taught in the 5th course at Universidad Politécnica de Madrid (UPM) as part of the Mechanical Engineering Degree, has been designed to fit in with the trends towards educational innovation and active learning set out within the framework for implementing the European Higher Education Area (E.H.E.A.) [1] following the purposes of the Bologna Process.

With this process implementation, higher education systems in European countries should be organised in such a way that:

- It is should be easy to move from one country to the other (within the European Higher Education Area) for the purpose of further study or employment.
- The attractiveness of European higher education is increased so that many people from non-European countries should also come to study and/or work in Europe.
- The European Higher Education Area should provide Europe with a broad, high quality and advanced knowledge base, ensuring the further development of Europe as a stable, peaceful and tolerant community benefiting from a cutting edge European Research Area.

The active learning strategy proposed in our subject consists in assigning groups of students different product development tasks, so that they can apply the design concepts learned to real problems, and then present their results to their fellow-students. It is thereby hoped to promote a set of abilities that are ever increasingly valued in the industrial and business world, such as teamwork, creativity and communications skills (ABET Professional Skills) [2].

The tasks begin with an analysis of existing products and end with the production of prototypes. This means that the new Rapid Prototyping Technologies [3] available in the UPM's "Product Development Laboratory" can be applied for teaching purposes, thereby implementing a teaching-learning method that at all times promotes active student participation.

The most important educational innovation objectives of this experience are:

- To enable students to experience a complete product development, from the conceptual design stage up to carrying out tests on a physical prototype.
- To follow the stages really used in industry, when it comes to designing and manufacturing new products.
- To encourage students to participate actively in their own learning process.
- To emphasise the importance of teamwork and finding solutions reached together.
- To continually induce students the use of critical thinking as essential tool for solving problems.

During course 2008-2009 the development experience was focused on "Toy design", as a way for improving student's motivation and results through play-based activities. Below are explained the tools used and methodology followed for supplementing the teaching of theory with the development of applied tasks, together with the results of this teaching experience.

II. Technologies and Tools Used

The use of "CAD-CAM-CAE" tools (computer aided design, manufacturing and engineering tools) is essential in any industrial machine or new product development process. The experience described has a highly praiseworthy teaching aim since it motivates students to use the different design and calculating tools used in mechanical engineering available in the Machine Engineering Division of the UPM, such as:

- CAD programs (Solid Edge, Catia, Inventor, Rhino), for modelling the different parts of a machine in 3D and obtaining the files needed to manufacture rapid prototypes.
- CAE programs (Solid Edge, NX-6 Siemens, I-DEAS), to undertake the simulations of kinematic function. In order to check both the parts design and the appropriate selection of materials, programs for finite-element calculation are also used (ANSYS, NX-6 Siemens, I-DEAS, Moldflow).
- CAM programs (Catia, Moldflow Mold Adviser), in manufacturing simulations and mould development for thermoplastic materials injection.

The Machine Engineering Division also places various "**Rapid Prototyping Technologies**" at the students' disposal so that they can materialise their designs, particularly:

Stereolithography.- A technology based on the possibility to activate a polymerisation reaction in an epoxy resin in a liquid state by projecting a laser beam, its power and frequency having been adapted to the type of resin. The laser gradually "draws" layers on the surface of the liquid resin, following a path marked out by the CAD 3D file containing the part geometry. The monomers in a liquid state, on being exposed to ultraviolet radiation polymerise and become solid. The operation is repeated until the end part has been obtained in epoxy resin by the successive superimposing of polymerised layers (Figure 1). The parts obtained by this process are particularly suitable for checking the parts visually and for size.

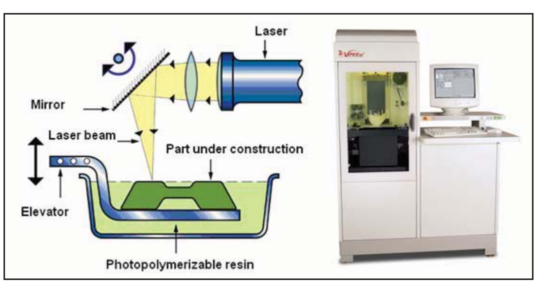

Figure 1. Stereolithography process and machine example.

Vacuum casting in silicone moulds.- The initial models or stereolithography parts can also be used for obtaining flexible silicon moulds which are subsequently used to obtain polyurethane resin replicas that are more resistant and suitable for working trials. These resins reproduce the mould cavities with great precision thereby obtaining working prototypes in materials similar to those of production.

These technologies serve to complement the "CAD-CAM-CAE" tools, enabling physical parts to be obtained in a few days, directly from designs carried out with the aid of a computer. Design iterations can be reduced and optimised, and therefore, production start-up accelerated, which means these technologies are highly valued in industry and so are very positive for training students.

This use of rapid prototyping technologies as a teaching aid is of recent appearance. Among some of the most innovative experiments it is worth highlighting those carried out in technical schools such as the "Massachusetts Institute of Technology" [4], the "Western Washington University" [5], the "Rose-Hulman Institute of Technology" [6], the "Massey University" [7], the "Universidad Simón Bolivar" [8] and the "Universidad Politécnica de Madrid" [9], [10].

In all of these schools, students have experienced the different product development stages: conception, design, simulation, analysis, manufacturing and tests, using tools such as Mechanical Computer Aided Engineering ("MCAE") and the most recent Rapid Prototyping and Manufacturing Technologies ("RP&M").

The application of these computer aided design, engineering and manufacturing technologies to teaching the subject "Design and Manufacturing with Polymers" during course 2008-2009, supporting the already mentioned "Toy Design Experience", is explained below.

III. Teaching - Learning Methodology

At the beginning of the subject, the students are divided into teams of three (exceptionally four), which are given different products to be developed. Products are chosen that can be mass produced by thermoplastic materials injection and which allow the knowledge acquired in theory classes to be developed in a practical way.

During the 2008-2009 academic course, a total of 71 students have approached the complete development of 23 different products. To promote motivation among students the experience was centered in toy desing and each group should find and design a different toy.

Studies do not include steel mould manufacture or injection machine tests due to the high investment costs and the time that would be involved. However, all injection simulations performed using "Moldflow" type programmes are very positively assessed. The stages that must be got through by students are enumerated below and are those corresponding to the development of a new industrial product [11], all of which helps to give a boost to the teaching aims proposed:

1. Approaching the problem and analysing the specifications.
2. Conceptual design and choosing materials and components.
3. Detailed design, including explanation of calculations.
4. Solution analysis and mould filling simulations.
5. Prototype manufacture.
6. Assembly and working trials.
7. Verifying results and drawing up conclusions.
8. Mould design.
9. Comparing and evaluating results.

A) Approaching the problem

The students gather information on their products and analyse existing solutions together as a prior stage to the design tasks. In any development process an exhaustive information search needs to be done on the product, and a comparison made between similar solutions that exist, in order to be able to prepare an appropriate planning schedule and fully and exactly define the aims.

The result of all this will be a list of requisites with the basic information for the project (desired toy to be designed). At every instant students must endeavour to comply with these basic specifications (or mandatory requirements). Moreover, it is important to make a list of pretensions (or requirements to be taken into consideration whenever possible) that will form a basis of negotiation with the client and increase competitiveness and profits.

B) Conceptual design

The teams continue to work on the list of requirements to identify any crucial problems and choose the best solution for each one, paying also attention to manufacturability, time optimization and costs reduction.

Using CAD programs and drawing sketches by hand (as shown bellow) sees the beginning of the work to obtain a pre-design of the different parts while comparing any possible alternatives. In this way, materials are chosen according to the initial estimations of resistance needed for the different components and parts. Figure 2 shows as example the conceptual design.

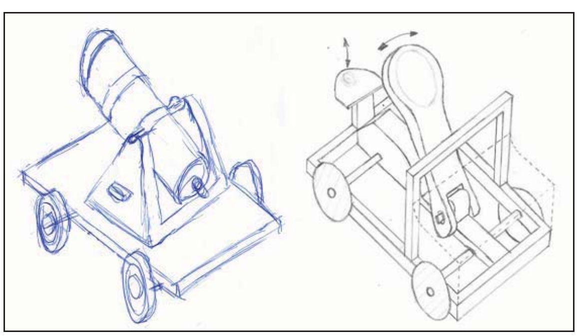

Figure 2. Different examples of conceptual designs.

C) Detailed design

Once the most appropriate solution has been chosen from the different pre-designs, the different parts must be exactly defined. Following the concepts explained in the theory classes, the students must use a design approach oriented towards manufacture and assembly, in line with the current trends in Concurrent Engineering. The results of some different tasks are shown in Figure 3.

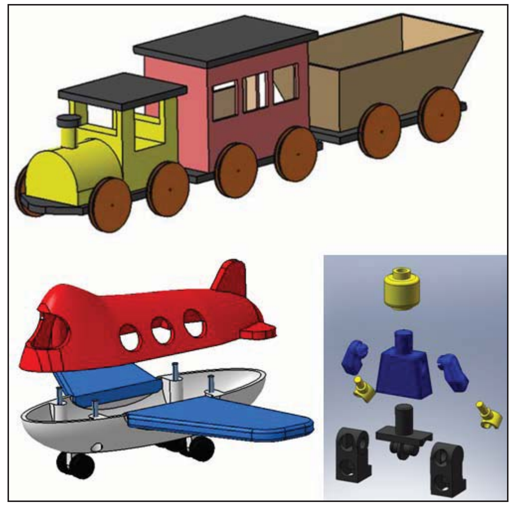

Figure 3. Different examples of detailed designs.

To check that the chosen materials are suitable, the estimates need to be compared, using simplified theoretical models, with the information provided by Computer Aided Engineering programs. The use of thermoplastic material injection simulation programs, which are habitually used prior to the construction of the moulds, is also important, in order to check that the choice of materials and injection conditions are appropriate, as well as an optimum distribution of the cavities in the mould, material inlets, filling channels and cooling system.

The teaching aim is worth emphasising, since it motivates students to use the different computer design and calculation tools used in mechanical engineering, as explained above. The basic concepts for employing CAD Tools are explained in previous subjects during their first years at Universidad Politécnica de Madrid. However 5 training sessions using the CAD Program “Solid Edge” are placed at students’ disposal at the beginning of the subject, so that every student has the opportunity to review the main concepts.

Moulding simulations are carried out in order to choose the optimum (theoretical) injection point or to evaluate times and temperatures obtained when filling the mould cavities. These are important studies for optimizing subsequent production processes. Additionally, Figure 4 shows different finite-element calculations in order to check both the parts design and the appropriate selection of materials.

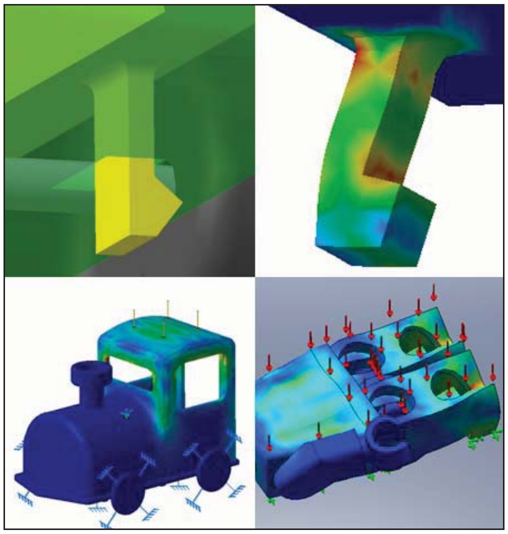

Figure 4. Different F.E.M. simulations for design validation.

D) Prototype manufacture

Using the CAD files provided by the working groups, and once the appropriate calculations have been made, the prototypes are produced by stereolithography technology as explained before. Using the rapid prototyping technologies available in the UPM's Product Development Laboratory (http://www.dim.etsii.upm.es/ldpdim/) brings students closer to these new technologies now becoming more widespread in industry, thereby giving added value to their training and allowing them to physically check the validity of their CAD designs.

Figure 5 shows some of the prototypes made for visual and assembly checks, paying special attention to tolerances, any possible interferences and empty or useless spaces.

Additionally Figure 6 includes a schematic diagram of the development process followed, from initial drafts to final pre-production prototype.

Figure 5. Different examples of manufactured prototypes.

Figure 6. Development process followed.

They also enable certain working trials to be performed, but the fragility of the epoxy resin materials of which they are made has to be taken into account. For tougher trials, a second prototyping stage can be carried out, involving the manufacture of silicone moulds for polyurethane vacuum casting.

During course 2008-2009 the costs for manufacturing the 10 prototypes of the selected best toy-designs laid around 2500 to 3000 euros.

The UPM's Product Development Laboratory, whose main objectives are to provide prototyping solutions for industrial requirements and to assist teaching-learning activities at University, helped at every moment with the costs not covered by the previously explained initiatives.

E) Verifying results and conclusions

Once the prototypes have been checked, the next stage is for the teams to make their final results public, and justify the decisions made in front of their teachers and fellow-students. The joint discussion on the different tasks performed means that each team learns from the work of their fellow-students thereby enhancing the teaching aims.

IV. Main Results of the Experience

At the end of the course, a survey was made so as to assess the quality of the teaching experience, based on students' satisfaction and understanding about their own knowledge. The results are summarized on Table 1 and explained further on.

TABLE I. Students' Personal Opinions

Students' opinion on different aspects	**Mean score from 1 to 5:**
Knowledge acquired compared to other Mecanical Engineering subjects	3,81
Comprehension acquired related to the product development process	**4,03**
Knowledge acquired regarding polymer technique and design	3,98
Knowledge acquired regarding CAD – CAE – CAM tools	3,94
Knowledge acquired regarding RP&M technologies	3,60
Importance of teamwork activities within the subject	**4,40**
Students' workload	3,77
Possibility to apply the knowledge acquired in professional future	3,90
Coherence between explanations and assessment procedure	**4,18**
Overall impression of the subject	**4,34**
Toys as theme proposed for the products	**4,42**

The results show students' overall satisfaction within the subject and the very positive perception of their own acquired knowledge. We believe the theme proposed "Toys" for the design team-works has enormously helped to promote students' motivation and final qualifications as shown in the assessment chapter.

Some future actions including visits to enterprises and technological centres, dedicated to product design and development, will help to increase their opinions on usefulness of the acquired knowledge for their future professional development

Regarding the play-based methodology, 100% of students answered positively to the question "Have you enjoyed your experience in the subject?" and 100% of the students answered positively to the question "Do you believe enjoyment helps general motivation and improves final results?".

Among other personal opinions and some suggested improvements to the subject were:

- "It would be interesting to make more complex machine prototypes or products by working together with different teams."
- "Producing a second stage of prototypes would enable the solution to problems found in the first stage to be checked, and the design improvements proposed to be verified."
- "The nicest thing about the subject is being able to see and touch your own designs."
- "The workload required to develop the product is excessive."
- "The number of theory classes should be reduced and the practical part of the subject increased."

Regarding the actual interest of using prototypes, a survey was carried out, after prototype assembly and trials, so as to ask students' personal opinion about rapid prototyping technologies and the importance of prototyping in order to validate the designs. The main results are set out below in Table 2.

TABLE II. Benefits of Using Prototypes

Evaluation of prototypes and RP&M technologies	**Mean score from 1 to 5:**
Importance of prototypes as support tool	4,625
Quality of manufactured prototypes	3,875
Prototypes for detecting design errors	4,625
Prototypes as complement for CAD tools	4,5
Importance of redesign according to prototypes	4,5
Interest of the prototypes for teaching aims	5

An additional survey was made in order to quantify students' real dedication to the subject and validate the number of European Credits assigned to the subject (between 25 and 30 hours of personal student work per credit). The results are included in Table 3 at the beginning of the following page.

A total average of dedication of 84,8 hours/student was obtained, which is in line with the 3 European Credits assigned to the subject (between 25 and 30 hours per credit), and combines attendance at theory classes with individual work in accordance with the European Credit Transfer System (ECTS) guidelines.

The balance between individual and teamwork is also noteworthy with 47% dedication to individual activities and 53% dedication to teamwork activities.

TABLE III. STUDENTS' WORKLOAD

Dedication to the different work stages	Total average (hours per person)
Formal lessons (35 scheduled hours, non-compulsory attendance):	32,54
Attendance at tutorials:	7,52
Product search and prior studies:	2,23
Conceptual design:	11,68
Detailed design:	18,95
Prototype assembly and trials:	6,44
Total	**79,36**
Dedication to editing and presenting papers	**Total average (hours per person)**
Preparing reports and presentations:	4,24
Public exposition:	1,5
Total	**5,74**
Work distribution (Individual / Group):	**Percentage (%)**
Percentage of INDIVIDUAL WORK:	47
Percentage of TEAMWORK:	53

From these results it can be concluded that the scores given by students are positive, particularly the scores regarding knowledge acquisition and satisfaction in obtaining prototypes of the designs produced. However, there are still certain points that need improving in the general approach to the subject and in the participatory working methods.

Finally we would like to note that the number of hours dedicated by teachers to monitoring, listening to presentations and marking student projects is considerable.

The number of hours dedicated to tutorials has also increased considerably with the introduction of application tasks, as questions had to be answered in a personal way, due to the great differences between the proposed toy designs.

For future experiences we will consider the establishment of an active tutorial plan, including students that have already studied the subject and can help their younger companions, so as to provide students with a more personal teaching.

V. ASSESSMENT OF ACTUAL BENEFITS

In order to assess actual benefits of the play-based methodology proposed, a comparison between final marks is included here.

Students' personal scores on satisfaction within the subject and understanding about their own knowledge have already been analyzed. Now we focus on teacher's evaluation of students' actual knowledge regarding product design with plastic materials.

During 2007-2008 course a total of 57 students coursed the subject and during 2008-2009 course the total number increased to 71. In this way teacher's workload also increased, but for assessment purposes we may consider both groups as comparable ones (both in size and previous knowledge regarding the subject).

In both cases assessment was mainly based on results from team-work / designed product (up to 80%), with some influence on personal activities during formal lessons and attendance (up to 20%).

Additionally the difficulty of developed products is considered to be similar, as well as the criteria for marks assignment, for both courses. Among most valued factors are:

- Originality of the proposed product.
- Systematic design and development procedure.
- Systematic comparison of possible solutions.
- Application of the design concepts explained.
- Comparison between calculations and simulations.
- Assembly and trials of prototypes.
- Final functional result.
- Final esthetical result.
- Overall product difficulty.

The results from such comparison are included in Figure 7 and subsequently explained.

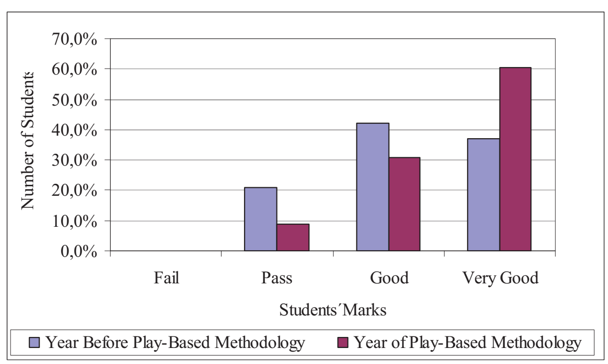

Figure 7. Evolution of students' marks with the introduction of play-based methodology.

From these results it can be noted that the proportion of very good developments increased from around 36% to around 61%. We believe such increase is completely linked to their additional motivation, and consequent workload devoted, due to the proposal of a monographic on "Toy design" (as also stated by students themselves in the satisfaction surveys gathered).

VI. Conclusions and Future Proposals

Learning through play has proven to be a great success, especially in areas such as primary education, foreign language courses and artistic education. In fact, several degrees on pedagogy include subjects for training future teachers in tasks linked to play preparation and its benefits for students.

However in recent years educational gaming has been progressively perceived as a very effective tool for improving teaching-learning activities in higher education. The use of such play-based methodologies for engineering education can promote several practical and communication skills of great value for students' future professional development, as our teaching-learning toy design experience has proved.

At the same time it is possible to increase students' motivation and to make them more aware of their own capabilities and the learning process. As a result there is an increasing interest among scholars in investigating this area, so as to quantify its actual effect on global learning and in order to apply its principles in a more efficient way.

Additionally, undertaking problem based learning and teamwork activities, where students can experience the complete development of a product or machine, following the stages used in the industrial world, brings them closer to future work experiences. Aspects such as active decision making, weighing up alternatives, self-teaching, time and cost planning, the application of regulations, design in line with commercial elements or contact with suppliers, are given an enormous boost.

Student learning, throughout projects such as these, benefits greatly from the use of computer aided design, manufacturing and engineering tools, (CAD-CAM-CAE tools) highly esteemed by companies dedicated to the development of machines and products.

It has been shown that the use of rapid prototyping technologies enables students to come into contact with modern manufacturing technologies that are becoming widespread in Industry thereby giving added value to training. It is, in itself, a way of learning, since it lets designs be tested by performing assembly and working trials with physical parts.

The experience implemented for the subject "Design and Manufacture with Plastic Materials" may be extended to numerous other subjects in Mechanical Engineering so as to obtaining integrated teaching in these subjects. The results have been highly satisfactory, both for students and teachers, all of which motivates us to continue with the experience and improve it in future courses.

The correspondence between students' dedication and the European Credits assigned to the subject is very satisfactory, as can be seen from the surveys' results.

We believe students' attendance, motivation and results have been promoted through play-based methodologies, specially taking into account that the subject is part of the final year course, when many students prefer active learning activities and assessment through development works, rather than traditional lessons and final exam.

We hope the explained teaching methodology and assessment process can be of help for future researches on these areas.

Acknowledgments

Authors would like to thank students for their interest in the subject and for the quality of application works carried out. The images shown are results from their designs and prototypes, within the subject "Design and Manufacture with Plastic Materials" during academic course 2008-2009. Such images have been included here also as a way for motivating future students.

Abstract—**Promoting personal and professional skills is becoming an issue of interest and major concern in university environments and this, in turn, is being driven by the demands of business. In this paper the authors, teachers from UPM and ISAT, present the basic features of the Formula SAE project and some other international competition such as Eco-Shell Marathon, Formula Baja or Formula Low-Cost, and analyze the way these competitions helps to promote 24 basic skills in the students, compared to other activities carried out during their engineering degree courses.**

Keywords-component;, automotive engineering, skills, competition, Formula SAE

I. INTRODUCTION

Universities are ever more concerned to open up students' training perspectives towards aspects that are not always a part of their studies, such as enhancing their personal and professional skills [1]. Thus, for several years the experiences of educational programmes have been regularly published where the enhancement of theoretical-practical knowledge is only one of the goals sought. E. Bowen [2], and D. Chadha [1][3], for instance, raise the issue of studying and assessing skills promotion in different university departments in the United Kingdom.

In a simplified way what is understood by skills is "a combination of knowledge, abilities and attitudes that are suited to particular circumstances" [4]. De Miguel et al [5] offer a fuller definition when they say, "by skills is understood the set of knowledge, abilities, behaviour and attitudes that favour work being done properly and which the organisation is interested in developing or recognising in its co-workers when it comes to achieving the company's strategic goals".

The European Commission [4] has recently highlighted eight key skills for continuous learning as a goal to be achieved by every citizen who aspires to "live and work in the new information society". These are communication in the mother tongue, communication in foreign languages, mathematical skills and basic skills in science and technology, digital skills, learning to learn, interpersonal, intercultural and social skills, citizens' skills, the spirit of enterprise and cultural expression.

The second definition of skills makes reference to the four successive psychological learning levels: knowledge, ability, behaviour and attitude. In the light of these, it can be said that, excepting some initiatives, university training has been focused mainly on strengthening technical knowledge and abilities, since these first two levels are the ones that can be attained with the traditional system of classroom lectures.

So, a genuine promotion of personal and professional skills has not been a generally sought after goal, since trying to make students change their behaviour and attitudes involves using other teaching methods that are usually more costly regarding time, space and personal resources, although on occasions these methods simply need to be more imaginative.

Likewise, student assessment has usually been based almost exclusively on their knowledge and skills in solving problems on paper in an environment where time is scarce, where information is restricted to the data given in the written instructions and a lack of sources for consultation. Therefore, certain personal qualities such as memory and speed are overvalued to the detriment of other qualities which are at least just as important.

However, the human resource managers of the major companies rate basic personal skills very highly in the graduates that they take on; skills such as the ability to work in a team, leadership, self-motivation and team motivation, a capacity for self-learning, etc, giving less importance to the level of technical knowledge possessed at the time of their being taken on [6], [7].

The study entitled "Tuning Educational Structures in Europe" [8], financed by the European Commission reveals the large discrepancies existing between the priorities given to different skills and personal abilities by university teachers, new graduates and employers. A summary of this study is shown in Table I.

Aware of all this, those who designed the great European university paradigm (Bologna Declaration [9]), recognise the importance of introducing activities into the training programmes that help to promote abilities and skills in students.

TABLE I. ASSESSMENT OF THE ORDER OF IMPORTANCE OF DIFFERENT PERSONAL SKILLS AND ABILITIES AS SEEN BY GRADUATES, ACADEMICS AND EMPLOYERS [8].

Personal skills and abilities	Academics	Graduates	Employers
Analytical and summarising skills	2	1	3
Ability to apply knowledge in practice	5	3	2
Basic general knowledge of the study area	1	12	12
Basic knowledge of the profession	8	11	14
Oral and written communication in own language	9	7	7
Knowledge of a second language	15	14	15
Basic computer usage skills	16	4	10
Research skills	11	15	17
Learning skills	3	2	1
Capacity for self-criticism and criticism	6	10	9
Ability to adapt to new situations	7	5	4
Capacity to generate new ideas	4	9	6
Decision making	12	8	8
Interpersonal skills	14	6	5
Ability to work as part of an interdisciplinary team	10	13	11
Appreciation of diversity and multiculturalism	17	17	16
Ethical commitment	13	16	13

The European Convergence process is now bringing about a change in the outlook of university teaching staff. Educational actions in the University in future years will need to be channelled towards becoming adapted to the European Higher Education Space, in addition to achieving an enhancement of training programmes and the incorporation of new goals aimed at developing personal and professional skills.

II. PRINCIPAL SKILLS OF AUTOMOTIVE ENGINEERS

In this context, a group of teachers and professors from Madrid Polytechnic University, UPM, belonging to the University Institute for Automobile Research, INSIA, being aware of the need to introduce changes into the teaching activities that would help to promote the most demanded skills by a sector as competitive and complex as the automotive sector, decided to get to know these skills at first hand. One of the reasons for conducting the study was their conviction that these skills might not literally coincide with those demanded by other sectors.

If they should know which skills the undergraduate and graduate students should need to acquire and develop, it would help them to organise the teaching activities and adapt the available methods and resources. It would also help them to set the goals to be attained by teaching staff as well as providing them with the tools needed for them to attain these goals.

A two-round Delphi questionnaire[1] was used to conduct the study which was directed towards professionals in the major companies in the Spanish automotive sector. These companies are divided into two large groups: vehicle manufacturers and component manufacturers. Thus, since their tasks are highly complementary but different, the experts were questioned as to the most important abilities and skills for new engineers taken on in their companies as well as in the complementary ones. In other words, each vehicle manufacturing company professional was asked their opinion about the most important skills for a new engineer in a vehicle plant, and also for one in a component plant; and vice-versa.

The procedure followed was as below:

- A "Panel of Experts" was set up, comprising 8 professionals representing different posts in each of the two types of company.
- A draft questionnaire was prepared which gave a choice of 30 personal and professional skills sought after in an automotive engineer. These skills were submitted to the "Panel of Experts" for approval so they could then be finally included in the questionnaire.
- The questionnaire was sent to selected persons in the automotive industry ("Consultative Panel"). 24 professionals were chosen in all. Mainly those holding technical positions and human resources managers in both types of company.
- A month and a half later 21 replies were received (87.5%) with an average response time of 23 days. During this time those polled were sent two reminders by e-mail until the survey was answered.
- The questionnaire was then dispatched a second time to the experts so they could ratify or change their responses in the light of the average given by the experts as a whole.
- Finally, after another month and a half's wait, 20 replies were received (83,3%), with an average response time of 17 days, where two reminders were also sent out.
- A statistical analysis of the survey results was carried out and a final report written.

The results obtained are shown in Table II. The first column shows the importance given by a vehicle manufacturer to a new engineer working in a vehicle manufacturing company, and the second column the importance for workers in a components manufacturing company. The third and fourth columns are the responses from the components manufacturers.

In spite of the profound mutual knowledge of both types of company, the table reflects significant differences concerning the type of work that each person thinks is done by the others.

The responses from both sides are also quite a fair reflection of the situation in the Spanish sector, where vehicle manufacturers are mainly concerned with production and to a much lesser extent with vehicle design, whereas there is a much larger and dynamic industrial fabric devoted to the design and manufacture of automotive components.

[1] The Delphi questionnaire was developed in the United States in the 60s. Its name comes from the famous Greek oracle in Delphos, which the ancient Greeks turned to in order to know their future. It is commonly used to conduct forecasts among professionals using surveys that are sent out in two rounds: in the second round the expert is informed of the response of the other persons polled, giving them a chance to change their initial response.

TABLE II. THE SKILLS AND ABILITIES MOST APPRECIATED IN THE AUTOMOTIVE SECTOR (RATED 0 TO 4).

	Skills and abilities	Vehicle Manufacturer		Components Manufacturer	
		Vehicle Man.	Comp Man.	Vehicle Man.	Comp Man.
1	Team leadership	4	4	4	4
2	Team motivation	4	4	4	4
3	Responsibility at work	4	4	4	4
4	Teamwork	3	4	4	4
5	Capacity for innovation	4	3	3	4
6	Common sense	3	4	3	4
7	Communication skills	3	3	4	4
8	Negotiating skills	3	3	4	4
9	Financial awareness	3	3	4	4
10	Capacity for initiative	3	3	3	4
11	Ability to convince	3	3	3	4
12	Sales ability	2	3	3	4
13	Emotional Intelligence	3	3	3	3
14	Non-verbal communication	2	3	2	3

The most appreciated skills were leadership and team motivation, responsibility at work and teamwork. Also highly rated are the capacity to innovate, and communication and negotiating skills.

III. THE AUTOMOTIVE UNIVERSITY COMPETITIONS FOR ENGINEERS

Nowadays, there are several automotive competitions oriented to undergraduate students in which the multidisciplinary groups of each university have to build a vehicle. Each competitions have different objectives on education as is teamwork, leadership, innovation, solve problems, among others. The most important are the following ones:

A. The Formula SAE competition

In 1982 engineers from Ford, DaimlerChrysler and General Motors, grouped together in the SAE (Society of Automotive Engineers), in the United States, being aware of how little newly graduated engineers were adapted to automotive companies, designed a competition for universities throughout the world, which involved conceiving, designing, manufacturing and competing with a single seat formula-type vehicle. This competition was called the Formula SAE.

They were of the opinion that this challenge would serve to accelerate engineering students' professional profiles, forcing them to work as part of a team, with high levels of communication, responsibility and motivation, forcing them to use in their work a large part of the knowledge acquired in their degree.

For there to be project uniformity and equal opportunities in the competition, the SAE sets strict standards as to the design and manufacture of the different vehicle parts in addition to severe safety standards. In spite of this, the participants enjoy a wide autonomy and capacity to innovate, as can be seen in the differences in the models from each university.

Each university must present a project as if it involved a company that manufactured 1000 vehicles per year for an amateur public competing at weekends, and with a cost of less than 25,000$.

The main condition refers to vehicle power, restricted by engine cylinder capacity (maximum 600 cm3) and by a restricted air intake. Therefore, most machines use motorbike engines which are standard engines of around 110 HP, but by restricting the air intake their capacity is reduced to around 70 HP after appropriately designing the intake and exhaust with fluid dynamics programs and after electronically changing the engine torque and power curves.

Other restrictions refer to vehicle size (minimum 1,520 mm wheelbase, and minimum 9 m slalom track pass), which means that the vehicles are around 2,700 to 3,000 mm long. There is also an exhaustive materials check of the materials making up the chassis, and close attention is paid to safety and driving seat ergonomics.

Competition score cards are divided into two kinds: static and dynamic. Also, there are some preliminary tests that do not score, but need to be overcome in order to compete. Table III shows the tests together with a brief description of each one.

TABLE III. DESCRIPTION OF FORMULA SAE COMPETITION TRIALS.

Events	Points	Description
Preliminary tests	**0**	Pre-competition safety tests.
Technical inspection	-	General check of car by judges.
Tilt	-	Car inclination up to 60º checking its stability and that no type of liquid is leaking.
Brakes	-	Simultaneous blocking of all four wheels after a brief acceleration.
Noise	-	Check to ensure vehicle emits less than 110 dB under certain acceleration conditions.
Static	**325 in total**	Presentations and oral defence in front of the judges of technical solutions adopted.
Design	150	Technical defence of vehicle design and solutions proposed.
Presentation	75	Marketing presentation, convincing the judges to choose their car compared to the others.
Costs	100	Written report detailing cost of each part and component of the unit built.
Dynamic	**675 in total**	Different on-track trials with the single-seater.
Acceleration	75	Cover 75 m on a straight run in the shortest possible time
Manoeuvrability (Skidpad)	50	Manoeuvrability to run a 9 metre circle in both directions.
Sprint	150	Quick lap of the circuit
Endurance	350	Overall vehicle performance and reliability in 22 laps of a circuit.
Fuel	50	Minimum consumption in endurance trial
Total	**1000**	

As can be seen, this is an authentic engineering competition where in addition to vehicle speed and performance the project and the product achieved are also appreciated. In this competition the students have a totally leading role. They have to organise themselves, find the resources needed, administer project time, costs, etc, and all this under the supervision and advice of the advisory teachers and the Faculty Advisor. They have to design and build the parts by hand (the fewer purchased the better), and four of them must finally drive the car.

What is new about this project, apart from it being a new, innovative educational methodology where the vehicle is simply the means to get the best possible training, is the challenge posed to the students by having to take on and participate in an entire vehicle development life cycle. This can only be achieved by forming a strong working team, promoting active participation, the assumption of responsibilities, decision making and involvement in reaching a common objective. In exchange the student gets the satisfaction of being able to take the vehicle built by their own effort to an actual competition.

Currently, more than 200 universities throughout the world take part each year in the Formula SAE. For this it has been necessary to extend the competitions to other countries, like England, where it is called Formula Student, Australia, etc, as well as the original in Michigan.

B. The Baja SAE competition

Baja SAE is a university competition whose aim is to improve the preparation and education of young engineers through an event that simulates a real engineering project where students have to design, manufacture, test, and compete with an off-road vehicle.

The participating teams have to assume that they have been hired by a manufacture firm to build an off-road vehicle capable of competing in any field. The restrictions are on the design of chassis, and the engine modifications are prohibited, as the engine is the same for all teams. Unlike Formula SAE standards these restrictions limit the design and innovation in these areas, leaving the engineer's imagination for other areas of the vehicle. This, in turn, results in a reduction in costs and activities compared with Formula SAE. The target for selling the prototype is the non-professional weekend racer, as well as the Formula SAE, and the teams must develop a product that has high performance in acceleration, traction, with common parts and easy maintenance. It is a competition that also simulates a case study of the life cycle of a vehicle, where students also have to get organized sponsorship for their project.

The engine is a 10HP, and it is not allowed to make any changes or modifications. The overall dimensions of the vehicle recommended to be on lengths of 275cm are the track is restricted to a maximum of 190cm. The cage in the chassis is very limited in terms of innovation to ensure the safety at all situations, as in the event of rollover or impacting with another vehicle.

Is highly valued by the judges the manufacturing capacity with conventional tools that are available to anyone. Teams will be evaluated on design, and marketing costs (not all of Baja competitions own this event). In the dynamic performance, the students must demonstrate their ability to accelerate, steer, and drive the vehicle to finally be evaluated in endurance where they are able to repair the vehicle in the race. Table IV shows the events with a brief description of each one.

The Baja SAE competition began in 1976, and currently has 6 competitions in the USA, Brazil, South Africa and South Korea are involved in more than 250 university total more than 4000 students participating.

TABLE IV. DESCRIPTION OF FORMULA BAJA COMPETITION TRIALS

Event	Points	Description
Static Events -	**300 in total**	Presentations and oral defence in front of the judges
Design Report & Evaluation	150	Technical defence of vehicle design and solutions proposed
Cost Report & Cost Production	100	Writing report dealing cost of each part and component of the unit built
Presentation	50	Marketing presentation, convincing the judges to choose their car.
Dynamic Events -	**700 points**	**Different on-track trials with the off-road vehicle**
Acceleration/Speed	85	Cover 30m o 45m on a straight run in the shortest possible time
Traction/Hill Climb or Pulling Event	75	The traction event will be either hill climb or pulling an object
Manoeuvrability	75	Manoeuvrability including tight turns, pylon manoeuvres, ruts and bumps, drop-offs, sand, rocks, gullies, logs, and inclines.
Specialty Rock Crawl or Suspension Traction	75	A special event to test the vehicle on unique off-road conditions
Endurance	400	Maximum distance performed in 4 hours
Total Points	**1000**	

C. Eco-Shell Marathon

This university and college competition has the goal to compete with more efficient vehicle for a given distance. There are two categories, one corresponding to futuristic vehicles where reducing drag and maximizing efficiency is the major premise and the second category corresponding to four-wheeled vehicle using conventional or alternative fuels.

Competition rules limit the size in wheelbase, track and height of vehicles, chassis design (to ensure safety), the type of propulsion (it can be used combustion, fuel cell or solar) and deposit size is limited to 30cc to 250cc. limiting the size of engine to use. The following list outlines the types of fuel that can be used:

- Shell Unleaded 95 (Europe & Asia) / Shell Regular 87 (U.S.)
- Shell Diesel
- Liquefied Petroleum Gas (LPG)
- Shell Gas to Liquid (GTL 100%)
- Fatty Acid Methyl Ester (100% FAME)
- Ethanol E100 (100% Ethanol)
- Hydrogen

Vehicles must meet travel between 22 km or 25 km depending on the category in which they participate. The assessment of efficiency is done in accordance with a table of equivalence developed by the competition.

The aim of the competition is to simulate a real art project where teams work for a year designing and building a vehicle. The event organizers also want students to integrate, design and develop a product that is sustainable, that controls the energy used and that is concern about environmental protection. This target causes that the greatest number of team efforts are focused in engines, transmissions and aerodynamics.

D. Formula Low Cost

Created by ISAT in 2008 with the aim of extend these kind of competitions to universities all around the world, regardless their economic possibilities, Low Cost Formula is a competition aimed at extending university engineering education through the construction of a kart type vehicle. The main difference with Formula SAE is the budget, which can not exceed 2.000€ for its build, based on fixed prices of components.

In this competition the teams have to assume they have been contracted to manufacture a vehicle whose main feature is that it has not suspension. For the chassis, the rules establish that they must be designed to ensure the safety, and the materials allowed are only steel and aluminium. The engine can not exceed 12KW and are well worth the innovations that can be made. Although the size of vehicle is complete free, the possibilities with the 2,000€ restriction are limited.

As an engineering competition, teams valuation is done through a set of tests, both static (where it is evaluated the technical and cost features) and dynamic (where it is evaluated the track vehicle performance). The statics events have the aim to assess the designs, innovations and cost of the prototype. The dynamic events are composed of three: a classification, a sprint race (15 laps) and resistance (60 laps).

This competition also provides an opportunity for students to participate throughout the life cycle of a real project, in order to prepare engineers to manage projects, budgets and learn to work as a part of a team. Table V shows the events with a brief description of each one.

TABLE V. DESCRIPTION OF FORMULA LOW COST COMPETITION TRIALS

Event	Points	Description
Static Events -	**478 in total**	Presentations and oral defence in front of the judges
Cost Report	183	Writing report detailing cost of each part and component of the unit built
Innovations	183	Technical evaluation of innovations
Design	112	Technical defence of vehicle design and solutions proposed
Dynamic Events -	**441 points**	**Different on-track trials with the off-road vehicle**
Acceleration/Speed	75	Cover a straight run in the shortest possible time
Sprint	183	A event to classified the vehicle for the main event
Endurance	183	60 laps to a circuit
Total Points	**919 points**	

IV. THE PARTICIPATION OF THE MADRID POLYTECHNIC UNIVERSITY, UPM, ON THESE COMPETITIONS.

As previously stated, after selecting the Formula SAE as the project to be embarked upon by our students, in October 2003 the University Institute for Automobile Research, INSIA, was set up; the first Spanish Formula SAE competition team, called UPMracing. It was made up of about 35 students from the final courses in the School of Industrial Engineering of the UPM, and the Master's course in Automotive Engineering (Figure 1). In the years that followed, several students from other university schools joined in, like the Aeronautic Techniques and Industrial Techniques schools, what lead to important improvements in the performance (Figure 2).

Figure 1. The team in England with the UPM-01 and UPM-02 cars

Figure 2. Competition pictures with the UPM-03 and UPM-04 vehicles

At present the UPMracing has accumulated six years of experience with the same number of single-seaters built that have taken part in the 2004 – 2009 editions of the Formula Student in England.

From the beginning the project has been based on four principles that are a statement of the teaching method used:

- Learn by applying
- Learn by doing
- Learn in a team
- Learn by competing

Moreover, in order to maximise student performance and progress, a whole strategy of learning situations has been planned which participants must pass through during their period in the team, as it will be referred in next epigraph.

With the aim of reproduce similar conditions to the work carried out in real companies, the team has been organized in several departments according to the main systems of the vehicle. These divisions, supervised by a small team of teachers, conform an operative organisation whose chart is shown in Figure 3.

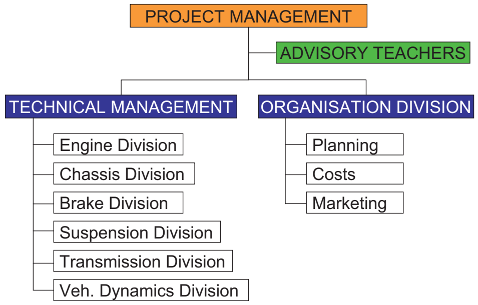

Figure 3. UPMracing team organisation chart

The students usually spend the last two years of their careers working at a division on the team: on the first one they do the training and computer design, and on the second the manufacture, testing and also attend the competition in England. Although there are planned two short non mandatory subjects and the most of them uses the work performed as the Final Career Project, the joining at the team is completely voluntary and the students have to develop the most of the work on their free time.

V. The Participation Of The Institute Of Automotive And Transport Engineering, ISAT, On These Competitions.

The Institute of Automotive and Transport Engineering (ISAT) in Nevers (France) is a state-run school committed to the comprehensive training of engineers, with a particular interest in the automotive sector.

The main aim of ISAT is to cover the whole range of jobs and skills related to the automotive and transport industries, with a strong expertise in mechanics: mechanical design and development, industrialisation, manufacturing, quality assurance.

Based on sound scientific and technological foundations, the training of the students during the 5-year programme (Master's Degree) is extended and strengthened by long periods of work experience and placements with various companies.

During the third year, as a part of the course's mandatory activities, the most of the students join in one of the four automotive competitions ISAT is taking part: Formula Student (Figure 4), Formula Baja (Figure 5), EcoShell Marathon (Figure 6) and Formula LowCost (Figure 7).

Each team is formed by 12 to 15 students that have to specialized into the different technologies involved. Although the schedule al ISAT is planned to work every Wednesday of the third year on these projects, the students used to employ many hours of their free time.

Figure 4. The Formula Student team at Magny Cours tracks

Figure 5. The Formula Baja team at the USA competition

Figure 6. The whole EcoShell Marathon team at ISAT

Figure 7. Some Formula LowCost members at the workshop.

All the work is supervised by teachers and workshop employees, but the students have a high level of autonomy and responsibility both in the technical areas as well as in the planning and budgeting activities.

Finally for INSIA-UPM and ISAT these projects represent opportunities to develop teaching programs, methods and activities oriented to improve the engineering education, with the special interest on the automotive industry.

VI. The Activities Performed At The Competitions And The Developing Of Personal And Professional Skills.

Although there are many differences between these competitions, all of them have in common the way the students do the work (with technical, schedule and budget requirements and constraints) and assume their responsibilities

On this point, it should be noticed that the responsibility given to each student is real: each is aware that a mistake by them is a mistake for the team. Equivalent responsibility would only be found in any company after a couple of years' work. The students themselves even take it upon themselves to raise part of the financial resources needed, and it is they, under the supervision of the teachers, who manage these resources.

The educational experience provided by taking part in these projects and the teaching methods used mean that the student must face up to specifically designed situations that will challenge them and promote their personal and professional skills. Table VI shows 16 different learning situations related to different moments or activities of the project, cross-referenced with 24 skills, which in the light of the literature consulted and the studies and surveys presented, are deemed to be the most sought after in an engineer getting ready to work in the automotive sector.

TABLE VI. PROMOTION OF PERSONAL AND PROFESSIONAL SKILLS ACCORDING TO DIFFERENT ACTIVITIES AND LEARNING SITUATIONS.

Learning situations / Skills	1. Initial training in all knowledge areas	2. Supplementary material and in-process tutorial sessions	3. Division into sub-groups according to work areas	4. Assigning duties, objectives and responsibilities.	5. Organisation and planning according to general costs and schedules	6. Every student is responsible for their work and collaborates with the others	7. Wide personal autonomy and possibilities for innovation	8. Periodic presentation and update meetings	9. Resources searches and usage management	10. All take part in vehicle manufacture	11. Former students coordinate activities of newcomers	12. Participation in a real experience	13. 24. Oral and written communication in a second language	X	X							X			X		X	X	X

VII. ASSESSING THE EXPERIENCES

Right from the start of their own projects, both universities have been interested to know the opinion of the students taking part, what needs to be kept as it is, what needs improving, and obviously, to what extent the project's goals have been achieved. And among these goals is the distinguishing improvement in students' personal and professional skills compared to traditional activities.

At UPM, for instance, students taking part were given a survey with the 24 most important skills for an engineer in the automotive sector in order to get to know their opinion of the importance of these skills when working in their profession, as well as the level of their success in the subjects taken as part of their degree, and likewise during the Formula SAE training process.

Various conclusions can be drawn from the general results of the survey that are shown in Table VII:

- Students consider the most important skills to be a capacity for responsibility and commitment, teamwork, decision making, creativity, solving conflicts and communication in English. This classification is in total harmony with the opinion of companies, which shows that the training experience suitably orients students towards the labour market, especially if we compare the results with those shown in Table I.
- The average score given by students to the list of 24 skills is 4.2 points out of 5, their average level of success during their degree being given 2.3 points,

while achievement during the Formula SAE project is 3.6 points.

TABLE VII. SCORES FROM 0 TO 5 POINTS OF THE IMPORTANCE GIVEN BY STUDENTS TO THE 24 MOST IMPORTANT PERSONAL AND PROFESSIONAL SKILLS FOR AN ENGINEER IN THE AUTOMOTIVE SECTOR, AS WELL AS THE EXTENT OF SUCCESS DURING THEIR DEGREE AT THE SCHOOL OF INDUSTRIAL ENGINEERS (ETSII-UPM) AND DURING THEIR TIME ON THE PROJECT (F SAE).

Skills	Level of importance for students	Degree of success in ETSII	Degree of success in F SAE
1. Ability to work as part of a team	4.9	2.0	4.1
2. Leadership qualities	4.2	1.1	3.6
3. Ability to motivate	4.4	1.3	3.8
4. Capacity for responsibility and commitment	5.0	3.2	3.8
5. Ability to innovate	4.2	1.3	3.6
6. Negotiating skills	3.6	1.2	2.8
7. Capacity for self-motivation	4.0	2.2	3.2
8. Analytical skills	4.4	2.8	3.4
9. Ability to summarise	4.0	3.1	3.3
10. Capacity for criticism and self-criticism	4.0	2.1	3.6
11. Ability for self-learning	4.2	3.9	4.3
12. Organisational and planning skills	4.0	3.2	3.2
13. Ability to identify problems	4.8	2,6	4.0
14. Ability to resolve conflicts	4.4	1.9	3.3
15. Ability to generate new ideas (creativity)	4.4	1.3	3.6
16. Ability to take up new initiatives	3.7	1.3	3.3
17. Ability to adapt to changing circumstances	4.1	2.7	3.9
18. Ability to work on one's own	3.4	3.8	3.2
19. Ability to make decisions	4.9	2.0	4.0
20. Interpersonal skills	3.8	2.7	4.3
21. Ability to assimilate and apply knowledge	4.1	3.0	4.0
22. Capacity for dynamism	3.8	2.0	3.7
23. Capacity for discipline and self-control	3.8	3.0	3.3
24. Oral and written communication in a second language	4.4	1.6	3.1
Mean value	**4,2**	**2,3**	**3,6**

The average score of importance given to the 7 most appreciated skills is 4.7 points out of 5, with a score during their degree of 1.9 points and practically double, 3.7 points for the Formula SAE project.

Similar results are given by ISAT student's evaluations: the students taking part in the four competitions highly appreciate their own experiences as an important tool to improve the most important personal and professional skills appreciate by companies, more than other activities and experiences carried out during their studies.

VIII. CONCLUSIONS

In this work we have reflected on the growing importance being given by universities to the promotion of personal and professional skills, and the most important of them, on the opinion of the automotive sector, have been found out thanks to the Delphi questionnaire.

The automotive university competitions are very useful activities for the improvement of those desired skills. In the competitions analyzed both at the UPM and at ISAT, a whole set of learning situation is been planned for the students, as well as the methods and means to solve them.

At the end of the experience, students' valuation of the most important abilities and skills highly agree with the requirements of companies.

It has also been showed that the involvement of the students in the whole activities of four competitions, has more contributed to the improvement of the personal and professional abilities and skills than the rest of the activities done during the whole career of five years.

Despite of the good educational results, the advisory teachers have designed a new set of experiences to improve the useful and time profitably of our students.

Although this study has been exclusively referred to the automotive engineering sector, the methodology used and the principal conclusions can be applied to any other sector. Indeed, the 24 skills selected to evaluate the project do not specifically belong to automotive industry, but they are really appreciated by any other kind of industry. The fact of had asked the opinion of their professional served us only to prioritize them.

Abstract— **MotionLab is an experimental system for the study of physical motion created as a learning objective of the Industrial Engineering students. MotionLab uses the accelerometers and the infrared camera of a game controller as a data acquisition interface present in the consumer electronics market. The aim of this system is to monitor and to study the results of physical experiments about solids motion under different conditions. This research line, aimed primarily at education, tries to build low-cost experimentation systems replacing the classic ones, which result, mostly, as less efficient and need more expensive laboratories.**

Keywords-Laboratory experiences; remote laboratories; accelerometer; low cost; motion; sensor, physical experiments.

I. Introduction

Currently, consumer electronics offers better performance features every day, thanks to its large-scale manufacturing, which has produced a decrease in costs. Two of the technology sectors in which faster evolutions have been made are the telecommunications and entertainment sectors in which new products incorporate advanced technologies that traditionally had a high cost.

All over the world the process of technological change resulting from the Information and Communication Technologies (ICT) is causing significant changes in areas like economy, society, science and education, which substantially influence the patterns of production, organization and development.

Two factors have enabled this fact, using ICT as tools of development:

i) Lowering the costs of technological devices (laptops for under 200 €, better and cheaper communication, etc.)

ii) The emergence of new devices equipped with different sensors that allow the capture of environmental information (such as smart phones, game consoles like Wii, equipped with accelerometers, proximity sensors, video cameras, etc.) at lower prices every day.

Nowadays there is a great activity on this field which is called to represent a cornerstone of worldwide engineering education. The recent popularity of the remote laboratories concept and the existence of abundant bibliography prove its importance in the education area. These activities are focused on research areas like [1], which is oriented to microelectronic device characterization, or on learning and educational methods oriented, such as [2], [3] and [4].

One line of the research of the authors is the research of new low cost learning methods in education through remote labs and the simulation of physical experiences for students of Industrial Engineering. Some of the research lines about a low cost laboratory can be seen in [5].

For engineering students, laboratory and practices constitute a fundamental step in the learning process. Indeed, laboratory experiments help them to improve the understanding of concepts and skills, to familiarize with the use and management of measuring equipment and to develop specific skills required for future work. For these reasons, the most important institutions, which deal with scientific-technological training, try to dedicate a large budget to equipment and maintenance practices' laboratories. However, the evolution of technology quickly results in these equipments becoming obsolete and needing replacement, consequently increasing the investment in this educational activity.

With the emergence of the last generation entertainment systems, focusing on getting a great user experience, researchers and professionals that come from other different areas and which are motivated by this reduction in costs and by the easy reuse of components have began to consider these technologies for very different purposes from those that were originally conceived.

In this case, this research line is focused on the reuse of low-cost devices used in the new generation of video consoles, which incorporate technologically advanced control devices. These controls contain different types of sensors such as accelerometers, infrared cameras, gyroscopes, etc. The reuse of these devices has allowed the construction of MotionLab, a high precision experimental system oriented to the study of physical experiments, such as motion experiments.

Consumer electronic devices, that incorporate accelerometers, which can be used for different applications of those they were originally conceived, as it is the case of the Wii remote controller (called Wiimote) connected to other devices with greater capacity to process such as a PC, can be found in the market. In the educational field there are other researches using this remote controller like [6].

The study of physical motion, such as kinetic motion, is essential for engineering students. Students begin to explore concepts such as velocity and acceleration. For a correct understanding, in addition to the theoretical knowledge of these concepts, experimental study is essential for their comprehension as well as practical experimentation. One of the best ways to study acceleration and its effects is using accelerometers to accurately show the characteristics of a concrete experiment. In this laboratory it is shown that it isn't necessary to use high accuracy sensors, and therefore high cost, but low-cost sensors that can perform these experiments and that allow to students acquire a high grade of assimilation of the theory.

In particular an experiment has been built consisting on the study of the movement of a mobile object in an incline plane.

As it will be described later, this is an ongoing project in which the first prototype has just been completed and although it has been tested in laboratory, it hasn't been used by students yet. The first tests will be done in this course (2009-10).

The structure of the paper is as follows. In section II, the system concept is reviewed. In Section III, one experiment as a concrete use case is described. Section IV shows the advantages of the system. Section V explains the experimental results. Finally, section VI draws some conclusions.

II. Description

A low cost laboratory is not just a set of applications that captures several physical data, but must meet certain requirements.

First, students must have in the same application a manual with the theoretical foundations, operating principles and objectives clearly and accurately expressed (operating manual, practice script, etc.).

So all the experiments that have been developed in this laboratory are not limited to programming and assembling of a device, (hardware and software), but require a careful design where certain educational requirements, besides the technical requirements, are taken into account.

User experience is another key factor and therefore the application should be handled easily, with an intuitive user interface. Students should focus mainly on the experiment design and the application has to let them do it.

In addition, it is really important to test the application, under conditions of normal use, with a sufficient number of subjects, and to make an evaluation of the results and to change everything which needs to be changed. Obviously the implementation of this process requires a multidisciplinary team consisting of software developers and teachers of the subject concerned.

The main objective and the origin of this system was to obtain a low-cost universal platform for studying the motion of solids in different conditions. As mentioned, MotionLab is a system for the study of kinetic experiments that allows the study of solids motion in different conditions (collisions, pendulum-like motion, etc.). As a fundamental element, the system uses the Wii remote control device (manufactured by Nintendo and available on the Wii console) and the built-in sensors. It is a flexible and scalable system that enables rapid incorporation of new types of experiments.

A remarkable effort has been made in the MotionLab design making an open and extensible development which enables its expansion and the incorporation of new sensors in the most simple and transparent way.

A web application complements MotionLab which allows students to share and to store the results of the experiments. It also allows teachers or administrators to manage the system.

A. Architecture

Different approaches [7] can be used in order to design the architecture of the system. Two approximations have been chosen, the first one a low-level controller, which is in charge of controlling all the equipment, and the second one a web based subsystem. Relevant technical aspects in this approximation are explained in this section.

Following, a general architecture of the system is showed:

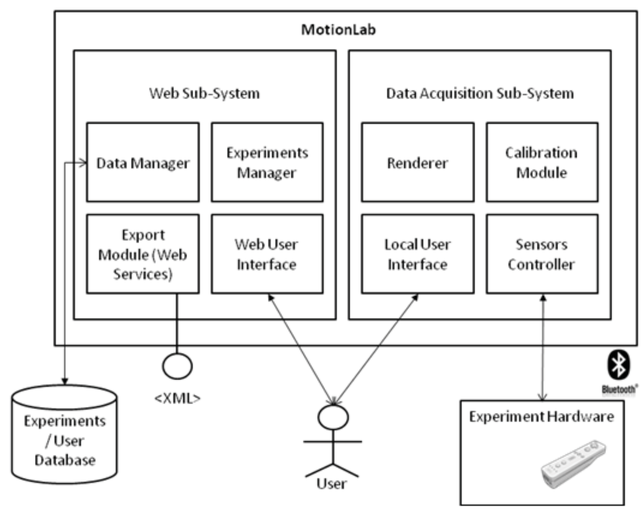

Figure 1. MotionLab Platform

As seen in Figure 1. , there are two main parts, the "Data Acquisition Sub-System" and the "Web Sub-System".

The first one is in charge of the acquisition and the data renderization, i.e. this sub-system controls the experiment hardware, calibrates the system, obtains data and then it makes the renderization process in order to represent it to the user through the local user interface.

a) The data acquisition sub-system manages and coordinates the modules of this sub-system and communicates with users through the local interface in order to receive orders and display information.

b) The graphics module is responsible for representing all information of the samples, sensors and application experiments. It draws and displays all the data in real time on the screen.

c) The Sensor Controller is the responsible of the communication with the experiment hardware and its sensors. It makes the connection with the Wiimote control and it receives data from its sensors in order to transmit them to the data acquisition sub-system.

The second one is in charge of the experiment management and the data exportation to third party systems, i.e. this sub-system manages all the experiments, user profiles, manages the experiment and the user database and exports the experiences to other systems using web services. Users can review the experiences and manage profiles using a Web user interface.

a) The data manager module is responsible of managing the system data at real time and to make them persistent. The database stores MotionLab projects, created from the web application and it can manage user permissions and projects stored in it. In addition, it can export experiment data to any physical storage medium.

b) Publications in the web site are done using web services, and all structured data are sent in XML format. Using web services enables to develop platform independent applications, making the system accessible for third parties (using a "Universal Description, Discovery and Integration" directory, UDDI).

c) Communication with other third party systems can be done through the "Export Module". It uses Web Services with structured data in XML. The use of standards of this technology provides extensibility and transparency.

d) This communication feature enables teachers from other locations to use all of the experimental data to their specific needs, without having their own laboratory.

Finally, .NET platform has been used for the system implementation as development environment, for both, data acquisition sub-system and web sub-system. Visual Studio 9.0 and C # development language have been used and for data persistence the database manager MySQL 5.0 has been used.

B. *Wiimote*

As mentioned before, Wiimote is the video game controller device developed by Nintendo for the Wii console. This remote control can be used for the development of positioning systems and it is a low cost device with a great performance.

Wiimote has three accelerometers, i.e. an instrument for measuring acceleration, detecting and measuring vibrations. The accelerometer built-in Wiimote is the ADXL330, a chip MEMS (micro electro-mechanical system) made by Analog Devices. This device is capable of measuring both acceleration and direction movement or rotation in three axes. Basically, the accelerometer operation is based on a piece of silicon, held to an end, and placed between the electric field exerted by two capacitors.

ADXL330 [8] is a small, thin and low voltage chip, which is composed of three accelerometers, one for each axis with variable voltage signal output. The device measures acceleration with a range of ± 3 g. It can measure the static acceleration of gravity in applications that require monitoring of tilt, as well as dynamic acceleration resulting from motion, shock, or vibration. The output signals are voltages that are proportional to the acceleration detected by the accelerometer. It offers an acceptable performance for the project and provides the following features: three axis sensors, small and thin potting (4 mm × 4 mm × 1.45 mm), low consumption. (200 uA to 2.0 V), a single point of supply (from 2.0 V to 3.6 V), shock tolerance 10,000 g and an excellent stability against temperature. It also contains a MOT (Multi-Object Tracking) sensor (engine vibration), a Bluetooth chip and a connection port for peripherals.

Silicon is in charge of transmitting the movement, when the Wiimote is moved, the silicon bar is closer to one of the capacitors, which makes the electric field changes, this change is detected and real-time translated into a motion. In Figure 2. , a Wiimote sketch can be observed.

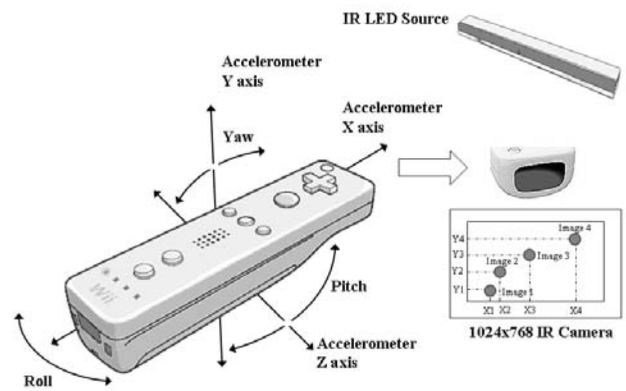

Figure 2. Wiimote

In the front of the Wiimote there is a translucent dark plastic, and behind it, it is placed the MOT infrared sensor made by Pixart Imaging. This sensor visually keeps tracks of multiple objects with a resolution of one megapixel. So to run, it needs an infrared source, consisting in this case of several LEDs arranged in a bar.

The Wiimote's sensor locates these LEDs, forming the ends of a "virtual display" that will be the relative action field. The computer screen acts, in this case, as a display.

To work properly the application must be set up, indicating the position of the bar and the aspect ratio of the display screen (16:9 or 4:3). In this way, the remote is able to continuously "know" its position in space and its accelerations in the x, y and z axis.

All data, motion detection and position are sent directly to the Broadcom Bluetooth chip (built in the remote). In addition, these data are sent from this chip to the computer's Bluetooth adapter where they are stored as well as real-time shown in the display. The recorded file can be exported in Microsoft Excel format in order to be treated (as for instance to represent the positions and accelerations of the studied solid).

III. Experimental Case

A. Types of Experiences

The experience object to study is the uniformly accelerated one-dimensional motion of a mobile in an incline plane. This is done on a leaky aluminium pneumatic rail connected to an air pump so that the mobile object is moved on an air mattress. This air mattress hugely reduces the friction.

The experiment allows students to get practical knowledge about the following three aspects of kinematics and dynamics of one-dimensional motion:

1) Uniform Motion (UM). As shown in the equations (1), (2) and (3) is characterized by a linear dependence of distance over time: so the velocity is constant and there is zero acceleration. On the mobile object any force is working.

$$v = constant \quad (1)$$

$$a = 0 \quad (2)$$

$$x(t) = x_0 + vt \quad (3)$$

To make this experience, a fork is placed on each side of the mobile object. The uniform motion is accomplished by pressing the cradle of the mobile object against the top of the rail and leaving it free.

In the experiment the graphs (4) and (5) are displayed.

$$x = f(t) \quad (4)$$

$$v = f(t) \quad (5)$$

2) Uniformly Accelerated Motion (UAM). The equation which calculates the position is (8), the velocity is (7) and the acceleration is constant (6) as it correspond to a constant force.

$$a = constant \quad (6)$$

$$v(t) = v_0 + at \quad (7)$$

$$x(t) = x_0 + v_0 t + \frac{1}{2}at^2 \quad (8)$$

This type of motion is achieved by tilting the rail. A flat piece of known thickness is placed under one leg (the supporting one) of the rail. Knowing the angle of inclination of the mobile, the mass and the acceleration obtained from experience, allows the students to verify the validity of the second law of Newton.

In the experiment the graphs (9) and (10) are displayed.

$$x = f(t) \quad (9)$$

$$v = f(t) \quad (10)$$

3) Collisions. The interest in this experiment is checking the law of conservation of linear momentum (11) and to distinguish whether the collision is elastic or inelastic taking into account the variation of kinetic energy, E_k.

$$p = m\,v \quad (11)$$

Two types of shock can be accomplished:

a) Elastic collision, it is achieved by putting two accessories in the ends of the mobile objects that will collide, a fork in the first one and an elastic accessory plate in the other one.

b) Perfectly inelastic collision, the two mobile after the collision must remain joined.

In the experiment the graphs (12), (13) and (14) are displayed.

$$x = f(t) \quad (12)$$

$$v = f(t) \quad (13)$$

$$E_k = f(t) \quad (14)$$

B. Prototype

Next figures (Figure 3. and Figure 4.) show two photographs of the prototype based on the platform MotionLab. In this case, MotionLab is being used as a data capture system for a low friction air rail. The pneumatic rail is an experiment that can be considered classic, which studies the kinematics and dynamics of solids in one dimension. The usual data acquisition devices for this experiment consist of a series of photoelectric cells, usually two, which besides being quite expensive only allows obtaining data in only two points of the track.

The pneumatic rail experiment consists of the following parts:

1) A pneumatic rail made of a square aluminium tube (63 mm x 63 mm), 2 m long, supported on three legs that allow levelling. It presents a series of holes through which pressurized air goes out, forming a pneumatic bed between the rail and the mobile object which minimizes friction. The air stream is supplied by a blower pump connected to the rail by a flexible hose.

2) Rail made of anodized aluminium, l = 130 mm, which can incorporate several elements.

3) Pluggable screen made of plastic, mountable on the rail to stop the rays of light from the photoelectric door. (L = 35 mm). This element is used in the classic experience and enables to obtain comparisons between MotionLab and the classic one.

A huge advantage of MotionLab is the data acquisition in a continuous way.

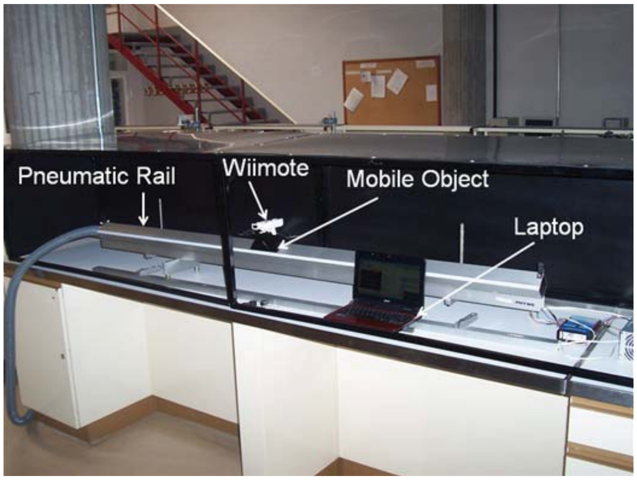

Figure 3. Prototype I

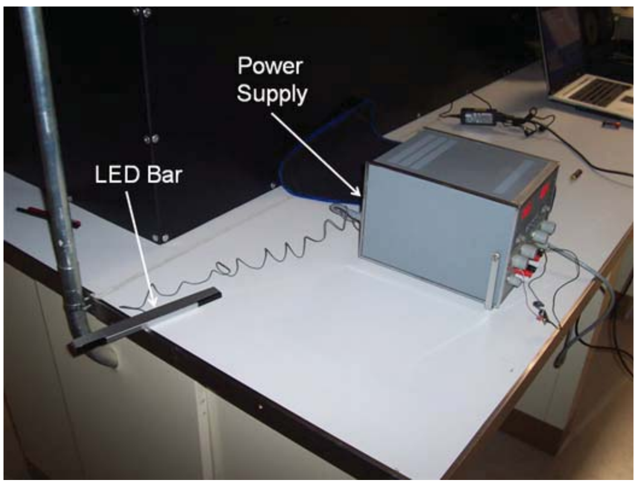

Figure 4. Prototype II

As shown in Figure 3. the experimental assembly basically consists of:

1) A Wii remote control (Wiimote), equipped with its corresponding sensors and placed on the mobile whose motion is being studied,

2) A computer (an ultraportable with a built-in Bluetooth adapter or a laptop perfectly suits the performance needs) and an infrared diode bar parallel located to the air rail and spaced about 1.5 m out (Figure 4. left).

C. Working with MotionLab

1) Getting samples

When a new sample is created, different options of calibration are possible, depending on the type of the selected experiment. Figure 5. shows the basic structure of the sample panel:

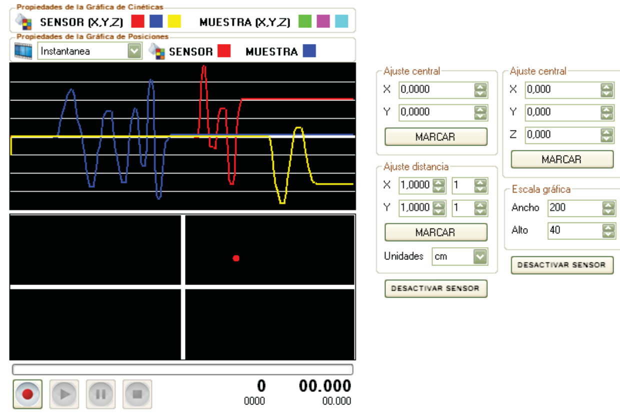

Figure 5. MotionLab Acquisition Application

In this panel, three elements can be seen:

a) Representation charts: in the top left, one or several charts represent real-time values obtained from the sensors.

b) Calibration panels: on the right of the charts, there are different options to configure and calibrate the sensor involved in the experiment.

c) Recording and playback panel: underneath the charts, the necessary buttons for recording and playback data from a sample can be found.

Before recording a sample, sensors must be calibrated. Depending on the sensor used, its placement and the characteristics of the physical experiment, parameters must be adjusted in different ways. MotionLab offers several automatic calibration tools to facilitate these tasks.

Once the sensor has been calibrated, the application is ready to record data obtained by each sensor, the procedure is the same for any of them. To start recording, simply press the record button. When the experiment is finished, users must just press it again to complete the data collection.

2) Configuring Experiments

To obtain an experiment is the main goal of MotionLab. An experiment consists of one or more samples combination. Once selected the samples of the experiment, students will configure them in order to have the experiment ready for analysis.

When students are working with an experiment, they can find, depending on the type of experiment, different charts and options. Figure 6. shows an experiment and all parts which it is composited (different samples, etc.).

Figure 6. Experiment

The main element is the centre panel where the samples selected for the experiment are rendered simultaneously. On the right, the list of experiment samples and the panel to configure them can be found. At the bottom the experiment playback buttons, its duration and some other controls are placed.

3) Exporting Experiments Data

With an already configured experiment, MotionLab offers several options to export data in different formats. This is an easy procedure in which both the experiment and the output data format is needed to select.

In the website all reports that students have published can be searched through the publication service. Then, all associated report data can be seen.

Next figures show some parts of the web sub-system, specifically Figure 7. shows the report management application. As show in the figure a form to enter search criteria is used to search experiments reports. It is possible to search by title of the experiment or by the author name. When the search is finished, all results contained in the specified text are listed. Each report has the author's name, a title report and date of execution as metadata.

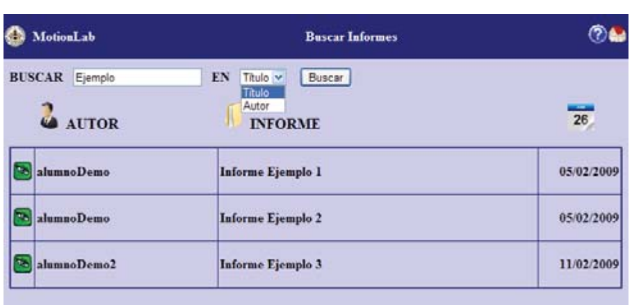

Figure 7. Report Management Application

In Figure 8. a report detail is shown as an example. All data that the report contains is displayed to the user.

Figure 8. Report Detail

Students who have published their reports can manage them using their credentials. They are able to view or delete them from the system using the web application. Only the owner or an administrator can manage them.

IV. ADVANTAGES OF MOTIONLAB

MotionLab provides significant advantages over the traditional experimentation systems. On the one hand, it substantially improves the cost per experiment, e.g. in some experiments a special paper is used for trajectories visualization in which the paper is literally "burned" by the moving object. This means a significant saving in cost per experiment and in cost per student.

TABLE I. shows a brief cost comparison between MotionLab and the classic laboratory:

TABLE I. COST COMPARISON

Modality	Cost	
	Element	***Total***
MotionLab	Wiimote, LED Bar, Power Supply	60 €
Classic	Equipment (photoelectric cells, etc.)	600 €

It also provides a greater cooperation among students and a higher apprenticeship allowing making comparisons among experiments of different groups of students which results in a higher quality education.

More advantages of this system are the following ones:

a) One of the most important advantages is that it is a very didactic system which enables the understanding of the experiment by the student far more quickly than with traditional systems.

b) Remote access. In order to allow students to conduct experiments from anywhere at any time, and remote controlling parameters of the experiment.

c) It is technologically advanced and the lab equipment has a better performance and it is available to students more time.

d) Distance courses. MotionLab allows the organization of engineering courses.

e) Autonomous learning. MotionLab promotes autonomous work, fundamental in the European Higher Education Space.

f) Furthermore these tools foster independent learning, as advocated by one of the main guidelines of the Bologna system marked by adaptation to ECTS (European Credit Transfer System).

g) Cool factor, wiimote has a very cool factor which is very important to encourage and motivate students in the learning process. Moreover, due to the fact that for engineering students laboratory and practices constitute a fundamental step in the learning process this is an aspect to take in account.

V. RESULTS

As shown in Figure 9. two experiments can be seen in the same graph. Both of them are plotted in two different inclinations of the plane. In the figure the curves with circles are those of the classic experiment using photoelectric cells while the curves with squares correspond to the experiment using MotionLab.

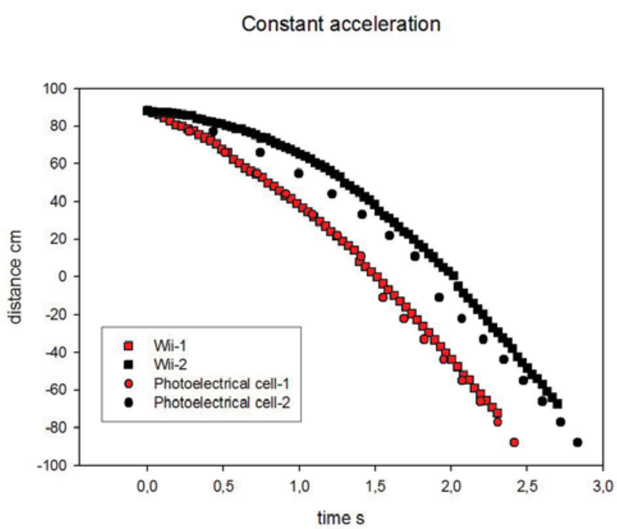

Figure 9. Comparison between MotionLab and the Classic Experience

As mentioned there are two graphs one of which shows the experience using MotionLab while the second one shows the results using the traditional experience with the photoelectric cell system that has the classic rail.

As it can be seen the experimental results are quite similar. But while the classic experience provides a smaller amount of data (limited to the number of photoelectrical cells), with the use of MotionLab a greater number of points are obtained, which enables to obtain more accurate results and closer to the theoretical model.

VI. CONCLUSION

The application of low cost sensors in building some real kinetic experiments have been presented. This is a low cost data acquisition system for physical experiments using the three-axis accelerometers and the infrared camera built in the Wiimote. The system has been used for experimentation of uniform motion, uniformly accelerated motion and several kinds of collision.

The results are really good according with the expected results. The system allows graphic visualization of the experiment and can be used to perform a wide number of experiments, for instance it can be used in all types of pendulums, simple, physical, coupled pendulums, springs... and generally in any experiment which involves motion.

This prototype has just been completed and although it has been tested in laboratory, it hasn't been used by students yet. The first tests will be done in this course (2009-10) and they will start soon.

Making real experiments, it has been found that the possibilities of the system would be increased if multiple sensors of the same type were simultaneously working. For instance, in some kinds of collision is really interesting to study the trajectories of multiple mobile objects in order to obtain a more complete experience.

Therefore, the addition of several Wiimotes is proposed as a future expansion to provide more functionality to the system. In fact, right now a new platform is starting to be developed and it will bring major improvements, like for instance including the ability to work with up to eight remote controls and incorporating a new more sensitive sensor (that Nintendo has just released last summer).

This second version is being developed using the LabVIEW graphical programming language instead .NET platform (it has been used in the prototype described in this paper). Nowadays using LabVIEW is a good option for remote laboratories and it has been used by some prestigious entities around the world [9] with good results.

The most remarkable thing of this work it is a low cost experience and quite easily applicable in any laboratory or educational institution that may be interested.

Polytechnic University of Valencia
Valencia, Spain
bego@mag.upv.es

Abstract— **This article contains some reflections about the experience of the authors after a decade teaching assignments within Engineering Graphics area, like Graphical Expression, Computer-Aided Design, Industrial Drawing, Descriptive Geometry and Technical Drawing, and others related to several Master Programs as Master in Graphical Design. Reflections consider advantages and disadvantages of those traditional experiences regarding to graphical aspects, such as the magisterial Class, practical classes in small groups or working out different tasks and how all of this affects the final results, considering students opinion.**

On the other hand of this traditional system is another one based on the learning directed to those students who have ECTS credits, inside the European Educational Higher Space (EEHS) and the experiences in several Universities before entering 2010-2011 season. Knowledge and competencies management are considered within this new system and they be included in the Teacher Guide so that those students who approve the subject acquires specific competences (subject specific knowledge). These competencies coordinated with those specific obligates teachers to develop particular activities, because the detailed knowledge of each is a main condition in order to program competencies briefings with a high detail level. This is not an easy task considering the experiences and opinions of famous professionals specialized in competences issues.

Therefore, new activities should be set up and include new Information and Communication Technologies, such as Internet, search of information, E-learning educational platforms, and a different orientation for individual and group follow up and for seminars and classes in the University environment as well. Sometimes, practical orientation of the lesson should focuses on real cases, on the solution of a real problem. This is more complicated in lessons during the first year when there is a lack of knowledge of other subjects considering that a lesson is not a knowledge "island" in a "sea" of subjects. Nevertheless, besides the difficulties those teachers who have not got that specific training have it becomes a closer challenge and a push to enter the EEHS with a renewed motivation and a different vision about new activities that should be develop.

Keywords- Engineering education; Engineering drawings

I. INTRODUCTION

Knowledge and competencies management [1] within Engineering Graphics subject [2] has been analyzed from different points of view several times, but only a few times it has been analyzed from transversal competencies related to the design of specific records for its evaluation.

University education considered inside the Europe an Educational Higher Space (EEHS), not only pretends to reach of professional competencies in order to get updated knowledge, technology and specific abilities and be in touch with the real professional world but also to make students acquire knowledge about modern languages, about how to use TICs, how to be creative and keep training constantly, be adaptable to job market, get abilities for teamwork, verbal and written expression and have critical spirit.

According to EEHS one goal of the learning process is the acquiring certain kind of knowledge and developing some transversal competencies according to each one's own academic profile and its correspondent professional profile.

There are basically two kinds of competencies: Specific (technology), related to technical knowledge and Transversal (general), not necessary related to technical knowledge.

Specific competencies are mainly based on the contents of subjects included in the program of the course and that fulfil those requirements described in BOE (Spanish Official Bulletin). Moreover, transversal competencies are generic and should be established in the degree and normally programmed for the subject.

Thus, for designing and evaluating competencies is necessary to know the content of the subject precisely in order to elaborate appropriate records for each one. [3].

II. PRACTICAL APPLICATION

Until a couple of years ago competencies treated in Teacher Guide were basically contents. Since the mandatory implementation of Degrees, as part of the adaptation process to EEHS, Teacher Guide should include activities in order to make students acquire some transversal competences.

As mentioned before, it is not about designing activities to evaluate all that competencies but those considered more appropriate for the subject. Table 1 shows some transversal competencies that can be included in Teacher Guide [3].

As an example, we take a main subject for getting the Engineering Degree in almost all universities, Engineering

Graphics. It has 6 ECTS credits (European Credit Transfer System) and it's also a common subject for several degrees during the first year.

The pilot experience of implantation of ECTS is being applied for some years and Engineering Graphics subject began to be taught 4 years ago. Definitive implantation will not take placed until next period (2010-2011), so this experience applied in the University of Jaén, is helpful to get as good Teaching Program.

Particularly, this subject has 6 credits in the ancient system (4'8 ECTS) and its content includes: Descriptive Geometry, Spatial Conception, Normalization and Industrial Design Basements and is taught in one hour of theory and 3 of practice per week.

Main goals of the subject are:

- To develop spatial conception and abstract thinking.
- To manage technical drawing elements and instruments, set up formats, scales and others.
- To dominate normalization and criteria applied to technical drawing and be able to understand and elaborate one.
- To work in group and use Engineering Graphics resources to share technical information.
- To be able to represent pieces and groups of Engineering Applications using representation systems.
- To be able to deduce and apply principles of Industrial Design in technical graphics.

TABLE I. TRANSVERSAL COMPETENCES

Nº	Transversal Competence
1	Planning and managing time
2	Verbal and written Communication
3	Using TIC
4	Managing Information (search, selection and integration)
5	Solving problems
6	Taking decisions
7	Critical thinking
8	Teamwork
9	Abilities for personal relations
10	Consciousnes of ethical values
11	Ability to put knowledge in practice
12	Autonomic Learning
13	Ability to adapt to new situations
14	Creativity and innovation
15	Responsability
16	Selfconfidence
17	Initiative and enterprising spirit

The experience of programming a Teacher Guide mentioned above has been applied in developing and evaluating (from 1 to 10) different activities as following:

- Practical final exam: max 7 points
- Constant evaluation of practices: max 1 point
- Doing and presenting mandatory group work: max 0.5 points
- Doing and extra exercise of increasing difficulty: max 0.5 points.
- Assistance to group tutorials, journeys, seminaries: max 0.5 points.
- Related information search through Internet: max 0.5 points.

As described before, exam has a quote of 70% of the final qualification and the rest 30% are activities in and outside the class.

Competences in Table 1 are related to each activity as following:

- Practical Final Exam (1-5-7-11).
- Constant Evaluation of practices (1-4-5-11-12-15-16).
- Doing and presenting mandatory group work (1-2-3-4-5-6-8-9-10-11-15-17).
- Doing and extra exercise of increasing difficulty (1-4-5-7-11-12-15-16).
- Assistance to group tutorials, journeys, seminaries (2-6-9-10-13-15).
- Related Information search through internet (1-3-4-6-13- 15).

But designing activities in order to get certain competencies is not always easy and depends on the nature of the subject. We honestly think this serial of activities reinforce an important amount of transversal competences explained before.

There are other examples of transversal competences much more detailed [3] that include 4 items as following:

1. **Competence Nomination**
2. **Definition of the Competence**: Definition, description, competences needed to develop this one and other competences developed from this one.
3. **Develop of the Competence:** Training activities used to develop it.
4. **Evaluation of the Competence**: Concrete and simple items used for the evaluation and its process, such as observation, interrogation or performance; evaluation instruments related to process; and bibliography.

Nevertheless, from a practical point of view it is better to develop a work report as following that includes the development of activities in a specific teaching week. Although only a practical session along a week is explained as an exam ple of aut onomic work rep ort, i t shoul d be a pplied during all weeks along 4 months.

3rd Week from October 19th to October 23rd 2009:
DIEDRIC SYSTEM I

Transversal Competences:

- Ability for putting knowledge into practice.
- Information m anagement (search, sel ection an d integration)

Specific Competences:

- To t rain for the c orrect representation of n otable elements (do t, straigh t line, p lane) and related position between each other in the Diedric System.

Objective:

- To dominate criteria and norms of Die dric Syste m (Representation System) applied to Technical Draw.
- Search Basic and c omplementary bi ographical information.

Content:

- 2nd Theme. Diedric System
  - Chapter 1: Nota ble ele ments. Representation.
  - Chapter 2 : Relative p osition between notable elements.

Development activity:

- Description: E laboration of a 4 exe rcises practice. Tiempo: 3 hours.
- Resources, bibliography and spaces:

Resources nee ded a re E uclidian tools (set square a nd triangle, millimeter ruler, compass, triangle, angle carrier, 2H hardness pencil and eraser as well). Besides, it is also required t he PDF document containing the exe rcises for the practice a nd locate d i n the file platform of t he university of Jaen.

Basic an d com plementary b ibliography is listed in th e Teacher Guide of the subject.

Practices will take place in room 31, building A4 in Las Lagunillas Cam pus, p rovided with projector, bo ard an d drawing tables.

Evaluation Criteria:

- Presential assistance to practice.
- Clean and draw.
- Correct result.

Nevertheless, one of the most complicated parts is how to evaluate learning pr ocess. B esides teacher evaluation o ther evaluation tools should be established, such as self evaluation, equal e valuation a nd co-evaluation between teache r and student.

There are se veral technol ogy [4, 5] that evaluate t he learning of facts and issues such as opinion polls, conce ptual maps, self v aluation and equ al ev aluation or th e learn ing of procedures (control lists, estima tive scales and polls); a nd the learning of attitudes, such as a nalysis of speech and productions.

Proposed e valuation t ools c ould be i mproved f or s ure i n order to get mo re clarity in t he process, but th e d iversity of evaluation too ls and th e lack o f tim e make it h ard to fi nd a valid result.

III. Final Reflections

We can list following final conclusions:

1. Designing activ ities in o rder to g et certain competences is not easy and depends on the nature of the subject.
2. Designing sp ecific and developed re port for transversal com petences is complicated at the very beginning due to a lack in teacher training. They are prepared i n their professi onal area but in most case s they do not know the pedagogic basements and other issues related to teaching innovation.
3. Recommending teacher training i n activities about learning evaluation considering that the output of that process can i mprove t he resul ts seri ously. B esides, making the student participate in the evaluation of its own learning process make it possible to detect weak points and reinforce the strong ones.
4. Establishing a national net of Teacher Guide that include recommendations about how to elaborate this text because although each professor ca n freely program the s ubject, the mix of expe riences from other professors from many Spanish Universities, is a more rich source to consult.

Abstract—**In this paper, we introduce several rubrics to measure a set of collaborative and creativity grading. Rubrics are powerful tools for both teaching - learning and assessment. Rubrics improve communication between teachers and students. This work relates the general criteria to measure the complexity levels in the development of creativity and collaborative work competences with concrete indicators associated with the use of Social Web tools and concepts. These indicators have been used in the assessment of competences in a particular course related with the use of collaborative networks.**

Keywords-component, Rubrics, Social Software, Assessment

I. Introduction

Engineer employers affirm that some competences in certain non-technical areas such as communication ability, economics, leadership, teamwork or creativity are not practically being considered in their formation. Accreditation Boards, Engineering Associations, are also demanding the incorporation of the called generic or transferable competences for the actual and the future engineering degrees. Generic competences constitute the basis for the ability to develop discipline-specific competences. At present, faculty and staff are developing and articulating these important linkages to create strong curricula plans. Firstly, it is needed to define competency mapping as the process of identifying key competences for a particular degree. This process involves supporting and enabling staff to fully reflect upon potential competences, conducting formal research to identify the most important competences, and reaching consensus. Finally, this approach supposed important changes in the current teaching-learning processes of many Institutions.

Key competences should be acquired by pass from a hierarchic model (where teachers are considered as knowledge dispensers), descendent and focused on the teachers toward a collaborative model/horizontal where the student is in the centre of the model and teachers fulfill their role of guides in the teaching - learning process. These key competences are all interdependent, and the uses of social web tools are potential facilitators of that change, especially with the creativity and collaborative work competences.

Creativity is considered as the ability to provide novel answers to a proposal or problem given, or to discover new relations and give them new mental structures, respectively. Rubrics are evaluation instruments that can be applied to assess these competences. But they require the identification of new indicators that can be directly assessed. This work relates the general criteria to measure the complexity levels in the development of this competence with concrete indicators associated with the use of Social Web tools and concepts. These indicators have been used in the assessment of competences in a particular course related with the use of collaborative networks.

II. Benefits of Rubrics Assessment

Rubric assessment of competences and skills results in a number of benefits to students and teachers in Universities [1,2,3].

Rubrics allow students to understand the expectations of their instructors. They provide direct feedback to students about what they have learned and what they have yet to learn. Second, students can use rubrics for self-evaluation. Finally, rubrics emphasize "understanding rather than memorization, 'deep' learning rather than 'surface' learning" [5].

Teachers also can benefit from rubric assessment in two important ways [6]. First, the rubric creation process provides an opportunity to discuss and determine agreed upon values of student learning. Rubrics "make public key criteria that students can use in developing, revising, and judging their own work". They also noted that once rubrics are developed, they could be used to norm teacher expectations and bring them in line with the vision for student learning.

Second, rubric assessment offers university manager and faculty assessment data full of rich description that can be used to document how to improve courses. Rubrics provide "detailed descriptions of what is being learned and what is not" [11].

"Rubrics improve communication between teachers and students," said *Andi Stix*, an educational consultant whose book *A Rubrics Bank for Teachers* will be published by Teacher

/

Created Materials. Stix noted that rubrics help students understand exactly "what is expected of them when they are writing a paper or designing a project.

Rubrics can be deceptively difficult to write. After carefully developing a rubric, it is worthwhile to test it on five or ten samples of student work to see how the rubric works.

III. Rubrics For Evaluating Collaborative Social Networks Course

Today we see an enormous use of Web 2.0 / Social Software tools and services outside the educational sector. A stronger use in the educational sector could have a considerable impact in terms of changes in educational practices. UTPL understands the necessity of shift towards practices that promote learner-centered as well as collaborative approaches. Social Software tools allow for easy publishing and sharing of ideas, content, experiences, opinions and links (“user-generated content”).

The developed of skills and competences for the knowledge society require decisive shift away from teacher-centered knowledge-transfer: a) students: active, constructive and collaborative engagement of students – as close as possible to “real world” problems, content and expertise, b) teachers: facilitators of learning processes – requires change in educational culture/mind-set and new professional understanding

Social Software or Web 2.0 provides a new window of opportunity for initiatives with focus on developing competences and skills for the knowledge society. Blogosphere and Wikipedia, has made possible that any person can participate actively in the society of knowledge. Social software allow collaborative filtering, discovery of “most interesting” web resources through social filtering techniques, also through ongoing conversations, recommendations and cross-linking of resources in social networks Weblogs, Wikis, content and bookmarks sharing, social networking, etc.

A. *Defining Criteria for Evaluation of Student Performance*

The purpose of use Web 2.0 in education is considerer the benefits from the collective intelligence, the positive effects of networks, and collaborative tasks through Internet. Specifically: Tools where every participant had the opportunity to participate in the elaboration, publications, consult, provision, improvement, and debugging of its contents.

Three rubrics based on Bloom’s learning taxonomy [4,8] (knowledge, comprehension, application, analysis, synthesis, and evaluation) were created to evaluate the students’ activities on the co-curricular activities of Social Web [13], *rubrics for evaluate wiki editing, blogging and social bookmarking*.

The use of social web wiki, blogs and social bookmarking enhanced learning, with these social tools, the knowledge is viewed as a social construct, facilitated by peer interaction, evaluation and cooperation.

B. *Rubrics for assessment wiki editing*

This is a rubric for the wiki editing, see table I. Wiki is a collaborative environment. Collaborative environments allow using tools for co-authoring and debating. The use of wikis is a good example of transition from static and restricted web to social and collaborative participation (co-authors). The wikis enable to create, modify, and delete content in collaborative way.

TABLE I. RUBRICS FOR WIKI EDITING

Dimension (rubric criteria)	**Levels of performance**			
	Poor	**Regular**	**Good**	**Very good**
Intellectual Engagement with Key Concepts.	The wiki pages make no reference to issues and key concepts raised through readings and/or module activities.	The wiki pages make some reference to issues and key concepts raised through readings and/or module activities.	The wiki pages demonstrate awareness of most of the key concepts raised through readings and/or module activities.	The wiki pages demonstrate engagement with the important concepts raised through readings and/or module activities.
Structure, spelling and grammatical errors	The wiki pages have poor spelling and grammatical errors.	The wiki pages have some spelling and grammatical errors. Text entered with limited enhancements	The wiki pages have few spelling and grammatical errors. Text is enhanced.	Spelling and grammatical errors are rare. The wiki pages have structure and are formatted and enhanced to increase readability.
Content and Understanding	The wiki pages are superficials, lacks of insight and depth.	The wiki pages show some insight and depth, and are some connected with topics and activities. The wiki pages attempts to address the learning objectives pages	The wiki pages show insight and depth are connected with topics and activities. The wiki pages address the learning objectives pages.	The wiki pages are relevants and show a high level of understanding and knowledge. The wiki pages clearly address the learning objectives pages.
Creative construction	Show no ability to incorporate creativity techniques throughout the wiki project. The content of wiki pages don’t meet the basic requirements of the wiki project. No creativity shown. Content has no imagination or surprises, is lacking information or is not creative.	Participants show some ability to incorporate creativity techniques during the wiki project with occasionally demonstrating awareness. Participant has created exactly what was required of him or her and nothing more.	Participants show a good ability to incorporate creativity techniques throughout most of the project.	Participants show a high ability of incorporate creativity throughout the wiki project. Content is filled with surprises and creativity. The content of wiki pages show that participant was thinking outside of the box - going beyond what participant would normally create. (Thinking differently or from a new perspective).

Wiki facilitates collaboration and sharing and enables the development of shared resources in a controllable environment. Mistakes are solved by social correction and with the support of content configuration management (version control).

Performance Criteria:

- Intellectual engagement with key concepts.
- Structure, spelling and grammatical errors
- Content and Understanding
- Creative construction

C. Rubrics for assessment Blogging

This is a rubric for Blogging, see table II. From an educational perspective, the blogging is autonomous, constructive and inherently conversational. Teachers or students can create a blog individually or in groups, they form their ideas about specific topics, gather, evaluate and interpret data and information, they assume positions, train in elaboration of arguments and evidence, and acquire abilities to express their thinking in the right way and style. Blogging allow creating, evaluating, analyzing, applying and understanding knowledge.

Rubric performance criteria:

- Intellectual engagement with key concepts;
- Structure, spelling and grammatical errors
- Linkage and cohesion among posts and use of external resources
- Timeliness and replies comments
- Understanding
- Creative construction

TABLE II. RUBRICS FOR BLOGGING

Dimension (rubric criteria)	**Levels of performance**			
	Poor	**Regular**	**Good**	**Very good**
Intellectual Engagement with Key Concepts.	The blog entries make no reference to issues and key concepts raised through readings and/or module activities. No comments are made on blogs of others participants.	The blog entries make some reference to issues and key concepts raised through readings and/or module activities. Comments have been made on blogs of others participants.	The blog entries demonstrate awareness of most of the key concepts raised through readings and/or module activities. Comments have been submited, though not all of them may give evidence of a substantial contribution.	The blog entries demonstrate engagement with the important concepts raised through readings and/or module activities. Blog includes many reflections. Comments have been submited, all of which are substantial contribution.
Structure, spelling and grammatical errors	The posts and opinions are short and irrelevants. The entries have poor spelling and contain grammatical errors. The entries lacks of structure and connection with topics and activities.	The posts and opinion are short and may contain some irrelevant information. Some of the entries have poor spelling and contain grammatical errors. The entries have some structure	The posts and opinions are expressed in an appropiate style and entries show a good depth of undestanding. There are few spelling and grammatical errors. The posts have structure.	The posts and opinions are expressed in an appropiate style and are connected with topics and activities. The entries have rare spelling and grammatical errors. The posts have structure and are formatted to enhance readeability.
Linkage and cohesion among posts and use of external resources	The posts don't have linkage and cohesion among themselves. The entries don't contain external links.	The posts have some linkage and cohesion among themselves. The entries may contain links to external digital resources.	The posts have linkage and cohesion among themselves. The entries contain links/images referred within posts.	The posts have linkage and cohesion among themselves. Each external link is referenced.
Timeliness and replies comments	The blog entries are irregular, tipically 1 to 2 for month	The blog entries have some timeliness. Some comments are replied to.	The blog entries are regular. Most comments are replied to in a timely manner. The reply shows understanding.	The blog entries are regular and timely. The replies show a depth of understanding and relationship to the comments.
Understanding	The posts are superficials, lacks of insight and depth. They don't express opinion clearly and show little understanding.	The posts show some insight and depth. The post have some connection with other topics and course activities.	The post shows insight and depth. The posts are connected with topics and course activities .	The blog entries are relevants and show a high level of understanding and knowledge. The posts show insight, depth and understanding, and are connected with topics and activities.
Creative construction	Show no ability to incorporate creativity techniques throughout the blog. The content of entries don't meet the basic requirements of the project. No creativity shown. Content has no imagination or surprises, is lacking information or is not creative.	Participants show some ability to incorporate creativity techniques during the project with occasionally demonstrating awareness. Participant has created exactly what was required of him or her and nothing more.	Participants show a good ability to incorporate creativity techniques throughout most of the project.	Participants show a high ability of incorporate creativity throughout the wiki project. Content is filled with surprises and creativity. The content of wiki pages show that participant was thinking outside of the box - going beyond what participant would normally create. (Think differently or from a new perspective).

D. *Rubrics for assessment Bookmarking*

This is a rubric for the Social Bookmarking, see table III. This is examining the process of recording and remembering key sites and URL's.

Delicious is a social bookmarking service that allows users to tag, save, manage and share web pages from a centralized source. With emphasis on the power of the community, Delicious greatly improves how people discover, remember and share on the Internet.

Instead of having different bookmarks on every computer, Delicious makes it easy to have a single set of bookmarks kept in sync between all of your computers.

Performance criteria:

- Storage and organization of bookmarks
- Tagging and comments
- Collaboration and relevance of bookmarks

TABLE III. RUBRICS FOR SOCIAL BOOKMARKING

Dimension (rubric criteria)	Levels of performance			
	Poor	**Regular**	**Good**	**Very good**
Storage and organization of bookmarks	Bookmarks are locally stored, lack of structure or organisation.	Participant add site favorites to Browser. Bookmarks are organised into folders with appropriate name.	Participant add web sites to a social bookmarking service (i.e. del.icio.us).	Favorites web sites are add to a social bookmarking service (i.e. del.icio.us).
Tagging and comments	Participant does not add tags or comments to bookmarks.	Participant sometimes adds either tags and/or comments.	Participant adds tags and/or comments. Tags are mostly well constructed.	Participant adds appropiate tags and/or detailed comments. Comments summaries the resource.
Collaborations and Relevance of bookmarks	Participant rarely shows any cooperation during the course. Exhibited little to no positive attitude. The bookmarks are personals.	Participant shows some level of cooperation throughout parts of the course. Occasionally exhibited a positive attitude. The bookmarks are irrelevants and don't be validates.	Participant showes a good level of cooperation throughout most of the course. Usually, maintaining a high level of commitment to a positive attitude. The bookmarks have some importance and exist attempts of validation. The student shares the bookmark with all members of their network.	Participant shows an very good level of cooperation throughout the entire course maintaining a high level of commitment to a positive attitude. The sites are bookmarked on the basis of relevance and validity. The student shares the bookmark with appropiate members of their network.

IV. RUBRICS APPLICATION

A. *Context Of Application*

Competences and learning outcomes have acquired renewed relevance for the *Universidad Tecnica Particular de Loja* (UTPL) process of curricular reform. UTPL are considered a key aspect for answering to the fast technological change in the Knowledge society and to the gap between the education and the labor market requirements. Although learning outcomes are concepts very used in United States and some European countries (United Kingdom, Denmark, Finland, France), in the Ecuador case they are in the early stages of developing and planning.

For UTPL, inspired in Bologna process, the official degrees will have to provide a higher education formation in which the generic competences are integrated harmonically with basic ones; transversal competences related to the integral formation of the student and specific competences than make possible a professional profile that allows the graduates integration in the work market.

The rubric discussed in this paper, was used within Computer Science School offered the Collaborative Social Networks Course (CSNC) as an elective course in 2008-2009. Collaboration and creativity are 21st Century competences of increasing importance and that are used throughout the learning process. CSNC has the following modules: blogs, wikis, RSS, social networking, and social tagging.

Course enrollment a total of 214 students and four tutors experts in Web 2.0 tools and evaluation in higher education. Given their practice nature, all modules were organized to assist students in their development and mastery of social software tools and services.

B. *Purpose of study*

This course explores the use of social software technologies as channels of conversation (and information) as well as how web 2.0's underlying principles change the way people communicate and interact in the knowledge society. Of particular interest in this study is how university students use social software to generate collaborative intelligence with partners, engage in discussion (and debate) and how they use tools to deliver innovative services.

The study objective is assessing and crediting the results of CSNC based at collaborative activities before and after.

Because rubrics are easy to use and to explain, they generate data that are easy to understand, defend, and convey [12].

/

C. Process

The first step in designing a rubric was to define the criteria that will be used to evaluate the assignment activities of participation and use of Social Web tools and services [7,9]. CSNC teachers have considered the assignment carefully and determine which aspects of the modules (Wiki editing, blogging and social bookmarking) should be evaluated. The second step was test rubrics with samples of student work to see how the rubric works.

The third step was to record academic performance prior to rubrics. The four step was to make public key criteria that students can use in developing and self-assess their work. Then, apply rubrics, record academic after rubrics and then provide those who have been assessed with clear information about how well they performed your work.

D. Performance levels

Making a rubric takes time in our case several days. Coming up with criteria and descriptors for a final product or assignment takes detailed thinking on what the product should like. Then, a teacher needs to think of what poor, regular, good and very good quality work should look like to conform to the university approved grading scale:

By making teachers expectations clear, rubrics make rankings, ratings, and grades more meaningful [10]. In this specific context, the performance levels, or anchors, are labeled:

- 0 - Absent—component is missing
- 1 - Poor, unsatisfactory: needs significant improvement
- 2 - Regular, somewhat satisfactory: needs targeted improvements
- 3 - Good, satisfactory: discretionary improvement needed
- 4 - Very good, very satisfactory: no improvement needed

The criteria are: Structure spelling and grammatical errors, linkage/cohesion among entries, use of external resources, timeliness, creativity, collaboration, understanding, scope, accuracy, coherence, and depth. These criteria are commonly applied to social web tools, as are other attributes such as clarity, rigor, appeal, and strength of argument.

E. Application of Rubrics for wiki editing

The procedures followed in this study can be divided into four parts. First, the teachers prepared the artifacts of student learning and study materials (modules: wiki editing, blogging, social bookmarking). Then, the students were trained in CSNC contents - without they know about rubrics score - its performance was evaluated and the results were registered. Third, students participated in training about scoring rubrics session, then, UTPL faculty evaluators scored and returned students works. Finally, the score sheets were prepared for statistical analysis. At the close of the study, all evaluators returned their rubric score sheets. The rubric score sheets were organized for data entry and analysis (see table IV).

Data for Table IV:

- Participant's number: 214
- Faculty evaluators: 4
- Quantity of wiki pages revised (*without rubrics*): 428 (two contributions per participant)
- Quantity of wiki pages revised (*with rubrics*): 428 (two contributions per participant)

The table IV shows academic performance before rubrics and academic performance after rubrics. We estimate the location of the statistical mode, the accumulate percentage in order to determine the number of students who shows academic performance above and below the Good category.

TABLE IV. TABULATION - RUBRICS FOR WIKI EDITIG

Dimension	Before/after rubrics	Very good	Good	Regular	Poor	Mode in category:
Intellectual Engagement with Key Concepts.	Without rubrics	34	137	**197**	60	Regular
	Accumulated	8%	40%	86%	100%	
	With rubrics	90	**175**	141	21	Good
	Accumulated	21%	62%	95%	100%	
	Variation	56	39	-56	-39	
Structure, spelling and grammatical errors	Without rubrics	30	141	**210**	47	Regular
	Accumulated	7%	40%	89%	100%	
	With rubrics	64	**197**	154	13	Good
	Accumulated	15%	61%	97%	100%	
	Variation	34	56	-56	-34	
Content and Understanding	Without rubrics	39	146	**193**	51	Regular
	Accumulated	9%	43%	88%	100%	
	With rubrics	120	**158**	133	17	Good
	Accumulated	28%	65%	96%	100%	
	Variation	81	13	-60	-34	
Creative contruction	Without rubrics	26	94	**223**	86	Regular
	Accumulated	6%	28%	80%	100%	
	With rubrics	47	137	**201**	43	Regular
	Accumulated	11%	43%	90%	100%	
	Variation	21	43	-21	-43	
	Mean without rubrics	**32**	**129**	**205**	**61**	**Regular**
	% Accumulated	8%	38%	86%	100%	
	Mean with rubrics	**80**	**167**	**157**	**24**	**Good**
	% Accumulated	19%	58%	95%	100%	
	Variation in means	48	37	-48	-37	

The right column of Table IV shows the statistical mode, the mode is the value that occurs the most frequently in the each rubric dimension. Before rubrics, the statistical mode is located in the *Regular* performance level. After rubrics the statistical mode shifts to the *Good* grading scale. The benefits of rubrics far outweigh the time and effort that goes into them. They force us to carefully consider what we are doing in the classroom, how that leads to student achievement of our course, program, and university, and how we will know when students have achieved those outcomes.

On average, without using rubrics the 39% of students (83 persons) have a good and very good performance at wiki editing. With rubrics there is an improvement in performance, in this case 58% of participants (124 people) is located in the range of good and very good performance.

F. Advantages of using rubrics in CSNC

According to the tables IV, the advantages of using rubrics in CSNC assessment are that they:

- Allow assessment to be reasonably more objective and consistent from activity to activity and from student to student, especially in our situations that involve collaboration among four teachers.
- The level of detail found in three rubrics: wiki editing, blogging and social bookmarking helps prevent inaccurate, clearly show the student how their work was evaluated and what was expected.
- Three rubrics promoted student awareness of about the criteria to use in assessing peer performance. In addition, provide useful feedback regarding the effectiveness of the instruction.
- Focus to our teachers to clarify his/her criteria in specific terms. Because rubrics clarify schemes for assessment ahead of time, they reduce subjectivity in grading.
- The rubrics provide benchmarks against which to measure and document progress.

V. Conclusions

Teachers and students exhibit a level of proficiency in the use of rubrics, this study demonstrates that teaching of Web 2.0 tools may be empowered through evaluation based on rubrics.

CSNC Teachers appreciate rubrics because their "accordion" nature allows them to accommodate heterogeneous social tools:

- With Rubrics, the writing from blogging and wiki editing is clear, concise, and easy to understand. Ideas and responses are communicated clearly and coherently. Timeliness, the responses are submitted on or before the due date.
- Rubrics reduce the amount of time teachers spend evaluating student work. Rubrics provide CSNC students with more informative feedback about their strengths and areas in need of improvement.
- Integration and synthesis of concepts and principles: The blogging and wiki editing responses demonstrate an integration of concepts and principals from classroom discussions and reflect an understanding of fundamental principles.

Critical Thinking: The interaction through of Web 2.0 tools demonstrate use of upper level thinking, analysis, synthesis, and evaluation and illustrate a thoughtful approach to the content.

Acknowledgment

Support for this work was provided by UPM under project AL09-PID-36, UTPL and scholarship provided by the *Secretaria Nacional de Ciencia y Tecnología* (SENACYT) of Ecuador.

***Abstract*— This digital divide case is sponsored by UNESCO and Brazilian Education Ministry as a pilot-project science and technology democratization initiative named RoboEdu. The main role is to allow that high school students can be the first technologies contacts using computers and robotics experiments due them low profile families remuneration. The initiative uses education interactions as main engine to guarantee the math and physics studies understanding and to reach the best cognitives practices approaching to the ideal pedagogic model. The teacher needs technical support also cause the language used must be translate to a simple vocabulary where students achieve the learning goals. The educator essential role starts to be several possibilities of knowledge generation not mattering anymore who knows technologies but through the part of the involved ones into orientation, participation and exchange of experiences. When the teachers and students are engaged on these activities pertaining to school evasion is reduced drastically**

Keywords-component: digital divide; robotics; technologies; educational learning

I. INTRODUCTION

This article describes the development of the activities under the RoboEdu project, which allows students from the public network to have their first contact with computers and robots, interacting during classes of Math and Physics, that deal with subjects from the practical experiments, in a more curious and questioning manner formatter will need to create these components, incorporating the applicable criteria that follow.

The use of tools that allow the improvement of the topics addressed by the educators is a key factor on the quality of learning at the schools. Educational, or Pedagogic, Robotics, is a strategy of exposure of the knowledge and takes the practice of the individual, by fixing issues by assembling and adapting equipments and models that shall present moves, such as robots.

This learning environment is characterized by the use of robotic systems, which allow students to build systems composed by a physical part (hardware), that constitutes the robot's structure, and programs (software) that sets the interaction of the knowledge acquired at the classroom and their behavior.

In this context, suggestions of unconventional learning present themselves for students and teachers of the public institutions, from practice to theory and from theory to practice, showing gaps of knowledge not explored until then, and, moreover, it allows these students that, many times, are poor, both socially and economically, the contact with state of the art technology, that ends up allowing curiosity and knowledge to act as stimulants.

II. JUSTIFICATION

In this pilot project, the learning stimulus focus on the involvement of the students in the activities related to studies performed in the classroom, applied through the simulation of throws in a basketball game, using the KickRobot software, and handling and controlling of robots physically composed, before their pairs or classmates, generating, this way, a more effective participation of the involved with a focus on the best work resulting of a team performance.

According to Resnick, when a person is committed into building something that is significant to the person itself, or to the people around, the building of knowledge happens in a more effective way. When the student is involved in building and modeling robots, this student starts to have a greater sense of care in the relation with this object, different than it would be if the student had received the robot already assembled. In this manner, the students are prone to explore and make deep connections with scientific concepts based on the activities performed [1].

Under the scope of digital divide it is necessary, besides making teachers and students familiar with the technologies of robots and computers, give support on the aspects related with the language or way of communicating this topics, the method employed during the demonstration of assembling, modeling and proper use of the different tools (hardware) involved and a proper environment to learning, among other social and cultural aspects, that intertwine the daily life of students with low income.

III. DIGITAL DIVIDE

The exclusion is mainly through the environment in which they socialize. The barriers may be present many difficulties such as access to technology, or a basic premise, the food. If the body is not nourished, strong and tuned barriers become insurmountable. Arises the need to help the company to break the problems encountered and form a virtuous cycle with a focus on social and digital divide.

The inclusion can not simply access to equipment or technology, but support for the formation of citizen and professional opportunities that will climb in the labor market. According to Paulo Freire [2], the inclusion should enable the inclusion of individuals with critical historical process, and create conditions for people to master the subject contents, the educational process must allow people to become aware of their potential, to become autonomous and able to free themselves from oppression in order to decide and choose - education should be a liberating action.

These activities have the potential to become the mind works, that is, showing how a person thinks, performs an activity and includes the realization of that done. Profits are able to go forward, learning and continuous production of new artefatos.A digital inclusion can then be identified when the individual is recognized as someone who will be able, who can believe in yourself, that is, increased self-esteem through the use of information technology and communications.

IV. EDUCATIONAL ROBOTICS

Educational robotics, or pedagogic robotics, is being used as a learning tool that allows the development of activities as stimulation tool to the creativity of students, due to the dynamic, interactive and even playful nature, further on, it serves as a motivator on the concern of students about traditional education.

Robotics have a great deal of potential as an interdisciplinary tool, seeing that the construction of a new mechanism, or the solution of a new problem, frequently exceed the classroom [3]. In the natural attempt of searching for a solution, the student questions the teachers of other disciplines that may help finding the best way for the solution of the problem [4].

Robotics, then, take the role of the bridge that makes possible the restoration or boarders previously established, acting as an element of cohesion within the curriculum. According to Simões, [5] the main pedagogic advantages of robotics are:

- It transforms learning in to something motivating, making principles of Science and Technology accessible to students;
- It allows testing on physical equipments what was learned using model programs that simulate the real world;
- It helps overcoming limits of communication, allowing the student to vocalize the knowledge and experiences, developing the capacity to argue;
- It develops the reasoning and logic in the construction of algorithms and programs to control mechanisms;
- It favors the interdisciplinary interaction, promoting integration of concepts from areas such as: math, physics, electronics, mechanic and architecture.

V. LEARNING ENVIRONMENT

During the development of this pilot project we tried to insert precepts that are named by UNESCO's Jacques Delors Report, a study recommended by the United Nations, as the four pillars of education. This study gathered the main features of the 21st century worker, with grounds on globalization and technological advances, and, furthermore, it has an observation on the need of development of the values and competencies of the students.

Mainly, in what connects to the pillars, it is applied on the project:

- Learning to learn: where we exploit the awakening of the pleasure of knowing, comprehending, discovering, building and rebuilding knowledge, having curiosity;
- Learning to do: developing competencies and abilities that bring about the application of technology in modern life;
- Learning to be: taking the student to the development of new logics and creativity, whole development of personality through self esteem, self determination, self realization and personal sensibility;
- Learning to live together: aspects that show the comprehension and respect to values and culture, developing the perception of interdependency, capacity of administrating conflicts and appreciation of people.

The proposed environment of learning is based on the application of the knowledge acquired by the students and supported by the teachers of the disciplines of math and physics through the use of educative robotics for practical measurement of the topics developed in class.

The proposed environment is based on the implementation of a competition of pedagogic robots using the software developed and named KickRobot.

VI. KICKROBOT

The KickRobot application is based on the competition among students that use pedagogic robots on an adapted competition of basketball. This competition focuses on the throw (kick) of balls at a virtual hoop, where the motto is the application of mathematical theorems and physics' formulas to achieve the goal, converting the throws in to points (Figure 1).

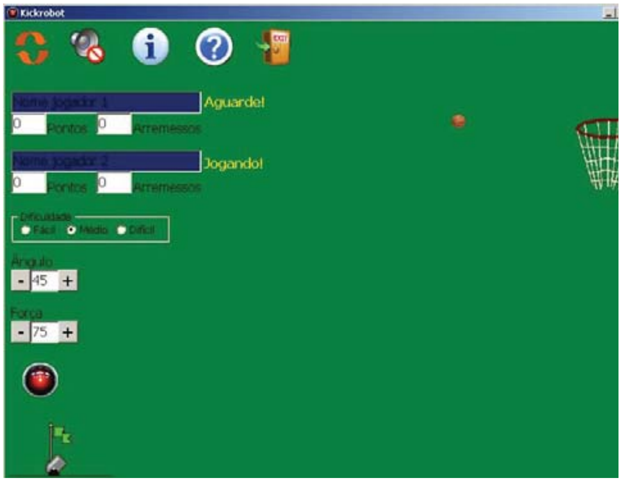

Figure 1. Basketball Court used in the KickRobot application

All the scores from the participants are registered and the five bets scorers will have their names registered at the gallery of players, what will promote the clash among students (Figure 2).

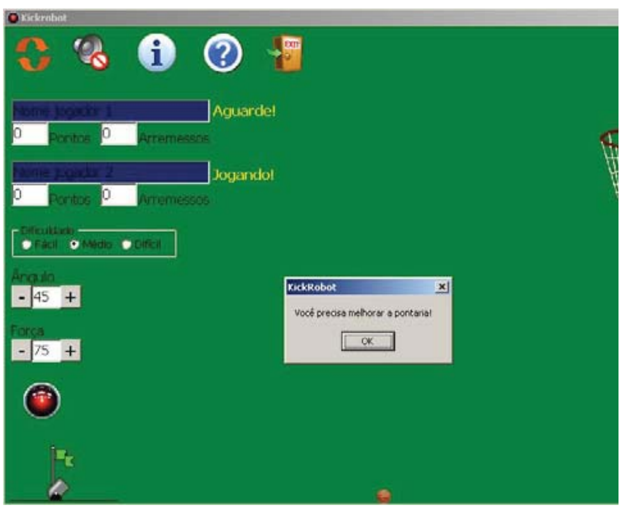

Figure 2. Cannon from the KickRobot application

The throws will be based on studies involving vectors, mechanics and trigonometry, and will be performed by the pedagogic robots in cannon format (Figure 3).

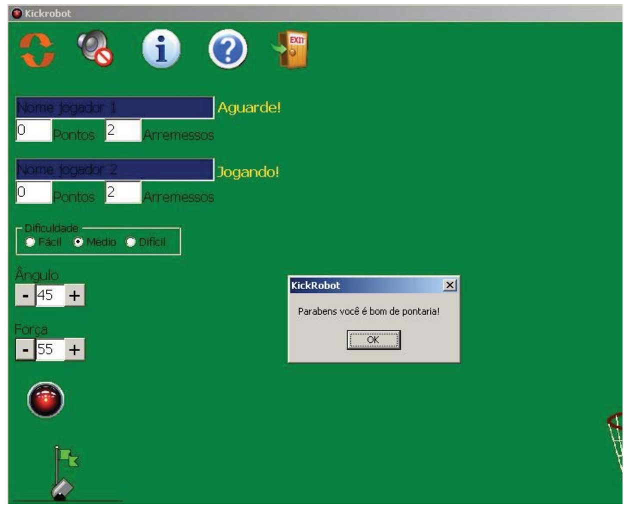

Figure 3. Hit of the "target"

So that it is possible to perform a precise throw, it is necessary to establish values based on the physical and mathematical experiment that used premises that involve concepts of projectile throws, vector analysis of movement, trajectory equations and parabolas (Figure 4 and 5).

Figure 4. Online Help

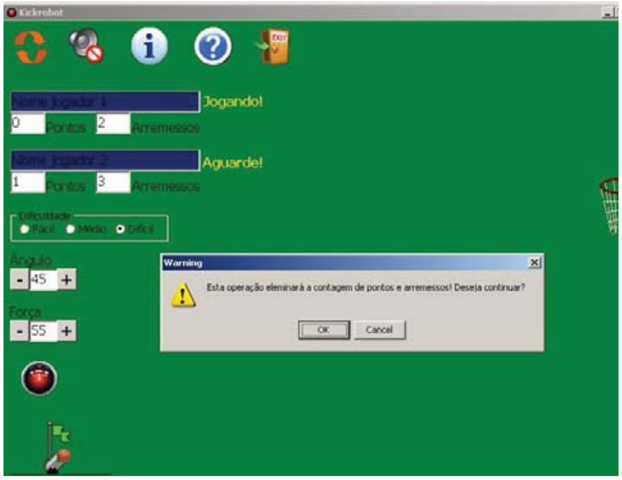

Figure 5. Finalization or Game Restart

VII. Physical-Mathematical Experiment

The principal of the involved study implemented refers to the theory of projectiles. At the implementation formulas applied on shooting allow us to observe the behavior of the projectiles on real experiments.

A projectile is an object that suffers an strength at a determined period of time, that we may call impulse. This impulse causes a variation of the target that we are willing to hit. One of the forces directly involved with the impulse is gravity.

At the experiment we will perform the throw to a target not on the same level; this way, settings will have to be applied. Principles that were developed originally out of Brazil, namely the measuring system that uses feet, instead of meters. Therefore, acceleration in the English system is $g=32.2$ ft/s², converting to the metric system we have $g=9,8$ m/s².

The movement performed by the ball is bi-dimensional and can be analyzed separately as two simple movements, one going horizontal (axis X) and other going vertical (axis Y).

From the movements, we have the formulas for the speed (Figure 6):

$$\vec{v} = \vec{v}_0 + \vec{a}t$$

E posição:

$$\vec{r} = \vec{r}_0 + \vec{v}_0 t + \frac{1}{2}\vec{a}t^2$$

Onde:

$\vec{v} = v_x\hat{i} + v_y\hat{j}$ velocidade;

$\vec{v}_0 = v_{0x}\hat{i} + v_{0y}\hat{j}$ velocidade inicial;

$\vec{r} = x\hat{i} + y\hat{j}$ posição;

$\vec{r}_0 = x_0\hat{i} + y_0\hat{j}$ posição inicial;

$\vec{a} = a_x\hat{i} + a_y\hat{j}$ aceleração.

Figure 6. Formulas used by the KickRobot software

Writing the bi-dimensional movement as two one-dimensional movements will give us, for the horizontal direction (X) and for the vertical direction (Y), the following equations for speed and angular position (Figure 7):

$$x = x_0 + v_{0x}t$$
$$y = y_0 + v_{0y}t - \frac{1}{2}gt^2$$

Figure 7. Formulas used on the axis X and Y by the KickRobot software

This way, the student must notice that there is a direct relation between the initial speed and the maximum distance that the ball can reach according to the amount of speed indicated, as we see in Figure 8.

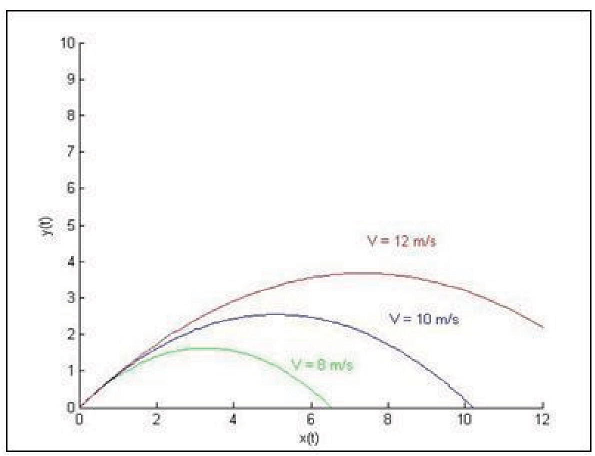

Figure 8. Trajectories with distinct speeds applied on KickRobot

Moreover, the student will notice a straight correspondence between the initial angle and the maximum distance that the ball might reach, related to the value of angle discovered during the experiment, as seen in Figure 9.

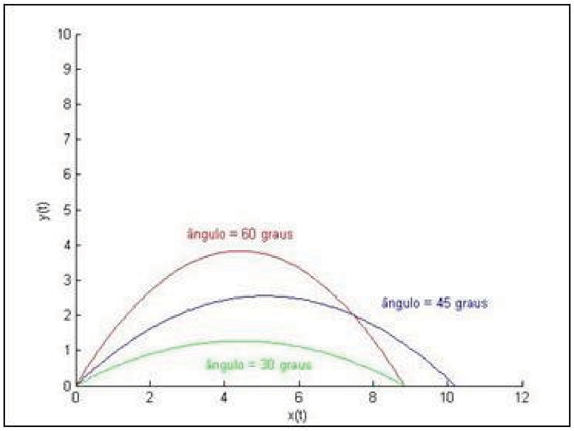

Figure 9. Trajectories with diferent angles applied in KickRobot

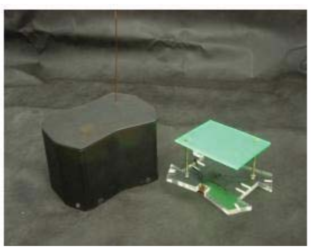
VIII. ROBOT SOCCER

The soccer competition among robots uses interconnected devices, working together, allowing the student-players to control their hardware tools. The used devices are: a camera, located on over the field, that captures image and sends it to the computer, where the computer will recognize the ball and all the robots, locating them within the field (Figure 10).



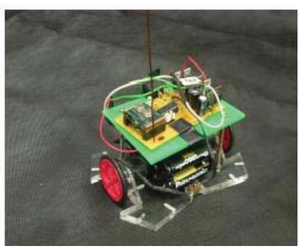


Figure 10. Robots used by the students to play soccer

An artificial inteligence algorithm receives this location and processes the game plan to be employed. After this, the movement coordinates are sent to the robot via radio frequency (RF). Following that, the robots interpret and execute the orders. This way, so that the system is really efficient, advanced techniques on computing, electronics and robotics are used (Figure 11).

Figure 11. Equipments used on the soccer match, with interaction with the students

IX. CONCLUSION

Through this article, the aim is to present a vision, both, macro and general of the pilot project named RoboEdu and the use of the KickRobot software on the aspects of digital divide and improvement of the knowledge acquired in the classroom. This is one of the first initiatives to spread the technology as a whole throughout the public network, but, mostly, under the scope of computers science on education supported by experiments with robotics.

Two public schools received the initiative, with a total of 50 students selected to take part on the experiments. Initial questionnaires were applied to outline the style of learning of the participants and knowledge about the technologies. The same questionnaires were applied at the end of the project.

After a relative evaluation on the gain of knowledge on technologies by the students, comparing the questionnaires, it's possible to conclude that the objectives were reached, on the aspects of technology, constructivism, and of social and digital inclusion. Around 25% of the students that started this project, identified by the questionnaires as shy students went on to take active part in the group of students that worked effectively and integrated within the teams.

Regarding the teachers involved, they obtained the same stimuli to develop the studies in the classroom, given the tasks defined focusing on the practice overlooking the experiments, that being said, we can say that the initiative contemplated not only students, but also teachers, that, during informal conversations, said that the activities had given them a new found interest for research and compilation of extra-curricular content, that were not a part of the daily activities.

This initiative doesn't end, it's funded continuously, aiming at covering as much students as possible with the experiments in question.

Abstract— **The present work focuses on the didactic approach for the HE in technical-scientific domains, namely Control Systems undergraduate courses, via blended e-learning. Material knowledge has to be learnt. So, tools to be integrated in Moodle to manage related didactic variables have been developed, such as an Immersive Telelaboratory. In such a context a team approach to teaching was adopted. It seems useful to summarize such experience putting into evidence its potential and some critical aspects related to the implementation of the approach.**

Team Teaching, Material Knowledge, Immersive Telelaboratory, e-Learning

I. Introduction

Engineering designer education involves training students to master complex physical phenomena, to acquire competence in the analysis of complex systems in several application domains and to become able to develop proper design processes. The focus should be on acquiring the competencies and abilities of an expert designer. One among them is "Material Knowledge" (MK).

According to [1] Material Knowledge is the Knowledge relative to the real operation conditions of engineering complex systems. Mains features of MK are: its owners are experts; it is compiled and implicit, and can be described as intuitive; it is empirical, i.e. the novice has to learn more "how to do" than "what it is". To try to teach MK asks for active, experiential and collaborative learning in a supervised way.

For such purpose laboratory activities are practiced Face to Face (F2F), with a limited number of students. In traditional laboratories (as part of institutional courses at the University) students have the possibility to practice real or realistic experiences under teachers' and tutors' guide. In this way they can match the theoretical aspects learnt during the lectures and practical experiences.

To build, to maintain, and to use such labs is difficult, sometimes even impossible for organization problems, and it is always expensive. A didactic laboratory is a costly installation exposed to a concentrated use at certain times of the year. The need arises of guaranteeing the access to existing labs for a wide student's population, surely wider than the users present on each laboratory site. This need is apparent both at a local level – more students belonging to the same University - and, in principle, at a University system level - students belonging to different Universities could use laboratory settings not available at their own University on a reciprocity base [2].

For these reasons, having many students that could profit of it at our University, an Immersive Telelaboratory (IT) accessible by the net is used.

Immersivity is specified as follows: remote users experience the operation within the real environment – a laboratory – by means of a rich perceptive Internet-based bi-directional interaction comprehending vision, hearing, and perception of current modification of physical quantities [3]. No haptic interfaces are required.

Compared to an experience of Virtual Reality (VR) [3], Immersive Telelaboratory allows being in touch with MK. In general terms VR is a technology that allows a user to interact with a computer-synthesized environment, be it a representation of the real or of an imaginary world, and in every case it is based on a model. It is exactly for this latter character that these solutions don't provide the richness of experiential elements implicit in a real laboratory practice, related to the acquisition of MK. The immersive experience of the laboratory, even if based on a didactic approach with some simplifications, involves the elimination of the significant simplifications intrinsic to the VR model.

The laboratory experience is scaffolded in a context of training and gradual activities (Tutorial, process analysis, clarification of the issue of control), comprehending documentation and reflection on the experience performed.

To try to verify in an empirical study the previous statements, an undergraduate Control Systems course has been given following a Team Teaching approach (TTa). According to [4] usually TTa involves a team of teachers, each devoted to different tasks, in synchronous/asynchronous blended learning. In our case it has been used in a F2F/online blended modality. The focus is on pooling different competences more than on reducing the cognitive workload of the teachers. This second objective appears to be prevailing in asynchronous/ synchronous blended learning.

II. Eucational Design of the Course

We refer to an undergraduate course of Automatic Control, compulsory for an Information Engineering curriculum, having many students (around 300), delivered in blended e-Learning.

/

Blended means a suitable mix of F2F lectures/numerical case-study presentation and on-line activities both tutored and untutored.

A. The Syllabus

In order to promote an active and collaborative learning an online course was devised. The course design required the definition of a detailed Syllabus. Main components of the Syllabus are:

Aim: the course will provide students with fundamentals of the theory and techniques of analysis and design of linear time invariant control systems single input single output. The control is usually feedback control.

Theory and techniques deal with a particularization of the Theory of Linear Dynamical Systems. In comparison with the international approaches to engineers training this course corresponds to courses named Linear Control Systems or Feedback Control of Dynamical Systems.

Learning Objectives: at the end of the course the student is expected to be able to explain to others the declarative knowledge learned in a clearly and compelling way and to apply operational skills in a competent way.

Course Description: the learning materials are learning objects (LO), which are collected in self-contained learning units (LU). A LU covers a topic autonomous from the didactic point of view, even if logically related to several others. In order to enable learning, the course also suggests many activities to be conducted alone or in small groups. All activities are always meant to take advantage from the discussion Forum where students, teachers and tutors are in touch.

Learning Objects (LOs): three kinds of LOs were developed.

1 Learning Objects related to declarative knowledge.

Declarative knowledge of the course is composed by definitions, conditions and theorems. These elements are available as downloadable documents that can be printed and studied offline. These documents are presented by synthetic introductory web pages.

2 Learning Objects that provide operational abilities. Learning operational skills is based on a number of examples and exercises, some of which are completely carried out and/or solved and others have to be played by the student. For this purpose, an Open-Source package SW – SCILAB™ - is made available and downloadable [5]. This package allows performing the calculations necessary to deal with a realistic example without facing with paper and pencil large sized computational problems, which would require a high amount of time and would be easily exposed to the risk of calculation errors.

The discussion of examples of this type is always preceded by exercises of limited computational complexity, which can be tackled with pencil and paper. Each student is asked to solve them and to post the solution on the forum. The review of these exercises is done by an online tutor. The tutor timely sends comments to help students to understand the reason for errors.

Each student is asked to address the more complex examples only if he/she has solved the simplest exercises correctly and safely.

3 Learning Objects for self evaluation test: aimed at verifying what students learned declarative knowledge and operational abilities.

Learning Objects of this type are inserted into each LU. They are composed of exercises, examples and a section of self-assessment test with score. The score is simply a tool for self assessment of student learning. It provides a measure of appropriateness of learning that the student has attained up to that point. It gives the tutors the possibility to monitor the evolution of learning in the class.

Course Outline: the course contents are organized in 8 LUs.

LU 1: Introduction to the control issues;

LU 2: Mathematical Models in an Information Rich world (state space models);

LU 3: Analysis of oriented abstract systems, differential linear time invariant, finite-order, lumped parameters, real constant coefficients;

LU 4: Introduction to feedback control systems;

LU 5: Poor information models Analysis (Input-output models);

LU 6: Solution to the control problem with poor models 1 (Industrial Regulator tuning);

LU 7: Solution to the control problem with poor models 2 - Servo-systems design in the frequency domain;

LU 8: Solution to the problem of control with poor models 3 - Servo system design with root locus method.

Learning Activities: the course offers different learning activities. These are delivered in asynchronous and synchronous way and refer to different pedagogic models. Most of the online activities are asynchronous and are based on students' self-learning and self-evaluation. The LUs from 3 to 8 comprehend the suggestion and the availability of Immersive Telelaboratory activities. These can be considered in some way synchronous activities for the apparent real-time interaction with the experiments to be performed. The laboratory experiences are meant to involve the students in collaborative, experiential and reflective activities, supported and enabled by a proper didactic context and suitable tutoring.

Didactic context is constituted by:

- tutorials describing the physical process under study, the assumptions made to define the related mathematical model, the difficulties for building up such a model, the real world aspects cut away to obtain a viable model, the characters of the physical devices involved in the experiment;
- summaries of the control theory relevant for the problem under study;
- a simple VR environment where the students can observe the representation of real experiments performed on the given physical process. It is a VR environment where the avatar of the physical process is driven by data and signals collected on the physical process itself;

- a GUI, where the student can specify the experiment he/she will perform and its main parameters;
- tools for the interaction with the Laboratory administrator and with the colleagues belonging to the group involved in a given experiment;
- a simplified e-portfolio space where results deemed significant (both satisfactory and unsatisfactory) can be stored by the students together with their reflections on the experiment performed.

It is self evident that these activities involve a certain level of organization complexity in case of large classes following compulsory courses. Complexity refers in particular to time management and to the proper level of cognitive load required to students. Time management will be discussed in the context of the architecture of the Immersive Telelaboratory.

As far as the cognitive load is concerned, recent theories take into account learning design implications of the human cognitive architecture. It is well recognized that the subjective measure of the cognitive load is related to the student' cognitive resources directed towards achieving certain learning objectives [6], [7]. The IT in the context of a compulsory course for undergraduate students is aimed at the attainment of a medium-high level of competence. This one cannot be considered the learning objective of all the students, neither of a majority of them that could be interested only in obtaining the credits associated to the course. For these students the cognitive load related to IT will appear too large and therefore it could be an element hindering the attainment of a reasonable mastery of the operation solution of the problem. This level of mastery is somehow higher with respect to the learning objectives of the whole course. Therefore such an activity is offered to the interested students to be freely undertaken, while the other on-line activities are considered essential part of the learning process.

For the interested students the constitution of small groups is suggested. Three to five people constitute the group. Schedule of the activities is usually arranged on a weekly base. The roles and tasks within the Group are the following:

- *Coordinator*: early in the week he/she sends the first message to the group in the forum with details of roles, general organization and agenda of the week; he/she cares the management of eventual meetings in presence, and the management of potential conflicts. He/she acts also as moderator, animates the communication in the forum with the support of the tutor, organizes and creates new categories for better organization of the Forum.
- *Editor*: publishes within 24 hours to the deadline, the diary of the week (five lines about what really happened in the group during the week); he/she is in charge of editing the final presentation of the group work.
- *Researcher(s):* each week he/she finds and provides to the group at least two significant references (websites or papers).
- *Devil's advocate:* he/she is a critical observer. The duty is to weekly express criticisms and suggestions on the product developed.

The group autonomously decides the roles. The groups have to interact with a teacher competent in the laboratory practice and capable to enable their activity (Laboratory Administrator).

Evaluation: the summative evaluation is carried out by a F2F exam where the students have to answer three questions. One of them is specifically relative to operational abilities and has to be answered in writing. The participation on Telelaboratory activities is not a matter of the summative evaluation. If satisfactorily undertaken it provides a bonus that will be added to the exam score.

Pedagogical models: F2F lessons and information materials follow a substantially directive approach. In synthesis the teacher supervises and directs F2F activity. Lectures and exercises are accompanied by self-assessment tools designed to assist students in the understanding and acquisition of the theory and of operational skills. In this case a constructivist approach is explicitly followed [8].

The Telelaboratory activity follows a constructionist approach. It is an experience built in relation to a problem well defined in a theoretical way that puts the student in touch with aspects of the problem not explored during lectures and numerical exercises. These aspects deal with the real operation conditions of an engineering system asking for proper control to attain a performance aligned to given requirements (MK).

As already mentioned the laboratory experiences are meant to involve the students in collaborative, experiential and reflective activities, supported and enabled by a proper didactic context and suitable tutoring.

B. Team Teaching Approach and Teacher Roles

Different kinds of knowledge and different pedagogical approaches are tackled in the delivery of the course. Therefore it could be self evident that different teachers with specific competences should be involved to attain the required learning/teaching efficacy. At a first glance a three teachers model would be appropriate. According to this model the roles of the teachers would be complementary: the coordination and the most directive activities are in charge of the responsible of the whole course, the F2F activities promoting active participation of the students (numerical case studies) are in charge of another domain expert, the on-line management and support for Immersive Telelaboratory are in charge of a laboratory technology and operation expert.

The asynchronous online discussion is promoted by the use of some Forum. Two kinds of Forum are available:

- a General Forum for the interaction with the first two teachers of the course; Questions and Answers relative to theory and numerical case studies are meant to be posted in this Forum. A fixed time limit for answering is guaranteed by the relevant teachers;

- a Collaboration Forum with discussion spaces for small groups of students (3 or 4 people), is foreseen. It is moderated by the third teacher (the one dealing with MK involved in IT activities).

According to a constructionist approach the aim of this interaction is knowledge sharing among the students and with the expert. For this purpose mentoring is a critical point. Mentoring has to be the duty of the expert of the relevant MK. In fact the success in learning MK is heavily related to the availability of an expert showing it in a perceivable manner. However the contribution of the other two teachers is deemed necessary. These are domain experts, namely Control Systems analysis and design theories and techniques experts, the third one has to be expert of physical process and physical implementation of control devices and apparatuses. This latter has to provide arguments for the reflection, the other two have to assist in the development of the reflections, by giving suggestions and asking questions that help the students to integrate in their cognitive models theory, operation and MK. The aim is to reflect together in a specific tutored forum and to produce an essay collecting the student's reflections on the experiments.

It is evident that such an approach is useful and significant not only to improve students' learning, but also to enrich the teachers competencies, in particular in case of young teachers with experiences limited to specific sectors of a very broad domain like Control Systems.

III. THE ARCHITECTURE OF THE IMMERSIVE TELELABORATORY

To overcome the organization, structure and cost involved in providing laboratory facilities for a potentially large number of students, an IT has been implemented and integrated within the University Moodle Learning Environment.

The architecture of the whole LE is illustrated in figure 1.

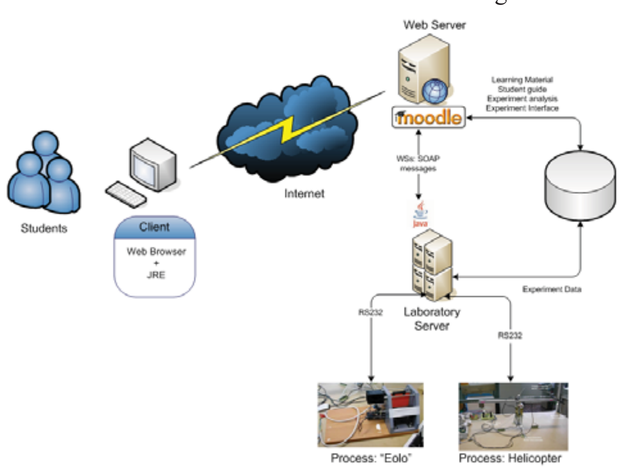

Figure 1: The architecture of the Immersive Telelaboratory

A module named MoodleLab has been developed and installed in Moodle.

With this new module, the integration of different functions in one collaborative Virtual Learning Environment (VLE) has been made possible: the learning materials, the tutorial for the conduction of the experiments, a reservation system, tools for remotely running experiments, tools for the analysis of experiment's data and some collaborative tools such as forum and chat is the whole set of tools made available. They allow the friendly implementation of the three main categories of Didactic Variables [9] relevant for an institutional course in technical scientific domains: What to learn, How to learn, and the time schedule of the learning process.

Main characters of the implemented module are:

1) The authentication of enrolled students follows standard procedures already present in Moodle. As far as the Roles considered in Moodle are concerned, the role of "Lab Manager" has to be defined for management of the experiment. To manage the experiments running it has been necessary to add to the MOODLE DB some important tables, including those relating to the accreditation of test and data collection.

2) The students access the Telelaboratory through a specific booking system. The student must choose the time period and the type of experiment among those offered during the course. The booking management is made through the LCMS MOODLE by the integration of the MOODLELAB module with the BOOKING module. This is a key issue with respect to student's time management.

3) During the booked period, the students connect to the chosen activity of Telelaboratory. The Laboratory Manager authorizes the execution of the experiment. Once enabled, the student invokes a Web Service through a specific Java applet for the experiment previously chosen. The application that manages the experiment will interface directly with the LCMS.

4) The student enters the data, starts the experiment, can display the output data through continuous or segmented charts, and can view the process by a WebCam that allow the real time vision of the physical devices.

5) After each session, the data relative to input, output and selected parameters are recorded, if confirmed by the user, in the DB "MoodleData" connected to the LCMS Moodle.

The students can perform different experiments on different physical processes: helicopter, fan-plate and robot mobile.

Figure 2: The processes of the Immersive Telelaboratory

The process called “helicopter” is a system with two degrees of freedom – pitch and rotate -, simulating the operation of a helicopter. The regulation of the process attitude has to be attained in presence of disturbances. The second process, called “Fan-Plate or EOLO” is a system with one degree of freedom. The attitude of a plate exposed to an air stream produced by rotating wings has to be controlled. There is a third process, constituted by an autonomous vehicle that has to be driven in a partially structured environment. It is not offered to the students of the Course here considered, because of the involvement of further methodological issues.

For each process, different experiments can be executed, ranging from the elicitation of the process output in response to standard inputs (open loop experiments) to the tuning of regulator parameters in various operation conditions (closed loop experiments).

The general rules, established in the official documentation of Moodle [10] have been followed for the development of the code. In the same module the database that interfaces with Moodle and with data coming from the laboratory was developed in XML [11], according to the indications given by the Moodle documentation.

It appears that in the learning environment, built up in this way, the Moodle platform plays the role of the Web Service client; the Web service at the server side is implemented by Java applets that interface with the microcontroller driving the motors propelling the devices.

The client has been implemented via a suitable Php function.

The server-side application has been implemented in Java language. It allows at one side the communication to and from the microcontroller, and at the other it manages trough a Web Service the data coming from the client for the activation of the applet.

The application has been implemented on a Linux server with Fedora distribution, with the Apache Web server, for the interpretation of PHP, Tomcat, to run the WSS, and the MySQL DBMS for managing data have been installed.

One important feature of the IT integrated in Moodle is the Portfolio of the experiments, in which each student group can save the work performed, can retrieve the input values, view charts, reproduce the behaviour of the process in a virtual environment fed by the real data.

A. Reflexes on Team Teaching

As mentioned in the previous section, course and courseware design, implementation and delivery followed a three-teacher model [13]. The responsible of the whole course has the coordination and most directive activities, numerical case studies are in charge of another domain expert, a technology expert gives on-line support for MK management. Given the relative complexity of the IT architecture and of the whole Learning environment, it is apparent the need of a fourth teacher managing the LE use and IT access administration.

It appears that a four teacher team would be ideal for the described experience. In particular the MK owner seems essential for the IT proper exploitation in order to provide the students with design competences.

The smooth operation of such a team can be a critical argument, due to the different and possibly conflicting commitments that the teachers can have in their professional activities. In fact, when teachers are expected to work together in one class criticalities related to practical or interpersonal issues, rather than to clashes in ideology or personality, can arise and serious difficulties can be encountered [14].

IV. STRENGHTS AND WEAKNESSES OF THE EXPERIENCE

The experience conducted has so far shown some strength mainly related to the improvement of teaching/learning effectiveness and to the openness to innovative teaching strategies. Notice that the experience has been performed in a not completely systematic way, so that the positive attained results about the quality of learning cannot be considered sufficient for an empirical study. A structured empirical study is planned for the coming Academic year. It will involve a structured monitoring activity relative to both the smooth delivery of the course and the student’s and teachers satisfaction appraisal.

The main points we already experienced and we would put into evidence are:

- Instructional design becomes a critical issue, especially as it applies to the development of instruction for novices. In fact, within the presented learning scenario students can be considered to be novice designers who do not yet possess the underlying mental models [15]. In this case, a teaching approach which moves from a more directive approach towards facilitating and mentoring seems to provide effective results.
- With respect to the IT, maintenance and supervision of the physical devices into the lab and level of students’

awareness of the MK involved in its proper use are also critical issues. The extension of the Team Teaching model to the four teacher's team could have important effects on the teacher's time management problem and on the effective coordination of the work. When it finds a satisfactory solution the quality of learning is significantly improved. Moreover it appears that the use of synchronous online tutor-students interaction could greatly improve student awareness of MK.

- Team teaching could be an essential experience both for teachers and for students. From the teacher's point of view, it is important a clear definition of activities and then the choice of the proper pedagogical model. A clear definition of an (inter)relations' model among actors is also needed to support teachers' coordination and leadership management. At this step, to analyse teachers' profiles and to clearly define roles is a fundamental task.

The modalities with which this interaction can be improved can be further investigated, as well as the students' reactions to the proposed team teaching model, in order to be able to facilitate learning and to improve interaction with the different teachers in future. In particular, it would be interesting to investigate in deep the students' reaction to the presence of different teachers, how the different roles are perceived and if they are perceived and, finally, how they can be better perceived by the learning group in a team teaching context. In fact, some students may feel frustration and discontent about having more than one teacher.

Nonetheless, team teaching seems to represent a great opportunity for the personal and the professional development of teachers, who are required to make a step forward and to develop new competences and new work practices, requiring cooperation and interaction with other colleagues. Collaboration is a process that happens if particular instrumental abilities subsist, not only related to the domain of expertise. Behavioural aspects of collaboration and communication are also important.

Team teaching requires the most mutual trust and respect between teachers and requires that they are able to mesh their teaching styles [16]. The creation of a community of practice [17] [18] to support teachers within the educational institution may help. It could happen in either informal or formal manner, but the support of the management is crucial.

Abstract— **There are many e-learning web sites and e-learning systems that are available with excellent content and design but they generally lack interactive response and face-to-face communication. Students cannot ask questions and get responses immediately. It is similar to one way communication for learning. However, learning is most effective when it actively constructs knowledge during group social interaction and collaboration. Therefore, this paper proposes to inspire creativity in e-learning called the virtual interactive classroom by using RTMP (Real-Time Messaging Protocol) which is a sophisticated TCP-based real-time networking protocol which supports the efficient exchange of messages, synchronized data, audio, and video. Teachers and students can publish streaming audio, video and other data messages to present streaming media with interaction or navigation. Using this virtual classroom on the internet, students can immediately interact with teachers as though they were studying in a real classroom. In addition to the virtual interactive classroom, this article also proposes using web-based collaborative work as an add-on feature to the learning system. Both teacher and student can use web-based collaborative work for sharing resources and exchanging ideas after the class. The integration of the two concepts of the virtual interactive classroom and web-based collaborative work in order to enhance teaching and learning performance has been created.**

Keywords- learning system; virtual interactive classroom; web-based collaborative work, Wikis

I. INTRODUCTION

Advances in technologies such as streaming video, virtual learning environments and teleported experiments are entering the Web-based learning arena [19]. Along with the development of a second-generation online education infrastructure, it will be necessary to consider changing the interface of web-based education such as reinventing pedagogy for the new interface, including multimedia and hypermedia enhancements as well as creating the educational standards necessary for generalized deployment. Instructional learning goals should drive media selection, applications, and the course development process. Characteristics of the distance learner and the impact of technology are also important considerations in instructional media selection and course development. The new streaming technologies have made it easier than ever for people to receive a quality education by bringing the classroom to the student. Imagine, a teacher at one university campus delivering a lecture while students in a classroom two cities away watch the same lecture in real time. In a residence hall not far away, a student recovering from an operation watches a lecture recorded from an earlier class he or she had missed that is delivered on-demand in the comfort of his or her own room. In a city 5,000 kilometers away, a student is using the on-demand lectures to take part in the same course delivered completely online [6]. With the advent of streaming technology and the possibilities it creates, scenarios like these have been repeated all over the world.

In addition to the virtual interactive classroom, this article also proposes web-based collaborative work as an add-on feature to the learning system. Teachers can assign a task or a group task as homework to the students after studying using a real-time internet classroom. They can also manage group work using the various tools provided in an application. They can use the system to monitor and evaluate the student's behavior during collaborative work. Students can collaborate or help each other and generate additional ideas to solve a given task. Using the two important features – the virtual interactive classroom and web-based collaborative work- in a learning system, both teachers and students can greatly benefit from distance learning. These features will enhance the performance of teaching and learning for distance learning. The key goals for this research were the development of: (a) a lightweight virtual interactive classroom, and (b) a web-based collaborative application.

This article is organized as follows: Section II addresses about the related work. Section III addresses a design framework for web application. Section IV describes about supporting technologies in more detail. Section V describes the implementation. Section VI presents conclusion and gives some perspectives and ideas for future work.

II. RELATED WORK

Traditional study using a blackboard provides a rich interaction between lecturer and learner that cannot easily be replaced with a PowerPoint slideshows. Satoshi Ichimura et al present a ChalkTalk system [20]. It is a system that automatically produces e-learning materials from a videotaped chalk talk lecture in front of an ordinary blackboard or whiteboard. But this approach lacks interaction activity. The Learning Activity Management System (LAMS) [12] provides more student interaction such as question and answer (with student answers shared with the group), asynchronous discussion forum, and synchronous chat. Based on the pilot evaluation of LAMS, only 15% of students were willing to discuss ideas in front of their peers in the classroom, but over 80% of the same students were willing to discuss their ideas within LAMS. E-learning provides for self-managed learning such that the learner can study when they want, but some people still like traditional teaching, where the lecture times are fixed [18]. Tungkasthan, et al presents an implementation of an interactive virtual classroom on Internet [23]. They implement several methods for the efficient exchange of messages, synchronized data, audio, and video by using a real-time messaging protocol. Their application allows multiple connected users to share data and user interfaces in real time. Currently, there are many collaboration and communication programs on the market such as NetMeeting, CollabWorx Virtual Classroom, Breeze, MSN, or Skype. Some programs are free and some are not. Each program has pros and cons. Let's us consider the features offered in each program.

NetMeeting [16] is a synchronous online collaboration and communication program. This means that NetMeeting collaboration with others happens in "real time." NetMeeting allows users to implement online meetings, hold online classes, and conference with individuals no matter how distant they may be. Some of the NetMeeting features also allow for efficient communication with people with certain disabilities such as hearing or mobility impairments. NetMeeting is an application sharing, which is suitable for online meeting or video/audio conference. The program still lacks some essential features for online virtual classroom such as classroom control, presentation control, and content review.

CollabWorx Virtual Classroom [5] is a complete software solution enabling interactive, real-time delivery of corporate training or academic classes over the network. The process involves an instructor and support personnel at one geographical location and a group of students at remote locations. Both parties (instructor(s) and students) use desktop computers as the only communication device. The notion of "remote" encompasses distances from "across the hallway" to "across the continent." This program contains full functionalities for online classroom but it still lacks of some interactive response portions for the students.

Skype [21] is a peer-to-peer Internet telephony network. Skype has experienced rapid growth in both popular usage and software development since launch, both of its free and its paid services. The Skype communications system is notable for its broad range of features, including free voice and video conferencing, its ability to use peer to peer (decentralized) technology to overcome common firewall and NAT (Network address translation) problems, and its extreme countermeasures against reverse engineering of the software or protocol. This program is not appropriate to apply with virtual classroom because of lacking tools for class management and learner collaboration functions.

Macromedia Breeze [2] is software used with Microsoft PowerPoint to create information and general presentations, online training materials, web conferencing, and learning modules. Macromedia Breeze includes four applications: Breeze Presenter, Breeze Training, Breeze Meeting, Breeze Events. This program is generally designed for conducting a meeting purpose not a virtual classroom but it can creatively apply to virtual classroom as well.

Sakai [24] is an enterprise application that supports teaching, learning and scholarly collaboration in either fully or partially online environments. It provided powerful functions with a suite of capabilities for faculty, students and staffs. Some of the many available tools in Sakai include general collaboration tools, teaching and learning tools, portfolio tools, and administrative tools. Moodle [25] is similar to Sakai. Moodle is an open source course management system (CMS). It is very popular among educators around the world as a tool for creating online dynamic web sites for the learners. Moodle has several features such as module, quiz module, forum module, and resource module that allow it to scale to very large deployments and hundreds of thousands of learners. However, such main features available with Moodle are essentially provided and supported for individual interactive learning. Although, there are the rich array of tools and features that are available with the Sakai and Moodle but such tools are mainly used for non-interactive mode.

Another technology enhanced learning approach proven to enhance especially informal learning is the application of Wikis as collaborative online tools [10]. Wikis are a technology developed by Leuf and Cunningham in 1995 [15]. They are designed to provide a simple tool for knowledge management, with users being able to collaboratively create and edit pages. Another of the central aspects of a Wiki is the revision history tracing every modification to a specific user. Recently, tools like wikis are being used to support collaborative aspects in e-learning [8]. With the power of Web2.0 technologies, wikis seem to be an appropriate tool for exchange between high numbers of learners. Lot of different research work carried out that wikis can successfully be applied in education [3], [7]. Wikis in general highly support the characteristics communication, collaboration and contribution to a pool of knowledge. Depending on the degree of freedom as well as the possibilities of active contributions within a learning community successful learning occurs [4], [17]. Furthermore, there is an impact for graduates on cooperative developing new knowledge as solving problems [13].

III. A Design Framework for Web Application

A. A Framework and its Functions

There are two main components in the proposed design framework for the web application. First, it is a virtual interactive classroom. There are some requirements that should be taken into consideration such as: 1) shared object component, and 2) VDO streaming component. In the first component, there are many objects such as a white board, presentation, chat, AV presence and list of people in the interactive classroom on the internet. These can be shared with other students. Remote shared objects are managed by a streaming server. Clients can access shared objects and get updates whenever a change is made to a shared object. The VDO streaming component is also provided by the streaming server. Second, it is a web-based collaborative work component. It consists of a workspace, chat room, comment tool, and e-mail. The framework and its details are shown in Fig 1.

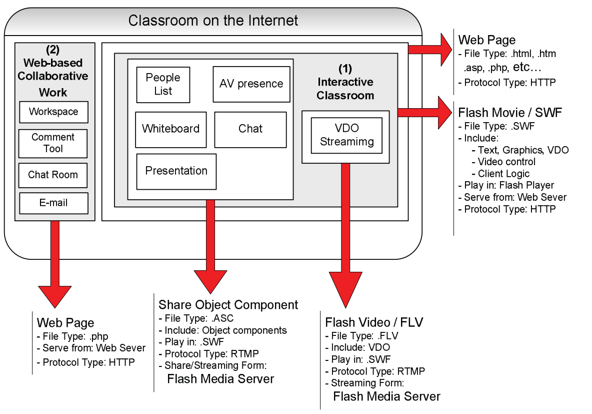

Figure 1. Top level design and classification function of virtual internet classroom.

B. *Client/Server Sequential Process for Virtual Interactive Classroom*

There are four steps in the sequential process utilized to obtain streaming objects. First, a client requests the HTML and SWF files by using HTTP on a TCP connection. Second, the web server sends HTML with embedded links and SWF files back to the client according to their request. Third, the client sends a message to a flash media server by using the RTMP protocol. Fourth, shared FLV files and streaming media are sent back to the client. The general connecting and displaying of shared files as well as streaming media are shown in Fig. 2.

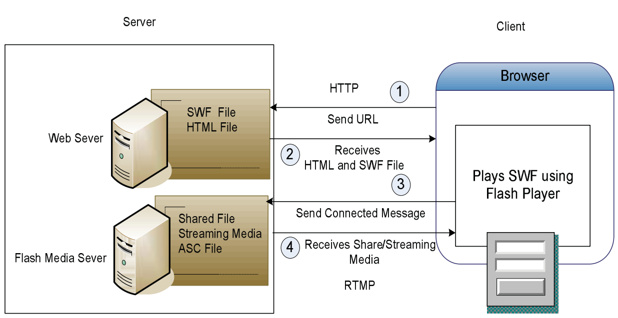

Figure 2. Procedural sequence steps in general connecting and displaying share and streaming media.

C. *Collaborative Functions for Lecturer and Learner in a Virtual Interactive Classroom*

1) Login function: When a student or teacher wants to enter the classroom, they must login with the correct username and password. In the classroom, they are allowed to use shared objects or resources.
