Educational Computer Simulations for Visualizing and Understanding the Interaction of Electromagnetic Waves with Metamaterials.

Ana Grande, Oscar González, José A. Pereda and Ángel Vegas
Dpto. Ingeniería de Comunicaciones
Universidad de Cantabria,
Santander, Spain

Abstract— **In contrast to ordinary materials, metamaterials show interesting properties that are not found in nature. These properties are counterintuitive and difficult to understand for the students. This work describes a series of virtual experiments that were carried out by means of an extension of the FDTD technique for modeling metamaterials. The result of the simulations was recorded and a collection of videos developed as a supplementary tool for teaching at advanced undergraduate and graduate levels. The objective is to help the student to understand the interaction of electromagnetic waves with these media by means of the visualization of the evolution in time of the physical phenomena.**

Keywords-component; educational software, visualization, metamaterials

I. INTRODUCTION

Over the last decade a great deal of attention has been paid to a new kind of media named "metamaterials". Metamaterials are artificially structured composite media with a unique electromagnetic response not present in naturally occurring materials [1].

The nonconventional properties of metamaterials were theoretically investigated by Veselago in 1968 [2], and stem from the fact that these media present simultaneously negative permittivity ε and permeability μ. However, it was in 1998 when the first possible realization of a metamaterial was achieved by the appropriate combination of metallic wires and split-ring resonators [3]–[4].

Since this first synthesis there has been an increasing interest on these media and nowadays, metamaterials are a relevant hot topic in science and technology becoming one of the fastest moving research fronts according to the Web of Science [5]. The keen interest on this kind of media is due to their exotic electrodynamic properties, such as the negative refractive index ($n < 0$), backward-wave propagation, negative Goos-Hänchen shift, reversal Doppler effect, inverse Cerenkov radiation,... and also for their important potential applications in the development of novel devices [6], perfect lenses [7], invisibility [8], [9], etc.

In general, students have difficulty in perceiving the behavior of electromagnetic waves. The situation is worsened when metamaterials are involved, since they exhibit an electromagnetic response not found in natural media that seems counterintuitive to the students.

Electromagnetic simulators have proven to be useful teaching/learning tools to provide physical insight into the phenomena under study. This goal is more easily achieved by time-domain simulators, since they emulate the progression of the fields as they actually evolve in space and time [10]-[12].

The finite-difference time-domain (FDTD) is an accurate numerical technique for solving Maxwell's equations. The conventional FDTD scheme has been successfully extended to incorporate the modeling of a broad range of electromagnetic simulation problems, what has made the FDTD method one of the most powerful and flexible numerical techniques that enables the solution of problems in the time domain [13].

In this work an extension of the FDTD technique for modeling metamaterials [14]-[15] has been used to carry out a series of virtual experiments. These experiments have been carefully chosen to illustrate the characteristic behavior of electromagnetic waves in these media. The result of the simulations has been recorded and a collection of videos has been created. The videos are intended for advanced undergraduate and graduate students and their objective is to promote understanding by means of the visualization of the evolution in time of the fields in metamaterials.

II. FDTD MODELING OF METAMATERIALS

When simulating the propagation of electromagnetic waves the starting point are Maxwell's curl equations. For two dimensional problems and for the TE_z polarization case, these equations can be written in the Laplace domain as

$$\begin{aligned} sD_x &= \frac{\partial H_z}{\partial y}, \\ sD_y &= -\frac{\partial H_z}{\partial y}, \\ sB_z &= \frac{\partial E_x}{\partial y} - \frac{\partial E_y}{\partial x}. \end{aligned} \tag{1}$$

In the Laplace domain, the constitutive relationships that characterize the metamaterials are given by:

This work was supported by the Spanish Ministerio de Educación y Ciencia under Projects TEC2006-13268-C03-03/TCM and CONSOLIDER CSD2008-

$$\vec{D}(s) = \varepsilon(s)\vec{E}(s),$$
$$\vec{B}(s) = \mu(s)\vec{H}(s), \quad (2)$$

where ε is the electric permittivity and μ the magnetic permeability of the medium.

Any physical realization of a metamaterial is dispersive, i.e., its effective constitutive parameters depend on the frequency. In those frequency regions where the permittivity and permeability present simultaneously negative values the medium will have a negative refractive index and will exhibit the interesting physical properties of metamaterials.

In the classical FDTD approach [13] the space and time derivatives in Maxwell's curl equations are approximated by means of second-order central differences and the computational space is divided into cells where the electric and magnetic field components are alternately distributed. This leads to a system of explicit finite-difference equations that allows us to iteratively compute the electric and the magnetic fields. The resulting algorithm is a marching-in-time procedure that simulates the actual electromagnetic waves in a finite spatial region.

The original FDTD scheme has been successfully extended to the modeling of different kinds of materials. In [14] an approach to incorporate metamaterials was presented.

In this work that extension of the FDTD technique has been used to visualize the most typical phenomena of wave propagation in these media. In particular we have considered two dimensional problems for the TE_z polarization case. The computational domain was surrounded by PMLs absorbing boundary conditions.

In our simulations, for the sake of simplicity, and in order to have a wide double negative frequency band, we have assumed that the permittivity and the permeability follow identical Drude dispersion models, which in the Laplace domain can be expressed as:

$$\varepsilon_r(s) = \mu_r(s) = 1 + \frac{\omega_p^2}{s^2 + s\omega_c} \quad (3)$$

where ω_p and ω_c are the plasma and the collision frequencies respectively. According to (3), in the lossless case ($\omega_c = 0$), for frequencies $\omega < \omega_p$ both constitutive parameters will be negative and the medium will present interesting electromagnetic properties.

III. Visualizing and Understanding Physical Phenomena in Metamaterials

A. *Negative refraction*

According to Snell's law, when a wave impinges at the interface between two media the relationship between the angles of incidence and refraction is given by:

$$n_1 \sin\theta_{inc} = n_2 \sin\theta_{ref}. \quad (4)$$

Natural media present positive refractive indices ($n > 0$), and therefore positive refraction angles. However, metamaterials exhibit a negative refractive index ($n < 0$). As a result, Snell's law is reversed at the interface between ordinary media and metamaterials. To display the anomalous refraction to the student we have designed two numerical experiments and generated the corresponding videos. In the first one we can visualize the incidence of a CW Gaussian beam on a medium with ($n_2 > 0$). As expected, the beam is refracted with a positive angle. Fig. 1 shows a snapshot of the simulation.

In the second simulation the same Gaussiam beam travelling in air impinges on a metamaterial with ($n_2 < 0$). By means of the recorded movie the student will be able to visualize how refraction is reversed, i.e., the refracted beam is on the same side of the normal as the incident beam is.

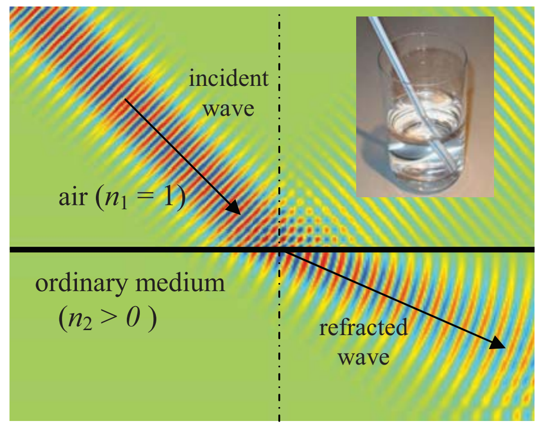

Figure 1. Positive refraction at the interface between air and an ordinary medium

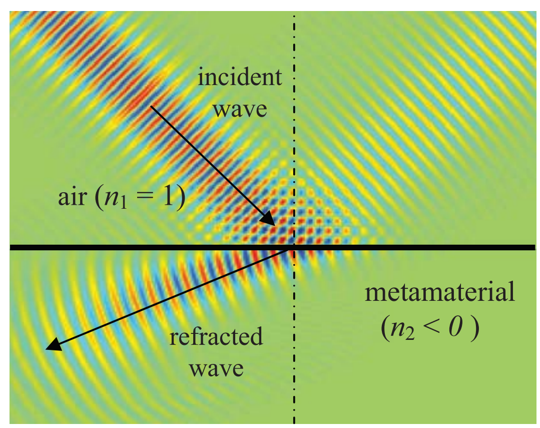

Figure 2. Negative refraction at the interface between air and a metamaterial: the light bends back from the normal.

B. *Backward propagation*

The phase velocity can be written as a function of the refractive index as

$$v_{ph} = \frac{c}{n} \quad (5)$$

where c is the speed of light in vacuum. Thus, due to the negative refractive index, metamaterials present negative phase velocity. However, the direction of the time-averaged flux of energy is determined by the real part of the Poynting vector

$$\vec{S} = \frac{1}{2}\vec{E}\times\vec{H}^* \qquad (6)$$

which is unaffected by a simultaneous change of sign of ε and μ. Therefore, in a metamaterial the energy and the wavefront travel in opposite directions (backward propagation).

For most students, it is difficult to mentally visualize the backward propagation phenomenon, since it is counterintuitive that the energy and the wavefront travel in opposite directions.

To promote the understanding of this phenomenon we have simulated the normal incidence of a wave on a metamaterial slab. Fig. 3 shows the snapshots of field propagating across a slab at two different time instants. In the figure we can see how in the metamaterial region the wavefront travels in the negative x-direction, while the power is flowing in positive x-direction, since the signal is transmitted into the second air region.

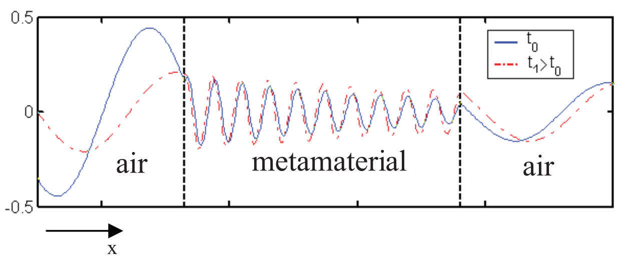

Figure 3. Backward propagation, in the metamaterial the power flows in the positive x-direction while the wavefront travel in the negative x-direction.

A static image like Fig. 3 does not clearly illustrate the backward propagation in the metamaterial slab. However, by means of the simulation movie the students will be able to visualize the evolution of the fields in time, which will help them to understand this phenomenon.

C. Pendry's lens

Another remarkable property of metamaterials is the possibility of creating flat lenses. Materials with negative refractive index refract light at a negative angle which allows a flat lens to bring waves into focus, whereas media with $n > 0$ always require curved surfaces to focus light. In fact a flat lens made of a metamaterial with $n = -1$ and thickness d, will produce two foci, one inside the slab and the other outside the slab. As can be seen in Fig. 4, for a source located at a distance d_0 from the front face of the slab the foci will appear at $d_{f1}=|d_0|$ and $d_{f2} = 2d-|d_0|$ [16].

In general, lenses introduce a phase correction to each of the Fourier components so that at some distance beyond the lens the fields focus. However for large values of the transverse wave vector these waves become evanescent and their amplitude decays exponentially so no phase correction will restore their original amplitude. As a result, for ordinary lenses, the evanescent waves are removed from the image.

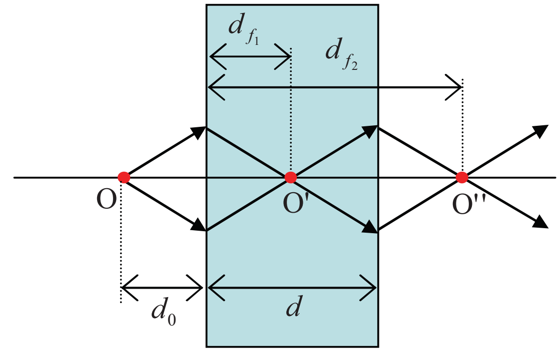

Figure 4. Flat lens: a slab made of a metamaterials with n = -1 focuses the waves producing two foci, one inside the slab and the other one outside

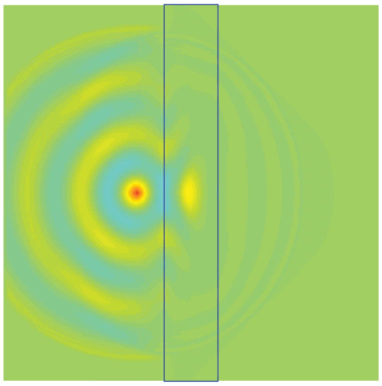
In the year 2000 Pendry [7] pointed out one of the most promising properties of a metamaterial slab. In that work Pendry theoretically demonstrated that a lens made of a metamaterial slab with $n = -1$ could restore the amplitude of evanescent waves, which may enable the development of "super-lenses" with a focusing resolution beyond the diffraction limit.

In order to show the student the behavior of Pendry's lens we have simulated a 10-mm thick slab of a metamaterial. A source is located 5 mm in front of the slab. The working frequency is f_0 = 30 GHz. At that frequency, the refraction index of the slab is $n(f_0) = -1 - j0.0011$. In Fig. 5 we can see three snapshots of the simulation. In the first one we clearly distinguish the location of the source. In the second one we can see how the first focus begins to emerge in the middle of the slab. Finally in the third image the second focus appears 5 mm behind the slab. In this last image we can also distinguish some surface waves at the first interface of the slab.

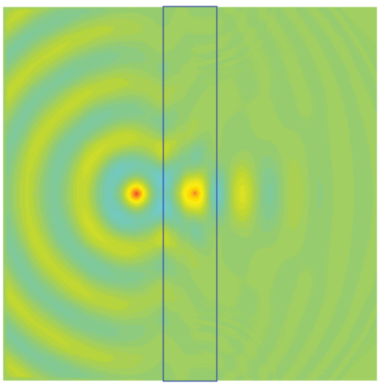
Although in Fig. 5 we can perceive the behavior of the fields in Pendry's perfect lens, it is indeed much more clearly visible when the time-domain solution is displayed. Thus, watching the simulation video the students will be able to see not only the formation of the two images by a flat lens but they will also be able to watch the dynamics of the surface waves, how they are built up and how they travel along the interfaces. It is of considerable interest that the students visualize and understand how these surface modes propagate since they are responsible for the amplification of the evanescent waves in a metamaterial slab.

D. Negative Goos-Hänchen shift

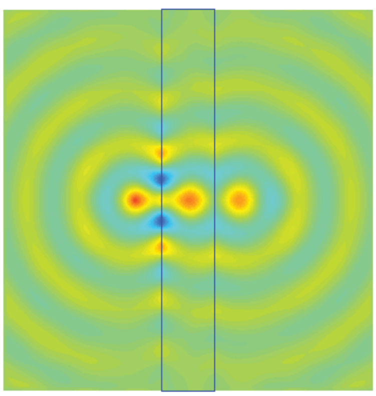
When a beam of light is totally reflected from a plane interface between two dielectrics, there is a lateral shift between the reflected light beam and the incident one. This lateral shift was predicted by Newton and experimentally demonstrated by Goos-Hänchen. However, when the beam is reflected from a metamaterial this phenomenon is reversed and the beam undergoes a negative displacement [17]. This phenomenon is schematically depicted in Fig. 6.



a)



b)



c)

Figure 5. Pendry-s lens: a) the source is located 5 mm in front of the slab, b) the first focus appears in the middle of the slab, c) the second focus emerge and surface waves travel along the interface.

To promote the understanding of this reversal phenomenon we have run two simulations and recorded the corresponding videos. The first video displays the propagation of a wave in a medium with n_1 = 9 that impinges with an incidence angle of 45º on a medium with n_2 = 3. In this situation the critical angle equals 35.26º. Therefore, total reflection will take place and the reflected beam will suffer a positive shift ($\Delta > 0$). Fig. 7 shows one of the last snapshots of the movie where we can see the positive Goos-Hänchen effect.

The goal of the second video is to show the students how this shift is reversed when metamaterials are involved. Thus if the medium 2 is substituted by a metamaterial with n_2 = -3, and we run the simulation in an analogous way we find that the totally reflected beam undergoes a negative lateral displacement ($\Delta < 0$). This phenomenon can be seen in Fig. 8.

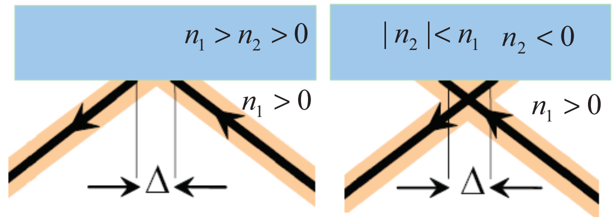


Figure 6. Goos-Hänchen effect: a) positive shift b) negative shift.

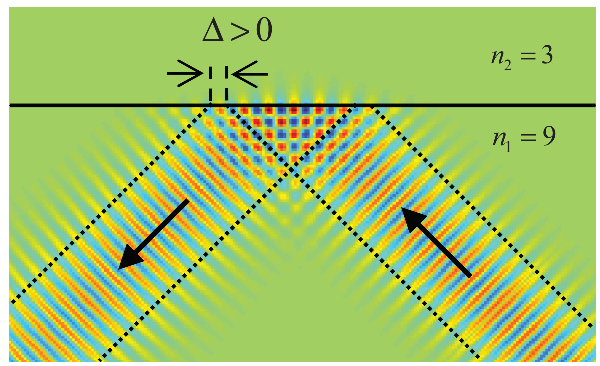

Figure 7. Positive Goos-Hänchen shift ($\Delta > 0$) at the interface between two ordinary media.

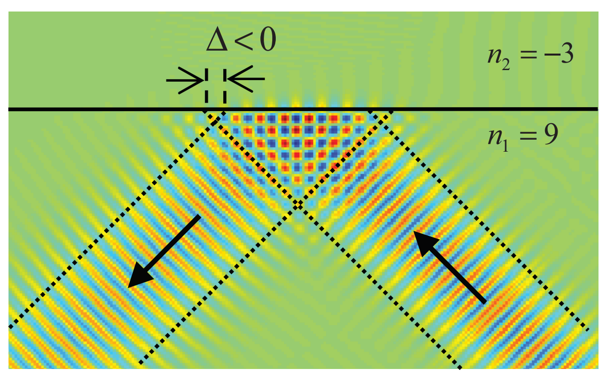

Figure 8. Negative Goos-Hänchen shift ($\Delta < 0$) at the interface of an ordinary medium and a metamaterial.

CONCLUSION

In this work an extension of the FDTD technique for modeling metamaterials has been used to carry out a series of virtual experiments. The result of the simulations has been recorded and a collection of videos has been created.

These videos provide aid in the teaching of the exotic electromagnetic properties of metamaterials, such as negative refraction, backward propagation, negative Goos-Hänchen shift, etc. By means of the visualization of the progression of the fields as they actually evolve in space and time the students will acquire a deeper physical insight into wave propagation in this kind of artificial materials.

***Abstract*—Optical systems may be complex to study, especially when they involve media with spatially varying refractive index. A fast, accurate and easy to use MATLAB code for solving the iconal equation in such media is presented. It is used for ray-tracing the propagation of light in non-homogeneous media and illustrating some amazing effects in modern physics that cannot be brought to the attention of students without the aid of numerical simulations.**

***Index Terms*—optics, ray-tracing, non-homogeneous media.**

I. INTRODUCTION

Ray optics is the branch of optics in which all the subtle wave effects are neglected: the light is considered as travelling along rays which can only change their direction by refraction or reflection. On one hand, when light propagates in media with constant refractive index, the SNELL-DESCARTES laws can be applied for implementing a fast numerical ray-tracing procedure based on a geometrical approach of the problem. On the other hand, when propagation takes place in media with non-homogeneous refractive index, the differential equation governing the propagation of light has to be solved with the aid of the computer. This contribution describes a fast, accurate and easy to use code for illustrating the propagation of light in such media, sometimes with amazing effects that cannot be brought to the attention of students without the aid of numerical simulations, or except at an expensive cost. It has been developed under MATLAB environment in the framework of an educational project, but it is general enough to be useful in most of the cases. All the lines of code are given so that they can be freely distributed and re-used.

II. SOLVING THE ICONAL EQUATION

With the incorporation of computers in the curriculum, it has become much easier to bring numerical simulations into the classroom. Since MATLAB is widely used in french universities, it is a natural choice for the authors. However, before delving into the details of the code, it is necessary to understand why the study of the propagation of light in some media sometimes raises difficulties that cannot be solved without the aid of the computer.

The iconal equation, which describes the path of the light propagating in a medium with refractive index n, is an ordinary differential equation (ODE) of the second order [1]:

$$\frac{\mathrm{d}}{\mathrm{d}s}\left(n\frac{\mathrm{d}\mathbf{r}}{\mathrm{d}s}\right) = \nabla n, \tag{1}$$

where $\mathbf{r}$ denotes the position vector of a point on the ray and $\mathrm{d}s$ is an element of length along the path. The classical approach for solving (1) is to set $f = \mathrm{d}\mathbf{r}/\mathrm{d}s$; however from the numerical implementation of a ray tracing procedure point of view it is more convenient to set $\mathrm{d}\ell = \mathrm{d}s/n$ so that (1) now reads [2]:

$$\frac{\mathrm{d}^2\mathbf{r}}{\mathrm{d}\ell^2} = \frac{1}{2}\nabla n^2. \tag{2}$$

When light is propagating in a plane, the vector equation (2) reduces to a system of two scalar equations of the second order. We therefore have in cartesian coordinates:

$$\left\{\begin{array}{lcl} \dfrac{\mathrm{d}^2 x}{\mathrm{d}\ell^2} & = & \dfrac{1}{2}\dfrac{\partial n^2}{\partial x}, \\ \dfrac{\mathrm{d}^2 y}{\mathrm{d}\ell^2} & = & \dfrac{1}{2}\dfrac{\partial n^2}{\partial y}. \end{array}\right. \tag{3}$$

As soon as the refractive index does not vary with x and y, (3) is straiforward to integrate and leads to a straight line path. When n is not uniform and according to the dependency of n with respect to x and y, it may not be possible to integrate (3) without the aid of the computer. This is why the capabilities of MATLAB [3] to quickly solve ODE is used here for studying the propagation of light in non-homogeneous media. However, since MATLAB can only solve ODE of the first order, (3) has to be rewritten:

$$\left\{\begin{array}{lcl} \dfrac{\mathrm{d}p_x}{\mathrm{d}\ell} & = & \dfrac{1}{2}\dfrac{\partial n^2}{\partial x}, \\ \dfrac{\mathrm{d}p_y}{\mathrm{d}\ell} & = & \dfrac{1}{2}\dfrac{\partial n^2}{\partial y}, \end{array}\right. \quad \text{with} \quad \begin{array}{lcl} \dfrac{\mathrm{d}x}{\mathrm{d}\ell} & = & p_x, \\ \dfrac{\mathrm{d}y}{\mathrm{d}\ell} & = & p_y. \end{array} \tag{4}$$

The MATLAB function `iconalODE` contains the final definition of the problem under study: in vector `f` are stored the values of x, y, p_x and p_y for a given value of ℓ, whereas the vector `df` returns the values of p_x, p_y, $\mathrm{d}p_x/\mathrm{d}\ell$ and $\mathrm{d}p_y/\mathrm{d}\ell$ for the same value of ℓ.

```
function df=iconalODE(l,f)
x = f(1);  px = f(3);
y = f(2);  py = f(4);
[dn2dx, dn2dy] = dn2(x,y,param);
dpxdl = 0.5*dn2dx;
dpydl = 0.5*dn2dy;
df = [px; py; dpxdl; dpydl];
```

The student has to supply a function `dn2` which should return the cartesian components of the gradient of n^2 at any point (x, y), the expression of which may depend on parameters stored in the `param` vector. The equation described in `iconalODE` is solved with the aid of the built-in function `ode45` whose integration scheme is based on a fifth order RUNGE-KUTTA approach [4]:

```
>> [l,f] = ode45('iconalODE',l,fi);
>> X = f(:,1);
>> Y = f(:,2);
>> dYdX = f(:,4)./f(:,3);
```

The solver is fed with a vector `fi` which contains the initial settings of the problem, namely x_i, y_i, $(\mathrm{d}x/\mathrm{d}\ell)_i$ and $(\mathrm{d}y/\mathrm{d}\ell)_i$ at a given starting point M_i. The values of the solution, namely x, y, $\mathrm{d}x/\mathrm{d}\ell$ et $\mathrm{d}y/\mathrm{d}\ell$ along the ray path, are returned in the array `f`: here, for convenience reasons, vectors `X`, `Y` and `dYdX` are used for storing the values of x, y and dy/dx.

III. APPLICATION IN NON-HOMOGENEOUS MEDIA

In this study, the refractive index of the non-homogeneous media satisfies the law:

$$n^2(\rho) = 1 + \frac{\rho_o^2}{\rho^2} \quad \text{with} \quad \rho = \sqrt{x^2 + y^2}, \tag{5}$$

which is inspired from previous work on relativistic particles in a KEPLER or COULOMB potential [5]. Another choice would have been to study the propagation of light in LUNEBURG lens [6], however contrary to expression (5) the refractive index would have not present a singularity and consequently the example would have been less constraining from the computational point of view and less illustrative from the point of view of the propagation of light in non-homogeneous media. However, according to the approach adopted by the authors, moving from one study to another just requires to change the lines of code written in the function `dn2` supplied by the student: this is exactly what is done in a classroom.

Coming back to (5), the region where the media is non-homogeneous will be restricted to a disk $\mathcal{D}$ with radius R. Outside $\mathcal{D}$, n will be supposed to be uniform and equal to:

$$n_i = \sqrt{1 + \rho_o^2/R^2}, \tag{6}$$

so that no discontinuity occurs at the boundary. Within $\mathcal{D}$, the components of the gradient of n^2 in cartesian coordinates are:

$$\begin{aligned} \frac{\partial n^2}{\partial x} &= -\frac{2x\rho_0^2}{(x^2+y^2)^2}, \\ \frac{\partial n^2}{\partial y} &= -\frac{2y\rho_0^2}{(x^2+y^2)^2}, \end{aligned} \tag{7}$$

whereas they are null outside $\mathcal{D}$ since n is there uniform and equal to n_i. The function `dn2` is therefore reduced to:

```
function [dn2dx,dn2dy]=dn2(x,y,param)
Ro = param(1);
R  = param(2);
if (sqrt(x^2+y^2) > R)
    dn2dx = 0;
    dn2dy = 0;
else
    dn2dx = -2*x*Ro^2/(x^2+y^2)^2;
    dn2dy = -2*y*Ro^2/(x^2+y^2)^2;
end
```

where `Ro` is used for storing the value of parameter ρ_o and `R` that of the radius R of $\mathcal{D}$.

Before solving the ODE described in functions `iconalODE` and `dn2` it is necessary to set the initial conditions of the problem. Let us consider an incident ray starting at a point $M_i(x_i, y_i)$ and making an angle α with Ox axis. In the neighbourhood of M_i, we have $\mathrm{d}x = \mathrm{d}s\cos\alpha$ and $\mathrm{d}y = \mathrm{d}s\sin\alpha$. Since at any point on the ray path $\mathrm{d}\ell = \mathrm{d}s/n$, we therefore have:

$$(\mathrm{d}x/\mathrm{d}\ell)_i = n_i\cos\alpha \quad \text{and} \quad (\mathrm{d}y/\mathrm{d}\ell)_i = n_i\sin\alpha. \tag{8}$$

Finally, the radius of $\mathcal{D}$ is set, for example, to $R = 4\rho_o$ with $\rho_o = 1$. Since the system exhibits a central symmetry, the study is restricted here to incidents rays parallel to Ox axis, so that $\alpha = \pi$, and starting from M_i located at a distance $y_i = h = 2\rho_o$ from Ox axis and with $x_i = 6\rho_o$. The following lines are the MATLAB code which corresponds to all these initial settings.

```
>> Ro = 1;
>> R = 4*Ro;
>> h = 2*Ro;
>> Xi = 6*Ro;
>> Yi = h;
>> alpha = pi;
>> Ni = sqrt(1 + (Ro/R)^2);
>> dXidl = Ni*cos(alpha);
>> dYidl = Ni*sin(alpha);
>> fi = [Xi Yi dXidl dYidl];
```

After point M_i, the path of the light is the solution of the ODE described in functions `iconalODE` and `dn2`. The complete path of the ray returned by the `ode45` solver, as described in the previous section, is represented on Fig. 1. It corresponds to the following lines:

```
>> figure(1);
>> plot(X/Ro,Y/Ro,'r-');
```

As expected, outside the disk $\mathcal{D}$, the light is travelling in

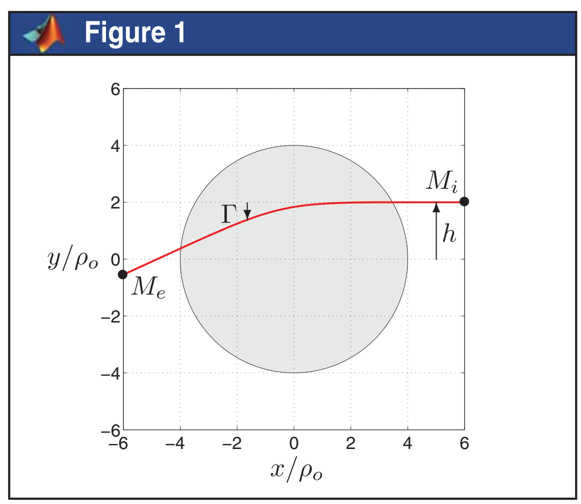

Fig. 1. An example of a ray path (in red) between points M_i and M_e. Outside the disk $\mathcal{D}$ (in grey) the media is homogeneous with a constant refractive index: the light is travelling in straight line. On the contrary, the media in $\mathcal{D}$ is non-homogeneous with spatially varying refractive index: the path of the light is curved.

straight line since the media is homogeneous with uniform refractive index (6). On the contrary, within $\mathcal{D}$ the path is curved since the light is here travelling in a non-homogeneous media with spatially varying refractive index (5). The curvature of the path is oriented towards the center of the disk $\mathcal{D}$, that is to say towards the direction of the gradient of n. The ray continuously tends towards the center without reaching it and moves away in a symetric manner with respect to the location where the distance from the center of $\mathcal{D}$ was minimal. The deviation angle Γ after travelling through the non-homogeneous media can be computed at any point M_e in the homogeneous media according to:

$$\Gamma = \arctan(\mathrm{d}y/\mathrm{d}x)_e + \pi$$

that is to say in MATLAB language:

```
>> gamma = atan(dYdX(end))+pi
```

As observed by students, h is playing the role of an impact parameter with respect to the singularity of the refractive index at the center of the disk $\mathcal{D}$ and the angle Γ that of a scattering angle with regards to the direction of the incoming ray. Shown in Fig. 1, for $h = 2\rho_o$, the deviation is about 25° with respect to the incident direction. An interesting and convenient aspect of conducting numerical simulations with the aid of the computer in a classroom with MATLAB is the capability to re-run the code with different initial settings and to obtain the new path of the light almost immediately. This is exactly what is done by the student for investigating the influence of the parameter h on the deviation angle Γ. As shown in Fig. 2, Γ varies with h in a non-linear manner. Values of Γ greater than $\pi/2$ correspond to rays which make a half turn, or even more than a complete turn, before leaving the non-homogeneous media.

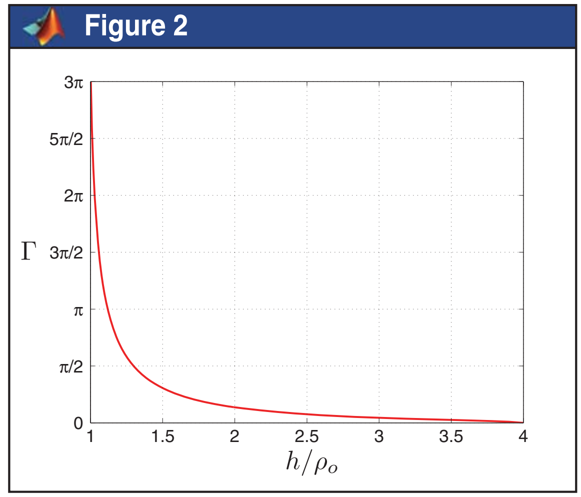

Fig. 2. Variations of the deviation angle Γ with the parameter h.

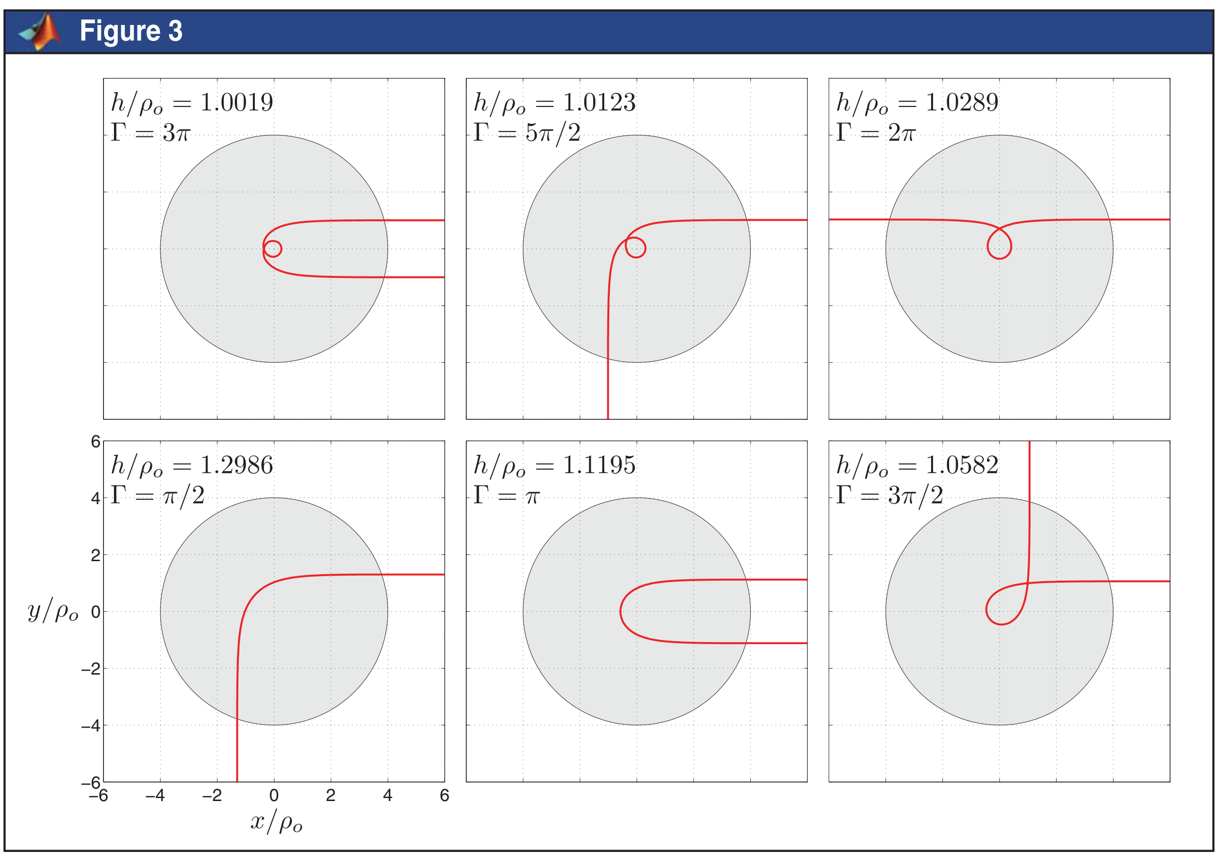

Fig. 3. Some light trajectories for various values of h.

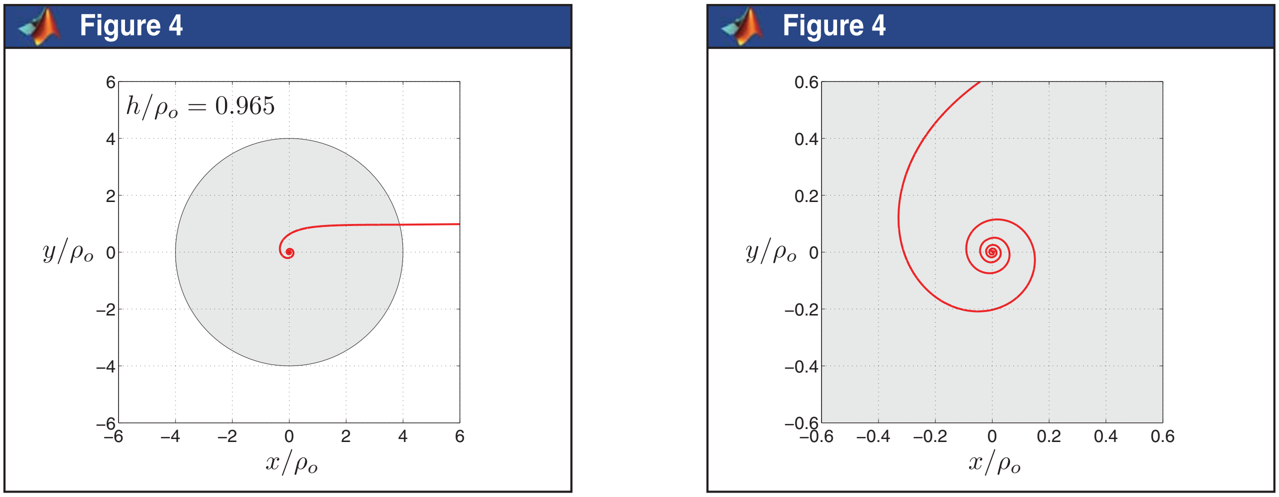

Fig. 4. Ray path for $h = 0.965\rho_o$ (central part is enlarged on the right).

Some particular situations are shown in Fig. 3 for different values of the ratio h/ρ_o.
One can think that the light can make a large number of turns before leaving the disk $\mathcal{D}$. On the contrary, below a limit for h, the path of the light identifies to that of a spiral: the ray seems to be attracted by the singularity of the refractive index of the non-homgeneous media for $\rho = 0$ and does not emerge from the disk $\mathcal{D}$. Such an amazing situation is represented in Fig. 4 for $h = 0.965\rho_o$.

IV. Conclusion

This contribution has described a MATLAB code for solving the iconal equation, especially, but not only, in media with spatially varying refractive index. The code is fast, accurate and easy to use. It has to be fed with only one function supplied by the student for switching from one study to another, the initial conditions of the problem being changed accordingly. Since the final trajectory of the light is obtained almost in real time, these initial settings can be changed at will so that an interactive study of the propagation of light is often conceivable with the computers in a classroom. In a classroom setting, the time to be allocated between the underground physics, the modeling issues and the freewheel experimentation is of course left to the teacher and may vary from one student to another. A numerical example conducted in a non-homogeneous media has demonstrated the capabilities of this code for illustrating in teaching conditions some amazing effects of the propagation of light in such media that cannot be brought to the attention of students without the aid of the computer.

A Simulation Software for Sequential Control

Pablo San Segundo, Diego Rodríguez-Losada
GSITAE research group
Universidad Politécnica de Madrid (UPM)
Madrid, Spain
pablo.sansegundo@upm.es

Finite state machines are a fundamental issue in a big number of fields in industry, such as sequential control, digital electronics, automated systems, automated reasoning etc. In our experience at the Universidad Politécnica de Madrid (UPM) we have found that the traditional approach of teaching the fundamentals of finite state machines through formal models is neither motivating nor allows to transmit the basic underlying principles to the student in a simple way.

Bearing this in mind we have developed a simulation software prototype in C++ programming language which uses the powerful 3D graphical libraries OpenGL and the portable Window Manager (GLUT) to develop simple 3D systems for sequential control which can be visually attractive to the student.

Keywords: Finite state machines, simulation, sequential control, PLC, physical systems.

I. Introduction

Finite state machines are a fundamental issue in a big number of fields in industry, such as sequential control, digital electronics, automated systems, and automated reasoning to name but a few.

The subject *Automatización Industrial* (Industrial Automatization [1]) is part of the current degree program of Industrial Engineering with specialization in Industrial Electronics, Automation and Sofware Engeneering imparted at the Escuela Universitaria de Ingeniería Técnica Industrial (EUITI) which belongs to the Universidad Politécnica de Madrid (UPM). This subject is taught during the fifth semester (third year, first semester) of the degree by the Department of Electrónica, Automática e Informática Industrial [2], to which the authors belong. The subject is worth 9 credits and has to be taken by all students of the programme, approximately 110 students each year.

The aim of the course is to be able to model and implement the control of industrial production systems using a PLC.
It is divided into theoretical lessons (5 hours per week) and practical ones (1 hour per week with a PLC). The subject is eminently practical and much of the time is spent in describing different technological components, communication networks, human machine interfaces, specific programming languages for PLCs etc. However our experience tells us that an extra effort should be made about the underlying model behind sequential control which is the finite state machine.

One approach to teach the basic underlying principles of finite state machines to the students at the beginning of the course is to employ simulation using as front-end SCADA (Supervisory Control and Data Acquisition) applications (as in [3]) together with a PLC simulation tool (as in [4]). This approach poses a number of problems. In the first place it becomes necessary to overcome the cost of software licenses which can be of several thousand of euros. In the second place, the level of abstraction is in many cases too close to the concrete system for an introductory course on finite state machines. Finally there is the drawback of using proprietary software as there are many practical examples in industry where finite sate machines need to be implemented in a general purpose framework.

Motivated by the above facts we have developed a simulation software prototype in C++ language which uses the powerful yet simple 3D graphical libraries OpenGL and the portable Window Manager (GLUT) to develop simple 3D systems which can be visually attractive for the student. Students are given a concrete control task and the access to the system control files. The tool allows testing the sequential control on the selected system to find out if the required specifications are met. Kinematics has also been included in the models so that erroneous control (i.e. a cylinder which exceeds a sensor limit) is also shown in the screen.

At the moment we dispose of four basic physical environments (garage door, elevator, cylinders and production chain). Each system requires a sequential control which can be implemented by a finite state machine. In each case the student needs to program the control in a plain text file written in C which associates sensor information with the corresponding control actions. After compiling the text file, the student can then watch the effect on the system. Additionally appropriate software engineering decouples the logical and graphical parts of the application so that it is relatively easy to add new elements to the graphical library which can then be employed in some or all systems.

We have used our prototype for the first time this year in the early part of the course Industrial Automatization both in theory (to illustrate the basic principles of sequential control) and in the laboratory (for physical system simulation). In the latter case we think that the prototype gives the students a better understanding of the system control requirements before they start programming the PLC. Additionally, we plan to use the tool in some of the SW courses (e.g. Industrial Informatics or Software fundamentals) to illustrate how to implement a finite state machine in a general purpose language.

The initial informal feedback of the students has convinced us of the effectiveness of our approach as the motivation of the students has become clearly visible. It is as yet too early in the year to correlate effort with understanding of finite state machines but there has clearly been an increase of hours of dedication as opposed to previous years. Additionally, personal opinions of some students have been very gratifying and encourage the authors to develop new 3D systems for future courses.

This paper is structured form here in five sections. Section 2 describes the current logical and graphical components in the application's repository and Section 3 the actual assignments which have been given to the students this year. Section 4 deals with implementation issues and includes an example of the language employed by the control function. Finally Section 5 presents conclusions and future work.

II. System Repository

At the moment we have implemented 4 systems in the 3D repository: a lift, a manufacturing line, a garage door and a pneumatic cylinder working table. Kinematic and logical simulation is provided. For example, if a motor is not stopped when it reaches its limit, it will break and not work any more. User interaction is provided by buttons and edit boxes in the interface. We will describe each system in turn.

A. Lift

Figure 1 shows the interface of our 3D lift in the repository. The system has the following inputs:

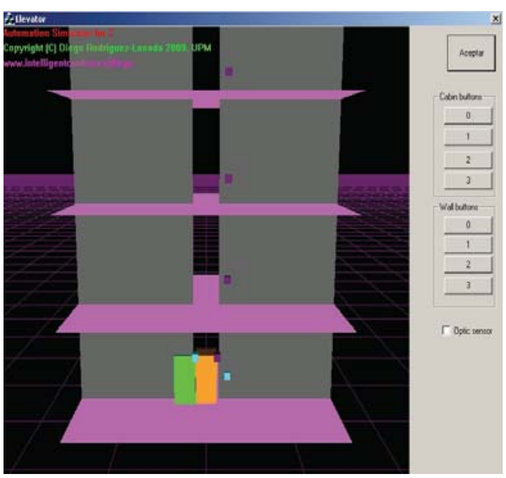

Figure 1. Interface for the 3D lift

- Cabin buttons and outside buttons to indicate the floor chosen by a potential user.
- An optical sensor which detects that a person is entering the cabin (this makes the user appear on the screen).
- A sensor at every floor to indicate the position of the cabin. These sensors change color to blue in the 3D simulation when the cabin is detected.
- Sensors that detect whether the cabin door is open or closed

Control actions are reduced to moving the cabin upward and downwards as well as opening and closing the door.

B. Manufacturing line

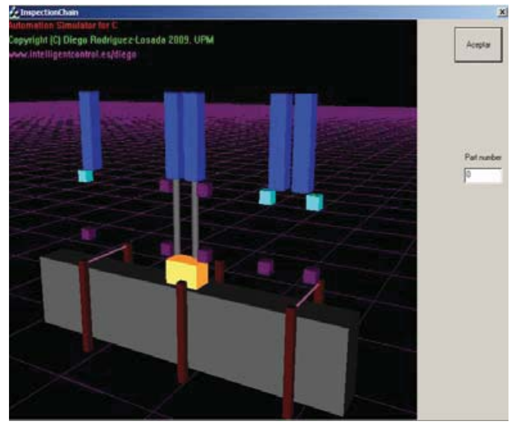

Figure 2. Interface for the 3D manufacturing line

Figure 2 illustrates our 3D manufacturing line made up of 3 different stations. A product (or subproduct) moves along the chain and can be attacked in one or both of the last two stations. In the first one (which is obligatory for all products) a code with instructions relative to the last two stations is read. The user enters this code in the edit box at the right of the screen and clicks on the 'Accept' button to start the 3D simulation.

The system has the following inputs:

- Beginning and end induction sensors for all cylinders in the different stations.
- A bar code scanner which reads the code number of the product (inserted before simulation by the student in the edit box).
- Three presence detectors, one for each station.

Control actions include compression and expansion of all cylinders (two in the last two stations and one with the bar code scanner in the first one) as well as the line movement (forward and backwards).

C. Garage door

Figure 3 shows two different views of the 3D garage door in the repository. The upper view corresponds to the initial state of the system: the garage door is closed and the system is waiting for a car to arrive. In the second view a client comes and the door is opens to his request. The entries for the control are in this case:

- An optical sensor to detect the presence of a car. This is simulated by a red line which crosses the screen in the upper view.

- An overcurrent detector which turns on the red light placed in the top left corner of the door. The event is simulated by a checkbox in the right hand side of the screen.

- Sensors which detect that the garage door is open or closed.

- Two ways of opening the door for a potential user: either using a key or a remote control. These two events are simulated by two push buttons in the right hand of the screen.

- A reset event which leads the system to its initial waiting state (i.e. the door closed and the emergency light closed, assuming the optical sensor detects no car).

Control actions include the emergency light activated by the overcurrent sensor as well as the opening and closing of the garage door.

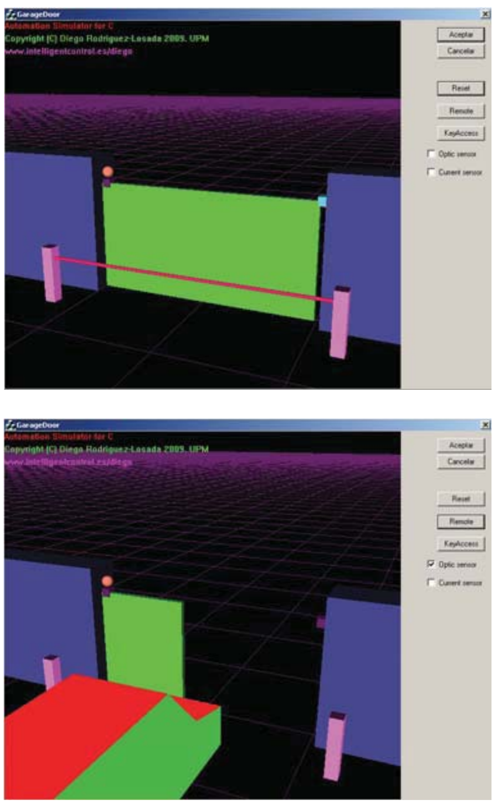

Figure 3. Two different views of the 3D garage door system.

D. *Pneumatic cylinder working table*

Figure 4 shows the 3D pneumatic working table available in the system's repository. It contains three double effect cylinders which expand and compress according to the controllers instructions attacking a piece situated at the centre.

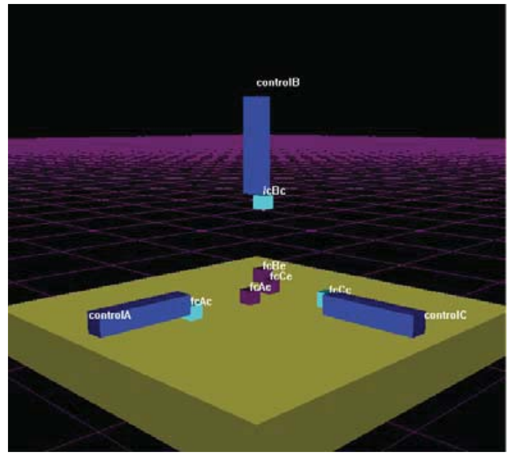

Figure 4. The 3D pneumatic working table

The inputs of the sequential control program are the following:

- Sensors to detect expansion and compression of all cylinders.

- A 'Start' button simulated by an equivalent push button in the right of the screen.

The system pre-actuators are three electro-pneumatic valves of two positions which allow expansion and compression of the cylinders.

III. ASSIGNMENTS

In this first course using the simulator we have asked the students to implement any reasonable control function for the four systems currently available (i.e. according to common sense semantics and avoiding the kinematic error models). It is to be noted that the systems, in spite of their apparent simplicity, are already flexible enough to allow for a wide variety of controlling schemes with different levels of difficulty.

A possible assignment for the manufacturing line is to assume that the bar code in the product (read in the first station) tells the controller that the product needs to stop at the last two. Another possibility would be to assume a stoppage in a different order (i.e. first in the last station, then back to the second and then once more to the first). Additionally, the cylinder expansion-compression sequences at each stop could depend on the concrete sequence read by the bar code scanner etc. Similarly, the lift could be programmed in a standard way or it could prioritize the latest order and similar variants can easily be found for the remaining systems in the repository.

Before you begin to format your paper, first write and save the content as a separate text file. Keep your text and graphic files separate until after the text has been formatted and styled. Do not use hard tabs, and limit use of hard returns to only one return at the end of a paragraph. Do not add any kind of pagination anywhere in the paper. Do not number text heads-the template will do that for you.

Finally, complete content and organizational editing before formatting. Please take note of the following items when proofreading spelling and grammar:

IV. IMPLEMENTATION

The tool has been implemented in C++ using the Visual Studio development kit, and is currently only available for Windows platforms. The system repository employs the 3D accelerator graphical libraries OpenGL (which come in the software development environment) and the portable Window Manager (GLUT).

The development process has strictly followed the object oriented design (OOD) paradigm and engineering software techniques have been applied to decouple the graphical interface from the logical parts of the system (to the extent of being compiled in a separate library). The graphical representation of the different systems is broken down into common parts (i.e. objects which encapsulate the drawing information of light bulbs, sensors, doors etc.) all of which share a common virtual interface. This makes the tool much easier to manage and, more importantly, allows building a repository of common elements which may then be employed in any new control system added to the repository.

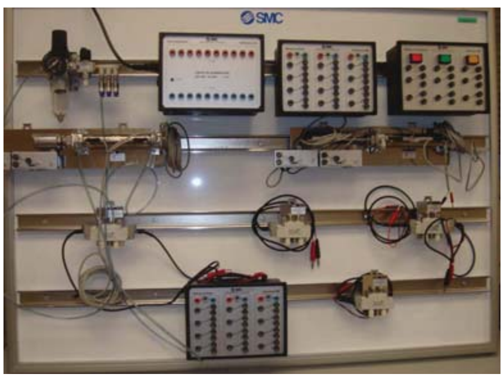

Figure 5. A two cylinder workbench used in practical lessons.

Adding a new system to the repository becomes a very easy task if it uses the components already defined in the repository. An example: the department uses in some of the practical lessons a two double effect cylinder pneumatic workbench (see Figure 5). It employs electro-pneumatic valves as pre-actuators to compress and expand both cylinders and uses different types of sensors to detect end of expansion and compression. The task is to program a PLC to produce a pre-defined sequence of expansion and compression of the cylinders. A more detailed description is available at [4].

It took only a couple of hours for one of the tool programmers to implement a very simplified, but yet again useful, simulated system of the workbench and add it to the repository. The system had only the two cylinders with sensors to detect expansion and compression and two state valves which had already been defined and employed in the four previously described systems.

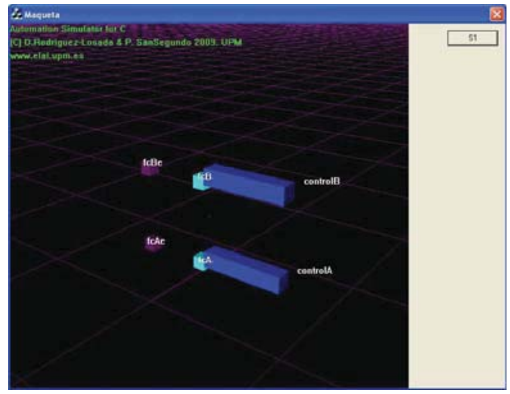

Figure 6. A two cylinder workbench

However, it could already be employed to define different kinds of assignments for the students. The graphical interface of this workbench is shown in Figure 6.

This year the students were assigned four different software projects which shared a common workspace. Once the finite state machine program (which must be written in C) is implemented, it is possible to compile the particular project with the new control function and simulate the system. Figure 7 gives a partial example of a typical control function that the student must implement. The declarative data defining the identifiers for sensor entries and actuators at the top of the file is already given to the student. The finite state machine program is encapsulated inside the definition of the control function (void *control* () in the figure) which is initially empty.

```
#include "control.h"

//Inputs
bool S1;
bool fcAe,fcAc;
bool fcBe,fcBc;

//Outputs
int controlA;
int controlB;

int estado=0;

void control()
{
    if(estado==0)
    {
        if(S1)
        {
            estado=1;
            controlA=1;
        }
    }
    if(estado==1)
    {
        if(fcAe)
        {
            estado=2;
            controlA=0;
            controlB=1;
        }
    }

    //...
```

Figure 7. Part of a typical control function for a system in the repository.

V. Conclusions

This is the first year that the tool is being tested and, as yet, it has not been possible to assess the overall effect on our students. The tasks given to them related to the software tool have been included as part of the requirements needed to pass the practical exam. We do have at the moment some personal very positive feedback from some of the pupils which would indicate that the approach taken is a step forward in the correct direction. At the end of the semester it will be possible to have a better formed opinion to this respect.

Further work in the near future will focus in developing new components for the repository (i.e. valves, pumps) and building additional system models.

Abstract— **With the growing popularity of mobile devices, several projects for mobile learning courses have been developed. Those equipments allow a superior portability and accessibility of the learning courses. In this context, the present paper focuses on the development of a mobile learning framework for an analog electronics course. This course was designed as a supplementary mean to the classic analog electronics courses. The course project consists of several interactive multimedia modules. At the end of each module, students have several oriented questions to answer. The set of answers, in SMS format, gives feedback to the teacher about the learning process. Another module, that is under development, is responsible for storing and managing the answers in a server, where all the results from students are processed in a competitive learning based methodology application.**

Keywords- Mobile learning environment, mobile devices, analog electronics course, competitive learning

I. Introduction

There are many different teaching/learning styles and methodologies described in literature. We can find differences in students' preferences in learning through experiential or concrete instruction, as well as we can find those who prefer collaborative activities to others with a competitive basis, and vice-versa. The style of an evaluation is also a key factor for the learning process of a student, because it determines the study procedure until the assessment moment.

As a complement, new technologies and methodologies have been used in order to allow students to learn in and outside the traditional classroom. E-learning systems enhance the possibility for students to attend lessons in remote locations, at a physical distance, being able to be at any place and to communicate actively by means of computers and networks. Being important that students have always the possibility to acquire their knowledge through traditional ways, balanced blended learning, combining e-learning and the classroom ambient learning, is a good solution for specific courses, if not for all.

However, mobile learning (m-learning) is, at the present, more innovative and student centered, concerning in the use of mobile devices, like cell phones, Personal Digital Assistants (PDAs) and smart phones. M-learning can be defined as "the exploitation of ubiquitous handheld technologies, together with wireless and mobile phone networks, to facilitate, support, enhance and extend the reach of teaching and learning" [1]. M-learning is a relatively recent concept, but by our group experiences, and by others described in literature [2, 3], it has been motivating students and teachers, representing an effective pedagogical method as any other conventional learning method. Nevertheless, the real problem with the concept is still the quest for an efficient and suitable adaptation of the courses contents to means with clear restriction factors [4]. The former restrictions are basically visual, technological and social (SMS costs, among others), which are mentioned in several works, measuring generally the impact of the handheld mobile devices in our society [5]. Therefore, in these days, the challenge for teachers is to prepare new courses based in a methodology that embraces the potential of the mobile devices and faces their restrictions. Innovative supporting frameworks should be implemented to accomplish that task. In an initial phase, these frameworks can be directed to specific courses, but they should be extended to accommodate more generic scenarios, being prepared to support almost any course.

The study of analogue electronics is fundamental in an electrical engineering course. Generally, in these courses, classical teaching uses textbooks as the main element. However, the use of textbooks is very limited, too flat and static. Therefore, in this new technological context, it is important to develop new m-learning tools for these courses. With that in mind, a new m-learning framework for the analog electronics course was developed at Superior School of Technology of Setubal (Polytechnic Institute of Setubal). The initial course material has been adapted to the m-learning environment and new contents were added, enriched with animations and interactive examples. Besides the traditional theoretical lessons, and laboratory practices, we propose the use of this m-learning system to reach a wider blended learning methodology, which also includes a Web-based module.

The current paper describes the course, which we consider original and innovative in the area of application, and the main points of the supporting computational framework development. The presented approach includes a competitive learning module, applied to the usual individualized and cooperative settings. It is essential for the growth of our students facing a very competitive global society.

This paper is organized as follows. In Section II, we introduce essential mobile and competitive lines that support some taken options. Section III presents related work regarding analog electronics course and mobile learning projects, while the course features description is presented in Section IV. Section V is dedicated to the presentation of the developed MoCoL framework and to the technology solutions used for that. Finally, in Section VI, conclusions are made and future work is presented.

II. Mobile and Competitive Learning Principles

Nowadays, mobile devices are essential tools for our daily living. With the evolution of their technologies, we see people adapting more easily to the use of the devices. According to [6], the mobile revolution is already here. "Wherever one looks, the evidence of mobile penetration and adoption is irrefutable…". "No demographic is immune from this phenomenon".

At the same time, with the evolution of the available functionalities, it also increased the diversity and capacity of multimedia options and wireless communication technologies of the devices. Seen as small computers, these devices can support diverse lessons, display animations for any kind of contents, be used for polling and testing, serve as a gateway to larger learning resources, among much more options.

With the fast growth of wireless handheld and mobile devices sales (Fig. 1), it has started to rapidly emerge the m-Learning concept as a new instructional method. M-learning is characterized by mobility and accessibility, since it focuses on the use of handheld mobile devices. These equipments have become very popular, especially among young people who use them not only for communication but also as a tool for other activities. There are almost one and a half billion mobile phones in operation around the world, and a large percentage of them are in the hands of students. In the coming 10 years, whether educators want it or not, more and more students will bring computing devices into the classrooms. In addition to the ordinary mobile phones, these devices can even be netbooks, notebooks and mobile music players, among others.

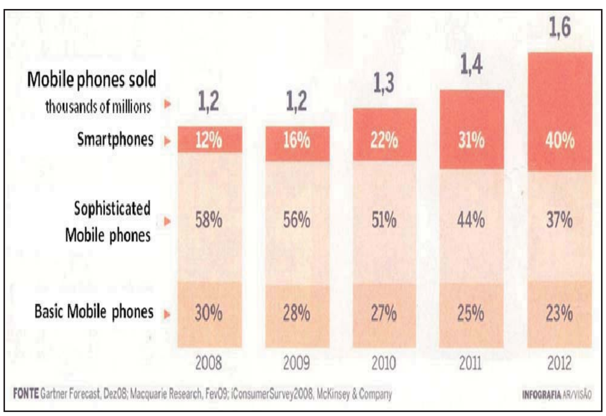

Figure 1. Number of mobile phones sold per year, worldwide [7].

For the development of the proposed project, it is important to have in mind that sophisticated and smart phones are increasing their sales in comparison to the basic cell phones (Fig. 1). Additionally, looking to the table present in Fig. 2, it is possible to establish a guideline between those sales and the increased use of advanced functionalities in mobile phones. These are important arguments, because the mobile application of the present work uses multimedia content and some connectivity options. Therefore, this is considered as a positive factor since the probability of finding devices with capabilities for playing lessons and testing contents is high, being excellent to the production of mobile applications with higher performance and better multimedia content.

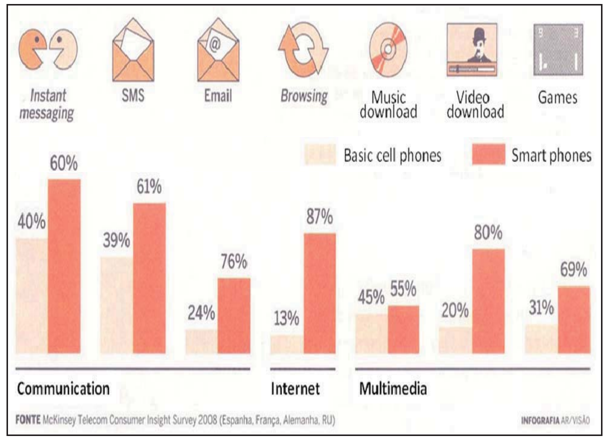

Figure 2. Advanced functionalities used in basic phones and smart phones (adapted from [7]).

As far as the use of these tools in education is concerned, not all courses are suitable for m-learning environments, but short courses are considered suitable for this kind of learning [8]. The use of quizzes, glossaries and the interaction with tutor and other peers may satisfy a wide range of needs and aims on behalf of students. Communication can be made through e-mails, SMS and MMS, and it is important for students to have feedback about their progress [8].

Johnson and Johnson suggested that an effective classroom must have the right mix of cooperative learning and competitive learning (along with individualized learning) [9]. Cooperative learning encourages students to work with and learn from each other. Alternatively, a competitive learning implementation places students against each other competing for best results [9]. For example, if a student gains a point, his competitor does not win anything. In a competitive setting, students judge their abilities to master content and knowledge relative to their competitors. In the business world people often work on a variety of team settings and cooperative activities. The context of the classroom should provide to students training for the business life and offer them some insights regarding competitiveness at work. The cooperative aspect of these set of activities may also offer a better learning environment to students. The cooperative component embedded into competitive learning represents a potential complement that may help to engage students. Once they are faced against each other, their competitive instincts can encourage them to increase their engagement in the learning process. Students who initially may not be inspired by the content may begin to be interested once they have to compete, seeing that like a game. Students must be prepared for all the adverse situations in an increasingly competitive workplace environment that they will face after finishing their graduation.

III. RELATED WORK

This section presents interesting related work, although we did not find m-learning systems delivering the pretended analog electronics contents.

With the rapid development of ICT systems, new educational opportunities and instructional methods appeared. Therefore, several e-learning tools have been developed to enhance the learning process in analog electronics courses [10, 11, 12, 13, 14]. However, these solutions do not have modules directed to m-learning, with the presentation of the functionalities and features required by our proposal.

It has to be noted that, nowadays, m-learning is a very active research field, with the development of important and interesting projects. In [15], Frohberg et al. made a deep and critical analysis of mobile learning projects published before the end of 2007. Mobile learning is rapidly growing from a set of research projects into worldwide deployment of services for classrooms, field trips, workplace training and informal education, among other areas. Major projects have concentrated on the generic platforms development for m-learning and explored new supports for a kind of technology-mediated learning across locations and life transitions [16, 17]. Smaller projects are more directed to develop new pedagogical solutions for specific cases and to explore how learning on handheld mobile devices interweaves with personal interests and individual learning needs [18].

In relation to platforms, the following projects support the implementation of specific mobile and wireless applications for mobile devices. It is important to know projects like MOBIlearn [19]. It pretends to deliver a generic m-learning architecture to support creation, brokerage, delivery and tracking of learning and information contents, using ambient intelligence, location-dependence, personalization, multimedia, instant messaging (text, video) and distributed databases. Another proposal, MADEE [20], is an execution environment and application development tool that supports and makes easier the development of mobile and wireless information systems that run on handheld devices, allowing communication and information sharing among users in an organization. Other older examples are: the Sync a Java framework [21] that allows asynchronous collaboration between mobile users; Rover [22], a framework for building mobile applications based on flexible client/server architecture; and LIME [23], a middleware package written in Java that supports mobile application development and coordination.

An interesting application of m-learning has been carried out by the Standford Learning Lab for the teaching of the English language [24]. Quizzes, glossaries and interactive audio-files were sent to students to improve their pronunciation and language competencies/skills. Interesting to us is that two other language experiences were followed for the acquisition of English vocabulary and idioms on mobile devices. The first one does it through SMS and the second by means of videos. Another application of mobile learning in the study of languages is Pocket Eijiro [25], an English-Japanese, Japanese-English dictionary, which presents some interesting features.

On the other side, the Moop [26] m-learning environment was developed for use in primary school at the city of Oulu, Finland. Moop has an interactive application for use in situations where primary school students take use of a cell phone to analyze their surroundings and to communicate within groups. The system supports the process of inquiry learning, during which a user outlines her thoughts on the current topic, collects information from the surroundings and reports the findings to the system. The HandLeR project [17], one of the oldest, is an attempt to gain an in-depth understanding of the learning process in different scenarios with the evaluation of a handheld device. The system is also "...intended to support children to capture everyday events such as images, notes and sounds, to relate them to web-based learning resources, to organize these into a visual knowledge map and to share them with other learners and teachers" [27]. This kind of systems promotes learning in complex scenarios where learning goals depend on a contextual factor.

Another system, related with context, is "Contextual Cues" that lets students, who have attended a lecture, to receive a copy on their mobile phone of key points that the teacher labels as important, which should be reviewed later [28]. To support this, a plug-in or application installed on the teacher's Bluetooth-enabled computer would make it easy to highlight important points in the teaching material. During the presentation, the broadcasting of the key points together with a timestamp takes place in parallel with the presentation of the related material.

Regarding quiz systems oriented for mobile devices, there are several commercial and free options that are interesting for our study. Moodle for mobile tests [29] is a module to execute Moodle questionnaires using CHTML (compact HTML) in compatible mobile phones with i-mode technology. Interactive test is a module of an m-learning system [30] specifically developed for use in Java-enabled mobile devices. Go Test Go's [31] is a commercial quiz system designed to be used in Java mobile phones which provides a great selection of quizzes about several areas. Finally, Quizzler [32] is a commercial product designed for PC, Palm and PocketPC platforms and provides a collection of tools (quizzler reader, quizzler software maker and quiz library).

IV. MOBILE COURSE FEATURES DESCRIPTION

The goal of this project is the implementation of an m-learning tool for the teaching of the analogue electronics basic subject. The purpose of this solution is not to replace the traditional teaching methods, but to create a complementary tool in order to improve the student's interest, motivation and the resources availability in any place, at any time.

The m-learning analogue electronic course consists in several interactive modules. The contents of the modules cover the following main topics:

- Semiconductors theory
- PN junction theory
- Diodes and applications
- Transistor and applications

The contents were developed in order to put an emphasis on demonstrating and assisting each theoretical concept with a practical application. Another important feature is the use of images and multimedia animations. As an example, Fig. 3 shows an animation about the semiconductor theory. With this image, students can see the movement of the electrical charges inside of the NPN transistor.

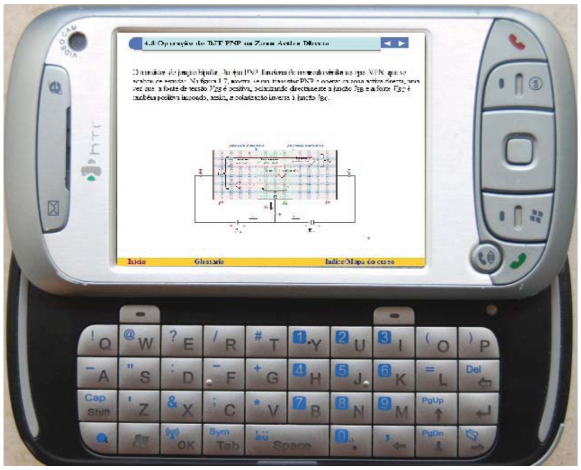

Figure 3. Animated figure of a NPN transistor (with descriptions).

Interactive figures are also essential for the understanding and motivation of the students. So, several interactive figures have been developed for this course. Fig. 4 shows an interactive circuit for the half wave diode rectifier with an output capacitor in parallel with a resistor. Students can change the capacitor value and verify the waveforms and at any instant if the diode is on/off.

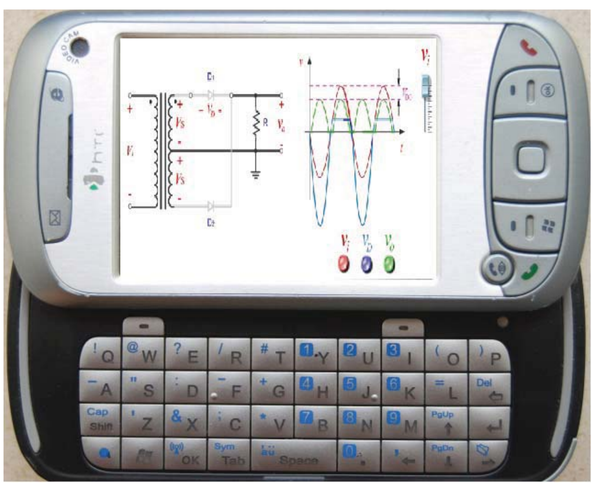

Figure 4. Interactive figure for the half wave diode rectifier (only animation).

Fig. 5 shows another interactive circuit that has been developed to explain the full bridge rectifier that uses a transformer with a center-tapped secondary winding and two diodes. With this circuit, students can change the amplitude of the input source voltage and select the waveforms that they want to see.

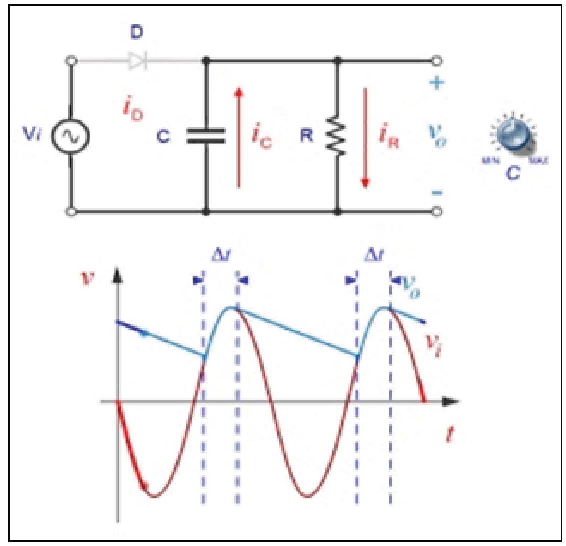

Figure 5. Interactive figure for the full bride diode rectifier.

One important feature associated with the figures and interactive animations is an option for comments. This way, students can make annotations and give feedback about those contents. With students' annotations, teachers can verify if those figures and interactive animations are clear or if they have to be improved. From those comments, teachers can also have some information about the student's knowledge. When students select the option to give feedback, an SMS will be sent to the teacher with the annotations.

In order to provide to the student an evaluation of his knowledge progress, at the end of each module there are several quizzes about the module. This also can help the teacher to verify the student's progress. At the end of the evaluative quizzes, if possible, an SMS is sent to the teacher, informing about the results to the questions. In case of failure, the student must start again the lesson. New quizzes will also appear and, in order to avoid the same questions, there is a large variety of XML quizzes that are generated from a teacher contents manager application.

The lessons are simple in order to avoid excessive information for students. However, in several pages there is an option called "to know more". So, the amount of information presented to students is adapted to their needs.

A. CL Competitive Learning Module

The competitive module implements a competition where the mobile students are selected to participate in a tournament similar to the well known UEFA® football champions league (CL), with a groups' stage and a knockout phase. This module is under development, being almost finished and in a phase of integration in the platform system.

For the competition, the students use the mobile device client application to answer to quizzes like the aforementioned ones for the auto-evaluations. One game is composed by a randomly generated quiz, being "played" by a student against an opponent and the clock. At the end of a game, the answers are automatically stored in the mobile device and sent to the server. The mobile application knows the games' results of the corresponding user/student, but the central CL application of the MoCoL framework (Section V) needs to have access to all the quizzes results, from all users. So, every now and then the applications must be synchronized with the central system, with the connection being made automatically at distance or established in the classroom. The framework automatically evaluates the obtained answers for the proposed game, elaborating the classification and managing future games.

The competition can take place for several sessions (lessons, marked days, etc.) and a teacher can configure it choosing, for example, the beginning time of the different group games, the level of the games (quizzes to be answered), the competition mode (auto-evaluation/training, assessment, or friendly), among other parameters. One additional parameter is the submission type of the results, which can be through the normal option or sending an SMS to the teacher at the end of the game.

Additionally, in the future, it will be possible for a student to submit to the database, and for a CL edition, quizzes questions to be answered by his colleagues. This is one of the most interesting functionalities in our methodology, since this can improve the learning performance of a student which has to find and know more exercises.

V. THE MOBILE AND COMPETITIVE LEARNING (MOCOL) FRAMEWORK

The present section presents the MoCoL framework, highlighting the main requirements, the supporting architecture, the development of the course mobile application and technologies used in the implementation.

A. Requirements

When implementing a new methodology and designing a framework like the one presented within this work, first, we have to establish some principles and requirements. Therefore, to support and complement the course lessons it is highly desirable to have a computational system working with the following main goals: to allow the mobile learning to run in a motivating setting; to flexibly the timetables for learning in order to complement classroom lessons, which can be important for workers; to allow the student auto-evaluation; to allow recovery modules in order to give to all students the same opportunities; and to add the option to be used interactively in different kinds of classroom lessons.

MoCoL uses four main end-users groups as system requirement. They are students, teachers, administrators and even parents. Students are the main end-users because they get numerous benefits from the system. The system provides notes and tutorials for the students to learn more about the subject. Besides, it has information about other links related to the chapter.

Teachers can use the platform as a teaching tool by looking at the lesson, tutorial and other links that will be provided by the system. Besides, teachers play an important role providing questions to the quizzes section. The system provides a function of auto-calculation, making the quizzes more or less difficult, according to the integration of questions. The teachers have to update the chapters' contents. Teachers also receive email from the student or his parents regarding his performance. Thus, the system provides good relations between teachers and student as well as with their parent(s).

The administrator has the role to access most of the functions in the system. This is because he has to update and configure the system to meet the requirements of the teacher.

Parents use MoCoL to guide their children's performance in the course. They can check how many times the children have accessed their study material and what exactly they do when entering the system. The parents will have a log file in their module for this purpose. Besides, the parent can contact the teacher if they want to ask anything regarding their children's performance.

B. System's Architecture

The architecture of the global system is the typical client-server solution with the two-tier separation (Fig. 6). The clients are the following: a web tool (e-learning) module, available through a web browser; an off-line module that is an e-book, or interactive DVD (iDVD), being easily carried by students; and the m-learning tool, with a competitive module and a reduced version of the e-learning contents.

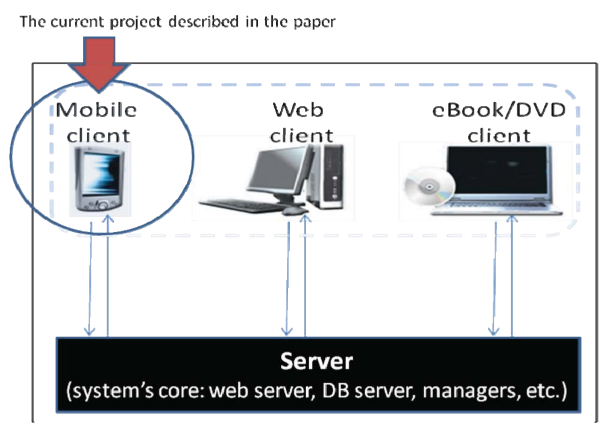

Figure 6. Client-server architecture of the framework.

The architecture for the competitive module includes four main sub-modules (Fig. 7). One of them is the manager of classifications and featured tournaments (CL). All the information is gathered from the central database of the system. Students login to a CL and games and submit results through their respective module, which also add the functionality of submitting new exercises to be played in a CL. The module related with teachers integrates all the functionalities necessary for the correct management of the competitions. One teacher can add new exercises, with the corresponding type descriptors, to the database and configure CL tournaments, which can be formative or for evaluation purposes. Through this sub-module, teachers access the Automated Evaluator (AE) sub-module, configuring it according to the class of students they have in mind to compete. This AE module crosses the submitted results (implemented programs) with the configuration made by teachers and the exercises descriptors taken from the database to evaluate how many goals were "scored" by students.

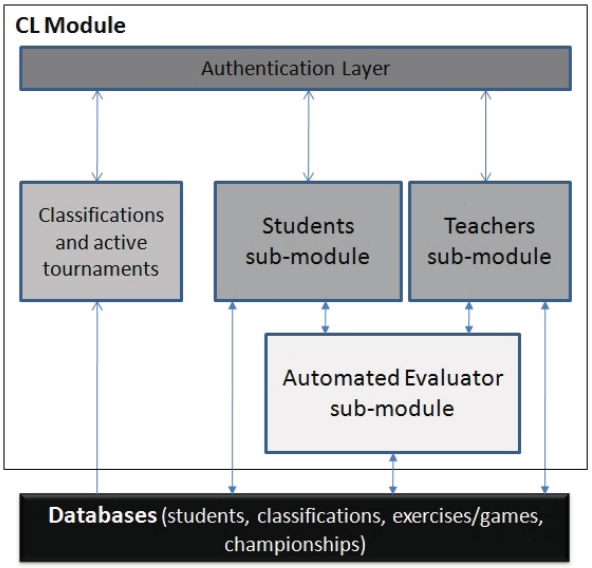

Figure 7: Architecture of the mobile device application.

C. *Development Issues of the Mobile Application*

The MoCoL client is a mobile application developed in Java (J2ME) for devices that support the MID profile. This application allows the user to interact with the central system and with teachers.

This client application is generic, in the sense that it is independent of the server-side applications. The application has some functions that are independent of the implemented prototype. It has two modules: one with functions to interact with the server via Bluetooth and another one to manage the possible information received from the system. Therefore, the client application uses the JSR-82 and the BlueCove APIs as the server application does.

Not all the mobile devices can run the first module to interact directly with the system. To accomplish that, the device must be embedded with the JSR-82 API. If a device does not embed the API, a possible solution is the implementation of a web server, making available an URL address to be accessed through the WAP browser of the mobile device. In this way, a student will be able to receive XML documents to consult later and to store them in the client repository, a Record Management System (RMS).

The module to manage the received information uses the kXML library in its implementation to make the parsing of the XML documents. kXML provides an XML pull parser and writer suitable for all Java platforms, including J2ME. Because of its small footprint size, it is especially suited for Java applications running on mobile devices.

VI. Conclusions and Future Work

The use of m-learning tools, if correctly conceptualized and built, constitutes an efficient complementary tool to the traditional teaching methods.

So, in this context, it was presented the development of a mobile learning framework for analog electronics course. The theoretical content of the course was structured in several interactive modules. At the end of each module, there are quizzes allowing students to be evaluated by themselves or by course teachers. The teacher receives automatic SMS from the student's mobile phone. This allows the teacher to have access to the student's progress and comments about the images and multimedia animations.

As future work, it is intended to study how to overcome some disadvantages found in m-learning, such as its high costs, the possibility for mobile devices to be misplaced or stolen and the difficulty to use mobile devices in noisy environments. Yet, another future step will be in the direction of creating the best interfaces to deal with the small screen size of the devices, the limited memory size, the small keyboards and limited battery life, among other issues.

Another important point for future work is the dissemination of the results of a questionnaire survey that is already being carried out among the students of the course.

***Abstract*—The vertiginous penetration and advance of mobile devices in all levels of our society leads towards new technological challenges. This paper is focused on the application of mobile devices in the learning environment, since the current mobile learning development is finding several problems and lacks, such as use of the new features (e.g. location and motion sensors) and the desigh without having including the existing e-learning services. This paper introduces a framework created as a need to interconnect the mobile learning environment with context aware systems and existing e-learning resources. The paper describes the requirements that a framework like this must support, to finally give an overview of the author's solution.**

Keywords-middleware; mobile learning; service-oriented learning; ubiquitous learning.

I. INTRODUCTION

Nowadays, mobile computing is one of the fastest growing areas within the technology industry worldwide. Rates of use of mobile devices in western countries are around 90%, having the youngest generations as main users [1]. One of the reasons of this success is the improvement in the devices' technical features and the low prices. New generations of mobile devices have wider and touchable screens, built-in digital cameras, and connectivity through Wi-Fi or 3G. In many cases it is even possible to find Global Positioning System (GPS) receivers, RFID, NFC readers or smartcards integrated.

All these new technologies inside a small and portable device are giving rise to a new generation of applications in all kind of environments. These are applications more aware of the user's context that enable connectivity and communication every time and everywhere. One of the environments where these devices can suppose an inflection point is education. Here, mobile computing acquires some specific features to support the enhancement of the learning process.

On the other hand, proliferation of mobile devices causes the increase of the demand of mobile learning development. As a result, it creates the need of some kind of software that could help in the development tasks. For that reason, many systems have been created to decrease the inherent complexity of the technologies implied in the mobile learning development.

This paper arises as a response to current research on mobile learning projects, which are geared mostly to implement the e-learning and traditional teaching methodologies on mobile devices. It means that many of the existing mobile learning applications are based on concepts such as study and assessment of digital material via mobile phones. Mobile devices are not the ideal technology to carry out these tasks due to the small size of its interface (display and keyboard).

The paper might be of interest for those involved in the development of mobile learning applications, since the introduced framework could become a powerful and useful tool for them; for those also designing supportive tools to simplify the development of mobile learning applications; and in general for those involved in the development of any kind of e-learning or m-learning application, since the paper introduces a service-oriented methodology for the development of applications.

The paper is structured as follows: Chapter II offers an overview of the main goals of the system. Chapter IV introduces the most relevant requirements to have in consideration to design a framework for supporting mobile context-aware applications. Chapter V relates the reasons why e-learning platforms and applications should not be left aside of mobile learning design. Chapter VI introduces the design of the proposed middleware. Chapter IX offers an overview of the evaluation to be carried out in the following months; and Chapter X some conclusions.

II. OBJECTIVES

Mobile devices are a very familiar tool for learners. Their experiences are closer to the use of videogames; watch videos; communication via mobile devices; and use of collaborative technologies (e.g. blogs, wikis, mash-ups and social networks) than to be a mere listener in a master class given by a teacher. Therefore, thanks to the use of these devices, students will take an active role in the learning process in a more interactive and according way to what they are accustomed to use. Learners will feel more motivated and engagement with learning. This idea was remarked by Elliot Soloway, an expert in mobile learning from the University of Michigan: "The kids these days are not digital kids. The digital kids were in the '90s. The kids today are mobile, and there's a difference. Digital is the old way of thinking, mobile is the new way."

M2Learn project is intended to give a step further in the state of the art of design of mobile learning applications. It supports the development of innovative mobile learning applications that really complement and enrich the learning experience. This is a learner-centred paradigm that really encourage the “anywhere, anytime”, improving the social interactions, providing a personalized educative experience to each learner, and reaching to places where traditional or on-line learning cannot reach. M2Learn Middleware is devoted to help mobile learning to find its place in education, as a complement to traditional and on-line learning instead of replace them and promoting blended approaches.

The main objective of the M2Learn project is to implement a middleware devoted to simplify the development of mobile learning applications based on the following characteristics:

- Middleware that simplifies the integration of:
  - Context-aware systems
  - Location-based technologies (GPS, RFID, Wi-Fi, ...)
  - E-learning resources (digital content, chat, forums, on-line labs, evaluation, ...)
- Offering collaboration capabilities (synchronous and synchronous communication; Web 2.0, ...)
- Open and flexible architecture with a service-based infrastructure (Through Web services and SOAP)

Through this development, educational organizations will achieve successful m-learning projects, because it encapsulates the inner complexity of the location techniques, learning services, context-awareness systems and management of e-learning resources.

III. Existing systems to support mobile learning development

Lately, many frameworks and middlewares have been created to decrease the complexity and simplify the design and development of mobile applications. Although few of them are devoted specially for mobile learning, we have focused our research in all the scope, i.e. learning-focused or general purpose. The reason is because any middleware for general mobile applications development can be also used for mobile learning purposes, although it will lack in some specific learning requirements, such as integration with e-learning platforms, protocols, applications and standards.

One of the first environments created to support ubiquitous computing is the Context Toolkit [2]. It is a context-aware framework developed at Georgia Institute of Technology. Its main strength is the use of Widgets to encapsulate the complexity of the lowest levels, as the sensor management. They also provide callbacks to notify applications of changes, and offer attributes that may be polled by applications [2].

Other related example is the SOCAM (Service-oriented Context-Aware Middleware) project [3], which uses a central server (context interpreter) and several context providers. The central server retrieves context data from the context providers, which have previously processed it. At the top level layer are the context-aware applications in the mobile device that make use of the context data provided by the central server.

A similar architecture is introduced in the CASS project (Context-awareness sub-structure) by Fahy and Clarke in [4]. This architecture is not designed for mobile devices with sensors embedded, but for context-aware environments with spread sensors that communicate with a mobile device.

A different approach is developed by Hansen in [5] within the HyCon Framework, which is devoted mainly to hypermedia services, although it also supports J2ME applications. The architectural design is similar to other hypermedia architectures, such as the Dexter architecture [6], the Open Hypermedia System Working Group’s Open Hypermedia Model [7] and Construct [8]. The difference is the sensor layer that encapsulates the sensing management. Other interesting feature of this framework is the integration of external services, such as a Weather Server and a Location Mapper, which use the information retrieved from sensors (Context Interpreter) to obtain a more sophisticated one.

Within the MOBIlearn project is developed the Open Mobile Access Abstract Framework (OMAF) [9] based on layers of infrastructure and application profiles. It is interesting from a design point of view because it is based on the IMS Abstract Framework.

IV. Technical Requirements involved in Development of Mobile Learning Applications

A. Architectures for Development of Mobile Learning Applications

This section describes the most common architectures used in the existing middlewares for the development of mobile applications. The objective is to establish the basis for the posterior definition of the M2Learn architecture.

According with Biegel, the main features that a programming model to develop mobile context-aware applications must address are [10]:

- Capture of context data
- Uncertainty of context data
- Representation of context data
- Privacy
- Scalability
- Synchrony
- Extensibility and reusability
- Centralized/Distributed resources

In relation with the first featured cited by Biegel, there are different approaches to acquire contextual information according with the work of Chen [11]:

- **Direct sensor access.** Used in devices with embedded sensors. The application gathers the desired information directly from these sensors. In this approach there is no additional layer in charge of retrieving or processing sensor data.
- **Drivers for the sensors are hardwired into the application**. This tightly coupled method is usable

only in rare cases and not suitable for mobile applications.

- **Middleware infrastructure**. Modern software design uses methods of encapsulation to separate the different layers involved in the design. The middleware-based approach introduces a layered architecture with the intention of hiding low-level sensing details. Compared to direct sensor access this technique simplifies extensibility and promotes reusability [12].

Other fundamental factor in the architecture design is the use of centralized or distributed resources. If the system is autonomous and does not require any connection with other systems, the architecture is considerably simplified. On the other hand, the distributed approach must affront the communication challenge, which can be carried out using different techniques [13]:

- **Widgets**. A widget is a component that offers a public interface for a hardware sensor [14]. Widgets hide low-level details of sensing and simplify application development due to their reusability. Thanks to the encapsulation in widgets it is possible to exchange widgets that provide the same kind of context data
- **Networked services.** This approach is based on a more distributed architecture. It requires a service discovery server that will manage the services offered in the network [15].
- **Blackboard model**. The blackboard model is an asymmetric approach that requires a server where the clients are subscribed to be notified when some specific event occurs. In this system, there are some components (e.g. sensors) that provide information to the blackboard. This information is used by other components to provide more information. When the existing information in the blackboard matches with the needs of some client (higher level components), it is notified.

The most common design approach for distributed context-aware frameworks is a classical hierarchical infrastructure with one or many centralized components using a layered architecture. This approach is useful to overcome memory and processor constraints of small mobile devices but provides one single point of failure and thereby lacks robustness.

And finally, the last relevant feature regarding to architectural design is the way to represent the contextual information. According to Stephanidis in [15] it can be structured as follows:

- key-value model
- markup scheme model
- graphical model
- object-oriented model
- logic-based model
- ontology-based model

This last one is considered the most promising for context-aware systems, due to the fact it offers reasoning features. However, for mobile systems the object-oriented model can be more effective and flexible as the Hydrogen project demonstrates in [16]. That is because some of them are able to manage their own context data without connecting with an external central server. Object-oriented models are usually supported by middleware architectures providing distributed context handling. Whilst ontology-based models usually make use of centralized context management components [15].

B. Interoperability through the service-oriented paradigm

Nowadays, technological interoperability is a fundamental component within complex systems, because of the need of interconnection among different environments and systems. It takes special relevance in the mobile field, due to the fact there are different kind of devices, with different Operating Systems and hardware features. Thus, usually new systems developed for these devices are not isolated programs, but they must connect to other services and resources to retrieve and send information. This connection is one of the key issues within the mobile computing paradigm.

According to the literacy there are no defined standards for interoperability in mobile learning that specify e.g. the interface between a mobile learning application and a LMS or a location service.

On the other hand, there are specifications, such as the "IMS Abstract Framework: Applications, Services & Components" (IAF), which is a mechanism to define the set of interfaces for which interoperability specifications will be needed by some application domain [17]. This specification can be followed as a guide for development of mobile learning frameworks. It offers a structured architecture that allows interoperability between different components, using mainly SOAP. It can be used specially in the interconnection with external services, e.g. services from a LMS, contextual services, etc.

The main principles of this framework [17] are:

- Interoperability – the specifications are focused on the exchange of information between systems.
- Service-oriented – the exchange between the systems is defined in terms of the services being supplied by the collaboration of the systems.
- Component-based – the set of services will be supplied as a 'sea of components' that can be mixed and matched to form a particular service.
- Layering – the total set of services required to make an eLearning system will be modeled as a set of layers.
- Behaviors and Data Models – a service will be defined in terms of its behaviors and data model, and can be supported through multiple bindings e.g. Java, XML, web services, etc.

IAF is a layered model, consisting of four layers [18] as it is shown in figure 1:

- Application layer.
- Application Services layer.
- Common Services layer – a set of services that are available to the application services.
- Infrastructure layer – this provides the end-to-end transaction and communications services for the application and common services.

The interface between layers is the Service Access Point (SAP), which is provided by the services. It means that each service will offer one or more SAPs, which will be the communication interface with other layers. This concept can be implemented for example through an API.

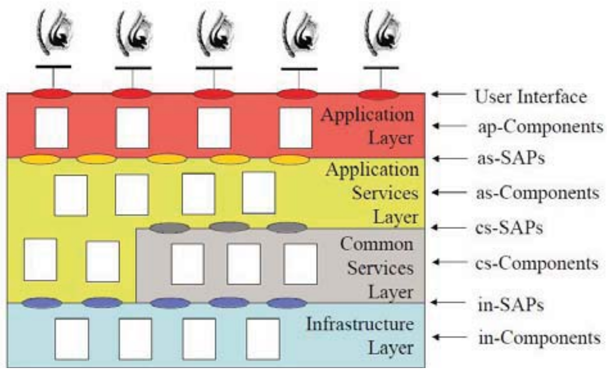

Figure 1. IAF Layers [17] includes, from bottom to top, the following layers: Infrastructure, Common Services, Application Services and Application.

V. ENABLING INNOVATIONS ON MOBILE AND UBIQUITOUS LEARNING

According with several authors, such as Shuiler [18], the successful implantation of mobile learning applications within the educational environment involves some changes in the mentality of both technicians and trainers. In first place, the development of new pedagogy theories that fulfil the mobility opportunities that new technologies are offering.

Secondly, the design and implantation of innovative learning applications that provide an added-value to the educational experience, complementing both traditional and electronic learning. Third, the support to fill the gaps between differentiated access and technologies. A wide range of technologies and their inner complexity are a challenge to overcome by teachers and learners. And finally, move these new innovations into the real educational environment by training teachers.

As a result, authors have developed a system to support the development of these innovative mobile learning applications within the new learning approaches. The M2Learn project arises as a response to current research on mobile learning development, which is usually geared to implement the same methodology used in the e-learning and traditional teaching on mobile devices. It means that many of the existing mobile learning applications are based on concepts such as study and assessment of digital material via cell phones. Mobile devices are not the ideal technology to carry out these tasks due to the small size of its interfaces (display and keyboard).

Therefore, new trends must exploit the potential offered by these devices changing the methodology and thinking on new scenarios. There, new mobility features must offer a complement to traditional education, as for example:

- Learning outside the classroom (botanical garden, archaeology, etc.);
- Learning on the move (transportation, running, etc.);
- Informal and lifelong learning (museums, aircraft, zoos, etc.);
- Collaborative learning (performance review in class, voting, resolving queries, etc.).

The other focus of the project is the fact that most mobile learning applications have left behind what has been established as the main repository of learning resources during the last years: the e-learning platforms, e.g. Web-CT, dotLRN, Moodle or Sakai.

Lately, much effort has been undertaken to develop e-learning platforms able to offer the services and resources that students need within the learning process. But most of these new mobile applications leave them aside, created ad-hoc, with almost none interoperability with other systems.

Finally, reviewing the technical literature related to the mobile learning field, we find that there are no tools to facilitate the development of mobile applications that comply with the new paradigm of mobility: integration of resources and services from e-learning platforms with context-aware systems and collaborative environments.

VI. M2LEARN: A SERVICE-ORIENTED MIDDLEWARE FOR THE DEVELOPMENT OF MOBILE AND UBIQUITOUS LEARNING APPLICATIONS

Achievement of a successful implantation of mobile devices in education requires the development of applications able to provide the needed support to the mobile learning experience. Thus, authors have committed to create a middleware devoted to support the development of new generation mobile learning applications.

Based on the analyzed features, the following technical requirements are part of the final design:

- Context-awareness through location technologies, e.g. GPS, Wi-Fi, RFID, etc.
- Internal context representation using an object-oriented model.
- Capture of contextual information through a middleware infrastructure. It hides low-level sensing details to higher level layers.
- Communication between components (both internal and external) through the use of Widgets and Web Services using SAPs (IAF based). Together with the middleware infrastructure it provides reusability and simplifies the application development.

These factors are common for the development of any kind of mobile application. However, focusing on mobile learning, other key factors have been kept in mind in the design are:

- Integration with existing e-learning resources
- Support for social collaboration

The reason is that e-learning platforms are currently the centre of the on-line and blended education. These platforms are a repository of both content and services. That is why mobile applications should not be designed independently of the already developed e-learning standards and platforms, without taking advantage of all the existing resources. Within the mobile environment, existing e-learning resources can be very useful to better personalize the services provided to learners. For example, using the credentials (login and password) it is possible to retrieve information about learner's educational environment such as student's degree or subjects. This information will be provided to higher level applications to personalize the services offered to the student. In fact, there is a lot of contextual information about the learner that can be used to improve the learning experience: for example, personalized information services or search results in the library.

M2Learn middleware interacts with the university LMS through a set of Web Services, providing an interface to implement some functionalities in a mobile device, e.g. access to forum rooms, content or FAQs. In addition, there are other advantages related to the re-use of services instead of creating them again: authentication, tracking activities, evaluation, content, etc. LMSs can provide also very useful contextual information. On the other hand, social interaction and collaboration is one of the key issues for modern learning. It has been widely implanted in the e-learning environment and must be moved into the mobile one.

M2Learn project offers several additional advantages that mean an advance in the state of the art of mobile learning development:

- Interrelation between hitherto isolated location technologies (e.g. GPS, RFID, Wi-Fi, etc).
- Interoperability between existing services in e-learning platforms and mobile devices.
- Encapsulation and homogenization of student's contextual information (based on geo-location technologies and other profile data).
- Encapsulation and standardization of services, such as those from e-learning platforms, which provide an added value to the mobile application, e.g. intelligent auto-response, information services, etc.
- Reduction in development time.

This middleware manages several location sensors to provide contextual information about the user. For that reason several sensor controllers (Widgets) have been developed to understand the information provided by sensors (Figure 2).

The system has been designed using open interfaces in order to make easy to add other services (e.g. new location methods such as cell towers or Bluetooth [19]).

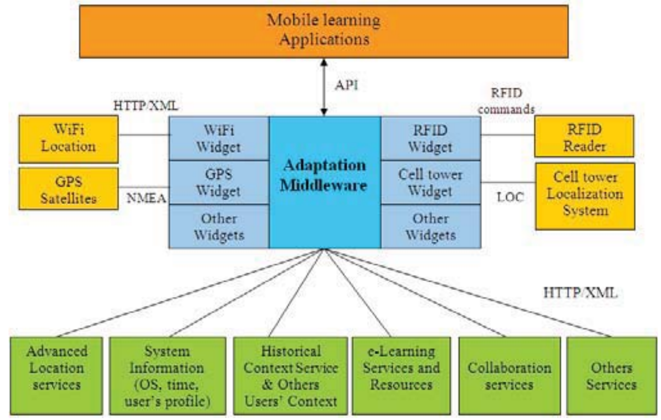

Figure 2. M2Learn Architecture includes location technologiesWidgets to manage e.g. Wi-Fi, GPS or RFID. The Adaptation Middleware integrates several services, some of them from e-learning platforms.

Adaptation layer processes the contextual information provided by widgets to access to other services, e.g. information in a LMS, e-mail, etc [20], to get more contextual information. This is the most important layer in the architecture because offers an interface to top level applications. Mobile applications will not have to interact with sensors or services, and even they will not know from which sensor or service the information comes from. This interface provides all the contextual information and educational services in a transparent way, ensuring the applications will not have to worry about the implementation of lower layers [21].

This architecture considerably simplifies the development of mobile learning applications. For example, users will be able to create a mash-up system using the location information instead of learning how the NMEA protocol of the GPS works; or communicating through a serial port with an RFID controller to read the information from an RFID tag, without understanding the RFID commands or the data organization inside the tag. Or they will create a mobile blog using the services provided by an e-learning platform, but they will not need to create any web service in the language of the platform or understand how its database is structured. They just use the simple interface with information and services provided by the M2Learn Middleware.

At this stage, most of the M2Learn framework has been already developed, although evaluation has not been carried out yet.

VII. Evaluation

Evaluation will be conducted through a pilot using students of a "Professional Expert Course on Mobile Programming". They will develop several applications using the framework. Later, students will complete a questionnaire on user satisfaction and the simplification degree obtained through the framework's use. Evaluation will also include other instruments such as interviews, and development time required.

VIII. CONCLUSIONS

M2Learn project gives a solution to the development problems within the mobile learning field. At the same time, this project promotes the creation of innovative applications and provides the guide for the development of new applications based on the new key factors of mobility in learning: context-awareness, social interaction and integration of e-learning resources.

ACKNOWLEDGMENT

Authors would like to acknowledge to the Spanish Science and Innovation Ministry for the support in the project TIN2008-06083-C03/TSI "s-Labs – Integración de Servicios Abiertos para Laboratorios Remotos y Virtuales Distribuidos" and to the CYTED-508AC0341 "SOLITE- SOFTWARE LIBRE EN TELEFORMACIÓN" project support.

Also authors would like to acknowledge the support of the Project 142788-2008-BG-LEONARDO-LMP mPSS – mobile Performance Support for Vocational Education and Training Project and IPLECS Project – Internet-based Performance-centered Learning Environment for Curricula Support Project ERASMUS 141944-LLP-2008-1-ES-ERASMUS-ECDSP.

Finally authors want to acknowledge the support provided by e-Madrid Project, S2009/TIC-1650, "Investigación y Desarrollo de tecnologías para el e-learning en la Comunidad de Madrid".

***Abstract*—An adaptive ecology m-learning framework applied for national parks is proposed in this paper. The traditional ecology guiding service uses static web page or fixed placard to prompt and provide ecology information to learners. It can not provide adaptive learning anytime and anywhere. Learners can not obtain real-time ecology guiding information and have a good adaptive learning based on learners' knowledge background, and time and location. This study proposes a framework based on Scaffolding Theory that provide learners mobile, dynamic and adaptive ecology guiding service to national parks. Scaffolding Theory is to support learners a knowledge structure for systematic learning. Based on Scaffolding Theory, learners are identified by background (e.g. age and gender), knowledge (e.g. cognitive base, knowledge requirement and learning objective), and interests. Moreover, adaptive and appropriate ecology knowledge based on learners' properties is provided dynamically. Furthermore, learning steps and contents are able to be adjusted flexibly by learners' feedback. In addition, this study also adopt context awareness to provide the learner a suitable route planning for ecology guiding service according to environment factors such as weather condition, time and season, prediction of tide, UV rays and rain rate where learners located. Landscapes and ecology events such as Migratory birds in transit within the route can be actively delivered to learners immediately using interactive applications such as multimedia messages (e.g. text, image and video). Attention and enjoyment of learners can be increased and ecology education purpose of national parks can be achieved.**

Keywords: Context-aware computing, m-learning, Scaffolding Theory

I. INTRODUCTION

A "national park" is an area with a country's special features or cultural or historic significance. The first national park in the world was Yellowstone National Park, established in the US in 1872 and, since then, over 3,800 national parks have been established worldwide [1]. International Union for Conservation of Nature, IUCN, founded in 1948 as the world's first global environmental organization, today is the largest professional global conservation network and a leading authority on the environment and sustainable development. IUCN's mission is to help the world to find pragmatic solutions to our most pressing environment and development challenges [2]. The management of national park gradually escapes the way of "no people in national park" and hopes to find a harmony way between human and wild life. By sustainable interpretation and the ecology tourism with profound experience and respect to nature, visitors can observe and learn from nature and then the sustainable management of national park can be achieved [3-7]. Therefore, ecology education is an important function of national park management. Figuring out how to achieve the purpose of guiding service of national park through new technology assistant and then let more people enjoying, understanding and acting to improve, the natural environment, more often is the intention of this study.

Traditional ecology guiding service of national park has its limitations. For examples, static web guideline and restricted interaction interface. In such ecology guiding service can not provide the learners with adaptive learning. The learner does not gather enough ecology information from the traditional ecology guiding service. If the learner desires more ecology information to help them to find out more interests about the national park, they have to discover by themselves, or ask local ecology interpreter for more information. However, it is difficult to preserve the learner's learning experiences and pass down the oral interpretation.

In this study, the Scaffolding Theory and knowledge creation procedure are proposed to provide an adaptive ecology learning approach for the learners. Meanwhile, new wireless telecommunication technologies and interactive applications are used to construct a framework of adaptive ecology m-learning. In this framework, the learner can obtain ecology route planning and adaptive m-learning according to their inherent properties and extrinsic environmental factors as well as on-line interact with the interpreters by multimedia messages. These precious multimedia messages can be preserved and passed down, and then carry out efficient utilization of ecology information.

II. LITERATURE REVIEW

A. Functions of National Park

Taiwan, Formosa, a little island straddling the Tropic of Cancer, was known for hundreds of years as Formosa. Taiwan covers an area of 36,000 square kilometers, which is 0.025% of the total area on earth. Taiwan has undergone dramatic mountain building periods, interference by ice age, and is thus miraculously endowed with diverse ecosystems that range from the tropical to alpine. Taiwan has a diversified natural environment that includes high mountains and sea waters. Its unique and varied topography and ecosystems give rise to a multitude of compelling and captivating images. The movement for national parks and nature conservation in Taiwan began in 1961 and has since led to the establishment of seven national parks on the island from 1984, including Kenting, Yushan, Yangmingshan, Taroko, Sheipa, Kinmen and Dongsha Marine National Parks. Each national park owns it's unique characteristics and educational indicators. For instance, Kenting National Park, locates at the southern tip of Taiwan, possesses diversified terrain and tropical climate, and breeds rich and fertile vegetation ranging from upland to coast with a full variety of living species [8].

The aim of national parks in Taiwan is to maintain the unique natural environment and biodiversity within the parks through effective operation, management and conservation. Thus national parks should maintain three goals: preservation; education and recreation; and research[9]. In terms of characteristics and management methods, national parks have four functions: 1.To protect the natural environment , 2.To preserve species and native genetics, 3.To furnish national recreation and support the local economy, 4.To promote academic research and environmental education [8].The fourth function highlight that National parks are rich in ecology resources and through offering resources for scientific research and environmental education, they can contribute to people's understanding of the natural and cultural assets of the country. Therefore, national parks are not only providing functionality of travel and leisure, but also playing an important role of environment and ecology education. Thus, National parks should provide educational and recreational activities to develop public awareness of the beauty of nature and establish environmental values.

To sustainably conserve natural resources, national parks shall provide recreational activities such as eco- tourism to minimize environment impact. This could make from interpretation service, a method of national park management, and its role of communication between park administration, park resources and visitors is shown in Figure 1. Through interpretation, visitors can understand the goals of park resources management and obtain a joyful and safe tourism experience of national park. Also, it can create a knowledge-based recreation experience, reduce the visitors' activity impact on environment and improve the visitors understanding to park recreation. The interpretation service in national parks plays an important role in the overall quality of the parks. It can assist in explaining services provided by the parks, the eco-system of the area and management regulations emanating from the national parks' headquarters [10]. Therefore the purpose of interpretation is promoting environmental education and environmental awareness through appreciation, understanding and the new experience. Interpreters can purposefully make influence in how audiences think, feel and behave with respect to things they interpret.

The Food and Agriculture Organization of the United Nations (FAO) divide interpretation resources to three categories: geological feature, biological feature and human history. U.S. National Park Service defines interpretation resources to six categories: landforms of the present, geological history, land communities of plants and animals, aquatic ecosystems, historic and archeological themes, and works of humans. For instance, Kenting National Park, the site of Taiwan's first national park, is a popular tourist destination for locals and foreigners alike. Due to its geographical location, it has a tropical climate, which has resulted in rich natural resources and scenic landscapes, as well as a unique cultural style. It's interpretation resources include not only the six categories as mentioned, but also special sky landscape, such as "mountain winds" [11]. Therefore, it's important to provide efficient and suitable self-guiding interpretation information to different visitors in order to lead visitors into profound experience of Kenting's unique resources. How can interpretation really make a difference? This paper introduce some mechanisms, such as scaffolding and context awareness, try to illustrate a adaptive system that fit visitors various characteristic, diverse park resources and real-time environment changes in order to provide an optimized interpretation service.

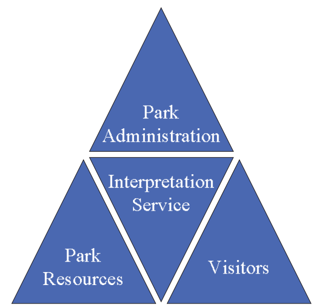

Figure 1 Relation between park administration, park resources, visitors and interpretation service

B. Scaffolding Theory

Scaffolding Theory was first introduced in the late 1950s by Jerome Bruner, used the term to describe young children's oral language acquisition and helped by their parents when they first start learning to speak, young children are provided with instinctive structures to learn a language. Wood, Bruner, and Ross' (1976) idea of scaffolding also parallels Vygotsky's work [12]. The term "scaffolding" was developed as a metaphor to describe the type of assistance offered by a teacher or peer to support learning. In the process of scaffolding, the teacher helps learner master a task or concept that learner is initially unable to grasp independently. The teacher offers assistance with only those skills that are beyond the learner's capability. The most significance is to allow the learner to complete as much of the task as possible, unassisted. The teacher only attempts to help learner with tasks that are just beyond his current capability. Learner errors are expected, but, with teacher feedback and prompting, learner is able to achieve the task or goal. When learner takes responsibility for or masters the task, the teacher begins the process of "fading", or the gradual removal of the scaffolding, which allows learner to work independently.

Scaffolding Theory proposes that teachers will act as assisting roles in the learning process to provide a temporary support (scaffold) in order to assist learners to construct self learning. Scaffolding Theory includes two main procedures, which are to setup the scaffold and phased removal of scaffold. The scaffold can be a teaching strategy or a teaching tool; it can be provision of clues, a reminder, encouragement, solution, providing an example or assistance through information technology. Meanwhile the learning responsibility is gradually shifted from teachers to learners and eventually learners can lead their learning [13]. That is to say, learners can construct knowledge of their own and develop themselves to be independent learners. Hwang, Lee and Chen's study [10] uses the interpretation service of five National Parks in Taiwan as an empirical study to create a relationship model for tourists' involvement, interpretation service quality and place attachment. Their results show tourists' involvement has a positive significant effect on perceived interpretation service quality, as does place attachment. Also, there is an indirect positive significant effect from place attachment to interpretation satisfaction. Therefore, self-learning with scaffold support is a feasible method to improve the satisfaction and knowledge transfer of interpretation of national park.

C. Adaptive Knowledge

In human-computer interaction, user interface events and frequencies can be recorded and organized into episodes. By computing episode frequencies and implication relations, we can automatically derive application-specific episode associations and therefore enable an application interface to adaptively provide just-in-time assistance to a user. Liu, Wong and Hui (2003) identify five issues related to designing an adaptive user interface: interaction tracking, episodes identification, user pattern recognition, user intention prediction, and user profile update. To adapt to different users' needs, the interface can personalize its assistance by learning user profiles or properties. For example, by detecting and analyzing users' behavior patterns in using Microsoft Word, the interface can automatically assist users in several Word tasks [14]. Personalized support for learners becomes even more important, when e-learning takes place in open and dynamic learning and information networks. Dolog, Henze, Nejdl and Sintek [15] proposed a service-based architecture for establishing personalized adaptive e-Learning systems with well-established personalization functionality, and open, dynamic learning repository networks, where personalization functionality is provided by various web-services. Computer can act as the supporter of knowledge construction by providing customized learning content which learners can Restructuring and construct to new knowledge and meaningful learning. Computer assist learning combined with integrated hypermedia interface can reveal information in nonlinear way and learners can reading the materials in their favorite order instead of in proper sequence. However, hypermedia system didn't present knowledge content in efficient linkage and ignore the relationships of knowledge. Some Web sites are intricate but not intelligent enough; while Web navigation is dynamic and idiosyncratic, all too often Web sites are fossils cast in HTML. Researches indicated the negative of traditional e-learning, such as : 1. Beginners lost the learning direction which cause the learning frustration , 2. Aimless browsing which cannot be construct to a comprehensive knowledge structure, 3. Overloading of information, 4. Weak relationship of information and hard to integrate the knowledge conception, etc [15-18]. Learners can not construct their own knowledge bases by making meaningful connections among the ideas as they perceive.

Therefore, adaptive web-based systems attempt to fight the "one size fits all" approach to e-learning. Farrell , Liburd and Thomas [19] describes one solution to the problem of how to select sequence, and link Web resources into a coherent, focused organization for instruction that addresses a user's immediate and focused learning need. Their Custom Course System consists of a Search Engine, the Dynamic Assembly Engine, and Course Player. A system is described that automatically generates individualized learning paths from a repository of XML Web resources. Each Web resource has an XML Learning Object Metadata (LOM) description consisting of General, Educational, and Classification metadata. Dynamic assembly of these learning objects is based on the relative match of the learning object content and metadata to the learner's needs, preferences, context, and constraints. Learning objects are connected into coherent paths based on their LOM topic classifications and the proximity of these topics in a Resource Description Framework (RDF) graph [19]. Brusilovsky [20] reviewed the adaptive functions, such as: 1.Adaptive textbooks created with such systems as InterBook, NetCoach or ActiveMath can help students learn faster and better, 2. Adaptive quizzes developed with SIETTE evaluate student knowledge more precisely with fewer questions, 3. Intelligent solution analyzers can diagnose solutions of educational exercises and help the student to resolve problems, 4. Adaptive class monitoring systems give the teachers a much better chance to notice when students are lagging behind, 5. Adaptive collaboration support systems can enhance the power of collaborative learning. He therefore presents an architecture for adaptive e-learning based on distributed reusable intelligent learning activities [20].

When interpreters present strongly relevant themes, their audiences are provoked to think in theme-related ways. Theme-related thinking impacts beliefs about the interpreter's topic, which, in turn, can impact attitudes and ways of behaving that are consistent with those beliefs [21]. The potential benefits include improved visitor management, local economic and environmental gains and fuller community involvement. However, there are several pitfalls of linking interpretation and sustainable tourism should be considered; those are the dangers of over-interpretation, intrusion, creating 'quaint' tourist landscapes, and those of elitism [22]. Therefore, the adaptive knowledge mechanism in this study is to provide learners adaptive guiding materials (subjects and levels) real-time according to the context (learner and environment) and the previous feedback records. Those adaptive materials include: 1. Personalized knowledge concept structure, 2. Relative linkage and resources, 3. Multimedia and virtual reality materials, 4. Dynamic and expandable nonlinear leaning support, 5. Interpreter's guiding and other learners' collaboration. Learners and interpreters can form a learning scaffold and add knowledge to empty grid of their knowledge scaffold by Play Jigsaw and Fill-in-the-Structure, and then complete their knowledge concept map. The adaptive knowledge mechanism based on Scaffolding can provide visitors suitable dynamic guiding materials according to their needs and interests in order to enhance their attitude to nature and self-learning.

D. Contex- Aware Computing

Context is an implicit situation information. For example, in the natural environment, weather is one of implicit situation information of context. The weather information of context is such as temperature, humidity and rain rate. If the information of context can be aware of change and treated with computing techniques, it should be to make interacting with computers easier. For example, if the sensor of air conditioner is aware of indoor temperature rising, the processor should inform the compressor to speed up the operation and release more cool air to lower the indoor temperature. Therefore, understanding how context can be used will enable designers to choose what context to be used in their applications, and help designers to determine what context-aware behaviors to be supported in their applications.

Most people tacitly understand what context is, but they find that it is hard to illustrate clearly. Brown *et al*. [23] define context as location, identities of the people around the user, the time of day, season, temperature, etc. Anind and Gregory [24] define context as: *Context is any information that can be used to characterize the situation of an entity. An entity is a person, place or object that is considered relevant to the interaction between a user and an application, including the user and applications themselves*. This definition makes context-aware easier for an application designer to enumerate the context for a given application scenario. If a part of information of context-aware is used to characterize the situation of a participant in an interaction, then that information is context. For example, if the learner's location can be used to characterize the learner's situation, then the learner's location is context.

Schilit *et al*. [25] claim that the important aspects of context are: where you are, who you are with, and what resources are nearby. They define context to be the constantly changing execution environment. They include the following pieces of the environment:

- *Computing environment* available processors, devices accessible for user input and display, network capacity, connectivity, and costs of computing.
- *User environment* location, collection of nearby people, and social situation.
- *Physical environment* lighting and noise level.

A categorization of context types will help application designers to find out the pieces of context that will be useful in their application. There are certain types of context are: location, identity, activity and time[24]. The location is meaning that the learners' physical position presented by longitude and latitude. The identity represents the learner's properties such as age, gender, attitude, preference, knowledge-based and learning period. The activity includes an environment where the learner located, and events what occurrences happened in that environment. The time is the local time where the learner located.

Context-aware computing was first discussed by Schilit and Theimer [26] in 1994. Context-aware computing is similar to an application that "adapts according to its location of use, the collection of nearby people and objects, as well as changes to those objects over time". The first definition of context-aware application also given by Schilit and Theimer [26] restricted the definition from applications that are simply informed about context to applications that adapt themselves to context. Hull *et al*. [27] and Pascoe *et al*. [28-30] define context-aware computing to be the ability of computing devices to detect and sense, interpret and respond to aspects of a user's local environment and the computing devices themselves. Dey *et al*. [31] begin to introduce the notion of adaptation by defining context-awareness to be worked leading to the automation of an application system based on knowledge of the learner's context. Ryan [32] defines context-aware application to be applications that monitor input from environmental sensors and allow users to select from a range of physical and logical contexts according to their current interests or activities. Brown [33] defines context-aware applications as applications that automatically provide information and/or take actions according to the learner's present context as detected by sensors. Anind and Gregory [24] define context-aware as: *A system is context-aware if it uses context to provide relevant information and/or services to the user, where relevancy depends on the user's task*. This definition is more specific adapting to context and requiring that an application's behavior be modified for it to be considered context-aware.

E. Interactive Applications

In computer science, the term of interactive is referred to an application or software which receives and responses the input from humans. For example, the learner inputs multimedia messages or commands to an interactive application, then an interactive application makes an adaptive response to the learner. The interactive application, such as Web 2.0, has already been a trend of next generation application interface. The term of Web 2.0 is commonly associated with web applications which facilitate interactive information sharing, interoperability, user-centered design and collaboration on the World Wide Web [34].

The term of "Web 2.0" was created by Darcy DiNucci in 1999. In her article "Fragmented Future[35]", she writes:

> *The Web we know now, which loads into a window on our computer screens in essentially static screenfuls, is an embryo of the Web as we will know it in not so many years.*
>
> *The first glimmerings of Web 2.0 are now beginning to appear, and we can start to see just how that embryo might develop. The first stages of mitosis have begun, and the cells of the organism have begun to differentiate. Now we can see that the defining thing about the Web won't be any visible characteristic at all. The Web will be identified only by its underlying DNA structure—TCP/IP (the protocol that controls how files are transported across the Internet), HTTP (the protocol that rules the communication between computers on the Web), and*

URLs (a method for identifying files). As those technologies define its workings, the Web's outward form—the hardware and software we use to view it—will multiply. On the front end, the Web will fragment into countless permutations with different looks, behaviors, uses, and hardware hosts. The Web will be understood, not as screenfuls of text and graphics but as a transport mechanism, the ether through which interactivity happens. It will still appear on your computer screen, transformed by the video and other dynamic media made possible by the speedy connection technologies now coming down the pike. It will also appear, in different guises, on your TV set (interactive content woven seamlessly into programming and commercials), your car dashboard (maps, yellow pages, and other traveler info), your cell phone (news, stock quotes, flight info), hand-held game machines (linking players with competitors over the Net), maybe even your microwave oven (automatically finding cooking times for the latest products).

Web 2.0 is the network as platform, spanning all connected devices; Web 2.0 applications are those that make the most of the intrinsic advantages of that platform: delivering software as a continually-updated service that gets better the more people use it, consuming and remixing data from multiple sources, including individual users, while providing their own data and services in a form that allows remixing by others, creating network effects through an "architecture of participation," and going beyond the page metaphor of Web 1.0 to deliver rich user experiences [36].

F. Wireless telecommunication Technologies

The evolution of communication technology has been migrated gradually from wired to wireless, from narrowband to broadband, and from desktop to handheld. Digital information and multimedia can be obtained anytime and anywhere with available portable devices. The portable devices are such as Personal Digital Assistant (PDA), laptop, smart phone and netbook. These devices may surf internet using different wireless communication technologies. Several wireless telecommunication technologies are popular in the worldwide, such as HSPA (High-Speed Packet Access) and WiMAX (Worldwide interoperability for Microwave Access). HSPA includes two technologies: High-Speed Download Packet Access (HSDPA) and High-Speed Uplink Packet Access. HSPA is developed by 3GPP (Third Generation Partnership Project). It extends and improves existing WCDMA performance in packet data transmission rate. An advanced standard, Evolved HSPA, all called HSPA+, is soon to be release. HSPA increases packet data rates up to 14.4Mbps in the downlink and 5.8Mbps in the uplink, while HSPA+ further improves the performance of packet data rates up to 42Mbps in the downlink and 11Mbps in the uplink. The other popular wireless telecommunication technology is WiMAX based on IEEE 802.16 standard. It includes two main standards: 802.16-2004 is also called 802.16d referred to as "fixed WiMAX" and 802.16-2005 is also called 802.16e referred to as "mobile WiMAX". WiMAX is an OFDM-based physical layer providing packet data rates up to 144Mbps in the downlink and 35Mbps in the uplink. Both HSPA and WiMAX can provide broadband transmission to satisfy the bandwidth requirement of multimedia.

III. Framework

In this study, a framework of adaptive ecology m-learning for national park is proposed. This framework is also based on Scaffolding Theory to provide an adaptive m-learning for learners.

A. Framework

In Figure 2, the learners can use laptop, netbook, PDA or any available devices which support wireless telecommunication technologies such as HSAP or WiMAX. These devices assist the learner to access to operators' base stations which provide radio signaling and connect to internet. Once the learners connect to internet, they can obtain adaptive content of ecology guiding information and interact with the interpreters via the scaffolding ecology m-learning system. The adaptive learning application server generates adaptive content according to the learner's inherent properties and extrinsic environment factors. In Figure 3 illustrates the learner's inherent properties consisting of age, gender, preference, knowledge-based and attitude, and the extrinsic environment factors consisting of location, time, weather, season and event. The learner's learning period means how much time the learner would like to spend on ecology learning. The learner can learn the ecology knowledge independently with the scaffolding ecology m-learning system, or learn the ecology knowledge collaboratively with other learners and interpreters through the scaffolding ecology m-learning system.

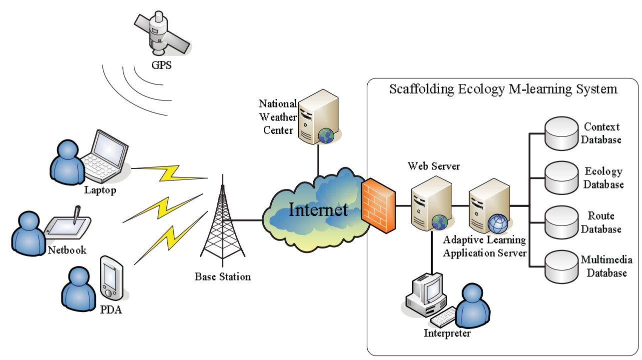

Figure 2 Framework

In this framework, four databases are deployed within the scaffolding ecology m-learning system. The Entity-Relationship Diagram (ERD) is shown in Figure 4. The context database stores the learner's inherent properties. The adaptive learning application server generates adaptive route plans based on context database and weather information retrieved from national weather center. The learner selects one of route plans, or asks the on-line interpreter to obtain a route plan depending on his/her interests. The ecology database stores related ecology information such as coastal and upland vegetations, animals, insects and marine creatures, etc. It can provide abundant resources of national park for the learners, or provide adaptive content for the learners based on their locations. The route database stores various paths for ecology guiding, travel and leisure. The route planning is based on the learner's properties and present environment factors to provide a suitable route planning for the learners. The multimedia database stores interactive messages such as text, audio, video and image from the learners or interpreters. For example, the learner records a piece of insect video, but he/she does not know what the insect is. He/She can upload the captured video to the multimedia database through the Web Server with Web 2.0 interactive application, and ask on-line interpreter about his/her question about unknown insect. The on-line interpreter searches the ecology database and responses the answer to the learner by multimedia messages. Therefore, in this framework not only provides adaptive content and suitable route planning, but also implement an interactive application between the learners and the interpreters.

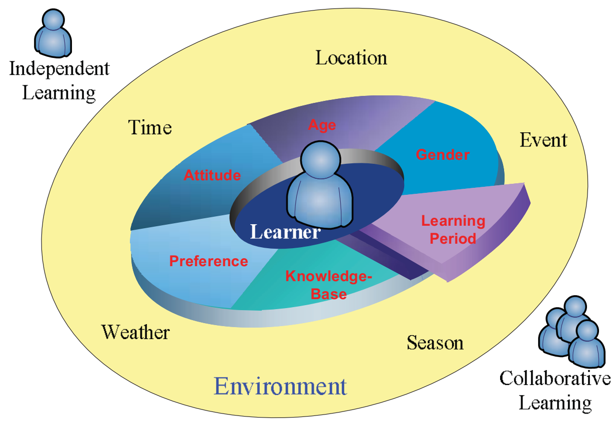

Figure 3 Learning context

The multimedia messages between the learners and the interpreters can be stored in multimedia database. These messages possess precious knowledge and experiences, and should be preserved. For example, if the learner records a piece of precious insect video, he/she can upload this video to the multimedia database through interactive application and share to other learners. Moreover, these messages can be preserved, shared and passed down through this framework.

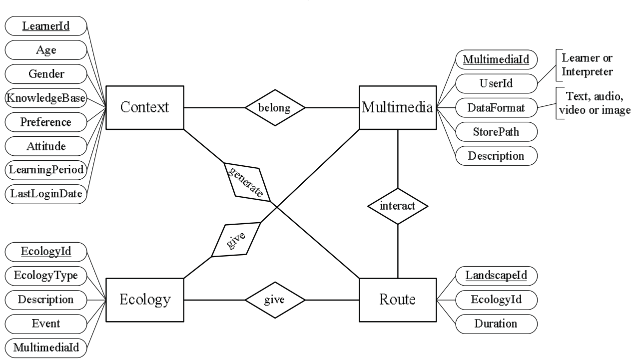

Figure 4 Entity-Relationship Diagram

B. *A Scaffolding m-learning model with Knowledge Creation process*

In Figure 5 illustrates that through "context check", "adaptive materials" and "knowledge construction" mechanisms based on Scaffolding Theory, learners can achieve self-guided leaning.

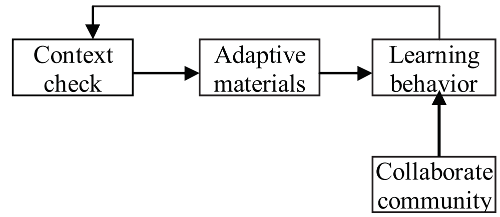

Figure 5 scaffolding m-learning model

Hogan and Pressley (1997) summarized the literature to identify eight essential elements of scaffold instruction that teachers can use as general guidelines as followings. Note that these elements don't have to occur in the sequence listed.

- Pre-engagement with the student (learner) and the curriculum
- Establish a shared goal
- Actively diagnose student needs and understandings
- Provide tailored assistance
- Maintain pursuit of the goal
- Give feedback
- Control for frustration and risk
- Assist internalization, independence, and generalization to other contexts

In order to assist learners to put what they learn into practice, this study makes use of further core knowledge management steps which are: creation, categorization, storage, sharing, updating and value [13]. In this study the listed above elements are applied to construct a scaffolding M-learning model with knowledge creation process, as shown in Figure 6.

Such a scaffolding m-learning model with knowledge creation process, the learners can understand more about the structure, connections, and combination of knowledge in ecology learning. The sharing and delivery quality of interpreter knowledge is also improved.

C. *Relative Techniques*

1) *Interactive Mechanism*

In this study, the interactive mechanism is an important feature in this framework. In Figure 7, a content delivery process is proposed with the interactive mechanism. The learner inputs personal properties, the system retrieves the environment factors from national weather center to generate an adaptive ecology content and/or provide a suitable route planning to the learner. It is a basic concept of interactive mechanism. An advanced interactive mechanism has to provide feedback function to the learner. It is important because the learner obtains desired adaptive content, the learner's knowledge can be improved, or called evaluated. Through feedback function, the learner's experiences can be fed back to the system, preserved to the database, and then passed down to other learners.

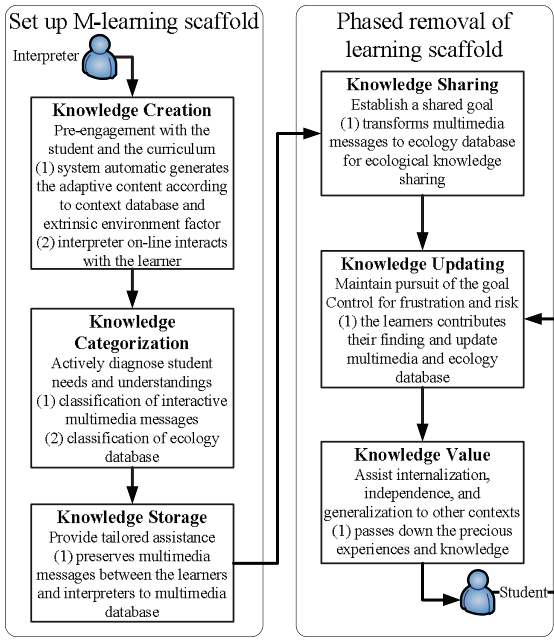

Figure 6 Scaffolding m-learning model with knowledge creation process

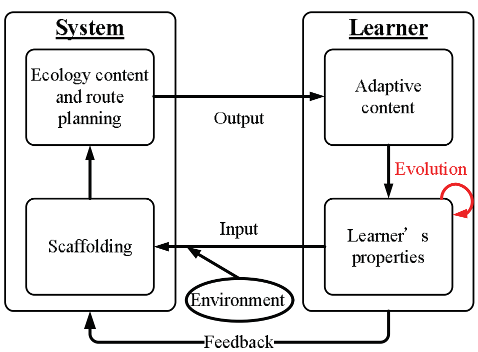

Figure 7 Content delivery process

2) Context-Aware Computing

The basic representation of how the context-awareness system functions as part of the content delivery system is illustrated in Figure 8. A learner with a mobile device is connected to adaptive learning application server, which in turn is linked to the context engine and database. The mobile device passes context state (input), learner context and environment context, obtained from national weather center, user input, and user profile to the context database which then compares this metadata to the content metadata provided by the content database and returns a set of content recommendations. These recommendations are used by the delivery system to determine which content to deliver to the learner, which is packaged as learning object (output), including ecology knowledge, route planning and peers experience.

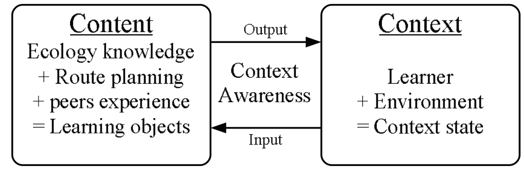

Figure 8 Context-aware schema

The primary purpose of adaptive learning application server is to perform intelligent matching between context metadata (i.e. input, metadata on learner and their setting, real-time environment factors) and content metadata (i.e. output, metadata on ecology knowledge, route planning, interpreter and other learners experience, services and options). By looking for content metadata that matches the metadata of the current context, the system can make recommendations about what content is appropriate. There are two crucial prerequisites for the successful completion of this process. First, available content must be appropriately marked up with a suitable metadata schema. Second, the system must have access to relevant metadata about the context, i.e. the learner's inherent properties and settings and extrinsic environment factors. The ordered list of ranked items of content is passed to content delivery subsystem for use in determining exactly what content should be made available to the user. In this way, the context-awareness system is intended only to make ranked recommendation route list to the system and to the user.

We consider this informal definition of context-awareness as a reference for our work. The LearnerProfile is a computer representation to structure a Learner's inherent properties that contains four components (PhysiologicalFactor, MotiveFactor, Cognition and Orientation).

[LeanerProfile

[PhysiologicalFactor [Age, Gender]]

[MotiveFactor [Attitude, Preference]]

[Cognition [Perceptual knowledge-base, Rational knowledge-base, Misunderstandings]]

[Orientation [Learning period, Problem, Goal]]

]

Any context-aware application or service depends on being able to obtain contextual information from the user's environment or setting. For this system, we anticipate relying on both automated input from sensors and other software and service such as weather server, and input from the user themselves about their state and the state of the world. Some possibilities for automated input include the use of location data derived from tracking a device within a wireless Local Area Network (LAN), GPS, and Bluetooth technology. Users also create their own context, and we anticipate the use of contextual metadata relating to both the learner status and learner profile above [37]. It has formed an important part of research into the design of intelligent interpretation systems.

3) Route Planning Approach

In this study, a route planning approach is proposed in this framework as shown in Figure 9. The route planning process requires two inputs: the learner's properties and the environment factors. The route planning process can be implemented by applying clustering algorithms to generate a suitable route plan for the learner. Clustering analysis or clustering is the process of classifying objects into subsets that have meaning in the context of a particular problem. It is a common technique for statistical data analysis used in many fields, such as machine learning, data mining, pattern recognition and image classification. Through the route planning approach based on clustering algorithm the output route plan provides a suggestion for the learners and assists the learners to enjoy the ecology learning.

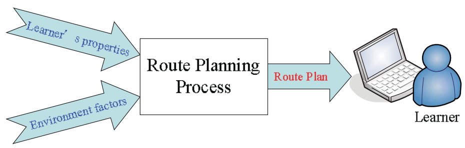

Figure 9 Route planning approach

D. Examples

In this study, all of related ecology guiding information and interactive application can be delivered to learners' portable devices such as netbook, notebook and PDA through mobile telecommunication networks such as HSPA and WiMAX. We assume that the learner plans to have a ecology learning with a netbook which equipped HSPA data card. We provide two scenarios for example.

Scenario 1: If the learner is a new user, the learner has to register his/her properties first. Then the system, the scaffolding ecology m-learning system, will generate a suitable route planning according to his/her properties and current environment factors, which is a good assistance for beginners to find the targets of nature observation. During the ecology learning, if the learner finds out a unknown organism, for example the coastal vegetation community, the learner can on-line requests an assistance and interacts with the interpreter. The learner can make photos for that unknown organism and submits these photos to the interpreter, then the interpreter will search a solution from ecology database and responses the explanation to the learner.

Scenario 2: The learner has registered to the system before and used this system to have an ecology learning. Therefore, the learner's properties has been stored in context database. The system allows the learner to update his/her newest properties such as age, preference or knowledge-base. When the learner uses netbook to connect with internet via HSPA or WiMAX data card and logins this system again, the system will provide a suitable route planning according to learner's properties and current environment factors such location, time and weather, etc. During the ecology learning, the system not only real-time provides ecology information by text, photos or videos, but also informs the learner to pay attention for changing of ecology environment. For example, during September, an amazing number of Chinese goshawks will pass through Hengchun Peninsula, or in October, Gray-faced buzzards, following Chinese goshawks' southbound migrating track, continue to pass through Hengchun Peninsula. The learner can on-line interact with the interpreters by text, photo, or video when events occurred on the way of route. Through this system the learner can learn independently. When the learner finishes his/her ecology learning and gathers new ecology knowledge, he/she can maintain his/her property of knowledge-base in context database. Meanwhile, by using this system the learner can share his/her precious experiences and knowledge of ecology learning to other learners. Furthermore, interactive information of ecology can be stored on multimedia database, shared to learners, and transferred experiences to knowledge of ecology education.

IV. Conclusion and Future Work

In this study an approach is proposed to take scaffolding and context awareness into account for the area of ecology education and learning, and telecommunication technologies are used to connect between the learners, the interpreters and the scaffolding ecology m-learning system through internet. This framework has shown how adaptive functionalities can be embedded into mobile interpretation services for retrieving ecology resources and suitable ecology route plans to enjoy the benefits of ecology guiding service. The interactive messages between the learners and the interpreters through knowledge creation procedure can be preserved, shared and passed down. Eventually, the learners obtain ability of how to learn independently and how to share their precious experiences.

Based on this framework, the integrations of ecology guiding service and user interface and implementations of interactive application, location-based service and multimedia messages are considered. The pilot run will be built up in future work.

***Abstract*—This paper introduces the concept of a Wi-Fi tag that can be used as an extension of the iLab remote laboratory framework. A Wi-Fi tag has been built by Tag4M of Austin, TX, USA, with the purpose of connecting sensors to the Internet where data is displayed using Web Pages that are posted and can be accessed from anywhere in the world. The Tag4M Wi-Fi tag is tiny and low cost works on battery power, and therefore it is very suitable for student experimentation as an extension of the remote laboratory framework. The tag allows remote students logged in the iLab framework to execute local or home based experiments, and by that brings more hands on capability to the framework. The paper introduces the Tag4M tag, the iLab framework, gives an example of using the iLab framework with the NI ELVIS station, and shows how this type of experimentation can be enriched using the tag to introduce local experimentation where remote students can perform hands-on sensor measurements, create their own web page instruments and also post their web page instruments into the general framework for other remote students to use.**

Keywords - Wi-Fi tag; iLab; Web Page Instrument

I. INTRODUCTION

The concept of Computer Based Instrumentation relies on the continuous advancement of PC technology – processor, memory, etc -, improved resolution and speed of ADCs and DACs, and easiness of programming with LabVIEW, the graphical programming environment used by scientists and engineers to build computer based instruments. The entire idea of computer based instrumentation has been built around LabVIEW. Plug-in computer boards, PXI, cRIO, cDAQ and USB devices have been built all with LabVIEW driver support in order to make the idea of computer based instrument viable. Traditional BOX Instrument based setups have been replaced or upgraded, where suitable, with computer based instruments built with LabVIEW.

Figure 1 The Tag4M Wi-Fi Tag

The concept of Virtual Instrumentation is larger than that of computer based instrumentation. A Virtual Instrument is an instrument that leverages **off-the-shelf technologies** to implement its capabilities for measurement, display, storage and communication. Computer based instruments are limited by the strength of one computer and LabVIEW running on this computer.

This paper defines a new class of virtual instrument which we named WEB Page Instrument or WEB Instrument. WEB Instruments move the concept of virtual instrumentation beyond computer based, beyond LabVIEW and into the Internet space where instruments are built, and shared across the world using web pages. WEB Instruments are built on the power of the Internet network (vs that of a single PC). WEB instruments need Wi-Fi tags (Fig.1) that connect sensors to the internet. Wi-Fi tags benefit from the latest advancements in RFID technology, the improved resolution and speed of ADCs and DACs, components miniaturization and low power requirements. WEB instruments also need the network infrastructure, the Internet, web pages, more advanced web page technology that has not been invented yet, Google search engine, etc, mainstream network technologies. Sensors connected to Wi-Fi tags send data to Access Points that push data further into the Internet to web pages, widgets and other web based applications that reside at IP addresses all over the world. WEB Instruments change the way we acquire data, control and share measurements. WEB Instruments will change the way we teach instrumentation.

II. THE SYSTEM

We have created a tag that links the physical world of measurements with the Internet. Tag4M is an active ultra-low power Wi-Fi tag (Fig.2) that has measurement capabilities. Besides a Wi-Fi radio, the tag contains minimal circuitry for signal conditioning front end to its 14-bit ADC, I/O connectors for signal wiring, and a battery holder. The tag is capable of running for years on a 3V battery if it is programmed with sleep times in the range of 100 seconds.

Figure 2 Wi-Fi Tag

The tag, if connected to sensors will perform two functions:

a) **Measurement.** The tag converts signals coming from sensor(s) into digital values. Tag4M tags are capable of measuring analog signals in 0-10V and 0-0.4V with 14-bit precision, 4-20mA current signals, and digital lines.

b) **Communication** (Wi-Fi). The tag is continuously looking for an Access Point(AP) who it can associate with. If at boot-up or wake-up time the tag finds an AP, then it will send data and get commands to/from this AP. The AP will further send data to the Internet. Somewhere on the Internet network there will be one (or several) computer that is hosting a web page which presents tag data for other client computers to access. The WEB Page is the instrument (Fig.3). Users of the web instrument will connect tags to their local sensors and run the web instrument for local data acquisition, processing, storage and communication.

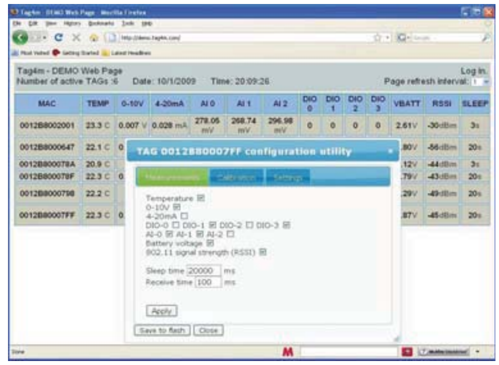

Figure 3 WEB Instrument Page with Configuration Panel

WEB Instruments can be shared in the classroom and school laboratory. In distance learning environments the web infrastructure for class material is located on a server. This infrastructure also includes the lab associated web page instruments. While measurements for this lab are done locally using Wi-Fi tags connected to sensors, the results are posted remotely by web pages inside the lab web infrastructure. This is something new, a new facility of the lab web infrastructure where students can perform local lab related measurements using Wi-Fi tags as hardware extensions of the lab web infrastructure.

III. WEB INSTRUMENTS IN WEB BASED TRAINING WBT

Distance education and traditional face-to-face classroom course delivery are not mutually exclusive. Each has positive aspects that can be maximized and negative aspects that can be minimized by combining them, an approach known as blended learning. Student learning is enhanced when technology is made available that allows for a live learning environment and remote labs are an ideal delivery method for distance education curriculum. The addition of Wi-Fi tags that connect sensors to web pages brings a new and powerful tool to remote labs. Instruments are supplied as web pages hosted by Internet services inside the actual Remote Laboratories (Fig.4).

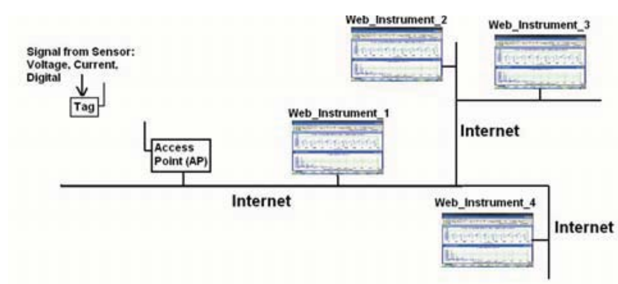

Figure 4 WEB Page Instruments

Academic departments seeking to reach students via distance education course offerings find that some on-line curricula require a traditional hands-on lab model for student evaluation and assessment. The authors solve the problem of providing distance education curriculum and supporting instruction lab components by using a low-cost remote lab based on WEB Instruments.

Web Based Training WBT as an E-learning technology or method is characterized by followings:

- Online computer education
- Education supported by web technologies
- Teaching synchronous and asynchronous online courses
- Studying materials that are mostly available via web browser
- Studying materials that are located anywhere in the world (on the web)
- Opportunities to work inside the virtual classroom

Researchers around the world are thinking about the possibility of enriching the idea of Web Based Training with some elements of local experimentation where students acquire and use small low-cost devices to complete so called "in home" experiments that are part of the weblab topology, described and scheduled inside the Web Based Training labs.

The Internet portal creates an entry gate to the world of information related to a certain subject. The technology of thin-client ("thin-client/server computing") is a model where applications are accessible, administrated and operated fully on the server's side. This technology provides advantages of better administration, access, performance and safety, which help reduce requirements imposed on property owners. But you do not want technology, even the one that is very good and very well administered, to eliminate creative thinking and hands on experimentation, the out-of-the-box element.

Remote laboratories can be **real** or **virtual**. The real model is based on getting information from real experiments, with visualization, providing information in the form of numbers and graphs. The virtual model is based on simulations with the help of software applications like Matlab's server / Simulink, or National Instruments' LabVIEW. Both models can now benefit for a complementary tool, the very low-cost Wi-Fi tag that can be used by the "educational client" in an "at home" type of environment for doing real experiments.

IV. IV iLAB INTRODUCTION

Our team has been involved in the implementation of MITs iLAB technology in Europe. The idea is to offer a standardized Remote Laboratory technology that is adapted and completed with local expertise in order to increase its efficiency.

There are many approaches to the design of Internet-based remote laboratories for education. Early systems required specialized platform-dependent software running at the client computer. Later approaches moved towards browser-enabled technologies for the client, including Java applets, static and dynamic HTML pages, and CGI scripts. HTML-based solutions often result in thin clients with little processing abilities and rely heavily on server-side technologies such as CGI that tightly couple client and server development.

The iLab architecture provides a framework for lab development and deployment. This approach differs from sockets-based solutions by hiding many of the details involved in network communication from the developer.

This was implemented using web-service technology, which provides an object-oriented interface to client/server communication based on traditional method calls that take place over HTTP. In addition, the iLab architecture decouples laboratory-specific operations related to running experiments from the more generic administrative tasks of user authentication, user authorization, group management, and results-storage functionality. The iLab architecture extends the client/server weblab topology by incorporating an additional third tier: the Service Broker, as shown in Fig.5. The Service Broker handles all administrative tasks, thus freeing the server machine (and its developers) from having to implement custom administrative solutions for each different weblab.

However, today experiments have become more and more complex. As a result, the demand for ever more specialized and expensive equipment has increased. Presently, only some large research institutions and perhaps some universities can afford such equipment, and even these more fortunate institutions can only partially have what they need. Remote Laboratories present a viable solution that permit greater access to resources, following ongoing changes in learner interactions online curriculum facilities.

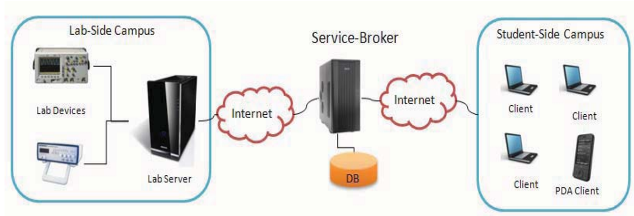

Figure 5 iLAB Shared Arhitecture

Meanwhile, modern learning theories, including constructivism, have emerged and have been employed more and more in Higher Education teaching practices. This trend has significantly modified the traditional learning process model. Students are now expected themselves to build their own interactions with learning experiences as well as materials and different actors that they have to interact with as they complete their curriculum.

In the field of Engineering Education, this suggests a stronger contribution of hands-on approaches in the process of quality of learning. Hands-on approaches are a support of several pedagogical objectives:

- *to compare theory and practice,*
- *to learn how to employ specific tools and devices,*
- *to face real-world situations,*
- *to interact with peers in circumstances that require problem solving skills developed through close*

collaboration, which is characterized by initiative, creativity, etc.

This also emphasizes the need to use experiments within online learning activities, in part, because these online activities permit students to interact multi-culturally across national boundaries, reflecting present and future business, academic and scientific interaction.

V. iLAB AND TAG4M

If we access the web page of the iLAB ServiceBroker and log-in as Guest (http://ilab.mit.edu/ServiceBroker), we will connect to the iLAB labs (Fig.6).

From the list, we choose to connect to the ELVIS laboratory. Using this laboratory as an example, we would like to show how we can add more functionality to the iLab system by having a student behind the iLab client use the Tag4M tag for local experimentation.

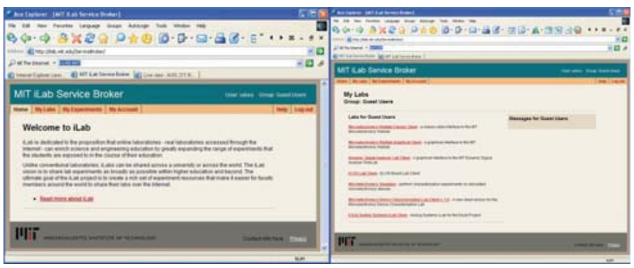

Figure 6 MIT iLab Guest access

Students may be located anywhere and have access to Internet connection so they can log in the ELVIS laboratory (Fig.7) and do some laboratory experimentation as implemented by the iLab platform.

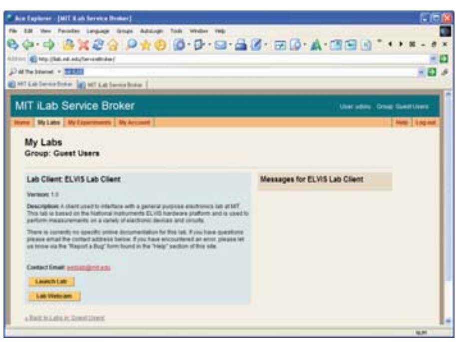

Figure 7 ELVIS Lab Client

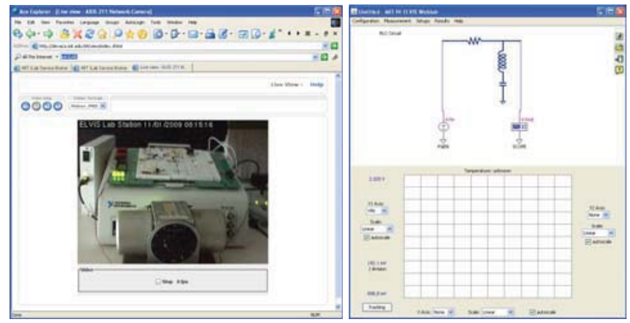
Here, inside the iLab platform we see two types of student user experience:

a) Completely remote experimentation user experience, or

b) Combination between remote and local user experience.

In the first case, the completely remote scenario, the student will simply log into the ELVIS lab and:

- Read the laboratory instruction
- Eventually enter the web site of National Instruments and read about NI ELVIS
- Have a passive look at the experiment using a web-cam (Fig.8a) and launch the experiment (Fig.8b)
- Configure the lab and remotely perform the LRC experiments (Fig.9)



(a) (b)

Figure 8 ELVIS experiment:
(a) web-cam image (b) RLC experiment

In the second case, there is an element of local experimentation inside the iLab content, a web page that can interact with the student and ask him to do some preliminary LOCAL experimentation using a WEB Page Instrument that has been build around the TAG4M tag and which is posted inside the iLab framework.

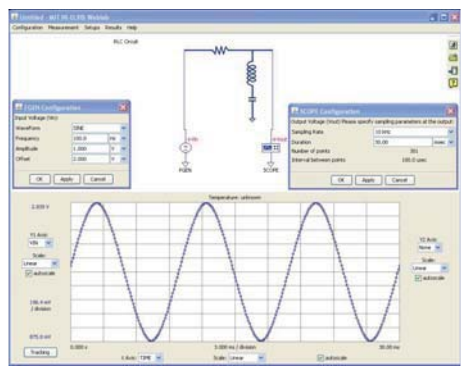


Figure 9 The RLC experiment: configured and executed

This web page instrument allows our student:

- To better understand the laboratory purpose
- To perform some “direct hands-on experiment”

The web page instrument has also a testing function where it will verify student’s knowledge and ability to perform some related home/local based experiment and if the test is passed, will offer the student permission to execute the next steps inside the iLab laboratory.

Referring to Fig.10 below, we give an example of such direct interaction between iLab’s Web Page Instrument and a remote student:

- Ask the student to implement a potential divider

- Fix the values for the resistors (R1 and R2)
- Select a fixed potential (for example the battery potential is measured using the Wi-Fi tag and the reading is sent via an Access Point into the Internet and to the web page instrument which is part of the iLab framework)
- If the WEB Instrument passes the iLab page a correct value then the student is allowed continue the experiment inside the iLab framework.

Using the Wi-F tag as a local extension of the iLab framework, remote students can:

- perform local qualifying experiments
- develop new WEB Page Instruments that are suitable for their experiments or new experiments that the students want to perform
- implement complex LabVIEW applications
- develop more laboratory material
- post their Web Instrument so other students in remote locations can use it with their Wi-Fi tags
- etc.

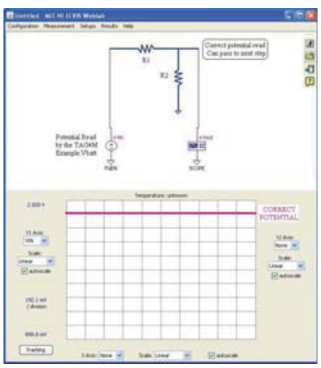

Figure 10 ELVIS + TAG4M experiment

VI. SENSOR BASED ILAB

The iLAB Service Broker may offer a Lab named Tag4M Lab Client. This lab could be structured around types of sensors, so the problem set is sensor based. The iLAB Service Broker for this lab would provide two things:

a) The tag4M Lab Client web page, which is a weblab very similar to the ones currently posted, and

b) One or several Tag4M Wi-Fi tags with sensor extensions to be used in the experiments.

Under this paradigm the tag becomes an extension of the remote lab into student's hands, and this allows for local experimentation with weblab interaction. The following is an example of content for the Tag4M lab.

Tag4M Client: Measurement of Acceleration, Motion, Tilt

1) Description of the type of measurement that is investigated. **Vibration, Motion, Tilt**

2) Description of the sensor used to implement this type of measurement (Fig.11).

ADXL330 3-axis accelerometer with voltage outputs connected to Tag4m Wi-Fi tag.

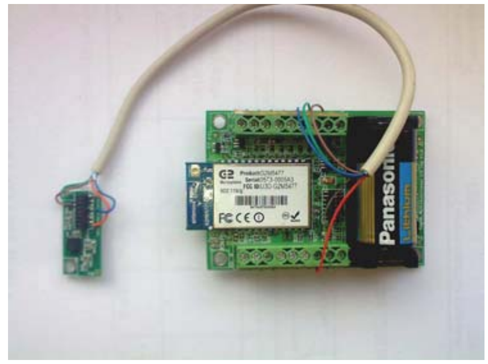

Figure 11 ADXL330 attachment board with TAG4M

3) Schematic or diagram of the circuitry showing how the sensor is connected to a measurement device - Web Page Instrument area that shows Tag MAC and IP address and a graph containing X, Y, and Z voltage levels that correspond to positions of the ADXL330 during the experiment (Fig.12).

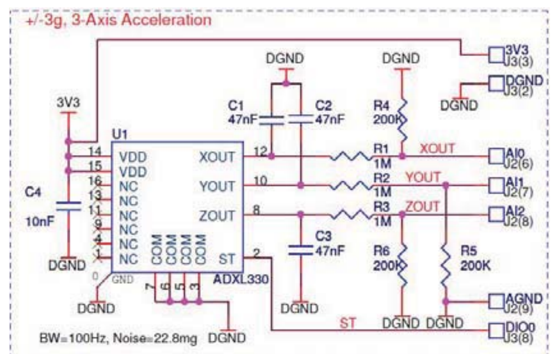

Figure 12 ADXL330 sensor attachment board circuitry

4) The Web Page Instrument is part of the iLab Tag4M Lab Client (Fig.13).

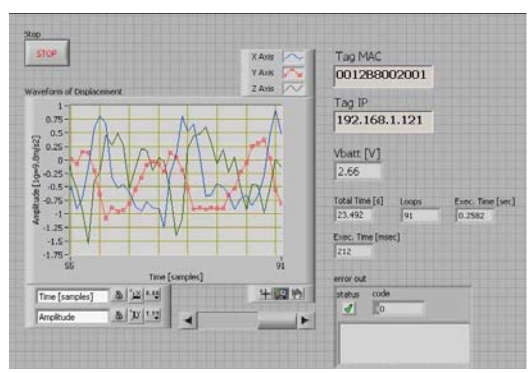

Figure 13 3-Axis Acceleration measurement using the Web Page Instrument provided by the Tag4M Client weblab

The student will physically perform the experiment using a small ADXL330 attachment board connected to the Wi-Fi tag (Fig.11). During the experiment, while the student tilts the attachment board, the tag reads ADXL330 X, Y, and Z axes and sends the data via a local Access Point to the Internet and further to the Web Page Instrument for display.

Similar experiments can be created to measure:

Light intensity (Fig.14)

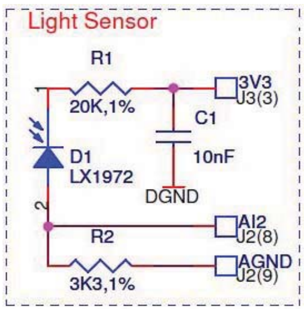

Figure 14 LX1972 sensor attachment board circuitry

Sound (Fig.15)

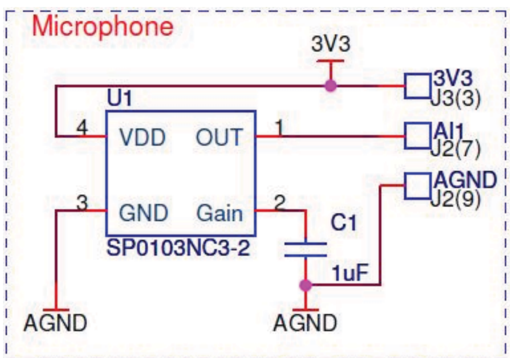

Figure 15 Microphone sensor attachment board circuitry

Temperature and Humidity (16)

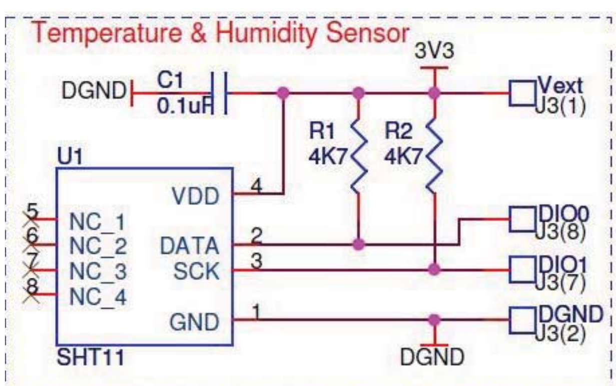

Figure 16 SHT11 sensor attachment board circuitry

LED Pattern (17)

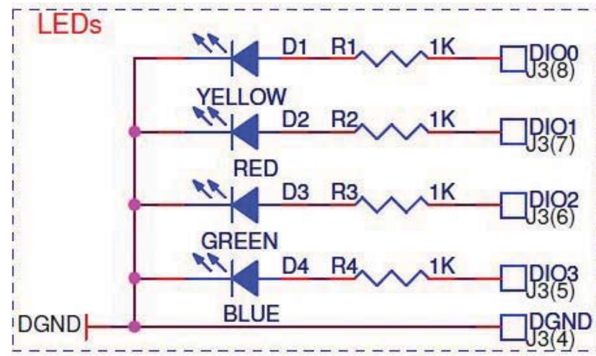

Figure 17 LEDs attachment board circuitry

VII. CONCLUSIONS

A Wi-Fi tag has been built in order to support the concept of a WEB Page Instrument. Tags with Wi-Fi and measurement capabilities are connected to sensors, and measurement data is sent to the Internet network to be posted on web pages. Client computers anywhere on the network can access WEB Instruments to monitor remote experiments or make local measurements using tags connected to local sensors. The concept of WEB instrument moves virtual instrumentation from the computer based space into the Internet networked space. The iLab remote laboratory framework can greatly benefit from using the Wi-Fi tag. Remote students will use the tag as an extension of the remote framework, in order to perform local or "home based" experiments that are part of the general framework but physically executed locally. This is a great combination of virtual experimentation with local flavor. Students can post their web page instruments in the framework for other students in remote locations to use them with their own tags. Work is done currently to create many web page instruments, a community of web page instruments that connect sensors to the Internet.

Abstract—**In the last decade, the effect of Internet usage in education has increased gradually and new technologies have improved student's learning. By using distance learning tools, the student education can be more flexible with respect to place and time constraints. So, students can access information in every time and everywhere either in libraries or during the lectures. As is widely known that, distance learning is costly, and cost-effectiveness becomes more important as the institutions become large-scale providers of distance education. Cost which is the most important disadvantages of distance learning according to traditional learning environments can be removed with the extensive features of the Open Source Software. Generalizing the usage of Open Source Software will provide development of learning tools and increases the educational quality. As far as the literature is reviewed, not much research has already been conducted about the comparisons of open source learning management systems in distance education. In this study, some analyses and comparisons were made about open source learning management systems and Moodle was outstanding with many features among other LMS that aims to improve the educational quality and include the tools that an e-learning system should have.**

Keywords-component; Moodle, Open Source LMS, Learning Management System, Distance Learning

I. Introduction

The tremendous improvements in information and communication technologies and increase in the use of internet brought lots of opportunities to different fields and also Instructional Technologies. Based on the new technologies, learning environments are able to provide a wide range of educational alternatives for learners. Distance learning is one of these alternatives which became attractive where student and instructor are physically in different location and time [9].

In relation Miller R.L states that, more and more educational institution and companies are adopting distance learning methods to train and develop their employees, because it delivers more training to wide range of people for the fewest cost [5]. What is more, studies show that, it is also effective through including e-learning tools, such as;

Güzin Tirkes

e-learning technologies reduce the learning time requirements by an average of 50 percent and retention rate of the trainees greater with e-Learning including interactive than with a solely classroom based model [11].

Learning management System (LMS) which have a significant role in distance learning is also known as the Virtual Learning Environment (VLE) or Learning Platform. Hall defines an LMS as: "software that automates the administration of training events [2]. All Learning Management Systems manage the log-in of registered users, manage course catalogues, record data from learners, and provide reports to management." The definitions of LMS systems and related terms encountered in this article are discussed in further details in the article Online Education: Discussion and Definition of Terms [11].

Many organizations are using learning management systems (LMS) to support and to improve learning within their institutions. According to Observatory on Borderless Higher Education, some higher education institutions continue to develop in-house systems or buy into open source alternatives, but an ever-larger majority is purchasing licenses for proprietary platforms [1]. However, the open source LMS may have an impact on the future LMS market with its cost effectiveness and advanced features.

Open Source Software

In a distance learning process, open source software can be used in many different phases such as application software that performs learning content preparation and in LMS which provides learning content presentation in a web based environment and as web server software (APACHE e.g.).

Due to the advantages of distance learning, schools and companies are adopting these new learning technologies and increasing their investments in it. However, along with the advantages, installation and support costs appear to be a disadvantage compared to a traditional learning environment. These disadvantages can be reduced to a great extent by the use of open source software which provides further gains. OpenOffice, StarOffice, KDE Office, GNU Office software, which are under

open source content authoring tools, are among the most widely used content preparation tools.
Statistical studies show that open source web server software is again found mostly preferred and widely used in learning content presentation in a web based environment such as (Netcraft Survey, 2008)[6]. Figure 1 shows that open source application and web server software are used in an open source e-learning system.

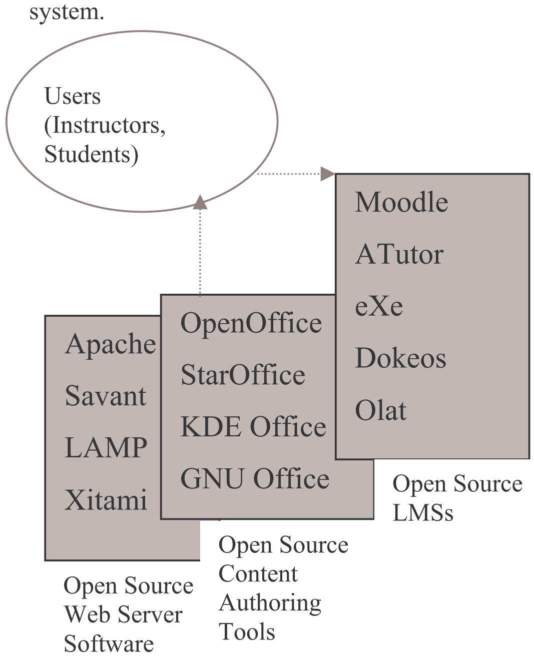

Figure 1. Open Source Application and Web Server Software

Advantages of Open Source Software

Most debated advantages and disadvantages of open source (OSC) software are; total cost, other financial and forensic subjects [8].
Advantages of using OSC software can be summarized as follows [8]:

There is no single feature on which the future of the software depends: Open source architecture enables the user to take away the software company dependency risk that originated the code chosen to stop development and increase maintenance and development fees.

Confidence:

Popular OSC software is examined by many developers and software experts so; it is filtered and cleaned of errors. In this way, with the increase in quality, the fundamental aim of software production and the process of usage, Users confidence in the software increases.

Sensitivity and flexibility for User Requirements:

OSC software is often updated more frequently than proprietary software. Most of the time, these changes reflect the needs of the user and the developer community.

The Support of Innovation:

The Production process of OSC software is improved by a broader range of diverse and creative ideas. In this way, each developer has equal rights to reflect his own innovative thoughts to the product.

Security:

OSC software provides security according to the level of user requirements but usually not at the level of commercial software. Users with commercial software do not have access to the underlying contents of the code, so they do not have a definite knowledge of their security.

In a study of Computer Science Corporation (CSC), total cost of ownership has been defined after the comparison between OSC software and proprietary software as follows [7]:

- Hardware costs (contains purchasing cost and maintenance).
- Direct software costs (contains purchasing cost, support and maintenance).
- Indirect software costs (especially license management).
- Personnel costs.
- Supporting costs.
- Breakdown period costs.

Requirements for Learning Management System in an E-Learning Process

A learning management system is defined as software that has been used in a learning content presentation which has a significant role and complexity in e-learning environment. An advanced e-learning system has to comply with the following requirements [3,4]:

- Compatibility and the ability to work with other LMS.
- Content management ability such as Electronic filing and file management,
- How the learning content is created and managed as a “learning object”,
- Reusability of the content (Content compatibility like Scorm, AIIC, IMS),
- Rapid content creation, distribution, integration and authorizing tools,
- Support for the tools using in content creation such as (Dreamweaver, Flash, Word, PowerPoint),
- Performance and extendibility of the environment,
- Multi-Language Support

In the light of the features mentioned above, when these headings are analyzed in detail, as shown in tables below, the analysis shows that the success rate and the rate of wide-spread usage goes up in similar order to the number of these features included in the LMS,. These features can be listed as follows:

- Creating content in different input format (Scorm, IMS Content Package, MPEg file, Office file, JavaScript, PHP),
- Including tools for content development and management of content installation (Modular Structure),
- Database support,
- Advanced search and header hiding ability,
- XML support to work with different systems,
- Compatibility with industrial standards (AICC and SCORM e.g.),
- Video Conferencing support,
- Exam module, Online exam (test based question preparation),
- Student education process prosecution,
- Multiple language support,
- Calendar,
- Backup support,
- Chat tool,
- Whiteboard,
- Group work, debate forums,
- Ease of system installation,
- Survey adding,
- System requirements (the less the requirements are the easier it is to set-up).

In this study, the mostly preferred four LMSs are selected among from fifty free and open source LMSs on the web site of UNESCO [16]. The features of three LMS's (ATUTOR, DOKEOS, OLAT) have been analyzed by using the full Access demo versions accessed from their web sites and a detailed analysis carried out by creating courses on each LMS. For Moodle LMS, by taking advantages of the trials on usage in different projects have been used to prepare the following table.

TABLE I. COMPARISON OF OPEN SOURCE LEARNING MANAGEMENT SYSTEMS

OPEN SOURCE LEARNING MANAGEMENT SYSTEM	MOODLE	ATutor [6]	DOKEOS [7, 8]	OLAT [9]
Support and Compatibility to Standards (AICC, SCORM)	Scorm and IMS Content Package support.	Scorm and IMS Content Package support	Scorm and IMS Content Package support. Ability to import different LMSs course that are in Scorm Format.	Scorm, IMS Content Package and QTI support
Multiple Language Support	77 different foreign language support	64 different foreign language support	5 different foreign language support	14 different foreign language support

Online Exam	10 different type question support exams can be prepared according to time, date and duration constraints. Includes "Secure window" option for exams.	8 different type question support Exams can be prepared according to time, date and duration constraints.	6 different type question support Exams can not be prepared according to time, date and duration constraints.	4 different type question support Exams can not be prepared according to time, date and duration constraints.
XML support	Exists	Exists	Does not exist	Does not exist
CHAT and GROUP WORK	Includes chat and group creating tools. Each user can work in his/her own group.	Includes chat and group creating tools.	Includes chat and group creating tools.	Does not include chat and group creating tools. Course content can be seperated according to goups
Ease of installation and maintenance	Installation and maintenance documents can be reached from Moodle.org and different sites.	Not enough installation and maintenance documents	Includes only flash based installation and introduction documents in their home site.	Not enough installation and maintenance documents
The follow-up of student's learning process	Visited links, contents, sources and all activities done by visitors can be seen in with date details.	Visited links and content usage by user can be seen statistically..	Visited links and content usage by user can be seen statistically..	Visited links, contents, sources and all activities done by visitors can be seen in with date details
Including content development and content authoring/editing tools ,modularity.	There is an Html based content editor. Course pages can be editted as Html pages and new application can be added as a modules.	There is an Html based content editor. Does not have a modular structure.	There is anHtml based content editor. Does not have a modular structure.	There is anHtml based content editor. Does not have a modular structure.
User Authentication	Rather than its own database, the data can be hold in different servers such as ; LDAP,IMAP..	User passwords holds in its database.	User passwords holds in its database.	User passwords holds in its database.
Survey and forum support	Exists	Exists	Exists	Exists

Calender	Course can be followed on calendar. Courses can be arranged weekly.	Does not exist	Does not exist	There is a calendar that can be used as agenda.
Video Conference Support	Exists. Also holds ”White Board” application. (For Moodle version 1.6 and upper WiziQ live Class Module existsl)	Does not exist	100 user can connect at the same time and ”White Board” application does not exist..	Does not exist
Backup Tools	System can get backup automatically in required time and date. Every module can be backup seperately.	All course content can be backup manually. Modules can not be backup seperately.	All course content can be backup manually. Modules can not be backup seperately.	All course content can be backup manually. Modules can not be backup seperately.
System Requirements	Apache, MySQL, PHP	Apache, MySQL, PHP	Apache, MySQL and PHP.	Java 1.5, Tomcat 5, MySQL 4.1, Apache 2.0 and OpenFire 3.3
User Interface and ease of usage	Extremely good. According to their profile, users can change their information and menus with a user interface that gives opportunity to design. Themes/skins allow for easy font/color/layout, etc. to suit local needs	Owns a good menu design. Very sleek, easily modified by individual user (e.g., menu locations, icons vs. text, font, colors)	Owns a good menu design.	Owns a complicated menu design.
Multiple Input Support (Multimedia etc.)	There is Scorm, IMS Content Package, mpeg, mov, mp3, flash, Office file, JavaScript based content support.	There is Scorm,IMS Content Package,Office file, mpeg,mov, mp3, flash support.	There is Scorm, Office file, IMS Content Package, mpeg, flash support.	No Multimedia support
Frequency of Usage	73.000 registered users	23,925 registered users	600 registered organizations	150 registered organizations

In Table I, it can easily be analyzed that, Moodle and ATutor stand out with their features among other open source LMSs. Moodle is the only LMS which has wider options with different access possibilities, modular structure, and advanced backup tools.

Comparisons show that, Moodle and OLAT have the ability to view full user logging and tracking and activity reports for each student are available with graphs and details about each module (last access, number of times read) as well as a detailed "story" of each student involvement including postings etc. on one page.

As a learning communication tool, Moodle LMS owns debade forums, file transfer, e-mail, calender and white board and real time chatting options.

As different from other LMSs ,in moodle there are different access possibilities from different groups for the administrators. These are administrators, educators, students and guests accounts.

Educators can save students text files that are limited only for course usage or students can save their documents by themselves.

Educators can put discussions and course activity to special dates however system can check these dates and synchronize course dates according to the corporate calender.

Moodle and ATUTOR have an advanced online exam module with time, date and duration constraints. As shown in Figure 1, with advanced exam and assessment modules, educators can create questions in many formats such as; Multiple-choice questions supporting single or multiple answers, Short Answer questions (words or phrases), True-False questions, Matching questions, Numerical questions (with permitted ranges), Embedded-answer questions (close style) with answers within passages of text. The answer to each question includes separate feedback.

Educators have the ability to view full user logging and tracking - activity reports for each student are available with graphs and details about each module (last access, number of times read) as well as a detailed "story" of each students involvement including postings etc on one page.

There are tree course format in the software such as by week, by topic or a discussion-focussed social format. XML support option in software adds a technical flexibility providing a basic syntax that can be used to share information between different kinds of applications. As shown in table above, Moodle and Atutor have the XML support. When system requirements are analyzed, OLAT is the only LMS having a difficult installation process because of the program requirements.

Analysis show that language is an important issue having an impact on the selection and use of LMS systems according to Paulsen's data [10]. With the 77 language support, and the numerical data in the frequency of usage as shown in Table I proves why Moodle is the most preferred open source LMS
Addition to the features listed above, only Moodle and Dokeos have "video conferencing" support within other softwares. With this software, virtual class application can be performed by using tools such as; online chat, file transferring (.pdf, .swf, .doc, .docx, .xls, .xlsx, .ppt, ve .pps), white-board application, two side video and voice transfer on a specified date and time. A screenshot from mentioned application can be seen in Figure 1 [10].

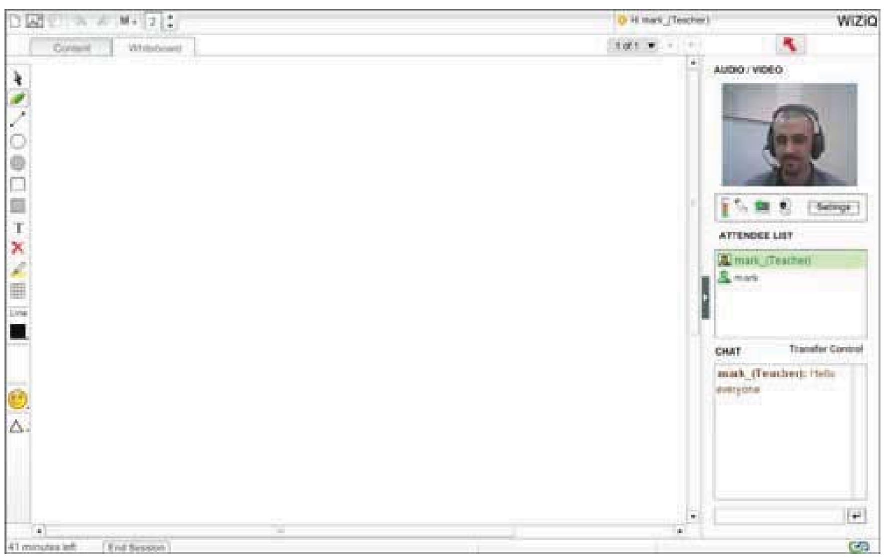

Figure 1 Video Conference and White Board Application Screen Shoot

Multimedia support in this software add a significant value to especially language teaching. As shown in Figure 2, with advanced exam and assessment modules, educators can create questions in many format.

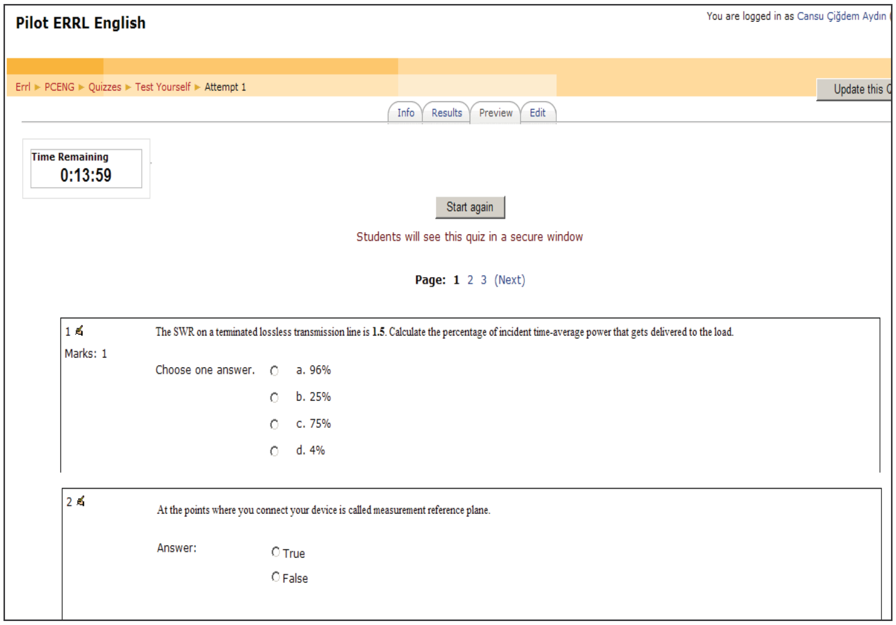

Figure 2. General Look of an Exam Module

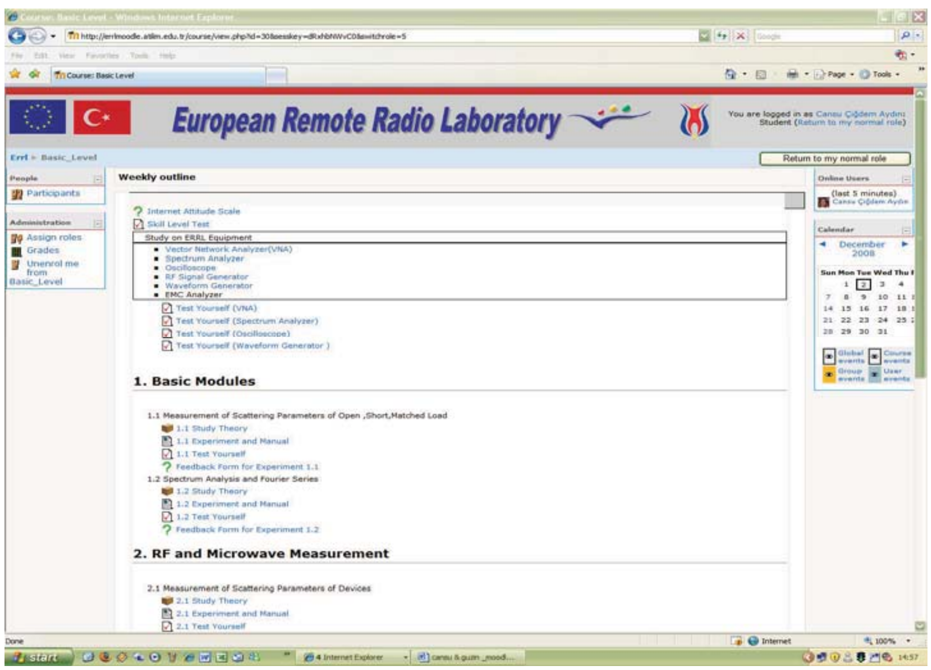

Figure 3. Weekly Course Schedule

CONCLUSION

In this study, open source LMSs were analyzed and it was observed that Moodle LMS among other LMSs, include many features that improve pedagogical quality and many needed tools that an e-learning system should have.

On the other hand, all three LMSs offer sufficient basic functions for their use as an LMS in an educational organization.

However, Moodle appears to present a clear advantage practically in all the features compared. Briefly put, these are:

(1) The modular design of the Moodle environment guarantees its flexibility: depending on the modules employed, it can

lend support to any type of teaching style or educational mode.

(2) A further asset resulting from its modular design and its greater attention to user interface is Moodle's superior rate of usability, compared with its competitors. In the case of the environment, the fact that it has a wider range of options does not make its use more complicated at all.

(3) A wider range of user authentication options, ease of installation and maintenance in Moodle increase the frequency of usage.

All in all, it is possible to state that; due to the fast improvements of distance-learning, generalization of the use of open source software would provide the development of learning tools and educational quality. Also, the cost, which is the biggest advantage of e-learning rather than traditional learning environments, is removed by the use of open source e-learning tools.

Cansu Çiğdem AYDIN
has received her BSc degree in Electronic Comunication Engineering and completed master education in Computer Engineering from Atilim University in 2008, Turkey. She has been working as an instructor in Atilim University. Her research interests include distance learning, learning management systems, e-learning and genetic algorithms.

Güzin TİRKEŞ
has received her BSc degree in Computer Technology & Information Systems department from Bilkent University, Turkey and MSc degree in Computer Engineering from Atılım University. She continues her studies with a PhD program in the same university in Modelling and Design of Engineering Systems PhD program. She has been working for Faculty of Management of Atilim University since 2006, as an instructor. Her main research interest is on distance education, e-learning, databases and academic data warehousing.

WikiDIS: a case of collaborative content management system for educative community

Adexe Rivera, Santiago Candela and Carmelo R. García
Dept. of Computer Science and Systems
University of Las Palmas de Gran Canaria
Las Palmas de Gran Canaria, Spain
rgarcia@dis.ulpgc.es

Abstract—**In this paper we describe a collaborative content management system based on Wiki Technology. This system, named WikiDIS, is designed to be used on a collaborative way by all persons who are part of an educational community (students, teachers, administrative staff, etc.) Functionalities of WikiDIS are friendly editing, editing and publishing workflows adapted to different types of users and communications facilities. The main functionalities and design aspects are explained in this work.**

Keywords-Wwb technology; Wiki technology; collaborative work; content management systems.

I. Introduction

Coinciding with the popularity of Internet, the Content Management Systems (CMS) has been developed during the last years. A CMS is a tool, that based on web technology, provides an environment where the creating, editing, managing of multimedia documents can be made on a friendly, reliable and secure way. These tools facilitate the tasks related to the web administration, offering functionalities such as: WYSIWYG editors, user communication (email, chats, forums, etc), resources for contents downloading and loading, web personalization and styles, language translation, etc. Nowadays there are multiple tools of this type that offers us these functionalities; one of them is the Wiki system that additionally has an important characteristic consisting in to permit the collaborative work of the users. A Wiki site is a collaborative web space where the user can create, edit and publish web contents on interactive, friendly and quickly way. With the Wiki technology, the contents of a Wiki site can be edited on a collaborative way using an Internet browser and a simple notation for contents formatting, indexing, etc. Additionally, this technology incorporates tools for versions controls of the contents permitting the pages restoration. The ideology of Wiki is democratic, it means that the contents changes in a Wiki site can be visible immediately but, generally, often there is a user who is responsible of verifying of the changes in order to permit only the publication of correct contents. The origin of Wiki is the community of the software designers [1], when the designers used shared information spaces in order to develop and discuss programming patterns. In 1995 Ward Cunningham created WikiWikiWeb, the first Wiki space, and he defined the Wiki of the following way "the simplest online database that could possibly work ". Later, in January 2001, the founders of the Nupedia project, Jimbo Wales and Larry Sanger, decided to use Wiki to develop the encyclopedia project, creating of this way Wikipedia the biggest Wiki space of the world. Initially, they used the Wiki tool called UseMod, but later they decided to develop a new Wiki tool that they called MediaWiki, being the base of many Wiki spaces nowadays.

In this paper we describe the functionalities and main aspects about the design of a collaborative content management system developed by us that we have called WikiDIS. This tool, based on Wiki technology and more specifically on MediaWiki, permits the editing and publishing of contents related to the activities of an educational and academic environment on a collaborative way. Specifically, WikiDIS has been developed to use by the community of the Department of Computer Science and Systems of the University of Las Palmas de Gran Canaria (DIS), in this context community means all the people which participate in an educational community, such as: pupils, teachers, administrative and services staff, academic authority, etc.

II. Wiki distributions

Multiple distributions of Wiki systems exist nowadays. These can be distinguished according to the type of organization they are designed, for example for personal or organizational use. Another classification can be established depending on the type of tools they have, for example version control of contents, security facilities, upload of different type of archives, etc. At last, another classification can be done depending on the technology used to develop the wiki distribution, for example:

- Java language has been used for Clearspace [2], JSPWiki [3], Kerika[4], Mindquarry [5] distributions.
- The technology .NET Framework has been used for FlexWiki [6], WWWiki [7] and ScrewTurn [8].
- The distributions Cliki [9] and SVNWiki [10] have been developed using LISP.
- Perl language for Twiki [11], UseModWiki [12] and WikiWikiWeb [13] distributions.

- The Wiki systems TikiWiki [14], DekiWiki [15] and MediaWiki [16] are based on PHP technology.
- Phyton has been used to develop the MoinMoin [17], OghamWiki [18] and Trac [19].
- Instiki [20] and Ruwiki [21] have been developed using Ruby.

Some of these Wiki distributions are not free, specifically Clearspace, Kerika. Others are software under GPL or GNU license, for example JSPWiki, ScrewTurn, Twiki, SVNWiki, MediaWiki and TikiWiki or under license which permits the free use, for example Cliki (MIT license). From the point of view of the relevance of the Wiki site, we must cite UseMod, used to develop Wikipedia, Trac that is used by NASA's Jet Propulsion Laboratory and TikiWiki to develop collaborative workspaces in educative context, Aulawiki [22]. We have chosen MediaWiki because it has a very important property in order to incorporate new functionalities, this property consist of the development, installations and using of new software components named extensions. Additionally, MediaWiki has an organization very structured and configurable, supporting Latex to edit mathematic expressions and different language generators.

A reference of specific Wiki system for educational contexts is the Aulawiki, having as the more important functionality the support of collaborative workspaces named Tiki Workspaces. In these systems, two main roles are defined: pupils and teachers; existing others roles: registered associated to all the registered users, anonymous for not registered users and owner to represent the owner of a workspace.The participants of a workspace can be organized in groups to work in different subjects. Additionally, the available resources in each workspace can be configured between a set of tools such as: Blog, Wiki page, file gallery, etc.

III. Goals and Requirements of WikiDIS

The main objective of WikiDIS project is to implements a collaborative content management system, based on free software, which permits to automate the documents flow generated in an educational university organization. The collaborative requirement means that the system must permit to all the people who integrate the educational community can produce, a controlled way, the contents for the information system of organization. Therefore, the system must to have a friendly user interfaces that permits to the users the creation, edition and publishing of contents regardless of the level of technical knowledge of the user.

Conceptually, we have identified three main entities in an educational organization:

- Participants that are: pupils, teachers and administrative and services staff. In the case of the DIS, the numbers of member of each category are 1200 pupils, 120 teachers and 2 administrative and service staff.
- Academic government that is formed by directive staff and commissions; in the DIS the directive staff is formed by the following figures: director, secretary and laboratory chief, existing 2 permanent commissions that are the academic commission and the economic commission.
- Academic demand configured by the academic qualifications and the subjects of their curriculums. The DIS develops its activity in 103 subjects organized in 13 curriculums of academic qualifications.

The contents are generated as consequences of realizing of tasks by the members belong to the categories of participants and academic governments. These tasks can be grouped in the following sets or categories:

- To coordinate and developing of the subjects teaching and learning. All the participants of the educational community execute tasks belong to this categories; pupils in tasks of learning, teachers in tasks of teaching and people belong to academic government and administrative staff in tasks of coordination of the teaching and learning activity.
- To elaborate the teaching project of each subject. This set of tasks are executed by participants belonging to the entities of teachers, academic government and administrative and services staff.
- To organize, coordinate and promote the activities related to research, technological development and innovation. The executors of this category of tasks are the same as reported in the previous category.
- To promote and developing the educational innovation. Like the first set of tasks, people belonging to all the type of participant entities can execute tasks belonging to this category.
- Management of the material, economic and personal resources assigned to the DIS. Basically, this set of tasks is executed by participants belonging to the entities of academic government and administrative and services staff.
- To elaborate, updating and publishing the internal regulations of the DIS. People belonging to the entities of academic government and administrative and services staff are the executors of this set of tasks.
- To develop and maintain the information system of the DIS. The participants are the same as the previous category.

In order to access to the different contents associated to these tasks, depending of its category, each participant have a set of functionalities and privileges. The main challenges of the WikiDIS project were:

- To improve the organization of contents of the Wiki system, that is lineal based on the concept of paper, in order to support more complex structures of contents required in an educational organizations, being frequent hierarchical organization of contents. To meet this challenge, we have introduced two new concepts named subject and prefix to organize the contents, now the contents are organized in subjects and the subjects are structured in papers. To allow sharing papers between subjects, we use the concept of prefix of the following way: each subject and paper has a set of prefixes associated; a paper is shared by all the subjects that have at least one common prefix. Thus, we can say that conceptually the contents in our model are structured as a undirected graph where the nodes represent subjects and paper and the arcs represent the relationship "to have a common prefix", having each arc a name that matches the prefix name that represents.

- To reconcile the democratic principle for the collaborative use of the contents Wiki Systems with the controlled and collaborative access to the contents required in an educational environment. Specifically, in Wiki systems the contents are organized in papers, each paper has a administrator user who decides if others users have the privilege to modify the paper. In an educational environment, the contents are structured in different subjects and each subject has at least one administrator who decides, between the users that can access, the type of privilege of each of them.

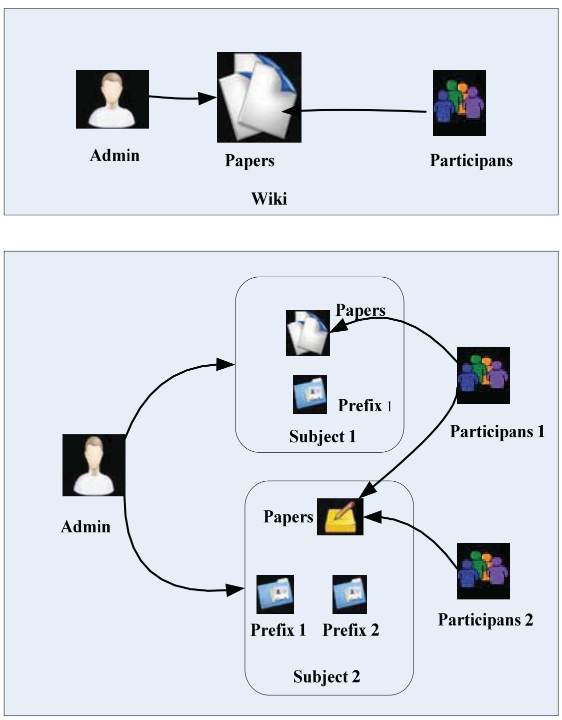

Figure 1. Wiki organization versus WikiDIS organization

IV. System Description

WikiDIS is a evolution of the software tool called MediaWiki (GPL license software) for this reason WikiDIS has functionalities such as: friendly editing of the web contents, using WYSIWG editor, building and publishing workflows adapted to the different users profiles, tools to translate for different languages (about 100), control of versions and control of expired contents. Moreover, it incorporates resources for user communication (email, chat, forums) and tools for loading and unloading of multimedia contents.

In WikiDIS all the elements that participate in the educational and academic activities are represented by entities, these entities are structured in three categories: people (pupils, teachers, administrative staff, etc.), academic management (directive staff, academic council, commissions, etc.) and subjects. The entities have different types of privileges for editing, publishing and visualizing of contents depending on the activity performed, for example: organizing, coordinating and controlling of the subjects teaching, resources management related to the educational and academic activities, building, updating and publishing of documents (manuals, procedures, teaching projects, regulations, etc.). Additionally, WikiDIS supports the contents management related to the teaching and learning tasks of the subjects realized by pupils and teachers.

To achieve all the design goals, we have developed and integrated new modules in the MediaWiki architecture, specifically in the named logical level and data level. In the logical level, new PHP scripts and extensions have been added in order to incorporate new contents and functionalities to the database, for example the content management required by subjects and groups of them . Moreover, several files have been modified to support the characteristics of the workflows of the academic and educational tasks. In the data level of MediaWiki, we have modified the design of the database by the incorporation new tables and fields. As a result WikiDIS has the same structure of MediaWik that is a layered structure [23], but its architecture is different because it incorporates new components and functionalities, for example new sections named prefixes, subjects and chat, are available in WikiDIS . For these reasons, we can affirm that WikiDIS is an evolution of MediaWiki; this evolution is specifically oriented to the educational environment.

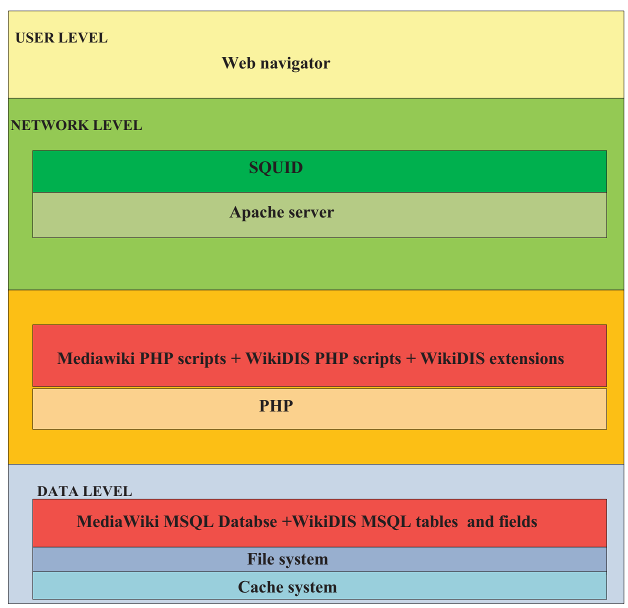

Figure 2. WikiDIS architecture

Following, the new modules developed for WikiDIS will be described. To build these components, we have used a set of development tools, specifically HMTL, PHP, JAVASCRIPT and AJAX for elements based on web technology and MSQL as database tool.

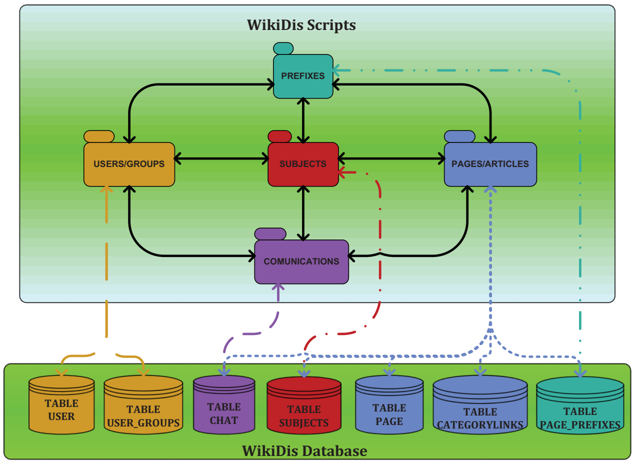

Figure 3. Relations between scripts and data in WikiDis

A. Users and groups module

This module manages the users of the system, here the registers of the users are performed, and the interaction with existing prefixes and grouping in different set of users called groups, being also the management of these groups responsibility of this module. As consequence of these functionalities, the users can be related to groups, subjects and to set to them the privileges of use of the system. Additionally to the two groups defined initially in MediaWiki, WikiDIS has three main groups defined initially: pupils, teachers and administrative and service staff. To set these three groups in WikiDIS initially and to garantee that these cannot be modified, we have introduced the specification of these new initial groups in the file named DefaultSettings.php, although in the specifications of MediaWiki the modifications of this file is not recommended. To permit the automatic creation of user from CVS format file, another modification has been made in MediaWiki, it consist in to develop a new extension based on the existing extension named Import Users created by Rouslan Zenetl y Yuriy Ilkiv [24]. By this new functionality we can set the users of the system (pupils, teachers and administrative and service staff) automatically from electronic document coming of the educative administration. Another new extension, named User Administration, has been developed to facilitate the management of the personal data of the users and the groups and subject related with them. To administrate the groups of the system, a new script has been developed, named Groups Administration and based on the existing extension Prefix Security created by Borut Tomažin [25], using this new extension the administrators of the system, they can create prefixes sets, for example related with subjects, with different privileges for different users and groups . Finally, in order to have additional information about users, new attributes are incorporated in the user registers of the database as well as their methods of insertion in the database.

B. Prefixes module

This module supports the controlling access of the different pages of the system. WikiDIS incorporates a new prefix named “Prefix Administration” which is based on the “Prefix Security” of MediaWiki mentioned in the previous point. Using this WikiDIS module, we can specify different type of access to the pages, for different users and groups, incorporating a contents management controlling based on user, pages of themes (for example subjects) and prefixes which permits the prefix administration (creating, modifying and erasing of prefixes) and the setting of relationship between prefixes and users . To achieve these functionalities WikiDIS incorporate a new file named “PageRestrictionHooks.ph” by this module, when a user tries to access a page, the system verifies if the user has the proper privilege of access , informing to the user in case of access denied. Figure 3 show us the relationship between this module and the rest main modules of WikiDIS. This figure shows us how the prefix manager is related with the user manager to control the users and prefixes groups. In the figure we can see how each subject has at least a specific prefix, of this way the access control can be achieved. The relationship between pages and prefixes is set indirectly; by the access privileges of all pages that have titles with some prefix declared in the system as restricted prefix. . Finally, also the database is used by this module, specifically the file PageRestrictionsHook and the table page_prefixes, to control the privileges of the users specified in the prefixes.

C. Subject module

A main entity of WikiDIs is the entity subject because all the contents associated with the learning and teaching process are organized around this entity, for example all the subjects of the academic qualifications have an instance of this type. This module is responsible of the management of all the instances of this entity, an extension named Subject Administration that has been developed to do this task. Additionally, a new class, named subject, has been necessary to implement in MediaWiki and like other new modules of MediaWiki it is based on the existing of another component of MediaWiki, specifically the class named user. The class subject has the following attributes:

- mId to represent a unique identification of the subject instance.
- mName: this is the symbolic name of the subject instance.
- mPrefixSubject: this is the prefix of the subject, using this attribute the control access to all the pages related with this instance of subject is achieved
- mKnowledgearea: it identifies the knowledge area of the instance subject. The Knowledge area is an administrative concept, used in the Spanish university teaching system. By the use of this term we can relate subjects belonging to the same administrative area.
- mShift to indicate the teaching timetable of the instance subject.
- mDescription: that is a description of the instance.

- mWebPage specifies a set of web sites related with the subject represented by the instance
- mReadPermissionTeachers controls the read privilege of the teachers, using the prefixes manager.
- mEditPermissionTeachers controls the modification privileges of the teachers, using the prefixes manager.
- mReadPermissionStudents controls the read privileges of the pupils, using the prefixes manager.
- mEditPermissionStudents controls the modification privilege of the pupils, using the prefixes manager.

Aditionally, associated with this subject class, a set of methods have been developed. These are:

- For creating and loading of instances of subjects: load, loadFromId, loadDefaults, loadFromDatabase, newFromName, clearInstanceCache, createNew, addToDatabase, saveSettings, createSubjectPageInitial, createSubjectCategory. By this set of methods, we can create and load the instances of the subject class, storing the data fields in the database.
- For editing the attributes of the instances: getCanonicalName, getID, setID, getName, setName, getGroupPermissions, getGroupName, getGroupMember, getAllGroups, getImplicitGroups, getGroupPage, getPrefixSubject, setPrefixSubject, getKnowledgeArea, setKnowledgeArea, getShift, setShift, getDescription, setDescription, getTitulation, setTitulation, getWebPage, setWebPage. . By this set of methods, we can obtain and modify the instances attributes of the subject class. The methods get to obtain and the methods set to modify the attributes.

The figure 3 shows us the relationships of the subject manager with other managers of WikiDIS. As we can see in the figure, to relate users, teachers and groups of them with subjects, this module is connected with the user manager. Also, the connection between this module and the communication module is represent in the figure, by this relationship WikiDIS provides a new functionality consist of virtual tutorials of teachers and pupil accessible in each page of a subject by a new section named communication section. To end the explanation of this module, we must to say that each subject has a set of pages and papers related by categories, these categories are set when the subject is created therefore there are two entities to control the pages of the subjects that are the prefix and the category. To facilitate the management of subject pages, WikiDIS incorporates a mechanism that every time that a subject is created a main page of the subject is incorporated automatically to the system and providing pages templates based on text formats of Wiki also.

D. Communication module

As in the cases of the above modules and in order to support the facilities of chat and virtual tutorial, WikiDIS has a new tool named Chat Action Hook based on the existing chat tool named Chatty developed in PHP by Marco Olivo [26]. Each page or paper belonging to a subject has a tab, using this resource the user can access to this resource. By this tool the users, related by a common subject, who have the proper privileges can communicate on a spontaneously way. The relationships between this module and other WikiDIS modules are illustrated in the figure 3. The relationship between this module and the user module is made to validate that the user has the proper privileges to participate in the chat and tutorial and to authenticate the chat messages. The relationship between this module and the pages module is established in order to register information about the pages for which the communication between users. Nowadays only the communications made in the last 24 hours is stored in the system.

E. Pages and papers module

This module is responsible of the creation and edition of pages and papers. To implement the conceptual organization of the contents around to the subjects and to speed the access to the pages, WikiDIS use the concept of category to organize the pages of the system. WikiDIS incorporates two existing extension named Require Category and Manage Categories created by Hendrik Brummermann [27] and Florian Mayrhuber [28] respectively. The first extension is used to guarantee that each pages belong at least one category and the second is used to facilitated the categorization of the papers, consisting this extension in three parts: a section to visualize all the existing categories of the system, a section to create new categories and finally a section to visualize the categories of the paper. This organization of the pages permits to the system collets papers that have some common aspect. The figure 3 show us that this module is connected with all the previous modules, the reasons of these connections have been explained previously. Finally we must comment that the connection of the manager of pages and papers with the database is made to manage properly all the information and to carry out all the cheeks of pages and papers, using the following database tables: page, subjects, chat, categorylinks and page prefixes.

F. Other developed components

Additionally to the modules modified or created previously explained, WikiDIS has a set of new modules in order to achieve specific functionalities of WikiDIS. These modules are:

- Main pages module: In a Wiki site the main page of the site is common for any use that access to the site. In WikiDIS when a user tries to access to the system, this module checks if the user is a system registered user. If the user is not registered in the system, then a common main page is showed for the not registered user. Otherwise, the system shows to the user the main page associated of the main category that user belongs. In the system there are three main categories of users (pupils, teachers and administrative and service staff). This module of main pages management is based on the extension named Group Portal created by Tim Laqua [29]. Additionally, this module checks if the user has administration privileges in order to provide specific administration options to the main page.

Figure 4. Initial page of WikiDIS

- User interface: In order to achieve a simple, usable, attractive and intuitive user interface we have developed a new interface based on other existing of MediaWiki named MonoBook and Modern. The first was selected because of its intuitive aspect and the second because of its attractive aspect and it is more readable for the user. A result of this new interface is the new skin for WikiDIS.

V. WIKIDIS IN ACTION

The execution of WikiDIS is illustrated in this section. To use WikiDIS, the first step consist of the user authentication, the figure 4 shows how to introduce the user name and the passwordDepending on the role of the user authenticated an initial page is presented. Te figure 5 illustrates this page for a user with the role of administrator or teacher. For all the kind of user, WikiDIS provides options for content management and preferences, additionally administration of entities (users, group of users, prefixes and subjects) are provided for the case of users with the role of administrator or teacher. This distinction of roles between users is an important difference compared to other wiki distributions where basically the roles are administrator, editor and reader.

The initial page for administrators and teachers has six sections, these are:

- My subjects: using this section the teacher can manage the subjects related with him. If teacher is not related with any subject, then this section does not appear.
- Other managements: using it, the user can access to some miscellanea functionalities, such as: search, files upload, my contributions, special pages, etc.
- User management: all the functionalities related to the users can be accessed by this section.
- Subject management: this section permits to access to all the functionalities related with subject admin.
- Group and prefixes management: using this section the users with role of teacher or administrator can manage the groups and prefixes.
- Profiles: using this section the user can manage his profiles and preferences to use the applications.

If the user has the role of pupil, then the initial page only will have the sections: My subjects, other managements and profiles.

- 

Figure 5. Mainl page for adminsitartor or teacher

To facilitate the entities management WikiDIS provides a set of facilities. For example, in the figure 6 the page to create a user is illustrated, by this page the common fields for any user are introduced.

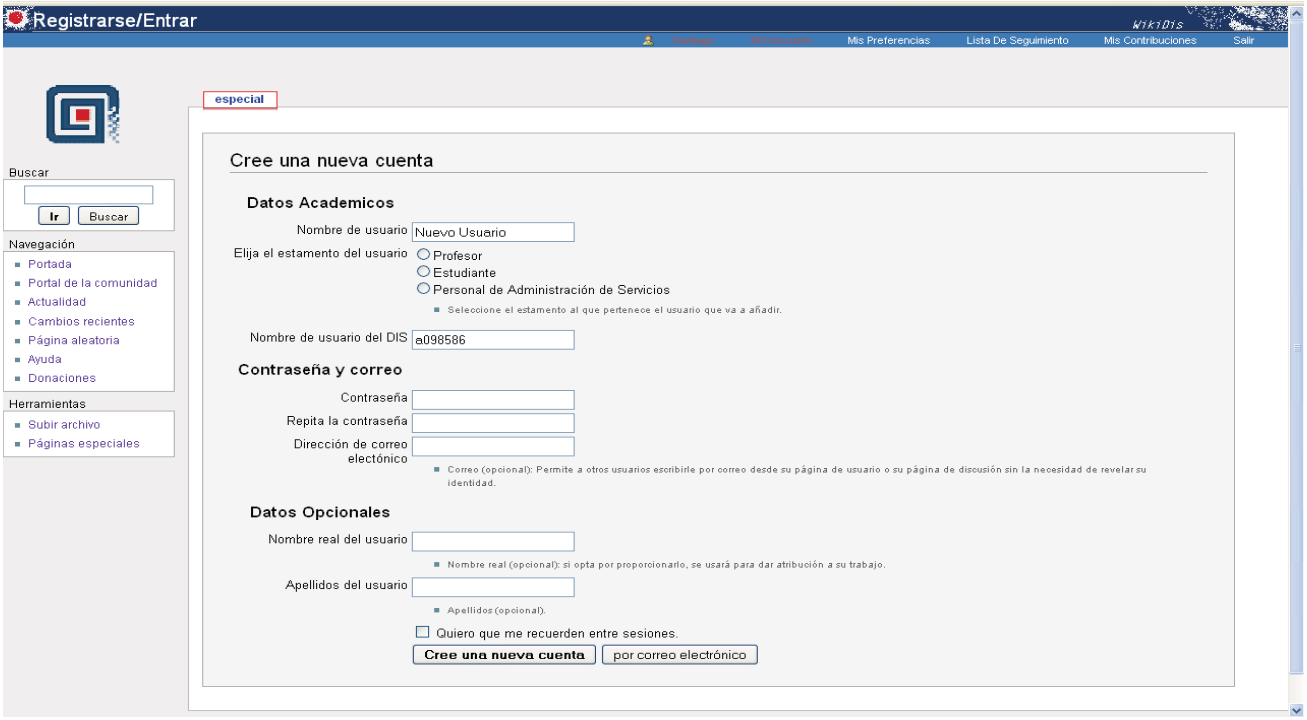

Figure 6. Page for seeting the common atributes of a new user

Depending on the role of the new user, specific pages are presented to complete the setting of attributes of the new user.

The figure 7 presents the specific page for a new user with the role of pupil.

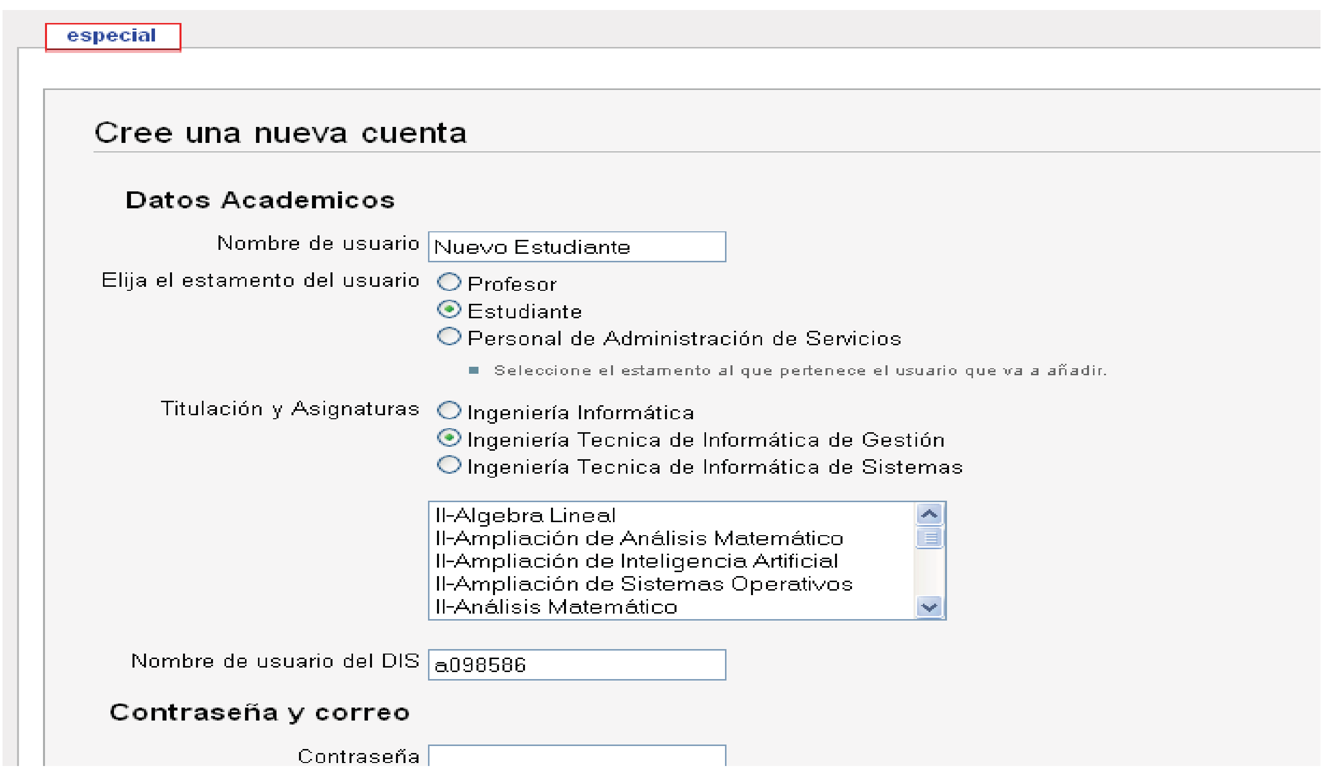

Figure 7. Page for seeting the specific atributes of a pupil

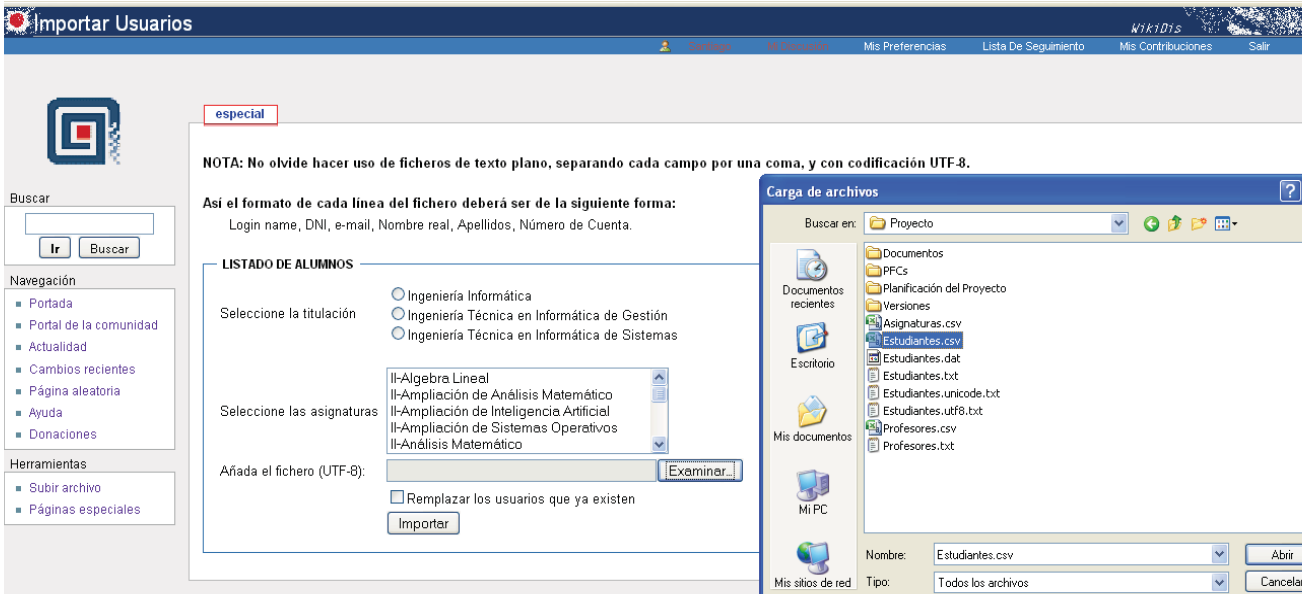

Figure 8. Page to create automatically users by the users import facility

To create a set of users on automatic way, WikiDIS provides a facility to import users. In the figure 7 the page to use this functionality is presented.

Additionally others facilities for entities management are provides by WikiDIS, specifically for the management of users groups, prefixes and subjects. For example, the management of the subjects is achieved by two main pages. The first page is showed in the figure 9, in this page all the subjects that can be accessed by the user are presented.

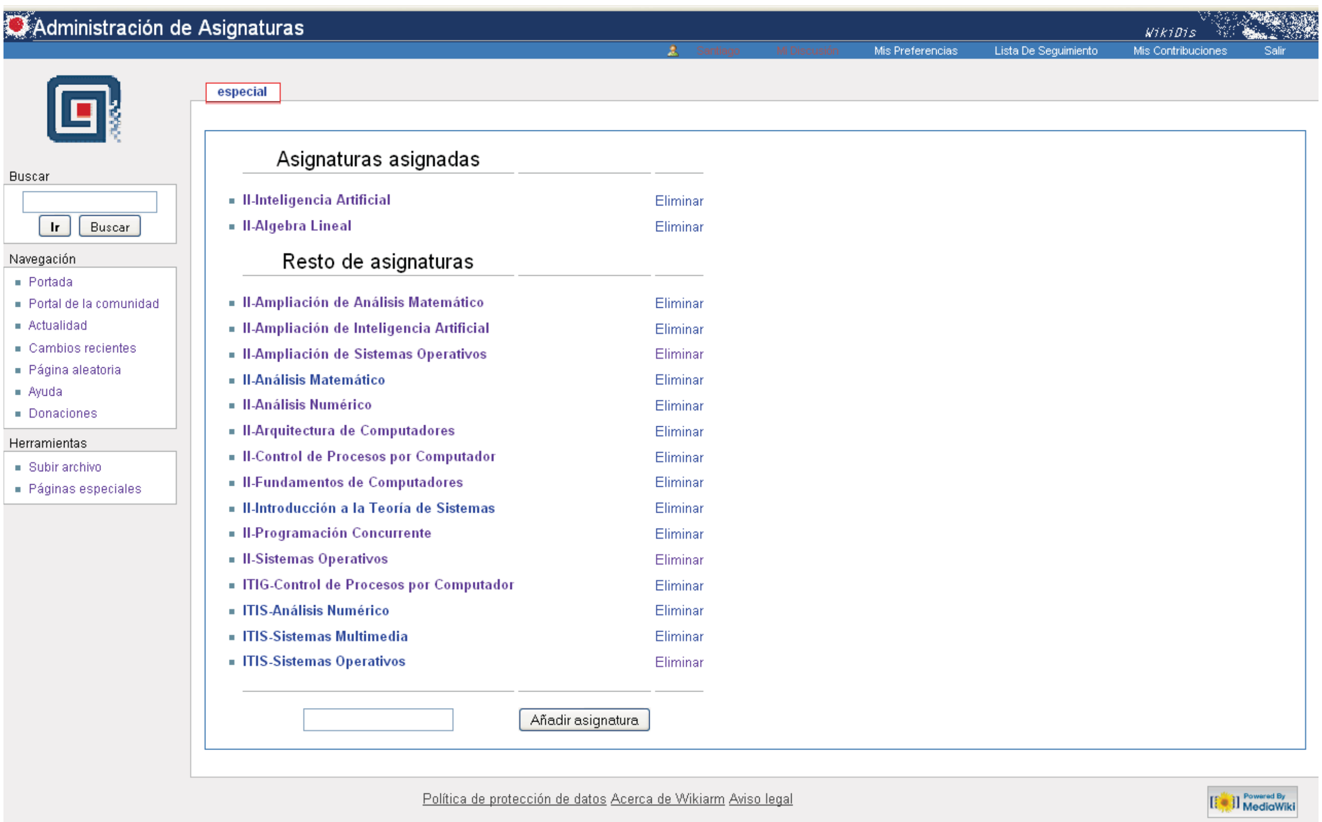

Figure 9. Page to access to the subjects management

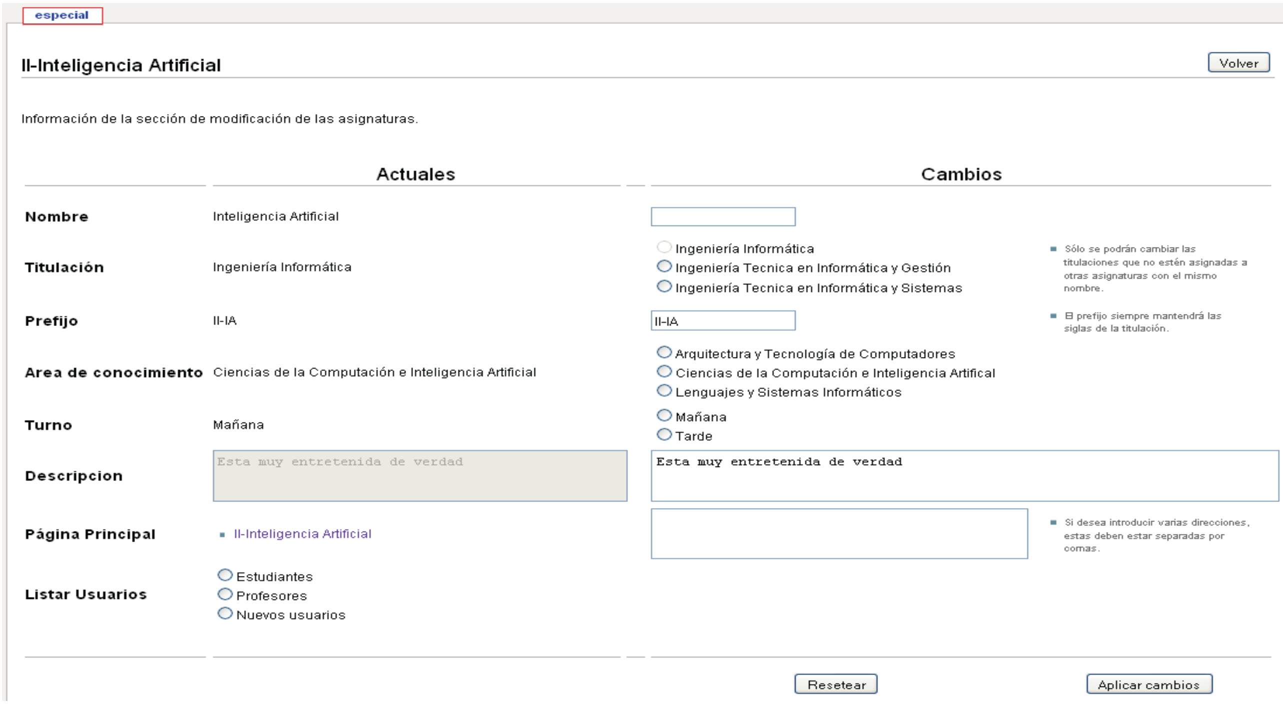

Figure 10. Page for setting the specific atributes of a subject

Selecting one of these subjects, then the second page is showed. Figure 10 illustrates this page; all the subject attributes can be accessed by this page.

This organization of content based on prefixes, subjects and articles is another significant difference of WikiDIS with respect to common distributions of wiki. In these distributions the content organization of a subject is carried through papers, so that content associated with a subject can be seen as a two-level tree where leaf nodes are papers. The content organization of WikiDIS is based on the concepts of prefix, subject and paper allows a more flexible structure, where the papers can be part of different subjects, that is sharing content, leading to a content organization as a graph

Finally, the WikiDIS communication module is illustrated. This module permits the chatting between users that can access to a specific paper. The figure 11 presents the chat page.

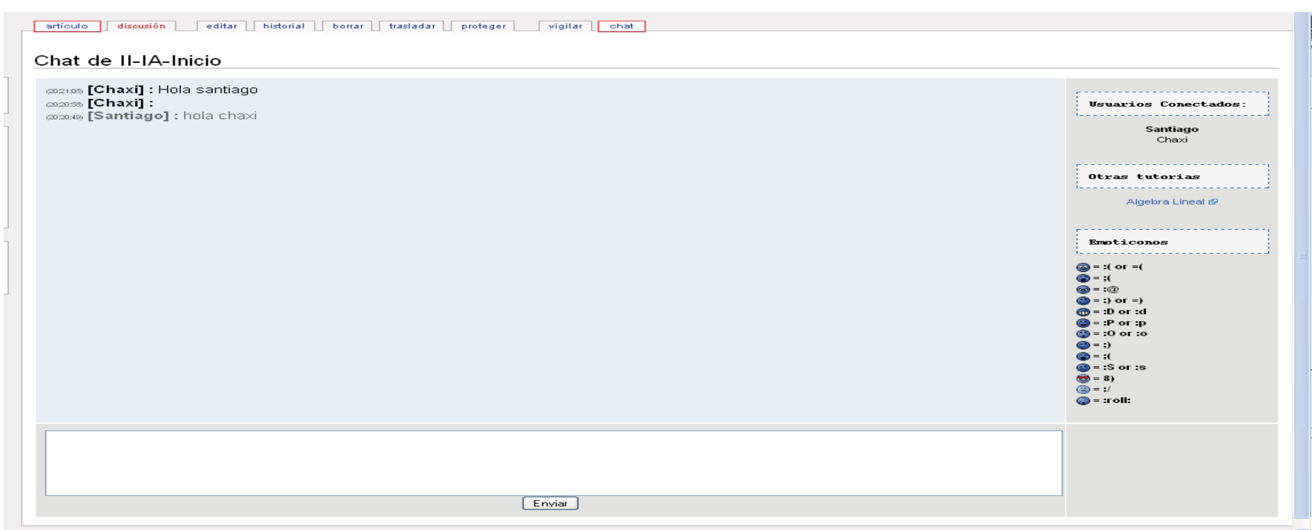

Figure 11. Page for chating about a paper

VI. CONCLUSIONS AND FUTURE WORKS

In this paper a collaborative contents manager system named WikiDIS has been presented, this system an evolution of the Wiki technology tool named MediaWiki. We can affirm as a main conclusion of the WikiDIS project that is possible to develop a collaborative contents manager system for a university educational organization based on Wiki technology. This system is able to support the controlled production and access to the contents associated to the work flow executed by all the participants of a university educational community. Although nowadays WikiDIS has been used in a university context, this system could be used in other educative contexts. Because WikiDIS is based on MediaWiki, WikiDIS has all the functionalities and advantages of the Wiki systems. One of these advantages consists of the possibility of adding new components and functionalities. In a general educative context and as future work, our group will try to integrate to WikiDIS in other very popular educative telematics platforms like Moodle. In the specific context of the computing science, a next goal to achieve is to incorporate resources to support collaborative and concurrent processes for learning and teaching in subject such as development of programs in different programming languages.

An enterprise e-learning solution:

The practical case of the UNED in the EHEA

Abstract—**In this paper, the European Higher Education Area (EHEA) adapted technological model is presented, developed in order to provide the e-learning solution for the new grades of the Spanish University for Distance Education (UNED). The transition of UNED's e-learning users to a new platform must focus on user experiences, so WebCT (used in the university from the beginning as its e-learning platform) and Moodle (open source elearning platform with numerous implementations in other universities) were analyzed from a user's point of view. This analysis allowed a set of interfaces/tools to be defined in order to fulfil the user requirements for the UNED enterprise e-learning system, called aLF (active Learning Framework). Actually, the new version of aLF has implemented the new improvements in order to start a successful transition.**

Keywords-user experience; e-learning platforms; enterprise e-learning system; adaptation; customization

I. INTRODUCTION

The Spanish University for Distance Education, UNED [1], is the largest public distance education university in Spain with over 200,000 students, 1400 lecturers and 2000 administrative staff. It has been in existence for more than 30 years. Since it is a distance education university students do not come to a central campus to receive their teaching. They attend regional study centres. There are currently over 60 of these study centres distributed throughout Spain and Europe. As well as the lecturers the university also has 6900 tutors working in these study centres. The tutors are an important figure in the teaching process because quite often they are the main contact the student has with the university. They provide the students with support in many ways, for example, giving taught classes, leading laboratory sessions, and helping to resolve any problems the students may have with the subject being studied.

One of the key features that sets the UNED apart from other distance universities is its consistent commitment to innovation, both methodological and technological. As such, it is evident that ICT (Information and Communication Technologies) has always had an important role within the UNED. Over the years its use has grown and currently forms an important part of the university's activities. As well as the online teaching activities it is also used as part of the administration process (where the UNED is moving towards the position of being a paperless university), admissions (where more than 90% of student admissions are being undertaken via Internet), and examinations (where the exams are no longer transported to the local study centres on paper but as encrypted electronic files). However, without a doubt the most important application of ICT in the university has been the development of our own online community-based learning platform, aLF [2], for use in our virtual campus.

When the UNED's virtual campus was started in the year 2000, a commercial e-learning platform was initially used. This e-learning platform was WebCT [3]. With time it became evident that this system was not sufficiently flexible for the university's needs, and hence the platform aLF (active Learning Framework, a system being developed by researchers in the School of Computer Science) was gradually introduced as a substitute. With the appearance of the EHEA (European Higher Education Area), modifications were required for aLF, but represented only a part of ongoing development activities, and did not by any means imply a drastic restructuring or rebuild of the platform or its tools.

These days it is very common for standard face-to-face universities, and other academic institutions, to offer forms of e-learning. As such, they are able with very little work, to configure existing online systems to provide the technological infrastructure for these taught courses. Since the student numbers in these cases are typically very small, and the online teaching is typically complementary to their main teaching activities, it does not matter that the underlying technological infrastructure is used or not enterprise by nature. In the UNED, however, due to its very distance education-based nature, all ICT used has to be EIS (Enterprise Information Systems). Any EIS should by definition be robust, scalable, OS portable, and interoperable with other systems. The currently popular PHP-based e-learning platforms (Moodle [4] is the most popular solution in the open software area) do not fulfil these requirements, and hence, any application for large student numbers requires custom ad hock solutions, which is far from perfect. Since aLF is built over dotLRN [5], which is an EIS, it is inherently robust, scalable, etc., as any system of this type should be.

However, in the UNED, all the e-learning users are accustomed to working with the WebCT environment so the portlet based interface of aLF (the standard view in web applications) was not easy for them to use. Focusing on the UNED user's experience, a new interface has been developed adding some icons/tools functionalities of WebCT 4.x. Furthermore, the influence of Moodle users in the methodological approach of the UNED lead to the development of a new planning tool that behaves like the Moodle tool. With this tool, the UNED Moodle users will be more at ease with the e-learning platform. Additionally, more improvements based on the WebCT and Moodle experiences were added. In the following sections the EHEA fundamentals and their importance for the UNED, and its need for a robust enterprise learning management system, will be presented. Subsequently, the tools developed in order to get a full new interface and tools oriented to the EHEA specifications, and based upon best practices taken from WebCT (the UNED's Learning Management System before 2009) and Moodle (a lot of users have been working with it), will be detailed.

II. EHEA SPECIFICACIONS

The EHEA directives present the evaluation of personal and group activity as the main feature of an EHEA e-learning space. So, a lecturer must build a planning model of a course based on autonomous tasks and collaborative activities between students. The first feature consists of providing an organizer tool to define the course structure, so from this organizer the student has a clear view of his/her objectives and who is going to undertake collaborative work in order to achieve good academic performance. In aLF this feature is provided by the planning tool (a Moodle-like tool). The planning tool has a user-friendly interface for thematic or weekly blocks that presents an organized view of the different resources of the e-learning platform.

Another problem is how to provide a unified view of content (like the content table of WebCT) and activities, avoiding the use of hyperlinks (created by professors, so mistakes are common) from content to activities. The idea is to have a navigation model using didactic units (like e-books) easy to define and use. These didactic units have activity sections in order to add platform resources, so for a lecturer it is easy to declare the planning of a course and add his/her own content integrated together with the platform resources (activities, assessments, forums, chats and so on). In order to provide this feature, a new tool called Content was developed to fulfill the requirements. In the following sections these tools will be explained.

III. WHY ENTERPRISE E-LEARNING?

The UNED has nearly 200,000 e-learning users in almost 5,700 learning communities (courses and working communities). So, the performance of the e-learning solution is very important for the university and its users. In Table 1, some important statistics are detailed in order to get an idea of the requirements the need to be taken into account for the e-learning platform. aLF is based on the OpenACS/.LRN [5] framework toolkit, and open source solution for enterprise systems which fulfill these requirements [6],[7] & [8]. Also, the toolkit has the property of clustering in order to provide a 24 hours service with no down time, so it is easy to add new front-ends in order to achieve the performance and availability of the solution.

As an example, a snapshot from Google Analytics is shown in Figure 1. The e-learning platform (November 2009) has been around 700,000 pages served (as peak) and 25,844 users viewing learning pages (as peak) during that period.

IV. ALF SERVICES AND USABILITY ISSUES

In order to provide a customized solution for the university, the development of aLF has been focused on two aspects: the addition of collaborative interaction tools (first problem) and to provide several workspaces where to share information from different groups, classes or communities (second problem). So, from the user's viewpoint, aLF provides a large variety of tools organized around three clearly distinguished workspaces: a personal one, the communities (to which the user belongs) and the courses (being undertaken by the user). The services offered, therefore, depend on the environment in which the user's interaction takes place:

- Communities: the organization of different types of work groups (teaching teams, research projects, various associations, departments, faculties, etc.) is made possible. To this end, several communication tools are offered (forums with notification services in e-mail and news), work management (documents shared with version and access right control, links of interest to the group and surveys) and task sequencing (agenda with appointments and weekly task planning).
- Courses: apart from the general services already mentioned for the communities, the following are included: document management (tasks, summaries, notes, course guides, and frequently asked questions), activity planning (weekly planning integrated with the course tasks) and several resources (links and shared course files, inclusion and edition of web pages with the course contents, exams, management of students and marks, etc.).

TABLE I. SOME DATA FROM OCTOBER 2009

Statistics Item	Value
Hits per day	2,000,000
Hits per month	50,000,000
Page views per day	550,000
Page views per month	15,000,000
Daily single users	15,000
Average users connected	400
Average response time per hour (in seconds)	2 s
Peak of connected users & hits	900 users & 3,200,000 hits/day
Number of communities (either subiste, or dotlrn classes, sub groups and/or communities)	5,700
Number of registered users	210,000
Number of active users per year	115,000 last year | 50,000 last mont

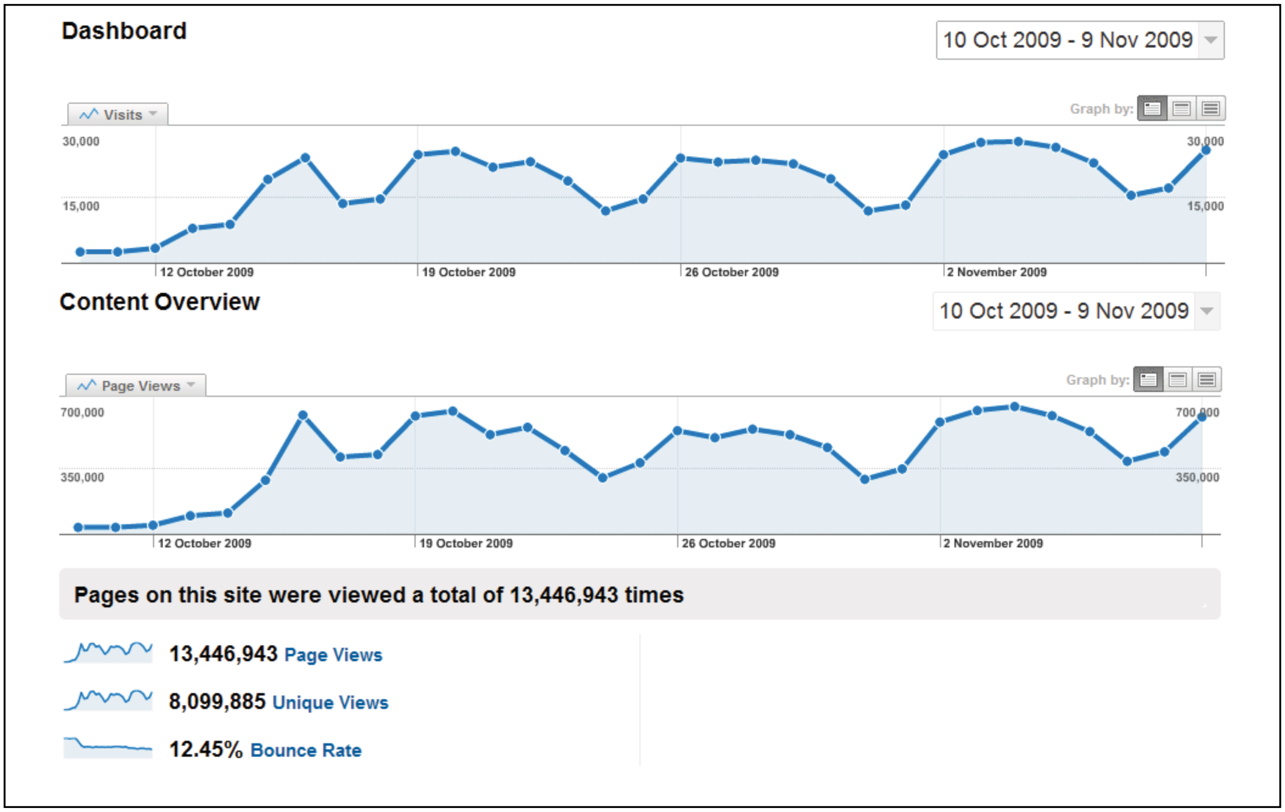

Figure 1. Snapshot from Google Analitycs

- Users: all aLF users have an agenda, a space for documents, links of interest and personal pages in the work area of any user/teacher/student which integrates with the rest of the services offered in the different communities or courses to which the user belongs. Furthermore, tools are offered for different types of users. Hence, the administrators and teachers have specific tools for following the work undertaken by each user and for each type of user. For example, statistics can be accessed by value and by user in each community or course.

In each case, when a user enters aLF, he first accesses his personal workspace ("my portal"), from which he can efficiently access all the novelties that have taken place in any of the communities and courses to which he may belong. In fact, one of the most highly valued aspects by users is the possibility of efficiently accessing any novelty, i.e., a new file added in such groups, the new lines in the agenda, the messages in the forums, the tasks and notes in the courses, the news, etc. Another question related to the management of novelties is the fact that the aLF forums can be managed through automatic response notification services. This allows user to be warned of any novelty appearing in a forum, without the need to be connected to the platform. Furthermore, the user can choose whether to receive news sent by a specific user (e.g., the teacher) about a certain subject and/or to receive an instant warning or report of the novelties that have taken place in the last few days.

Finally, aLF facilitates the organization of the interconnections between the different workspaces, both those related to the personal and collaborative work in the different communities and courses, and those related to the groups and subgroups defined in such communities and courses.

As has been seen above, aLF provides several advantages: customization adapted to the UNED methodological model; a robust and scalable solution focused on corporative environments; and an integrated portal environment for virtual communities (classes and work groups). There are several systems used in different institutions. Maybe two are the most referenced: WebCT [3] and Moodle [4]. The UNED has been using WebCT since the year 2000. WebCT supports big institutions (like the UNED) and it is a consolidated solution for enterprise environment. Moodle is an open software solution which has a great projection, but it does not have implementations on big systems (the UNED has nearly 200,000 users). Furthermore, both of these solutions are based upon the concept of course with no interaction between courses and group works, and no sharing of educational services between courses. aLF provides these features, sharing all the objects available in the groups (calendar entries, tasks, assessments, news and so on) publishing them in different group targets (for example, from a personal space it is possible to share, not to copy, owned documents to a class, allowing to rich the learning environment [9]).

So, aLF is oriented to users but the interface used it was not pleasant for users and it was necessary to get "best practices" from two well know platforms (WebCT, implanted in UNED, and Moodle, due to its impact in the open source e-learning platform world) in order to assure a smooth management change.

V. WEBCT BEST PRACTICES

WebCT was implanted in the year 2000 (when the UNED started to work with Learning Management Systems), so a lot of practices and experience has been gained using it. In 2008, an exhaustive work of requirements analysis was undertaken to get all the mayor functionalities that university lecturers wanted to be in a new platform (and not present in aLF). The main features were:

- A simple content table. aLF did not have a tool similar to the WebCT Content Table tool.
- Icon based interface. All the users are used to work with the icon interface provided by WebCT so a first section on courses was developed to provide a smooth user interface change for UNED's professors.
- Simple panel control. aLF's panel control is difficult to manage because it has a lot of options. This ammount of options makes the course/community configuration complicated.

All these tools and their aLF implementation will be show in the following subsections.

A. The content tool

The Content tool [10] is a simple and easy tool for content creation in an educational context. It focuses on the teacher that wants to create the content of a course in a simple way with a navigation and presentation that will be easy for the student to use. This tool helps the user focus only in the content and text rather than in the presentation, order and navigation that is already done and organized.

The Content tool is fully integrated with the e-learning platform template (see Figure 2), so the navigation menu is always present for the user. This provides an easy layout focused on the didactic unit defined for an EHEA course space. The content tool has several functionalities, so the four most important are detailed here.

The integration of activities: A course in .LRN has many tools available to be linked to the content base. In order to simplify the process of linking activities, a new interface was created to guide the teacher with the process. The process of linking activities has several steps, which is why this new interface was designed to guide the user through those steps, since a multi-step process can confuse the user. This interface works mostly with javascript using visual effects for each step in order to improve usability.

The functionality of the interface, see Figure 3, is divided into two main steps with the option to go back and forth between them, when possible. The first step is selecting the activity (there is a section with the information about all the activity types), after selecting "select the activity type", the current activities of that type along with the option to create a new activity of that type are shown in an emerging section, after an existing or new activity is selected, the third sections appears with the OK option to confirm the selection and continue to the next step. If another activity type is selected after the third section is open then the third step is closed. This will force the user to select an activity from the type selected (the current selection is not lost but simply not shown until the same activity type is selected again).

The second step, see Figure 4, is to set the details of that activity, a location for the page (where the activity is going to showed) and an optional description for that activity to be displayed in the page. If the selection was an existing activity the interface will add a link to the activity selected. If however, the selection is to create a new activity, then the interface will redirect to the activity type context in order to create the new item, after which, the item is created and automatically added to the content page (but the user will remain within the new activity context in order to be able to configure the activity).

The use of these steps gives the user the option to go back one step without having to start all over again. In this interface the user always knows how long the process is going and can focus only on the current action.

Each activity is displayed inside the content of a page, where the title of that page is the same as that of the activity created (and the optional text is shown above the activity link). The link for the activity shows a message according to the type of the activity, and some validations are done before presenting the link, to be sure that the activity is published (if it is not the case, the message has no link).

Navigation issues and group template: The Content tool displays the content of every course with a template that is dynamically generated. Multiple templates for content sections are an additional option for the teachers to change the way in which the content is displayed to the users in each course; there is a set of templates available to choose.

The whole template is divided into the following parts:

- Sections: an unordered list with links to the first page of each section.
- Sub-sections: an unordered list with links to the first page of each subsection.
- Units: a combo-box with all the units available.
- Navigation: three links with an image to navigate left, right or to go to the unit's first page.
- Order section: two links with an image to move the page up or down in the list.

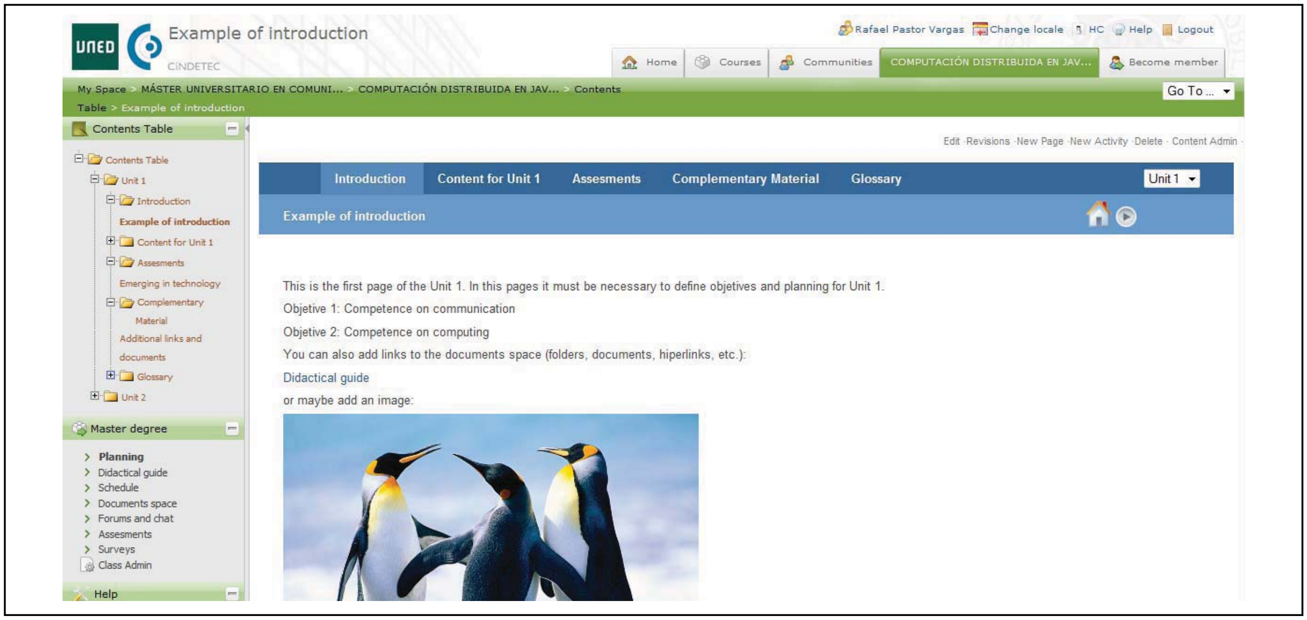

Figure 2. Content tool: Activities section of a didactic unit.

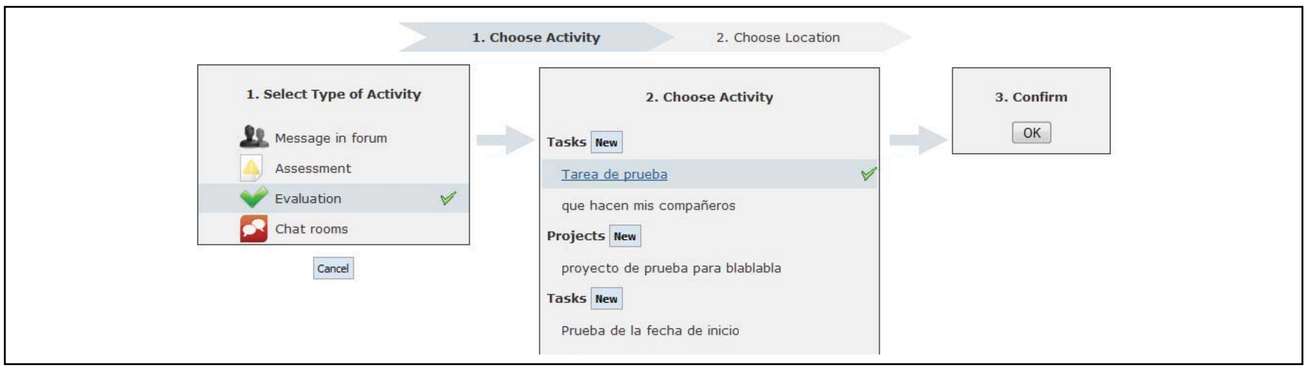

Figure 3. Step one of the linking activities process.

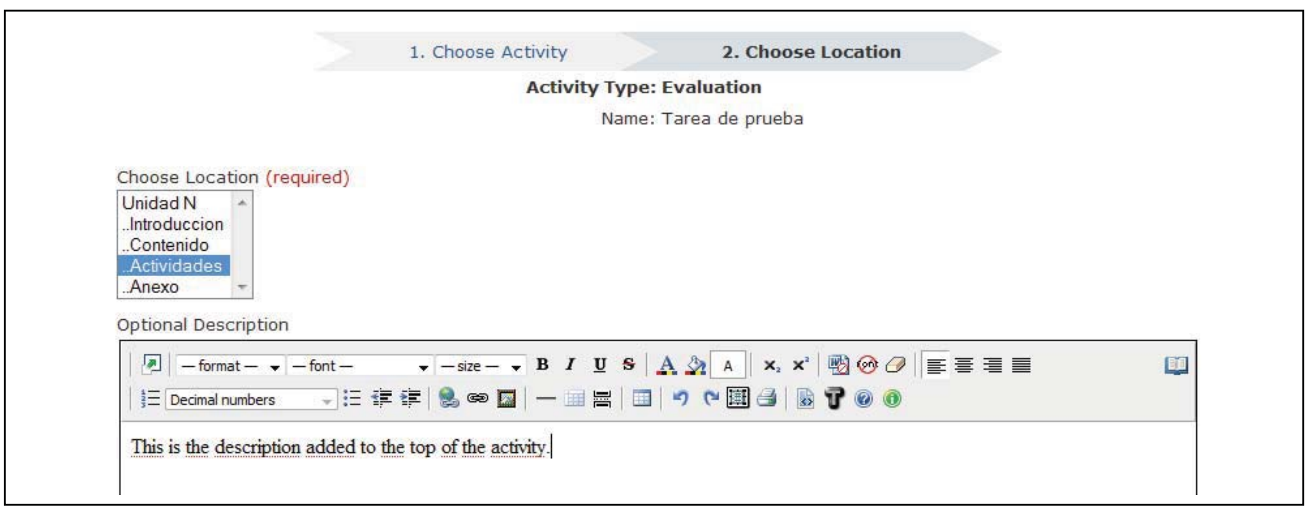

Figure 4. Step two of the linking activities process.

Content Glossary: A glossary is a very useful tool for lecturers to provide a better learning experience to the students. In every page of the content, words can be marked to have a glossary definition by an interface provided inside the rich text editor. A plug-in for the Xinha rich text editor was created to provide an interface where the terms and definitions are inserted, updated or removed. This plug-in has a main javascript file which handles the startup of the plugin and related validations, a dialog is open when the plugin is activated, the dialog has three areas, the term, the definition and the existing words. The plugin works by selecting a portion of text to add a definition to, and a dialog opens with the text selected in the term field in editable mode. A definition needs to be added for that text and all the current definitions in the course are shown in the interface, where, depending upon the selected text for the term, the definitions are ordered as being related or not related.

In every page the glossary words are links with different color and a tooltip property. If the mouse is placed over a word, the definition is shown in a popup. If the link is clicked it will take the user to the glossary page with all the terms.

In the content interface there is an entry for the glossary as an extra section in each unit. This glossary section has one page that shows all the glossary entries, and each entry has a counter that shows how many times the word is being used in all the pages. There is also an option to edit the word on a separate page and an option to delete individually or by group. This page is related to the unit where it was opened from. The navigation tree is focused on the glossary of that unit and the template shows all the sections of that unit.

Automated Copy of Content between Courses: In the content tool there is an automated option to import/export group (course/community) content pages (activities are course-based and are not exportable). The export is done by taking care of the sections/subsections related to the content and the files inside the content pages. The import is undertaken normally, following which, the import of each page is mapped to the sections/subsections, and for each activity page a new empty entry is added to the activities table. This will allow the system to treat the pages as if they were activities and link a new activity to them (the glossary word count entries are also added for the target content instance).

B. Icon based entry in a course

A WebCT user is used to have an initial view of the course based on icons in an organizational page, see Figure 5. In aLF this feature (organizational page) is not possible due to the portlet view provide as default. However, in this case a new section in the initial page of a course (joined to the planning tool which will describe later) have been added in order to add navigation icons to the most common tool provides by aLF (and WebCT): forums, study guide, content table, assessments, evaluations, glossary, tutoring (special work subgroups in UNED), news, frequently asked questions, previous exams, chat, File storage (Documents administrators) and so on. In Figure 6, it shows the default configuration on the icons navigation sections. In order to add more icons, the edition mode must be activated and then, from the select box it can be chosen from the list of available (as seen in Figure 7). Also, it is possible to move the icons using drag and drop capabilities of the section, and removed pressing the "forbidden" small icon.

Using these new features the "WebCT users" are more comfortable with the initial configuration of course, because it is similar to what they already know how to use.

Figure 5. The initial icon-based page for a WebCT course.

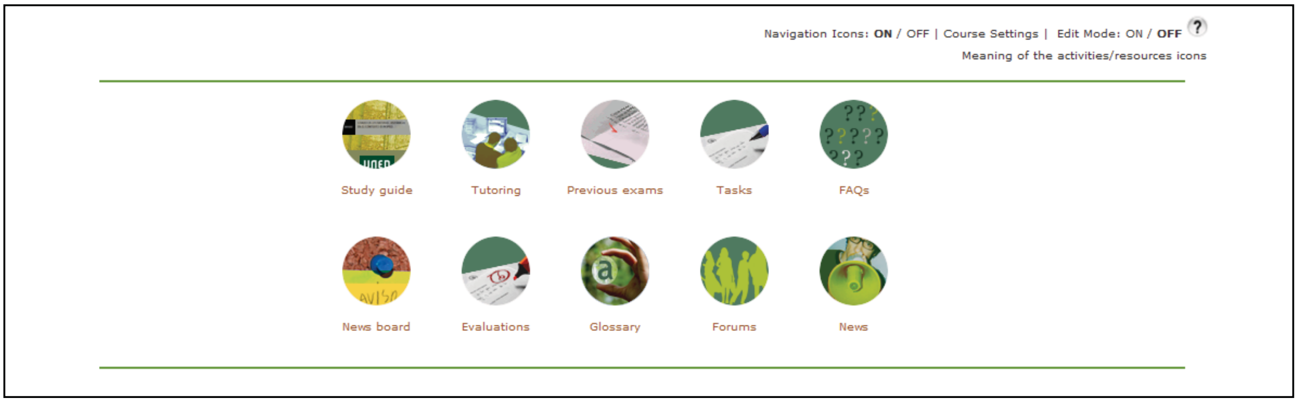

Figure 6. The initial icon-based page for an aLF course.

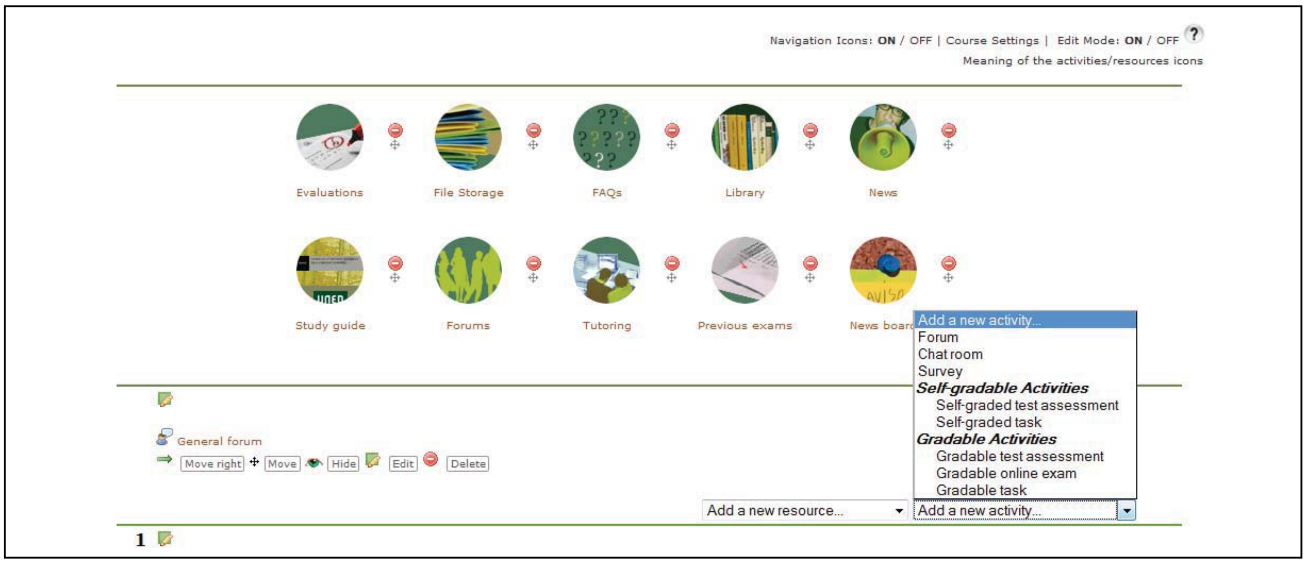

Figure 7. The tool for adding new icons to an aLF course.

C. Simple panel control

Another important feature for a lecturer is the use of a control panel in order to configure the main tools of a course, In the case of aLF, all the tools are configured in the same page (based on portlet properties for the tool) so for a WebCT user is seems complicated to find the correct portlet configuration tool and the use of scrolls and clicks are usual in order to get the correct configuration. Like WebCT provides (see Figure 8), a simplified view of the panel control was developed to have a similar interface for "WebCT users". In this case, there are four sections which provide most common administrative actions:

- User's management. Located in the upper left part of simple panel control (see Figure 9).
- Course properties. Located in the upper central part of panel. Provides features about changing of course name, description, left menu organization, etc.
- Tools configuration. Located in the upper right part of panel. Provides quick access to the configuration portlet view for the tool. Also allows the installation of new tools.
- Working subgroups list. Located in the lower left part of the panel. Provides quick access to the working subgroups and the creation of new subgroups.

VI. MOODLE BEST PRACTICES

Moodle provides an excellent tool in order to have a visual representation of didactic guide (temporal or module based) so in order to facilitate to UNED professor the definition of the course plan, a similar tool from Moodle was developed to satisfied the actual "Moodle users" from the university. In the next subsection it will be detailed.

Figure 8. The simple panel control for a WebCT course.

Figure 9. The simple panel control for an aLF course

A. The planning tool

In order to achieve the EHEA requirements, a didactic guide based on activity items (assessments, tasks, forums discussion, etc.) must be produced by teachers in order to describe the overall work that students have to do in the course. To support that, it has been created an organization and planning system by blocks where information (resources and activities) can be added by teachers from many sources and ordered in any way.

The blocks (organizational unit) [11] can have a topic or weekly format, and a summary is available for each block to describe the contents on that topic or week. For each block new and already created resources and activities can be included, so reusable activities can be defined in order to help teachers in every term (one planning, several terms).

The planning interface [10], see figure 10, becomes the Community/Course home and is organized in blocks. There are currently two formats for the blocks:

- Weekly Format: each block represents a week, the week start the day the community starts, this value is set in the Course Settings of the Blocks View. The current week is highlighted.
- Topics Format: each block represents a topic, all the activities and resources in this block are related to the topic (in this format the start date of the community is not relevant). This format lets the teacher select the current topic and highlights that topic automatically until the teachers mark it as not selected or another topic is selected, only one topic can be selected at a time.

This option is available for all communities inside the admin panel, there's a link to enable/disable this view, when the view is enabled a default empty block is created inside the community (this initial block it is always shown on top with no format), it adds the navigation bar to the master section inside that community and it automatically mounts the resources needed (evaluation, assessment, forums, content, pages, chat, etc.) on the community.

Each course has many available tools; inside each block there is an option to add a resource/activity, the supported packages are: evaluation, assessment, forums, file-storage, content, pages and chat. All the location actions are drag-n-drop based, so all the items in a block can me moved over the same block or others.

VII. Conclusions and Future Work

In this article the way in which the UNED's e-learning platform aLF, an EIS, has been developed to support virtual communities, adapted to the EHEA, has been presented. It has been argued that any e-learning platform that underlies these communities in such a fundamental way, has by its very nature to be an enterprise system, due to its robust nature, scalability, etc.

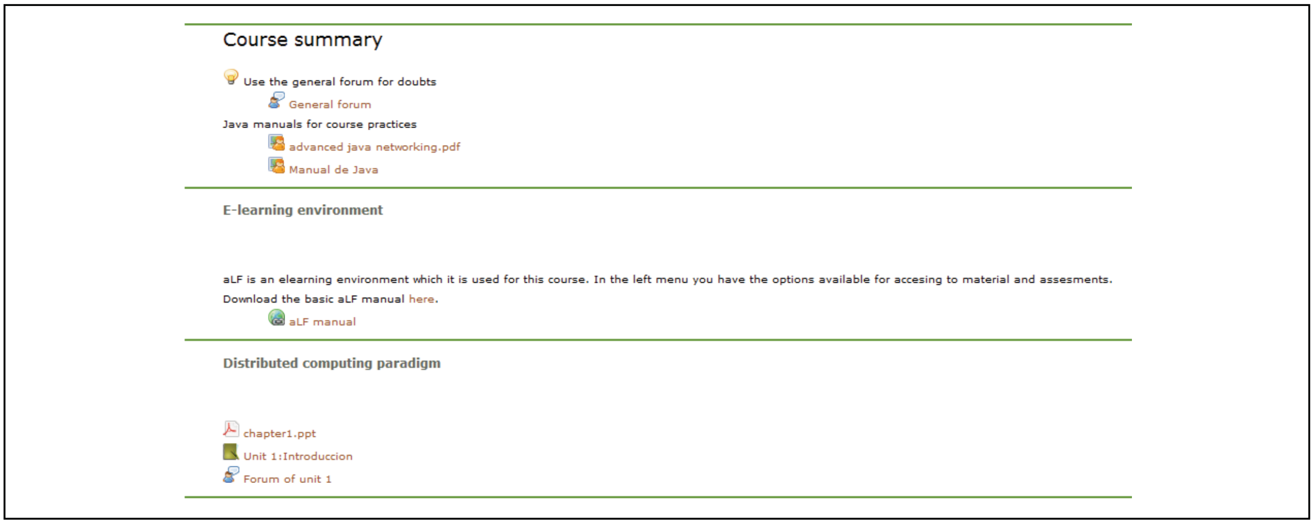

Figure 10. The planning tool based on organizational units called "blocks".

While other types of architecture (not EIS) such as the currently popular PHP e-learning platform can be made to support high student numbers (using imaginative clustering techniques), their inherent lack of scalability and other EIS characteristics, unnecessarily complicates their overall performance.

It has been noted that for the EHEA, a practical study of best practices implemented in WebCT (tools based) have been included in the development of aLF in order to minimize the transition to the new platform. Also, a planning tool like that of Moodle has been incorporated to provide a natural way for the course organization defined by the didactical guides elaborated for the EHEA. The advantage of this way of presenting a course to students is that they can see easily what work has to be done and what the sources they have at their disposition to undertake the work. The fundamentally sequential nature of each block provides a sequencing of activities for the students. For example, a student can see that initially they have to read a text, enter into a forum to discuss it, undertake a practical activity based upon it, and finally, undertake some kind of online evaluation.

As was noted at the beginning of this article, innovation is a standard ongoing activity within the UNED. As such, the development of aLF over the next few years will continue in the current direction, expanding the possibilities of online distance education, making it more ubiquitous. In basic market terms, as traditional face-to-face universities are increasing their use of virtual communities on online teaching, the UNED must extend its online teaching model to become more "face to face", in the sense of using both the synchronous and asynchronous capabilities of aLF and its tools to shorten distances and enable students to access the tools and educational resources they need to undertake their studies. As such, the future work being contemplated at present, is envisaged to focus on providing a better user experience: copying items and organizing sections, automatic show/hide functions for temporal planning, integration of didactic guides elaborated by professors from other scenarios, SCORM (Sharable Content Object Reference Model) support for the content tool (allowing users to publish and author SCORM objects) and marking up content pages for users (to provide visual tracking of content views).

Educative use of simulators in free software for the education of the physics in the engineering programs

Ariel Adolfo Rodríguez Hernández
Facultad de Estudios a Distancia.
Universidad Pedagógica y Tecnológica de Colombia UPTC
Tunja, Colombia
ariel.rodriguez@uptc.edu.co

Abstract - **See of the necessity that the education has of incorporating the technologies of the information and the communication TICs to the teaching-learning processes. The investigation group TICA: Technology, Investigation and science applied since for several years come developing projects of incorporation of TICs in the education.**

One of these projects is the one that today is presented in this document and whose purpose has been to identify solutions of educational software: simulation systems, virtual educational environments, educational software, among the most outstanding. But with an added value that you/they should be developed standard first floor of free software that you/they guarantee their use, modification and execution without restrictions for the final user or the institution that he/she wants to use them.

Around this topic you beginning an investigation from the year 2007, which begin with the topic of pretenders developed in free software for physics, when going developing this topic was being identified all kinds of solutions of free software, making with it that in a parallel way you began to inventory these solutions.

Today per today they have been identified near 2500 solutions of free software among pretenders, learning environments and other solutions with educational use.

And seeing this great volume you design a repository of pretenders in free software which has been denominated Open Simulates Source. This portal has as purpose to index all development of free educational software.

Keywords-component; *e-learning and learning colaboratives environment, simulation, educational software, open source educational software.*

I. Introduction

The free software has penetrated today per today all the areas of the knowledge and of the development of the society, its organization and development model has allowed him to be positioned like a true solution to the necessities and computer of the current world.

But little it is known about systems of free software for educational use, and it becomes necessary to study the evolution and the state of development of the free educational software.

Their main objective was to identify and to document the state of development of the topic in the current society and to transform this study in a repository or bank of digital resources initially conceived for pretenders that it stores the results of this study and it publishes them in the Internet by means of a place Web. And later on it includes all the types of educational software.

Defined this purpose the project gave beginning to the study on the topic and along this document the obtained results are exposed, categorizing and analyzing the low results certain variable ones.

It is presented studies by type of identified software, for type of language in that you/they were developed, for license type with the one that are distributed, for the operating system platform in that you/they are available and for the case of the physics that is the central topic for area of knowledge inside the physics.

This study takes to the reader from all over the world for projects from the local thing, projects in Colombia and going by United States, Canada, Argentina, Peru, Europe (Spain, Portugal, France, Italy, Germany, England) Asia (Japan, China, Taiwan) among the countries with identified projects. They were identified in total 50 projects of pretenders in free software, with a total of 2097 pretenders for physics. And as regards learning environments around 6, and another type of educational software to the moment d this article has been identified but of 15 projects.

Many of these projects of which an individual synthesis is made, for professors of the different universities is led, others for software communities sponsored by universities. And for the international community of free software.

1.1. Problem of Investigation

1. Do pretenders exist for educational use in the teaching-learning of the physics, developed in free software?
2. of existing these resources which the effect of the educational use of pretenders is developed in free software in the learning of the students of the class of Physics in programs of university pregrado?.

1.2. Objectives

To design, to develop and to evaluate, an on-line repository that contains material, documentation, sources and executable of simulation systems for physics laboratories developed in free software "open source" and a methodology pedagogic pilot to prove their use and implementation like educational material for pregrado courses.

Specific objectives

- To identify the simulation systems for physics laboratories developed in free software, their characteristics, functionality, technical information and the code source and the executable ones.
- To define and to design the guide of implementation of a pretender like educational material in a real course.
- To design and to develop in tools of free software the repository on-line pilot that will contain the simulation systems for physics laboratories, their documentation, sources and executable.
- To validate in a course the use of one of the pretenders and the education methodology or defined pedagogic model to implement them in a course.
- To establish the diagnosis in front of the validation of the use of the pretenders and to identify the strengths, weaknesses and opportunities of improvement that allow to use in a more efficient way this type of materials in the classroom.

1.3. Justification.

When developing this work a database it is believed with the simulation resources to support processes of teaching-learning of the physics and developed low environments of free software, which is published through Internet in order to putting it to disposition of the educational community.

On the other hand the project after developing this informative source and of resources it allows to identify a methodology for the use of these resources in order to validate and to diagnose the educational use of the same ones inside a real course of this area of the knowledge, settling down and identifying with it the strengths, weaknesses and opportunities of improvement that allow to make use in a more efficient way this type of materials in the classroom and to diagnose the disposition of the student community toward this type of resources.

Contributing with this to that you/they begin this type of works in the other areas of the knowledge, an advantage of this work is that as what is looked for it is free software, when being able to centralize the information of these solutions and the access to the same ones in a single place you can provide to the educational institutions of resources that improve the education and that they truly give solution to the social necessities that the education today per today it should satisfy.

When identifying the strengths, weaknesses and opportunities of improvement that the software pretenders get rid it contributes to the technological development of the education, besides reducing costs in the use of audiovisual resources for the educational ones, being that these resources are more economic than the use of specialized technical material of laboratory and in some cases they are gratuitous.

Also, you offers an opportunity to the educational community at all the levels to be added to the use of this innovative technology like strategy for the learning, breaking the paradigm of the use of traditional strategies.

2. IDENTIFICATION AND CLASSIFICATION OF THE SOFTWARE

The project left of two questions:

1. Does software exist (pretenders, operating systems, educational software, learning environments) for educational use in the teaching-learning of the physics, developed in free software?

2. Of existing these resources which it is the use and diffusion of the same ones inside the community.?.

With this couple of queries beginning was given to the field work that consisted on to identify software of the mentioned characteristics and to document it in order to including them in a repository or bank of pretenders.

One works during long eleven months making searches in Internet, sending letters to universities and communities of free software in order to obtain sources of information on the topic.

Parallel to this work and linking an investigating youth, technologist in systems you beginning the design and development of the on-line repository that I eat in the initial project approached single pretenders you denominates Open source he/she Simulates.

For effects of organization of the information he/she was defined a categorization system, which I include the type language in the one that you development each software, the license type with which is distributed and for the physics the category to which belongs according to the thematic one.

These variables were used to classify the results.

3. ADVANTAGES OF THE USE OF FREE SOFTWARE

The derived advantages of using solutions (operating systems and programs) based on free software they are:

Under cost. It is the first motivation for the use of the free software the cost of acquisition of the software it can already be free or of very reduced cost.

Total independence of any private sector or company. This supposes not to be bound to the market conditions imposed by software companies that sometimes show monopoly situations.

Security and privacy. When having the code source, the internal operation will be known and they will be and they will correct the possible errors, shortcomings and holes of security. At the moment Linux is immune before the immense majority of virus computer specialist that affects to the systems almost exclusively Windows.

Adaptability. The modifications and corrections of possible errors are carried out in an immediate way. This way, the applications are in continuous improvement and evolution process.

Quality. The free software, to the domain being publishes, it is being continually used and purified by a great number of developers and users of the same one that add and they demand constantly new functionalities.

Regarding the standards. The use of free software and open systems facilitate the interoperability among different organizations.

Predistribution. Any change and improvement that it is introduced in programs lower it licenses free it should be included in later versions and added to the code source. The technological development is this way continuous and dynamic.

There is not legal restriction of use. There is not limitation in the number of licenses neither of copies inside the organization like it happens with the software he/she doesn't liberate where the payment settles down in function of users' number, size of the organization, etc.

Continuity. The right of any user is guaranteed to continue the development.

Easiness. They can begin new projects based on the code of a free program or to adapt it without necessity of requesting authorization in this respect.

4. PHASES OF DEVELOPMENT OF THE INVESTIGATION

4.1. Identification phase and documentation of software resources

In this phase you looks for and I identify the solutions of educational software of type pretender for physics laboratories developed in free software in the national and international environment. This stage or phase include that to each opposing solution and that it finds been developed in the last ten years he/she was identified their characteristics, functionality, technical information, the code source and the executable ones insofar as possible, or in their defect the place Web from which you can use.

These programs were selected previous analysis of the characteristics that should complete in terms of the topic that approach, the one which you development with base in the contents that become trained in the Physical I of the pregrado programs. Those which in particular should give computer treatment of the simulation of phenomena related with the topics.

At the same time, in this phase a revision of works was made on the didactic problem of the experimental learning of the Physics [1] and [2], with object of identifying the most important pedagogic aspects that it should complete a simulation system for the educational use (theoretical contents, virtual experiences [3], tasks of development of dexterities, activities have more than enough learning [4], methodologies for development are practiced supported in pretenders [5])

4.2. design phase and development of the repository of the software resources

Previous to the design and development you selects as tool of development of the repository the PHP 5. as language programming base for those additional functions that are required, and you uses for their design Web the environment Mambo or Joomla whose use license is LPG. As agent of databases MySQL, as servant Apache Web. To configure the place web cpanel use it was made.

In this phase use of the software engineering was made to design the solution Web that would serve as repository of the pretenders and its respective documentation. I design that include the integration inside the place Web a system administration of educational contents that is MOODLE for the project, since it is free software, compatible with MySQL, PHP and Apache.

Parallel to the design you proceeded to develop the solution Web and it is necessary to begin tests of the gathered pretenders, to validate their functionality and the access to the resources that each element of the repository provides.

4.3. Phase of identification of the educational methodology and the design of implementation guides.

This phase required him to be defined the educational methodology to use to validate the educational use of physics pretenders in a real course. You proceeded to define the population of the course, the level, and the educational modality.

Selected as group pilot the course of Physical I of the Technology in Civil Works from the Ability of Studies to Distance of the UPTC.

At the same time that you identifies this educational methodology of use, you elaborates the guide of implementation of the pretender like educational material in a real course, which should help the students to carry out in a practical way a series of experiences of Physics, using the pretender selected in order to validating the strengths, weaknesses and opportunities of improvement that allow to use in a more efficient way this type of materials in the superior education the classroom [6].

Of equal he/she is formed they defined in this phase the indicators that allow to diagnose the educational use of the pretenders and the impact of the same ones in the education.

4.4 application phase

Once the educational methodology has been identified, they have been designed the implementation guide and one had available the pretenders and the system of administration of educational contents you proceeded to it incorporates these resources to the educational practice, as complementary tool in the programming of practical works of physics, in the first engineering course in programs of pregrade of superior education [7].

And you proceeds to validate the use of pretenders. You also looks for to analyze the influence of these computer applications, and of the complementary didactic materials, in the learning process that the students carry out through the laboratory experiences, evaluating the reports of the work sessions carried out with the software.

4.5. Phase of I diagnose

This final phase as its name indicates it I look for to establish the diagnosis in front of the validation of the use of the pretenders in the education and to identify the strengths, weaknesses and opportunities of improvement that allow to use in a more efficient way this type of materials in the classroom.

5. IT FOCUSES METHODOLOGICAL

It is good to specify that the methodological focus of this investigation is to describe the current situation of the topic, identifying the projects and developments of pretenders, making this investigation of descriptive type, having as primordial purpose to establish the state of development of the topic educational use of pretenders developed in free software for physics. To have presents this consideration it is fundamental to understand the results that they are presented fruit of this investigation.

As one of the objective it is to create a bank of information that identifies and present the developments of software type pretender based on free software, he/she gave place to establish the characteristics of the analysis of information in front of the topic and defining the general mark for the investigation. The characteristics that have been defined for the identification of data, their treatment and analysis are:

Software type: characteristic centered under the types of free software or the conditions of a software to be denominated free software. Taking as concept that at least fulfills one of the freedoms that have been defined in the concept of free software.

It licenses under which the software is distributed, it became necessary to identify this characteristic for this way to present in a more solid way the results.

Programming language, this characteristic looks for to settle down which languages are those that lead the development of pretenders in free software.

Platform or Operating system, this characteristic looks for to settle down in that operating systems the identified software can be used

Area of the knowledge, although the project is defined for single physics, this science has multiple areas for its development, the fundamental areas of the physics were identified and you looks for to associate each result to one of these areas.

TABLE 1. VARIABLES OF INVESTIGATION

CHARACTERISTIC	VARIABLE
Software type	Web o Applet
	Application instalable
	Operating System
	Directory
	Development Solution
	Learning Managent System
Programming language	C++
	Java
	Python
	Perl
	Swish / Flash
Platform	GNU/Linux
	UNIX
	Windows
	Mac OS
License type	GNU GPL
	Freeware
	LGPL
	Creative Commons
	Shareware
	BSD. Berkeley Software Distribution) Licences

6. ANALYSIS OF RESULTS.

For the process of documentation of the results the used instrument was a registration leaf, which you uses along the identification process and it allowed to analyze and to process the data obtained according to the necessities and objectives defined by the project.

In synthesis projects of educational software that are totally free software they are few, a good percentage of resources and projects identified in this study are partially since free software they don't fulfill the four freedoms required to be free software.

This work has allowed to establish three big categories of solutions of simulation software, of equal it forms as the physics it is a very wide science it became necessary to identify the area to which belongs each solution of identified simulation.

Finally this characterization of results taking as relating the existent types of free software and indexed in the numeral one 2 of this article and they are analyzed and they classify the results according to the types of licenses that belong to the free software.

It is important to recognize that you looks for to identify the language in which the solutions and identified projects were developed, being the language Java that of more use, followed by languages like C, C++ and Python among the most outstanding.

6.1. Identification of resources for software type.

This analysis allowed to determine the quantity and the percentage of pretenders for class of identified software, with the objective of knowing the tendency of the market in front of the software types.

TABLE 2: CLASSIFICATION PRETENDERS FOR TYPE OF SOFTWARE

Software Type	No. Projects	%	No. Objets	%
Applet (Java /Flash)	22	44,0	2069	98,7
Opetaring System	1	2,0	1	0,1
Aplication Solution	15	30,0	15	0,7
IDE	5	10,0	5	0,2
Directory	2	4,0	2	0,1
LMS	5	10,0	5	0,2
Total projects	**50**		**2097**	

Analyzing table 2 could settle down that the developments type Applet is the most common in the simulation in free software for physics. The cause of this result this in the portability of the applets, its easiness of being executed about the Internet, and the robustness for the mathematical handling of the languages used for these simulations is Java and Flash (Distributed the executable one gratuitously not the code source).

The Figure 1. Percentages of pretenders according to software type, it shows as the population of physics pretenders developed in software he/she gets rid they distribute according to the software type.

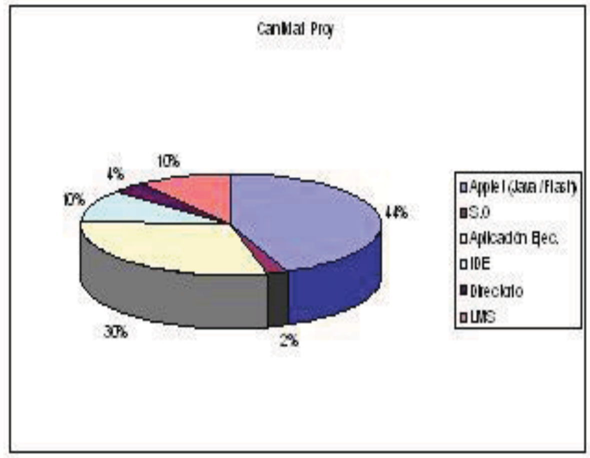

Figure 1. Percentages of pretenders according to software type

The pretenders identified type applet developed in language Java, allow to discharge the code source or binary and the execution files (. jar).

As regards applications executable type, it could settle down that they correspond in their great majority to applications to simulate graphic of high mathematical complexity.

Finally the environments of development type IDE for creation of simulations in free software is scarce but little by little they consolidate as the future of the pretenders in free software. In a numeral one later on are described with detail these solutions.

To level of directory Web or repositories of resources it was possible to identify two repositories of those more than 50 projects, these repositories are of type informative database.

And at level of operating systems of open code you identifies the operating system Ing-X that integrates the most robust and complex developments for simulation in their distribution. This project has its origins in the republic of the Argentina and it integrates more than 15 simulation solutions for multiple areas of the scientific knowledge.

6.2. Identification of resources according to the development language

Inside the investigation process and rising of the projects, to each project he/she is identified the programming language in which was developed, the object of this analysis it is to establish the tendency in programming languages for the development of pretenders and to identify the causes of their use.

TABLE 3: CLASSIFICATION PRETENDERS ACCORDING TO PROGRAMMING LANGUAGE

Programming language	No. Projects	%	No. Objets	%
Java	29	58,0	1880	89,7
Python	6	12,0	7	0,3
Flash	3	6,0	198	9,4
C++	10	20,0	10	0,5
NA	2	4,0	2	0,1
Total	**50**		**2097**	

In a conclusive way this analysis hurtles that the language Java is the more used for the development of pretenders, followed by Flash, C++ and Python. This finishes language this being proven in the system SimPy = Simulation in Python, project that has created a solution based on this language to develop pretenders in free software, see you Figure 2 Percentages of pretenders according to programming language using.

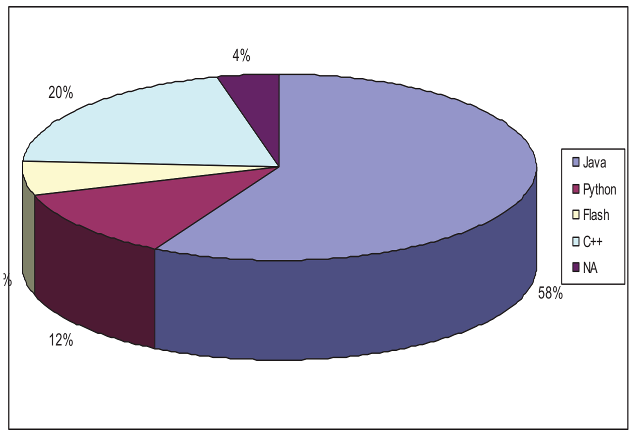

Figure 2 Percentages of pretenders according to programming language using

The reasons for those which the language Java is the more used in the development of pretenders for physics they are:

- Java is a language multiplataform that allows to develop from an independent way to the operating system the applications. Making completely portable and scalable all development in Java.
- Their packages and APIs for mathematical handling and graph in 2D AND 3D allow to integrate and to manage the complex operations and graphic that the physics requires to simulate the different events and study areas.
- Java is a language to modulate reutilizable that allows to create a development highly and then without many changes to translate it, reason that has made that in the market the pretenders type applet in java are available in multiple languages.
- On the other hand its robustness in advanced mathematical prosecution makes it very useful in the simulation topic in physics, the same as the packages of classes for handling of 2D and 3D and the graphic handling.
- On the other hand to the power to execute an applet on a navigator of Internet, he/she gives place to that their distribution and use you simple and work in practically all team of I compute.

Special case is the topic of pretenders developed in Flash, it is one of the systems of development of better graphic and very versatile prosecution when being integrated with the Internet, since these developments are guided the Web, contrary to alone Java it is possible to obtain in the great majority of the cases the executable one but not its code source, making it free in use but not in the other defined characteristics for the free software

The central difference of the developments in Java, C++ and Python in front of Flash this in that the developments under the first three languages offer the four established freedoms for the free software, while alone Flash grants the freedoms one and three, execution and distribution.

6.3. Identification of resources according to the type of distribution License

The object of including inside the characterization of the study this aspect was the one of identifying the tendency as regards licenses of the identified resources type pretender and the level of implementation of the commitments of the free software and according to the license of distribution of each resource or project.

The table 4 reflective the results of this study, when analyzing them one can do with clarity that the Freeware and knows to the software that is free as soon as I use and distribution not in permits to consent to the code source and to change it or to improve it leads for wide margin the results.

Leave with concern that in this topic the total freedoms of the free software should be approached and concerted in order to take advantage of the strengths of the development communities in the remarkable improvement of these resources.

TABLE 4: CLASSIFICATION PRETENDERS ACCORDING TO THE USO/DISTRIBUCIÓN LICENSES

License type	No. Projects	%	No. Objets	%
GPL	16	32,7	120	5,7
LGPL	1	2,0	1	0,0
BSD	2	4,1	2	0,1
Freeware	28	57,1	1867	89,0
Creative Commons	2	4,1	107	5,1
Total	**50**		**2097**	

The analysis takes to conclude that the freeware in 57.1% is the form but common of to publish and to put to disposition of the I publish a software, and the disadvantage of the same one is that they don't fulfill the four freedoms settled down by the free software, leave equal it forms that the license LPG occupies the second place with 32.7%, see you the Figure 3. Percentages of pretenders according to type license with the one that is distributed.

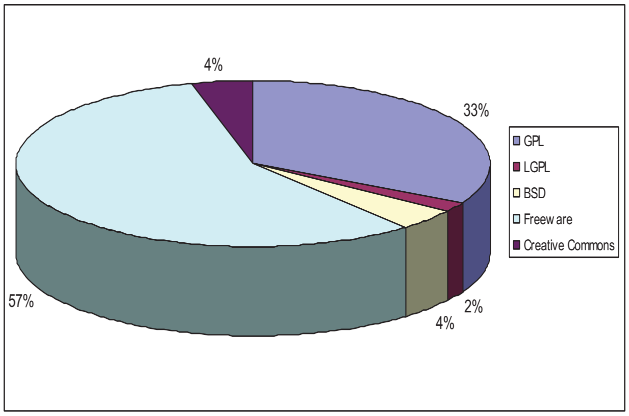

Figure 3 Percentages of pretenders according to type licenses with the one that is distributed

This takes to that thinks about the necessity to take place under oneself approach the form of transforming the freeware into license LPG to guarantee the 4 freedoms of the free software and potencilization the advantages that this development model offers.

6.4. Identification of resources according to use platform

Necessarily to identify the platform or operating system on which the pretender can be used, it is fundamental. This assures the portability between one and another operating system.

TABLE 5: CLASSIFICATION PRETENDERS ACCORDING TO THE OPERATING SYSTEMS FOR THEIR USE

Plataform	No. Projects	%	No. Objets	%
GNU/Linux	8	16,0	8	0,4
Windows	5	10,0	202	9,6
Multiplataforma	35	70,0	1885	89,9
Mac OS	2	4,0	2	0,1
Total	**50**		**2097**	

The results described in the table 5 in a conclusive way identify that the developments are in 70% multiplataform assuring with it the use of the same point in GNU/Linux, like in Windows or even Mac OS. To see Figure 4. Percentages of pretenders according to their readiness for Operating system.

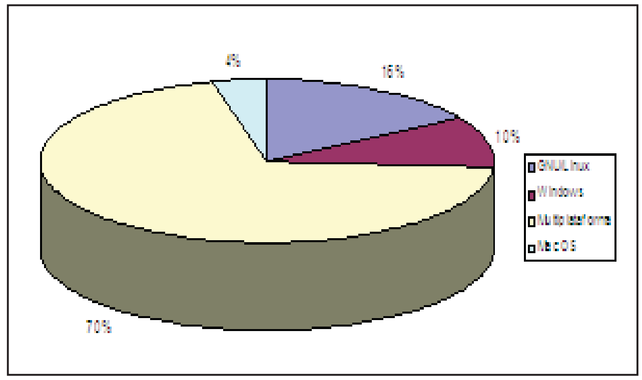

Figure 4 Percentages of pretenders according to their readiness for Operating system

This obeys to that the great majority of solutions is developed in java, and this language to be portable it allows that in a very simple way it can be used in multiple

The case of the operating systems GNUI/Linux surprises to be so low, although when analyzing it with the fact of already belonging to the category multiplataform it this being in GNU/Linux of for if.

7. CONCLUSIONS

7.1. Conclusions

In the work he/she intended to identify and to document the projects of educational software developed in free software by means of the development of an on-line repository, equally developed in free software.

It is of specifying that the results fruit of this stage of the project are satisfactory in quantity, you to identify around 2000 software solutions, each one documented and organized according to the application area.

Of this study you concludes that the educational software that you/they are hundred free percent is few hardly 42.4% in I number of identified projects and in I number of pretenders 11.4% of the total, situation that obeys the non identification of the authors with the models of licenciamiento of free software, situation that takes to conclude that in l present time the concept of free software under the principles that to this they not yet govern it they are clear for the development communities and the institutions.

Bigger effort is required on the part of the associations and foundations agents and promoters of the free software and the experts in the topic to clarify the concept.

On the other hand in their great majority these pretenders are personal initiatives and professors' of different institutions singular that moved by the desire of improving the education they have developed this type of resources and that for the necessity of the same ones they have been able to link to these initiatives to other colleagues.

It is required to lead in a more organized way and with approaches of quality of educational software and of the dynamics of systems this type of projects so that inside a community of developers a model of development of free educational software consolidates.

From the educational point of view several projects were identified that are very solid in the methodological and pedagogic that can be the courses to consolidate the educational use of pretenders inside the society.

7.2. Future works

Identified those more than 2000 software solutions developed in free software a very important future work would be given by the validation in educational terms of these resources and under the approaches of quality of the educational software. Investigation that would allow to have better elements when making use of these resources to the educational and educational organizations.

Of another part with the existence of integrated environments of development of free software should be carried out the analysis and study that it takes to define the methodology for the development of pretenders and free software using these systems and with their respective validation processes from the pedagogic thing, the instructional design and the theories of the learning that sustain the quality of these systems.

He/she thinks about the possibility to investigate this same topic enlarging it to other areas of the knowledge, since when developing this project it was possible to glimpse that there are pretenders for many other areas, but that of equal it forms they could be identified and by means of a repository to place them within reach of the community.

A later project to this he/she should take these pretenders and to validate them from approaches that measure the learning and their impact in the processes of development of knowledge.

8. GRATEFULNESS

Thank you to the Pedagogic and Technological University of Colombia for their economic and logistical support for the development of this investigation.

***Abstract*—This paper describes the importance of Engineering Societies inside the educational environment, focusing on the new learning models that appear in the student branches. This model involves pedagogical methods differents than the more formal ones used in the classrooms. They are based on more informal approaches where learners are the real center of the process and teachers appear just as tutors or learning drivers, providing the required material and support to learners. The paper describes the successful experience of a Student Branch in a University for Distance Education, overcoming the traditional collaboration and interaction lacks that these kinds of institutions own due to its inner organization and learning methodology.**

Keywords: Engineering Societies; Student Branch; blended learning; active learning.

I. INTRODUCTION

Engineering societies play an important role inside the university environment, due to they can become a vehicle between university and industry, helping learners to acquire different knowledge than the provided by the formal education. This knowledge could be an important added-value for students when they arrive to work market because they will own more knowledge, experiences and capabilities than the other applicants [1] [2] [3]. These new skills will be the key for their future professional development.

In addition, active participation on these Societies can help learners to improve their self-learning abilities, because they must learn by themselves many technical concepts to put them into practice [4] [5] [6]. They also improve their social skills, such as leadership; organization of projects, talks, workshops, publications, etc; and work scheduling (for themselves and for the group). On the other hand, other advantages are the improvement of their own technical knowledge in the areas where they are interested in (they have access to the latest information about technology), social networking and knowledge about other cultures (with other students or professionals interested in the same areas all over the world).

But in these groups usually learning does not happen spontaneously. Some kind of impulse is required to encourage students to participate in an active way. Usually, it happens through the participation on contests (e.g. robotics, programming, networks, etc) or through interesting projects to achieve a particular goal. Other incentives for the engagement could be attendance to technical talks, workshops or publication of papers on journals or conferences. Enjoy, learning and success are guaranteed when a student is suitably motivated.

A very good example of the successful implantation of these societies at Universities is the IEEE Student Branch of UNED (Spanish University for Distance Education). This group has overcome the problems of having the members spread all over the country [7]. The paper describes the distributed organization of this group and the use of virtual tools to support the communication and collaboration among group members.

Engineering Societies arise as a very good vehicle to complement the formal education, providing at the same time experience in real projects that will be very useful in the integration within the work market.

II. POWER AND POTENTIAL OF ENGINEERING SOCIETIES

It is a fact that in order to teach anything, you firstly must know something about it. Engineering Societies had been working in their knowledge field during many years. That is why they are the source of many answers to learn and subsequently to teach. Usually, students only connect with Engineering Societies when they finish their degree. This situation generates an important gap between learnt theory in their degree and real life. The solution would be to keep in touch students and Engineering Societies during academic time. This new approach will give students the possibility to use their recent knowledge gained in their degree, in real life without gapping. This possibility promotes students to pay more attention in their studies. It means that the acquired knowledge will be more useful and enjoyable in their careers and, most important, in their degree years.

In fact, when a student finishes the degree, Engineering Societies will be the link between academic and real life, and will be the new way to continue self-training. The adaptability that Engineering Societies have is a key feature that new degrees should acquire to develop a professional success. In this point, the IEEE-UNED Student Branch thinks that this feedback after degree must start during academic formation. The IEEE-UNED Student Branch has been working in that line for many years, trying to look for the mechanism to obtain the most of this relationship during academic years.

In our case, we are working with the IEEE (Institute of Electrical and Electronics Engineers) organization. IEEE has several levels for professionals and students to develop before, during and after his/her academic and professional career. We are using the called IEEE Student Branches.

An IEEE Student Branch is an association for students in Technical degrees (Physics, Engineering, Maths, etc...). Its labour reflects clearly how it must articulate the relationship between academic and real life.

In the situation of the UNED, Engineering Societies promote students to develop their own projects. On the other hand, Engineering Societies give them support and advising. The most important part in this relationship is the freedom of students to manage and develop their own objectives. That is the reason why motivation has a special role. The only way to give students responsibilities and maturity in their actions is give them the opportunity to make mistakes and learn from them, at the same time that they solve them. That must be the worker's behaviour in real life.

To train students you must give them skills, but these ones not only must be academic in their area of study, but skills in other areas. These new areas of work may have interest to teach them about management, organization, working in group, collaboration activities, language skills, commercial skills, etc. This Engineering Societies have the possibility to offer those skills to the students because they own as members enterprises; mentors; academic professionals; engineering professionals; public and private employers; business partners; or big and small enterprises. Definitely, they have the most representative roles that students will have to face when finish their degree.

Currently, the IEEE-UNED Student Branch has four important ways to connect Engineering Societies and students:

1. Through Contests. One of the usually ways to motivate, develop and check students' skills is with contests. Most of engineering degrees are related with experimentation and mechanical experiences. This is a good excuse to make a contest. The key is showing the students that academic theory is useful to provide answers to real life. Activities like Robotic Contests, Olympics Maths games, Innovation Contests, and others similar activities work because students learn the practice of their studies and develop competition and cooperative skills. A very good example of this in the IEEE is the IEEE Xtreme programming contest. In this competition, students in all IEEE Students' Branches around the world will compete to show that their students are the best programmers. In this challenge, a team of students will have to solve several problems in 24 hours. It is obvious that a contest like this will teach students a real experience in solving problems with a deadline, work in group, work under pressure, etc. Of course, the winners will get fame and maybe some new opportunities will appear for them to get their dream's job.
2. Through Formation. We can talk about two formation ways:
   a. Academic Formation: With several activities like technical workshops, language workshops or attendance to technical conferences. It helps to develop academic skills.
   b. Professional Formation: With Management Workshops, visits to enterprises, financial and marketing workshops. It helps to develop professional and personality skills.
3. Through Labour Market. Put real life in front of students is the most important thing. And real life means to talk about the success, but even more important is to talk about the failure. Students must know enterprises into technical studies and learn about that, visit them and learn their growth process and fall. If students know that real life can be dangerous, they will be more motivated to think about their skills and lack of them that they have. Academic world is a quiet environment for the students, only exams time generates a few of stress in that environment. Usually, they have only one deadline: the day before the exam. Real world is an aggressive environment with daily deadlines, study, work, or family, with more stress and less time to react, usually without second opportunities. The only way to train real life is living it, and the only chance to students to experiment real life is through the important experience of Engineering Societies about it, its advices and by using its skills. Moreover, the societies have experience in project failures, and it is very important to teach students about the mistakes of the past, as it is the best way to avoid having the same mistake over and over again in the future.
4. Personal Issues. It is important to motivate students with Engineering Societies and vice versa. But there is another factor: the personal one, which belongs to other scopes besides the professional one. Engineering Societies help students to work together, helping themselves to study better and so making their work also better. At the IEEE-UNED Student Branch, this is a very important factor. Students have not direct contact with teachers, so they have to study by themselves and help (and be helped) by other colleagues. That is one of the reasons why the personal inter-relationship can be very important and make to grow up these Societies.

Another very important factor for the Engineering Societies is that they give the opportunity of networking. In today's world, there is a lot of competition to get a job. One of the best ways to help students to be successful in obtaining their dream's job, is having contacts everywhere. For sure, all readers going to know at least one case of a person that got a job because of a friend, teacher, parent, etc. Engineering Societies bring the possibilities of put in contact all the persons interested in the same engineering field. For example, according with the experience in the IEEE-UNED Student Branch, through the robotics workshops, all students with interest in robotics have been in contact, resolving problems together, developing projects or even just having fun in general meetings. Of course, inside of this contact groups there are professors and professionals. Therefore, through the participation in the Society, professionals will meet students that can be a good future bet for their company. On the other hand, students will meet professionals that can give them a job in the future.

This kind of socialising can be seen in all the IEEE structure because of its division in professional Chapters and Societies: communications, signal processing, information theory, broadcast technology, etc. All engineers with a common interest will be put in contact easily through each particular society. In the IEEE-UNED Student Branch we have students with interest in several technologies. In this way, if they get enough people with interest in the same Society, they will be able to create a Chapter of the Society. The advantage of this is getting funds from the society to develop projects, the possibility to do contacts with engineers with interest in the same field and be informed of the new related technologies.

On the other hand, Engineering Societies are very important to achieve sponsors to student projects, because the enterprises get publicity and have the opportunity to evaluate at the students in real time. We don't forget that more of those students would be potential employees in the future and they would be trained in the last technology and resources of sponsor enterprises. At the same time, students know the enterprises around their academic specialities and have the chance to keep in contact with them before, during and after project finish. Usually, during academic years, students have to study old systems and technical resources, mostly obsoletes. Introducing enterprise vision in a real project, students can use new resources, even experimental resources, and keep in their minds the necessity of stay update in their studies and in their work if they want to be competitive.

An important aspect of this relationship is that Engineering Societies can act like a tool to show to the Bachelor's School the way to adequate academic formation and real work. This mechanism could be seen in the collaboration of both sides; Schools and Enterprises; through the Engineering Societies in the elaboration and preparation of contents of academic studies. Joint projects and periodical activities would be the better way to keep and enrich this contact. These activities could offer to the enterprises a real vision of the weaknesses and the strengths of the students to solve and potential those weaknesses to get the best of them.

Finally, we can think of this relationship is a cost or an investment for Engineering Societies. We must not forget that Engineering Societies are formed by enterprises and institutions. They work with money and they plan their investments, actions and efforts to achieve the success and challenges. As we said, these activities and efforts focused on students are, without doubt, an investment. There are many reasons: new trained professionals, new future and motivated employees, important marketing activities, better knowledge about employee market, and a way to show the Engineering Societies, and their member enterprises, the important social implications they provide to the society.

III. MOTIVATION IS THE KEY

It is difficult to keep the attention of students in an academic class, but it is easy keep the attention of everyone in a game or in an enjoyable activity. This objective is the path of a teacher. If he/she want a thoughtful audience must turn his/her class in an interesting moment for feedback, interchange of opinions, look for answers, and above all, set out questions. What can we do about motivation? The answer is simple; student must be involved with the lesson. One of the ways to accomplish this goal is to transform the student into a teacher. In several workshops the IEEE-UNED Student Branch have worked with students with knowledge about robotics, electronics, web development, etc. in this cases, student has been invited to participate in the class like a teacher, he/she have to explain the others students the lesson of the day or, in some cases, he/she can suggest the lesson of that day. This activity reinforces the attention of students and increases their self-esteem.

It is true that this kind of class requires more flexibility and participation from teachers, but in a few time this effort is rewarded with the attention of students.

With the attention focused, we can look for motivation. Everyone has skills but not everybody discover them. In this moment, teacher has the opportunity to show at students how other people works day by day in different; technical areas in our case; exploiting their capacities. Using Engineering Societies like a model, it is easy to show students how they can work in group, and the first thing they must learn is that in the group everyone is important and everyone has a function. What is the function? That is the first step to take the student at a motivation attitude. In our workshops this is the moment when the teacher hands over the word to every student and every of them have to show the others his/her abilities and how they can help to the group to achieve the objective.

As you can see in this moment, IEEE-UNED Student Branch is changing the workshop into a meeting, it have achieved to dissolve the figure of the teacher; although he/she stays there monitoring and supervising every step; and students are working together imitating how it works an associated group.

This is the moment to purpose a project or a challenge, because we have captured the attention. Students are motivated and that is the moment to prove if they can work like a team and have a success or if they can work like a team and to bear a failure.

We can say that this behaviour is the one of Professional Societies. Their members are working together to achieve one objective and if they fail, the Society give them support to accept the failure or reduce its negative consequences, if it is possible. In fact, activities like contests, or similar, are looking for foster this aptitudes in the students.

Motivation is linked with social activities too, like contest or similar. On this way motivation could be an economic price, an opportunity to work in a real project of one of the sponsor enterprises, technical resources (e.g. tools, information or publications), an academic publication with national or international importance, etc. Engineering Societies have the possibilities and contacts to get these prices. As we said, Engineering Societies act like a connection between different enterprises and institutions, they know potential clients and suppliers, and everyone could be future sponsors in a student activity, everyone could need publicity, employees or, even, new future clients or suppliers, because students today could be successful professionals or enterprising tomorrow.

In Spanish University for Distance Education IEEE Branch, we have other motivations to study. Usually, we join this university because we are workers and we want to grow up in our life and jobs. One of the motivations is that we cannot see the teacher neither all the students can receive face-to-face classes. So, one of the motivations could be to think that nothing can "stop" us in our chance to study, neither our families, neither our works, etc. Then, we can afford the study of the subjects with the idea of passing the exam, that really it is more than that, it is passing many issues of the life itself. Therefore, motivation is very important for that reasons.

IV. ACTIVITIES

According with our experience, main activities can be split in two groups:

1. Collaboration activities are looking for reinforce group figure in the real life environment. Projects are the most representative figure in this way. In the engineering field, we can find projects in public or private enterprises (NASA, ESA, Telecommunication Societies, Aeronautic Societies, Automation Societies, etc...) and usually these enterprises have representation in Engineering Societies so, when it is called a project for students it is a good moment to prove if they are ready to work in group, to assume responsibilities, and to involve in a common objective. If students have success or not, is not so important than they can think, the important is working together and learn for the next project. In fact, the most important thing is that regardless whether there is economic award or not, students have been motivated during the project and they have developed new skills during this time.
2. Individual activities are necessary because there is a leader in each group, or a project manager to take difficult decisions or assume failures if would be needed, but everyone have, in any moment of his/her life, to take decisions, to have success or to make mistakes. In this moment individual contests, or similar, show to the students their possibilities, their real skills and teach them how to acquire other tools to face the professional world.

To develop both groups the Engineering Societies give support, help and advice to call activities in this way into the student branches. Any of them would be:

- Technical Workshops: About students' career, like robotics, programming, wireless, etc. To develop their technical skills and complement theoretical knowledge.
- Non technical Workshops: About management, leadership, marketing, organization, e-commerce, e-learning, etc, offering tools to complete student formation.
- Nationals and internationals congresses; conferences and other meetings; travels and visits to different places (NASA or INTA installations, private or public companies, etc.). There, students can meet other students and interchange experiences; or with professionals, generating an interesting feedback for their learning.
- Contests, projects, or championships for the students to motivate, award and recognize the students' efforts every year.

IEEE-UNED Student Branch organise some similar activities in different Associate Centres of UNED in Spain and we can say that results had been very positive.

Taking a look over the activities, we can find out some of the most successful activities of IEEE-UNED Student Branch:

- Robotic workshops: Initially, professors of UNED with the collaboration of some students did an initial workshop. Through it, students had the opportunity of learning with a real robot the basics of robotics and automation. This initial workshop let students organize their own workshops, until the point that now every year IEEE-UNED Student Branch has one or two workshops about robotics in several centres. Now, those students can be proud of having reached a third position in a national competition of robotics. The role of IEEE was essential to reach the success of this activity because part of the sensors used by the students was bought with IEEE funds. Currently, some students are thinking in doing a Chapter of the Robotics and Automation Society, to have access to the latest information in the robotics technology and even more funds to get new sensors or develop new activities to continue going into depth in their knowledge.
- SSETI SWARM project: Students of IEEE-UNED Student Branch got the opportunity of participating actively in this project to develop a Cubesat. All the participants have gained very important skills for their future career (work under a deadline, management, communication skills, and work in group).
- National and international student congresses: IEEE puts the funds and organizes multiple conferences for students. In Spain, we can emphasize the CNR (National Branch Congress in its acronym in Spanish), which every year concentrates students from all Spanish Student Branches. It let them meet students with the same areas of interest of the whole country, share experiences and ideas, learn about the activities of other branches, start projects and extend one's

social network. At an International level we can find the SBC (Student Branch Congress) which meets students of the entire IEEE region 8 (Europe, Middle East and Africa). This is an amazing congress for students because they can socialize with students of several countries, know about the engineering concerns in each country and even try to start student international projects. All of this without forgetting what they can learn in the congress about leadership, career development, communication skills, etc.

- IEEE congresses and paper presentations: IEEE organizes plenty of conferences with special offers to students. In those congresses, students have the opportunity of learning about the latest technology in different topics.
- IEEE online webinars: IEEE offers online seminars and students can attend to them and learn from experts the news about the engineering technologies.

Obviously, this is an ideal stage for the companies that look for new qualified employees.

V. THE IMPORTANCE OF FEEDBACK

One thing to remember in this kind of associations is the fact that their development is based on volunteering. That means that every participant in the Society is collaborating by free, or even they have to pay to belong to the Society. For that reason, the Society has the obligation to offer compensation to every volunteer collaborating in the activities.

Here there are two profiles which the Society has to cover offering a feedback.

In first place, we can find students. They want to learn, they are looking for developing a great career and they want to know how the real life works. After reading that, the reader can think that is all done: they have all they want and need in the Engineering Society. Unfortunately, it is not so easy.

The experience in IEEE Student Branch of UNED tells us that almost all activities have to be organized by students. That means they use their free time to pursue the success of the activity after a tiring day at the university or, if we speak in the concrete case of UNED, after a hard day of work, study and attend the family responsibilities. How can we achieve the involvement of the students in their free time? Engineering Societies have to show them that they are not going to get only some extra knowledge about the topic of the activity. Recruiters are looking for people who have good communication, leadership and organization skills, who are capable to work under a pressure of a deadline and with capacity of working in group. Students have to see how they can develop those skills through the organization of the activities; they need to know that they are using their time to gain abilities that going to put them in advantage in a job interview in front of people who have not participated in any society. Moreover, because of pure practical feature in the activities done in Societies, all students will get a real vision about all the theoretical studies they have done.

Following this way, we are going to have two kinds of students inside of the society. On one hand, it is possible to see the "active" student, who is the responsible of the development in the activity. This person will learn new skills that cannot be learnt inside of a classroom, such as previously described, and he/she will need use one's free time. In addition, the initiative showed by the student, will put him in contact with professors in a closer way, having the opportunity of getting involved in their projects and therefore, and learning advance knowledge in the topic of those projects.

On the other side, we find the "passive" student. This will be the person who belongs to the Society only for the advantages of being able to attend to the courses and activities done within the Society. Of course, the pupils will be able to participate with both roles depending on the activity.

In second place, the professor/tutor profile. We have to think that professors in Universities have their own projects, obligations and duties. In most of the cases, the Societies have limited economic resources, so they cannot offer money to professors to help in the activities. For that reason, it is necessary to find a way to attract tutors in the activities that are developed within the Society. Professors have their career done, it is improbably for them to learn something interesting in these extra-activities and almost for sure, they may have a complete CV that does not need more elaboration. So, how can we do it? Maybe a professor has their career achieved, but there is something that whatever engineer wants to get within their career: reputation and recognition.

IEEE, as engineering society, let people grow up inside of the organization. To get a promotion, they must do something to contribute with the society and with the engineering community. As professors, they can collaborate in create a new student branch inside of IEEE and get more members for the society. Moreover, IEEE offers to the students the possibility of giving awards to the mentors that are helping them. Through an active collaboration as tutor, students will give them that recognition. This fact will help the professor to have more reputation inside the society.

Finally, they will be able to see in first hand, students that are more brilliant putting in practice the skills learnt in the subjects, that show more initiative and that have good ideas to develop projects. This will let to professors, selects students that can help them with their own projects.

Figure 1 represents a summary of the feedback given for the Engineering Societies:

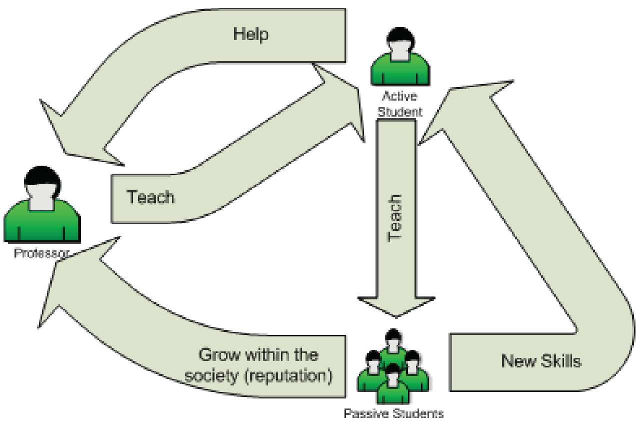

Figure 1. Feedback work flow.

The following are the roles involved in this process:

- Active student: He/she will develop new skills with the organization of the activities (communication, leadership, organization, work in group, etc). He/she will learn advance knowledge collaborating directly with the professor, and will be able to transmit this new knowledge to other students.
- Student Group (passive students): He/she will learn knowledge from the active student and will let the active student to acquire new skills. They will recognise the help of the mentor.
- Professor: He/she will be able to select the most appropriate students to help him in his/her projects. He/she will help in the activities done in the society, and will grow up in the society and get reputation and recognition.

VI. FROM THEORY TO PRACTICE: IEEE STUDENT BRANCH OF UNED

Since 2004 we work together in IEEE Student Branch UNED. The first steps were very difficult because UNED is a distributed geographical and physically University. At the beginning, our objective was to develop several work teams in different Associate Centres of the UNED in Spanish geographic: Madrid, A Coruna (Galicia), Terrassa (Catalonia) (Figure 2). Today, IEEE-UNED Student Branch can brag about have achieved this objective and go far away.

The key was the strength collaboration with IEEE organization and the hard work with students interested in learn more about engineering and cooperation like a work team.

Figure 2. Scheme of distribution of the activities in IEEE Student Brach UNED: an example of collaboration between IEEE (Engineering Societies) and UNED (University).

Why IEEE? Many reasons can answer this question:

- It is an international organization: This is an important point because most international and national enterprises belong to IEEE and this is an advantage for students that find closer new opportunities of work.
- It is the bigger Engineering Society in the world with more than 350.000 engineers belonging to it in 150 countries.
- The academic teacher of IEEE-UNED Student Branch and counsellor knows and belong to it. It was very easy for students of UNED to link with IEEE for the experience of one of its members. Students knew the possibilities and benefits of this Engineering Society and they knew the mechanism to belong to it.
- IEEE manages most of the international standards in Engineering. Belonging to it makes easier to know the latest researches and technological advances in many fields that engineering students have to know. This is very useful in order to have the best and upgraded formation; and information; in this fields. The only fact of being member gives you the access to IEEE Spectrum Magazine, The Institute Newsletter, IEEE Potentials Magazine and more. It will let members be informed about all the new technologies and save time in future as one does not have to "reinvent-the-wheel". We have to think that these IEEE publications are not available on Google for free, so the membership of IEEE can save time in research.
- Long years of life. IEEE is 125 years old, years of investigation, knowledge, standards, linked market and technology, linked enterprises and Academic institutions, linked governments and engineering.

Definitely: a lot of experience to absorb and to use for students.

- And networking. A lot of possibly contacts, to learn, enjoy, participate in contests, and even to teach or to work. An important and recognized organization like IEEE has the possibilities that student wants.
- IEEE offers multiple advantages for students to develop their career, like scholarships, the continuing education partners program or the IEEE job Site, which let look for jobs and career opportunities.
- IEEE is a very successful institution with a worth recognition for all the companies. IEEE offers the possibility of getting professional certifications to demonstrate your professional abilities. By gaining these certifications, you will enhance your CV with an international certificate with credit in all the companies.

On the other hand, by using several of the resources of IEEE, we have been able to call and organize several projects during recent years. For example, in 2008/2009 term these have been some of our activities and projects:

1. Annual Workshops: We are working in workshops about different areas in A Coruna and Terrassa Associated Centres.
    - Robotic Workshops: Today, IEEE-UNED Student Brach have a lot of activities related to robotics like coordination of contest, conferences about it, "webinars" (on-line seminars), etc... Student Branch is looking for more interaction with enterprises in this way, to give to students more opportunities in employee market in their future.
    - Wi-Fi Workshops.
    - PIC's Programming Workshops.
    - Joomla Web developed Workshops.
2. International Projects: Working like a team let members of IEEE-UNED Student Branch to take part in international projects. At this moment, students are working in two of them:
    - SSETI Swarm Project: In collaboration with other international universities some students are working since august 2008 in a space project where their work is designing and building a communications system to keep in touch a satellite with ground on Earth and vice versa.
    - Proposal to REXUS/BEXUS project from E.S.A. (European Space Agency): In this moment, IEEE-UNED Student Branch has a team working in the proposal to send to ESA in a space project for European students.
3. Informal meetings to explain our activities and present new projects: These informal meetings are executed during different months along the year in the Associate Centres of UNED. We explain our activities, offer our infrastructure to other students and talk with them about IEEE and other Engineering contests and activities in and out of our country.
4. International meetings with other students and with Engineering Societies to link students and enterprises: IEEE-UNED Student Branch has been enjoying in last meetings in Lisbon ISBC, London SBC, etc. Also, Student Branch has coordinated a Robotic International Contest in April 2009. In fact, the success of this events, are encouraging us to organize the next Spanish National Student Branch Congress with participation of international students and collaboration of Portuguese students branches.
5. Web resources: to keep in touch every moment we need to use tools like MSN, Skype, Google docs, Internet is our better tool to link different cities in our country and develop projects together despite the distance among us. Obviously, we have meetings when we have the opportunity, but sometimes distance makes it very difficult. In these cases, we use Internet tools to solve our technical problems, coordinate our projects, and organize our workshops. Discipline, a good use of time and organization are the keys to make this methodology works.

Definitely, contacts, links, enjoy, but also earning, formation and work. Engineering Societies may work like the nexus between real and academic life, they can be the support of enjoying and funny during academic years, and they can make that students' formation will be complete. Not only academic knowledge builds good professionals, but relationships, market knowledge, organization, etc. All these characteristics and skills will make of student a better professional in the future.

VII. Conclusions

At first, we can think that Engineering Societies and students are not related, but we are wrong. The relationship is very important, because both concepts have a big interdependence and they are complementary. Engineering Societies are useful to students, because they contribute with theory of the practice given in engineering degrees.

Definitely, two ways but only one objective, growing like highly-trained students is the key to allow Engineering Societies have highly-trained professionals. Often when students finish their academic career the labour market has to contract and train them again. That supposes money, time, and a considerable effort for the enterprise and the student. If we keep in touch student and Engineering Societies, during academic years, we are reducing that costs and we are showing at both sides to use the potential of academic and enterprise philosophy, the basic formation in Engineering and the specialization in different markets and business engineering fields. In fact, what we are doing is forming realist professionals and taking advantage of their university formation to put into real engineering practice. Through the use of Engineering Societies, students, besides additional study motivation, also gain experience in scientific experimental design, project team work and management which are important knowledge for their future careers. Moreover, if Societies help students to grow up in their careers and form new professionals, they will keep alive their own future, because are these students who have to be part of the Engineering Societies in the future.

We must think that students today will be the new professionals tomorrow, and they have the responsibility of improving life, environment, technology and security of our future.

If students have the support of Engineering Societies they can know their weakness and solve them. Then they can fight against the new challenges of the real world. On the other hand, Engineering Societies can know the abilities of future employees or professionals and show them how work like a team, how engineering enterprises actually work, and how use their knowledge to boost the enterprises and institutions they will work for.

Our Student Branch is an example of this rich exchange between students and Engineering Societies, between academic and professional life, it is, between theory and practise. All this effort will be beneficial for the two sides: students will be better professionals and will have more skills to solve problems in their future work. On the other hand, Engineering Societies will have new active members with new professional contacts that will look for new technological challenges and will enrich the knowledge of Engineering Societies, reinforcing its role in the society.

Abstract— **Since the European Parliament has given an according recommendation, qualifications are to be described in terms of knowledge, skills, and competences. In this paper, these terms are redefined in a way that they are put into relation to learning-models, thus making possible to describe qualifications in engineering education in a more rigorous and verifiable way.**

Keywords- education;qualifications frameworks; assessment

I. INTRODUCTION

In December 2004, the Ministers of 32 European countries, responsible for vocational education and training, decided to create a European Qualifications Framework (EQF). The European Commission presented a proposal for this framework, which in a revised version was confirmed in 2008 by the European Parliament [1] with the explicit statement that it might be applicable not only to vocational education and training, but also to general and higher education.

In the corresponding documents, it is requested that the different levels of qualifications be described in terms of knowledge, skills, and competences, which in turn requires that the latter might be assessed on a largely objective basis. That would not be possible without a clear definition of these terms.

This is the point where first difficulties arise, since the different branches of science use these terms in different contexts and with different meanings. However, as largely objective comparison of learning outcomes is the main aim, science-based definitions only will be considered in this paper. Hermeneutics will not be discussed here, though these might give rise to interesting disputations.

Another restriction suggests itself: Since learning-outcomes are to be assessed, terms should be defined with strong relation to accepted learning theories.

Therefore, a short introduction to some essentials of a learning model will be presented that gives insight into the different steps of learning. With respect to this model, different definitions of terms will be discussed, ending up in a suggestion for their re-definition. As a consequence, some methods of assessing knowledge, skills and competences will be considered.

II. FIVE STEPS OF A LEARNING CYCLE

It is meanwhile widely accepted that learning is a cyclic process (see for instance [2] - [4]). Following [5], the steps of a learning cycle are given as in Fig. 1.

The different steps of learning in a cycle are:

1. Get to know facts

   This is the most basic learning step. It serves to memorize basic pieces of information. This type of retrievable information is called *factual knowledge* in Bloom's revised taxonomy of learning [6].

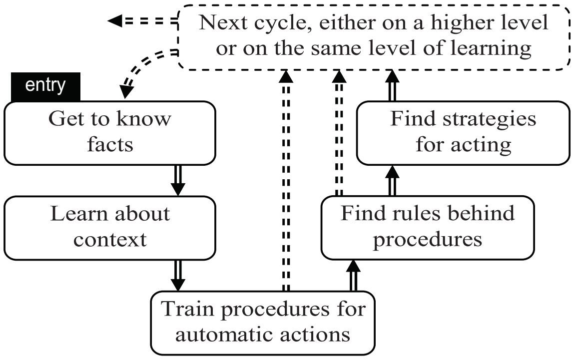

Figure 1. Diagram of a learning cycle on a specific level of learning (from [5] with permission by IEEE)

2. Learn about context

   Knowledge on facts must be linked to other pieces of information in a context. Facts could have completely different meanings in different contexts.
   This might be demonstrated by the example of memorizing (English) vocabulary. If, for instance, a newspaper headline reads “The president is holding a ball”, is he then having an elastic sphere in his hands, or is he heading a social event?
   Knowledge about context is called *conceptual knowledge* in Bloom’s revised taxonomy. It must be learned like learning facts.

3. Train procedures for automatic reactions

   Knowledge about facts in contexts is the prerequisite for adequate reactions to changing situations. If these reactions happen without or nearly without conscious awareness, then they are memorized in the implicit memory [7], which is also called procedural or non-declarative. The corresponding process of learning is a *training-process* in this case. Following Squire [8], trained procedures are stored in the striatum, which is a part of the brain. Neuroscientists call that part of the memory *procedural*, while they call these procedures *skills* and *habits.*
   Note that this usage of wording is closer to the colloquial use of this term, and much more specialized than the usage of the term “skills” by some schools of educational scientists.

4. Find rules behind procedures

   A very important step in learning is to find out rules that govern procedures and to store them in memory. Their conscious application is basis for thoughtful action. Following Squire [8], these procedures are stored in parts of the brain that are different from the striatum. They are parts of the declarative memory. Since in contrast to training procedures, this type of learning needs a purposeful action, and since it is stored in other parts of the brain, finding rules cannot possibly belong to the same category of learning as compared to training of procedures.
   Following [5], this type of knowledge is called *canonical* [1], since it comprises awareness of rules.
   Acquisition of canonical knowledge needs analytic capabilities.

5. Find strategies for acting

   The most advanced type of learning evolves from thinking about what would happen, if rules that are valid in one particular context would be applied to another context, or what would happen, if rules would be broken. Possible actions might then be stored as potential strategies for handling future events.
   Following [5], this type of knowledge is called *strategical*. It is the basis for creative thinking.

A cycle of learning starts typically with the acquisition of factual and conceptual knowledge in Bloom’s sense. The memorized information is stored in the declarative memory.

Provided that the information could be retrieved by the learner at will, this step of learning is seen to be successful: That piece of information has been learned by heart.

Steps 1 and 2 of learning are usually followed by a training period, which leaves procedural knowledge in Bloom’s sense in the procedural memory. The ability to retrieve this information *and* to apply it is called *skillful acting* in Squire’s wordings.

Often, the cycle is then closed by starting another cycle, without using steps 4 or 5, i.e. the cycle finishes with the acquisition of skills (in the colloquial sense or in terms of neuroscientists).

A deeper understanding can only be acquired, if the three previous steps of learning are followed by step number four, in which rules behind procedures are discovered.

Bloom and colleagues did not yet have access to newer neurological results when they created their model. Therefore, they did not distinguish between information about automatic reactions and information on thoughtful action. Therefore, they called both of them *procedural knowledge*.

Based on the newer findings, however, which were summarized by Squire, it is known that these types of information differ not only by the methodology, with which they are acquired, but also by the location where they are stored. Therefore, a clear distinction must be made between learning results from steps 3 and 4.

In most cases, learning cycles are finished after step 4. Indeed, all days’ situations might be successfully handled by application of procedural and canonical knowledge.

Step 5 is performed on highest levels of learning only. It concerns memorizing of potential actions and reactions for future events. It is not necessarily result of a verbalized way of

[1] canon = rule

thinking. It rather could be the result of a figurative way of thinking, too.

After completion of a cycle, seldom after step 2, usually either after step 3, or 4, or 5, another cycle will be initiated, either on the same level of learning or at a higher level of learning.

Having these processes in mind, a critical analysis of terms and definitions used in qualifications is now possible.

III. The EQF-Definitions for Knowledge, Skills, and Competences

Following a convention signed by the council of Europe and the UNESCO [9], qualifications are papers giving evidence for achieved degrees, diplomas or other certificates issued by a competent authority attesting the successful completion of a higher education program. Qualifications frameworks serve to compare qualifications awarded by different institutions, often from different countries.

The European qualifications framework (EQF) [10] differs from prior attempts to compare qualifications, amongst others, by categorizing learning objectives using the *three qualifiers* “knowledge”, “skills”, and “competences”. It is a particular feature of the EQF that it gives definitions of meaning of these qualifiers.

This is not a matter of course, since methods used in educational science are dominated by hermeneutical approaches, which live from interpretations. Rigorous definitions would leave not much space for these.

Bloom’s taxonomy is a nice example of advantages and disadvantages of that approach: Categories and in particular descriptions in Bloom’s original taxonomy concerning the cognitive domain [11] deviate from Bloom’s revised taxonomy [6]. Essentially, this change was not caused by falsification of a model, but by re-interpretation.

As a consequence, assessment of learning outcomes that one and the same person has demonstrated at a given point in time, could change (slightly) by changing the set of interpretation rules in the two versions of Bloom’s taxonomy.

This change was made possible by categorizing all different results of learning processes as “knowledge” in a wider sense, and by distinguishing different types of knowledge by attributes that could be replaced easily by others.

The advantage of this proceeding is that initially many people could agree to that approach, while fine-tuning is possible until a wide consensus is achieved.

The disadvantage is missing clarity and reliability.

By the way, interpretations of the other two domains of Bloom’s taxonomy, the affective domain [12] and the psychomotor domain [13], were much less successful, since until now, interpretations are too much diverging, which again demonstrates a weakness of the hermeneutic approach.

Nevertheless, Bloom’s taxonomy has its undisputed and highly appreciated value, since it cleared the way for the application of scientific methods, in particular statistical methods, to the evaluation of learning outcomes.

This is exactly what is needed in order to compare intended learning objectives and actual learning outcomes of educational programs, provided the results of comparison leave only little space for individual interpretation.

This is why clear definitions are needed.

Indeed, there are many different paraphrases on the meaning of the qualifiers “knowledge”, “skills”, and “competences”. Surprisingly, however, most of them are not very rigorous. They are often quite imprecise, or they are even contradictory.

The late F.E. Weinert, a well-reputed psychologist, who did not have the opportunity to get to know newer theories of learning, even stated in 2001: “There is no basis for a theoretically grounded definition or classification from the seemingly endless inventory of the ways the term competence is used” [14].

There appears to be a tendency, thus, to avoid the definition of terms. This applies also to prominent predecessors of the European Qualifications Framework. These are the Tuning projects [15], and the Dublin Descriptors [16], [17], where the impression arises that the authors have a clear imagination of what they mean by terms like “skills” and “competences”, but where they obviously assume that the readers share this imagination, thus making it unnecessary to define the terms.

This is different in the European Qualifications Framework [18], where the attempt is made to create definitions of terms that could be commonly accepted by educational scientists as well as of psychologists, of natural scientists as well as of representatives of humanities and of social sciences. They do not coincide, however, with Bloom’s terms.

The EQF-definitions are given as follows:

1. *knowledge* means the outcome of the assimilation of information through learning. Knowledge is the body of facts, principles, theories and practices that is related to a field of work or study. In the context of this framework, knowledge is described as theoretical and/or factual.
2. *skills* means the ability to apply knowledge and use know-how to complete tasks and solve problems. In the context of this framework, skills are described as cognitive (involving the use of logical, intuitive and creative thinking) or practical (involving manual dexterity and the use of methods, materials, tools and instruments).
3. *competence* means the proven ability to use knowledge, skills and personal, social and/or methodological abilities, in work or study situations and in professional and personal development. In the context of the EQF, competence is described in terms of responsibility and autonomy.

This is the welcome attempt to reconcile scientists of different disciplines. However, there is still a need to improve the given definitions, since in particular skills and competences could not be distinguished clearly by these definitions.

The EQF-definition of knowledge, for instance, includes terms like "theories" and "practices". With reference to the above cited model of learning, it comprises attributes of all different steps of learning, thus making impossible to clearly distinguish between different categories of the process of learning.

Does knowledge about theories in the EQF-sense include know-how of their application? If so, why is it then necessary to introduce the qualifiers "skills" and "competences"?

It might be supposed that the creators of the EQF-definitions intended to separate pure retrieval of information from application of stored procedures. Unfortunately, this has not been clearly expressed in the definition.

A similar critique applies for the EQF-definition of skills that includes the "use of logical, intuitive and creative thinking", while "competence" is defined as the "proven ability to use knowledge, …, social and/or methodological abilities, in work or study …".

What is the essential difference between these categories? Is it the difference between "use" and the "ability" to use something? Or is it the requirement that in the definition of the term "competence" the attribute "proven" is used?

Having these questions in mind, it appears as if the EQF-definitions suffer from soft compromises that prevent rigorous classification.

IV. The 4ING-Definitions for Knowledge, Skills, and Competences

4ING [19], the umbrella organization of the four councils of schools of engineering and of computer science and technology at German research universities, therefore, suggests to use a definition that is based on the learning model from section I, and where qualifiers are defined as follows:

1. *Knowledge* related to a field of work or study, means the learnt, retrievable information on facts, the context, to which facts are associated, and the rules interrelating facts to contexts.
2. *Skills* means an ability that has been acquired by training and that makes use of the implicit memory [2], to apply knowledge to *standard* situations, and to use know-how to complete *standard* tasks, and to solve *standard* problems.
3. *Competence* means the proven ability to autonomously recognize interrelations between facts and the contexts to which they are linked, to apply this ability to systematically develop new methods, and, if indicated, to apply them to changed situations. This includes application to work or study situations, and in professional and personal development.

A strong interrelation to Bloom's revised taxonomy of learning and to the cited learning model is seen, since

- knowledge in the 4ING-sense could be measured as retrievable information of factual and conceptual knowledge as defined by Bloom,
- skills in the 4ING-sense would be found as implicit, procedural knowledge (the latter being defined as in Bloom's taxonomy), and
- competences would be classified as application and further development of declarative, procedural knowledge, i.e. as canonical or strategical knowledge as defined in [5].

In a strongly condensed form, it might be said that in the sense of the 4ING-definitions,

- knowledge is learnt by heart,
- skills are acquired by training,
- competence is developed by using sense and intellect.

V. Measuring Knowledge, Skills, and Competences

Having in mind that the European Qualifications Framework defines "qualification" as a formal outcome of an assessment and validation process [18] [… stating] that an individual has achieved learning outcomes to given standards, it is necessary to *measure* knowledge, skills and competences.

This is not too difficult in case of testing knowledge, since knowledge can be retrieved, by definition. It is also obvious that knowledge in the sense of the 4ING-definition might be tested on different levels, since it relates to learning cycles.

A simple means for testing knowledge would be for instance a multiple choice test or cloze text. As an example for an inquiry on different levels, consider the question for the correct formula of Ohm's law. When testing a pupil in the last class of secondary school, a relation between voltage and current could be asked for, while on a bachelor-level, a relation between current-density and electrical field might be the required result [3].

Questions like these would be typical questions for facts in a context and the rules governing these facts. A correct response would not yet tell anything about the ability of the respondent to apply this law to a standard problem.

Indeed, one of the present authors once asked a sophomore student in an oral examination for Ohm's law, which the

[2] Earlier definitions given by 4ING did not yet include the attributive clause "and that makes use of the implicit memory". Also, the clause "that has been acquired by training" was not yet included in earlier versions of the 4ING-definitions. The latter wording has already been used by WordNet [20], an electronic lexical database that is being maintained at the Cognitive Science Laboratory of Princeton University.

[3] It should go without saying that a careful formulation of questions is needed in order that candidates are able to recognize what is expected.

student answered with a correct formula. The following question, what the symbols in the formula would mean, however, could not be answered satisfyingly: The student had some knowledge in the sense of retrievable information, but he certainly had not yet achieved competence, and, as it turned out later, he even did not have the necessary skills.

Within the framework of 4ING-definitions, skills differ from knowledge by that the learner needs not only to retrieve some information, but that s/he must also be able to apply an appropriate, *trained* procedure to solve a standard problem.

In contrast to competences, skills are based on implicit, procedural memory, while competences make use of the explicit memory. I.e.: applying skills does not necessarily require reflecting what one is doing.

The above explanation might be easily accepted for the psychomotor domain: Peeling an egg or driving a bicycle is a skill, not a competence.

Ít is more difficult to transfer this definition to more abstract domains. However, an example shows that this act of transfer is not only possible, it is even sensible, rather.

Every bachelor of engineering knows for instance how to solve a linear, ordinary differential equation with constant coefficients by the method of Laplace-transform. Once the problem is identified, it might be solved by completely schematically applied procedures. Even the steps of transform and inverse transform will be performed without reflecting the mathematics of complex integration, and just by reading out tables. This method of solving a certain type of differential equations is thus a skill in the sense of the 4ING-definition.

Testing for skills using the 4ING-definition might be done by asking for the solution of standard problems that could be solved by standard procedures, which are applied automatically and without intensive reflection of the problem, and that have been trained during studies. Actually, most written exams in engineering subjects do test candidates for skills.

Using the 4ING-definition, even assessing competences is a solvable task. With reference to the definition, it requires posing non-standard problems in the field of study or work.

Problems could be posed and solved in the context of a larger home-work, or by working out a presentation in a seminar, or by giving a more complex problem to a group that has to solve it as a team, or by demanding to work-out a complex thesis etc.

In any case, supervisors have to pose the problems very carefully, such that students must give evidence for their ability to recognize relations between facts, and to apply this information for problem solution. Supervisors must urge candidates to give account of all their decisions such that the latter could be evaluated.

Assessing competences is thus a highly demanding task for supervisors. It might well be that this is one of the reasons why some people declare that it would be impossible to test for competences. However, this is disproved day-to-day by those working successfully in human resources management.

VI. Competence Profiles

A field of work or study, in which knowledge, skills, and competences are to be assessed, might be more or less narrow, or the requirements for achieving a particular level might be higher or lower. It is obvious that a good result of assessment could be easier achieved for a narrower field or for lower requirements. A too vague specification of the field of work or study, however, is certainly not a good idea, if transparency and clarity are the main aims of using a qualifications framework.

While the European Qualifications Framework (EQF) and some other frameworks clearly define levels, most of them including the EQF do not even specify width of knowledge, broadness of skills, or depth of competences, nor do they clearly tell whether their requirements for achieving a certain level must be achieved in full, or in the average, by every candidate, or by the majority of a cohort. This is certainly a serious weak point that must be overcome urgently.

A first step into direction of a possible solution to these problems would be a detailed description of the concrete, intended learning outcomes of a field of work or study.

During the last three years, so-called sectoral qualifications frameworks have been created that apply the categorizations of the European Qualifications Framework to a coherent group of professional subjects. An example is the sectoral qualifications framework for engineers and computer scientists for the bachelor-, master-, and doctorate-level that has been worked out by 4ING [21].

In parallel, an attempt has been made to create a national qualifications framework in Germany [22]. Unfortunately, this framework is not compatible with the European Qualifications Framework. Anyway, it brings in a further categorization of competences that has already been incorporated into the 4ING-definition of the term “competence”: It is the differentiation between subject-specific competences on one hand, and self-competences, and social-competences on the other hand. (See fig. 2). The latter are sometimes called “soft skills”, or “generic skills”, though part of them are not necessarily skills in the sense of neuroscientists or in the sense of the 4ING-definitions.

Virtually all significant qualifications frameworks consider educational careers only that follow a straight way. This means that qualifications levels have been achieved in an increasing order from lower to higher, and ending up in one particular specialized professional field. More than one specialization is not normally taken into account.

However, there are enough persons having qualifications in more than one field of profession.

As an example, consider an artist with a qualification on level 7 in musical sciences, and who had a vocational training in building musical instruments first, and that finished with qualifications-level 5. It might well be that competences had been achieved during the first educational period that either are not required in the second educational period, or that were assessed to have a higher level than the average level of the first qualification, and that could be transferred to the second

(level indicator)

learnt, retrievable information on facts, the context, to which facts are associated, and the rules inter-relating facts to contexts; related to a field of work or study.	an ability that has been acquired by training, and that makes use of the implicit memory, to apply knowledge to standard situations, and to use know-how to complete standard tasks, and to solve standard problems.	the proven ability to autonomously recognize interrelations between facts and the contexts to which they are linked, to apply this ability to systematically develop new methods, and, if indicated, to apply them to changed situations in a		
		subject-specific	social	personal
		environment		

Figure 2. Schematic of descriptors for knowledge, skills, and competences, including generic competences

one. Such a situation could not be described adequately by most important qualifications frameworks.

Thus, for an adequate assessment, it does not suffice to specify the highest level of qualifications. Rather, any assessment must be accompanied by specifications of what has been assessed, in what professional field, in what width (i.e. which subfields are covered), and on what level. The result would be a *profile* of knowledge, skills, and competences. Such profiles are shown in Figs. 3 and 4.

Fig. 3 shows a profile of someone who has achieved level 6 in some area of expertise (“field 1” in this example), and who has considerably lower knowledge, skills, and competences in two other fields (“field 2” and “field 3”). Also social and individual skills and competences are attested on different levels.

In contrast, Fig. 4 shows the profile of an individual with the same level of knowledge, skills and competences in field 1, but with enhanced levels of knowledge, skills and competences in field 2 and field 3 of expertise, as well as in the fields of social and individual competences.

These two examples reveal two problems that have not yet been solved by the European Qualifications Framework and other national qualifications frameworks.

If fields 1, 2, and 3 are rather narrow, but complementary fields that together form a broader field of expertise, should then a candidate with a profile following Fig. 3 be given the qualification level 6? And should a candidate with a profile following Fig. 4 be given the same qualification as to the first candidate?

A competence profile is thus much more meaningful than a simple qualifications level!

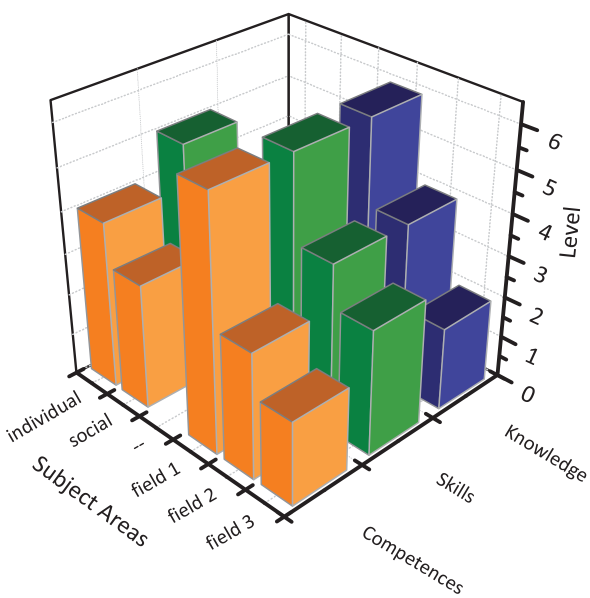

Figure 3. Competence profile with limited width on level 6

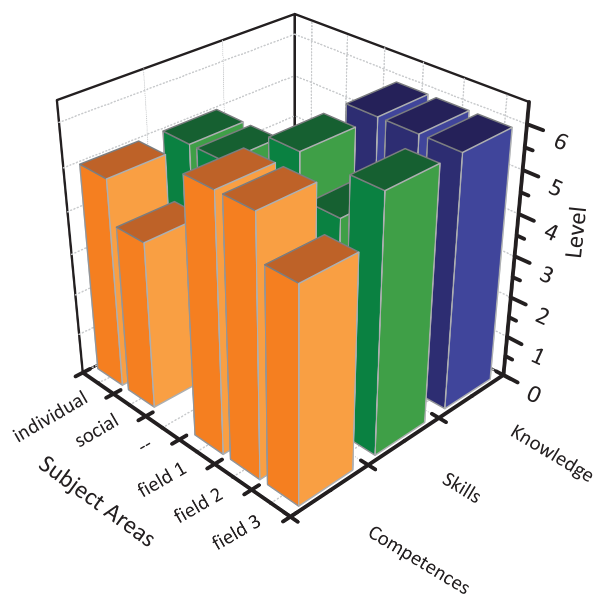

Figure 4. Competence profile with a wider width

4ING suggests, therefore, completing qualifications frameworks, in particular the European Qualifications Framework and related national frameworks, in a way that such profiles would be specified following commonly accepted rules. A characterization by just one number, namely the level, is certainly not enough.

VII. Conclusion and Outlook

Qualifications frameworks are tools for transparency and comparability of qualifications. The EQF uses the categories “knowledge”, “skills”, and “competences” to describe qualifications on several levels. It has been demonstrated that a more rigorous definition of these categories could be given based on accepted learning models.

With these definitions, “measuring specifications” are made possible that enable educators to assess whether a certain level of qualification has been achieved.

A suggestion has been made to better characterize competences, and to specify qualifications profiles in order that they could be used as tools for comparison. However, to make that tool efficient and effective, much remains to do.

A further development of qualifications frameworks with respect to improved competence profiles appears to be sensible.

Such an improved framework might include refinement of the class of subject-specific competences, e.g. by subdivision into Bloom’s taxa of being able to analyze, to evaluate, and to create.

Another focus might be a thorough analysis of individual and social skills and competences. These are certainly not exclusively competences in the sense of the 4ING-definitions. In fact, they are a combination of specialized knowledge, skills, and competences in some subfields of psychology and sociology.

For a classification into one particular level of qualifications, it must be clarified how this level is determined from particular levels of the profile.

Abstract — **COPEC - Council of Researches in Education and Sciences education team has designed a new program in graduation level: the Professional Engineering Education. The goal is to improve the formation of the engineering educator providing them with all the competencies needed to teach at the state of the art with the best available teaching technologies. The PEE Program offers two graduate degrees: the Master of Science and the Doctor of Philosophy. It is a very dynamic and rich program, developed in modules, following the trend of global formation of professionals, mainly to attend the need of a prepared engineering educator to act in the several different cultural environments, which mobility has imposed as a fact of life for researchers and teachers at graduation level. Not to mention the necessary new competencies of educators such as: evaluation management; development competencies; communication skills; teamwork; ethics and intercultural competencies. So this program has been designed to fulfill this lack of engineering educators.**

Keywords: Education sciences, competencies, technology, intercultural skills, qualification

I. Introduction

The education in any level is watching the deep transformation of world in every level trying to change in order to accomplish its noble mission of prepare future generations of people to work hard for the betterment of human conditions.

Engineers are one of the main agents of promotion of development in the world and the formation of a new kind of engineer is the priority to face the new world environment, which aspects are not always positive for a large proportion of humanity [01].

Engineers as problem solvers should be more aware of the impacts of any development also in social level once the impacts of unification of world in any level has consequences for the entire world. International experience shows to be one of the best ways to teach at the present conditions once mobility is higher, communications are easy and accessible for the majority of the world population.

Some educators advocate that the world as the classroom for engineers has a possibility since men started to navigate to far seas. The world has been and now more than ever where engineers can find inspiration, knowledge, employability and opportunities.

Education without any doubt is a science in constant construction like any area of men's life: dynamic, challenging and alive.

One key question of how to form the best professional is always being made and answers have been so many that it is difficult to say it is this or that. Many Institutions of Education have been seeking goes the best ways to provide high level education goes their society worldwide. Anyhow the quality of the Institutions of Education implies several aspects such as the: quality of classrooms, labs, libraries, communication systems etc; students ' services, qualification of human resources; pedagogical scientific quality, credibility as a good institution. However quality in education speaking about what is called of technical competence is essentially the use and dominium of the cognitive means of teaching learning process as well as the available technological means. This level of quality of education has the dependence and straight relation to the teacher and his/her qualification and competence. Good programs have good motivated teachers in addition to modern installations and dynamic planning. The Faculty of any Institution of Education is one of the most important element, which provides or not its qualification of excellence [02].

In order to fulfill a lack of engineering educators for high education for engineering and technological fields in the country COPEC - Council of Researches in Education and Sciences education team has designed a new program in graduation level: the Professional Engineering Education. The goal is to improve the formation of the engineering educator providing them with all the competencies needed to teach at the state of the art with the best available teaching technologies.

The so called PEE Program offers two graduate degrees: the Master of Science and the Doctor of Philosophy and it is a very dynamic and rich program, developed in modules, followed in several countries in the world. It follows the trend of global formation of professionals, mainly to attend the need of a prepared engineering educator to act in the several different cultural environments, which mobility has imposed as a fact of life for researchers and teachers at graduation level [03].

II. Historical Aspects of Globalization and Education

Along the History it can be seen the human achievements in altering and dominating nature in favor of better ways of surviving. This is how technology was born and prevails improving and now more than ever in much sophisticated levels. Men can now more than ever reach levels of comfort, healing of diseases, increasing age level expectations, moving around the world, watching the news and communicate in real time.

All this thanks to the development of sciences and technology and engineers all over the world are in many ways shaping a new life style, helping to save lives, making transportation faster and more secure, enhancing communications and etc. This isolated aspect – the development of sciences and technology, helped to make the globalization phenomenon a reality once more in human history. In the past Alexander the Great was may be the first leader to promote the globalization through wars and invasions followed by Genghis Khan, Cesar and others. Now the big corporations are promoting the globalization in a more subtle way, may be less painful and traumatic but still invasive. If it is good or bad the future will tell us, there are pros and cons being widely discussed but the fact is that it is there. It is the evolution of the capitalism system predominant in the world and sciences are occupying its place of relevance in world scenario [04].

One positive aspect of present world is that the nation's world wide is recognizing the importance of engineers once they are the ones that make possible the world goes round.

In academic midst the discussions about the formation of engineers are receiving more and more incentive and many real actions have been applied with success. Many new engineering programs have been conceived and are working well, more flexible programs, more investments in labs and equipments, more exchanges programs and so on. It is the education evolution in order to adequate the formation of engineers for the future. So Future is the keyword once the world is changing so fast as well as the labor market.

The Universities and their Schools and Institutes have been sacrificed by the so called globalization that imposes certain needs that are absolutely new and many of them not so necessary. It is no longer a matter of using multimedia equipment in classroom but fundamentally to look for new more appropriate and captivating contents to present to the new plugged students. Besides all of the technical and pedagogic aspects it is necessary to think about the psychological aspects of this great and passionate process of teaching. For the good or for the evil, there it is this new socioeconomic and political world of contrasts in which only the education can really change for better [05].

Speaking about education for best, the professionals who leave the universities today leave already with a stock of knowledge that is partly obsolete and s/he has to run fast to adapt to the new job market. Is this the fault of the University? The answer is no, the University has been serving the society for centuries and without interests others than the investigation and the improvement of the knowledge that generates benefits for the humanity as a whole.

What about the teacher? The new teacher has to preserve the curiosity, to urge the capacity of the students' inquiry; he has to teach them to learn and not to suffocate them with a mountain of scientific and technological knowledge, that today the teacher does in the anguish of teaching better.

III. Some Considerations about Globalization

Globalization could be defined as the transformation of the world in a global village, that means "closer contact between different parts of the world, with increasing possibilities of personal exchange, mutual understanding and friendship between "world citizens", and creation of a global civilization." Nevertheless analyzing Globalization on the economical-financial side it began in the 80's with the integration at world level of the economical and financial relationships. It presents two aspects: the negative and the positive.

As positive aspect is the cultural and commercial exchange among people and nations; in the course of two generations the gap between the industrial and the developing regions narrowed substantially everywhere; the overall poverty, when defined by health of population and life expectancy, as well as by income has diminished [06]. By the other hand the results of globalization have not been what was predicted when the attempt to increase free trade began, and many institutions involved in the system of globalization have not taken the interests of poorer nations, the working class, and the environment into account; developed countries are the largest beneficiaries of this system and they are becoming richer while the developing countries are becoming poorer.

The discussions about Globalization in general show a bad scenario and the future is unpredictable once it is not possible to foresee the big players' next movement in such huge business game of fighting for markets.

IV. Science and Technology in global world

Scientists for centuries can see the world as a unified heterogenic content and capable to comprehend the whole. In a sense, science is responsible for the idea of globalization. Furthermore, as a system of knowledge, science has been uniquely successful at building widely shared understandings that transcend political and cultural differences.

Information Technology known as IT is a driving factor in the process of globalization. Improvements in the early 1990s in computer hardware, software, and telecommunications have caused widespread improvements in access to information and economic potential. These advances have facilitated efficiency gains in all sectors of the economy. IT provides the communication network that facilitates the expansion of products, ideas, and resources among nations and among people regardless of geographic location. Creating efficient and effective channels to exchange information, IT has been the catalyst for global integration [07].

V. THE NEW WORK MARKET

Science and technology innovations have shaped the present work market in such a way that from now on "changing" is the role and not the exception. It is a changing world and a changing work market in every level. Technology has enhanced work place that means less hand work and more mental work. Thanks to information technology the workplace is now team-based. Management styles have changed with horizontal structures where everybody is responsible for the results of the work requiring less supervision. For workers in any level the expected profile comprehend attitudes and behaviors to work in teams. The job environment is different due to the way that companies run the busyness now; jobs positions are displaced, others take places and shifts are always changing in according to the new necessities.

Among the dramatic changes in work market it is noticed that now more jobs are part time; more people are self employed; less staff needed to accomplish works; paid and unpaid overtime work are increasing; global competitiveness; flatter organizational structures; companies downsizing, less job security [08].

Human beings are living now in a changing work environment full of surprises and unpredictable events in a daily basis. The best way to overcome and to survive is to be prepared achieving knowledge and be willing to develop new skills.

VI. HOW BEST TO EDUCATE THE NEXT GENERATION OF ENGINEERS

The global expansion is here to stay.

Advanced communications technologies continue to alter the way businesses and societies conduct themselves and interact with each other. Today's engineers are expected to work globally-collaborating with team members located in various countries with diverse languages and business cultures to engineer products and services that insure the company's competitiveness in the global economy.

How best to educate the next generation of scientists and engineers, who will enter a workplace that has become truly global environment?

There is not only one answer and the point is that the engineering schools are the ones responsible for the formation of generations of engineers who are among others the main responsible for the development of sciences and technology seeking for the betterment of humanity.

Despite the negative aspects of globalization all the scientific and technological advancements have one main goal: make men's life better. That is why machines were designed to do the hard work so that men can have more time for other more pleasant work; the search for new drugs to defeat diseases, to live better and more and so on. Nevertheless all the achievements bring also new situations that are not always positive that is why engineers should to be more aware of social responsibility, to be aware not only about the economic and environmental issues but also the impact of new technologies in the society. Any isolated event in the current world in one or another way has some effect in other regions of the planet and sooner or later they will be felt. To deny it is the same as to "sweep the dust under the carpet" [09].

So, summarizing the formation of the engineer for the future must consider besides the strong basis in basic sciences and basic sciences of engineering the development of:

- Communication skills;
- The willing to learn all life;
- Positive attitudes and behaviors;
- To work in teams;
- Responsibility for actions and results;
- Respect to diversity;
- Entrepreneurship;
- Self employability;
- Self management.

May be the main skill is the development of the capacity to see the opportunity of a new work, a niche that can be explored and generate good results no matter where it is. The experience of studying abroad is an efficient way to give the students an opportunity to get in touch with other cultures and to develop communication skills in an upper level. The learning of languages and the sensitiveness to behave properly are some the positive results of this kind of experience. It has to be a structured program with defined goals and flexible schedule [10].

VII. THE CHARACTERISTICS OF THE NEW PROFESSIONAL

In this new world scenario the skills, knowledge and training that are required are fundamental to survive in the changing labor market. It is imperative to be able to manage technological changes, be creative, take calculated risks, manage stress, think conceptually and recognize and respect people's diversity and individual differences.

The knowledge required includes the general knowledge of the busyness, the understanding of the total organization, at least a general knowledge about computers among others. The academic knowledge must provide the basic foundation to get, keep, and progress on a job to achieve the best results.

It is necessary more than ever to develop multi skills, communication skills in order to work in teams, to be willing to retrain, to study constantly in order to learn new technologies rapidly; it is life-long education [11].

VIII. THE PROFILE OF 21ST. ENGINEERING EDUCATOR

Specifically speaking about the profile of next generation of engineers committed with education, working in classrooms it is important to discuss some points such as the basic research that is now recognized as an important element in the development of high technology. Universities are in a good position as they have been recognized by the governments and industries as crucial to foster their development.

The formation of good engineers and professionals in technological fields is fundamental for the governments, the industries and societies. The relevance of teaching practice is increasing in order to provide good teaching and guidance for the future professional, researcher or teacher.

The profile of an Engineering Educator is based on three fundamental premises [12]:

- A solid base of disciplines of Sciences of Engineering is the basic demand for the professionals of Engineering and Technology fields dedicated to the Education.
- A good knowledge about Education in Engineering is in the same way important and a course of appropriate training should be equivalent to one semester in university (a minimum of 200 hours) in content terms.
- A minimum of a year of practical work as professionals in one of Engineering and Technology area dedicated to the Education.

IX. The PEE Program

The PEE program follows the patterns of IGIP - International Society for Engineering Education registration for Engineering and Technology, the qualifications and professional experience at an advanced level. This society provides a title that has been recognized in several countries in Europe and now spreading all over the world.

The formula for the title "ING-PAED IGIP" is:

Qualification in Engineering
+
Training of Education in Engineering and Technology
+
Practice in Engineering and Technology Education Area.

The engineering qualification should correspond preferably to "Europe Ingenieur (EUR-ING)" qualification for FEANI. In Brazil it follows the defined patterns for CFE/CREAs – Federal System of Engineering in the engineers' case and of the organizations responsible for the other professionals of Technology area.

X. Admission Requirements

The basic candidate requirement for admission is [13]:

- a bachelor's degree in science, engineering, or technology, or in such fields as computer science/engineering, electrical/ control engineering, industrial engineering, environmental engineering, manufacturing engineering, materials science and engineering, mechanical engineering, or management, etc.
- Students with other backgrounds will be considered based on their interest, formal education and experience in teaching.

XI. Course Information

The Master Degree in Engineering Education requires 30 credits in ECT's of graduate studies. The 30 credits consist of a minimum of 12 credit hours of coursework, plus 12 credit hours of any combination of coursework, independent study, directed research or thesis that complies with the following constraints: if there is a thesis, it must at least 6 and no more than 12 credits; there can be no more than 9 credits of directed research; and the total number of credits from the Management Department cannot exceed 14 [14].

The minimum of 12 credit hours of coursework must include a minimum of two credits each in at least four of the seven core areas. The coursework should be selected in consultation with an advisor from the EE faculty. All full-time students are required to participate in the non-credit seminar course.

XII. The modular curriculum

The PEE curriculum is a modular one and it is as follows:

Module Description	*Credits at least*
Core Modules	**8**
Theoretical and Practical Engineering Pedagogy	6
Laboratory Methodology	2
Theory Modules	**4**
Psychology and Sociology	3
Ethics (1 credit) or Intercultural competencies (1 credit)	1
Practice Modules	**6**
Oral Communication Skills, Scientific Writing	3
Working with Projects	1
Media, E-Learning, Computer Aided Technologies	2
Elective Credit Points	**2**
Electives	2
In Total	**20**

Each module has the goal to enhance the development of a competency so necessary for the improvement of teaching styles. There is a demandfro educators connected with the new students'Profile.

XIII. Conclusion

It is a reasonably flexible program that is developed in according to the needs for the accomplishment of the main goal to form engineering educators.

The main characteristic of the program has been to lead the attendees to think "out of the box" imprinting the notion of dynamic teaching environment that is necessary in order to form the new professional. It has been designed in order to fit the necessities of professionals and institutions interested in the improvement of career and quality performance.

All the course evaluations have been very positive. The attendees are satisfied with the approach and the content of the courses. It is a great achievement for academic midst once it can provide for engineers and professionals of technological areas the opportunity to update the knowledge about education as a whole.

It is important to point out that it is a very dynamic program once the content of the courses can be developed constantly taking into account the characteristic of the groups. This aspect is relevant because it helps to overcome the obstacles such as communication problems, stress management and so on.

The number of professionals interested in the program is growing and it is expected a larger number of attendees for next group.

Besides the professional receives a diploma that is recognized national and internationally.

enginy@eps: Motivating the Engineering Courses

Social Valuation as a Motivating Factor

Abstract—**This paper presents an academic initiative to increase the motivation of students for engineering topics, and discusses the results obtained. The initiative is a journal where students may publish, both in paper and in electronic format, the final reports of their laboratory works or research activities. The name of the journal is enginy@eps. The existence of this journal becomes an external element for motivating the students, since their documents are going to be reviewed by an editorial staff and are going to be published out of the classroom. The collected data shows that social recognition is still a useful element to motivate the students in technical courses.**

Keywords- student motivation; educational innovation; formal writing profile

INTRODUCTION

In the last subjects of engineer courses, students participate in autonomous works, research activities and laboratory sessions where it is necessary to go further than just to apply previously learned concepts. This kind of activities requires a lot of time and hard work not only from the students but, also from the teacher. Finally, once the work is evaluated for the course, it is usually forgotten and often the work conclusions are not used anymore. So, it seems contrary to the student's and to the teacher's motivation to foresee that their efforts will not be useful to anyone else, and that their work will be forgotten when the course ends. That situation is not a good motivating factor for the student and, of course, for the teacher.

The student motivation is a complex topic, and it is difficult to quantify [1]. In some cases, the same thing does not motivate all students at the same time. Two factors that impact on student motivation are: the social valuation and the perception of the expectation of success [1]. It is important to note that both factors are part of a multiplication equation, so if anyone of these factors is zero, the result is zero too. This means that, the student must find some positive attraction toward the educational activity, but in addition, it is necessary a positive perception regarding the accomplishment of the learning activity. There are a lot of learning environments proposed to increase the students' motivation, as an example in [2] and [5-6] a game based learning environment is used to increase the motivation of students in different courses.

Furthermore, the students in first courses, in general, have initiated the Engineering careers without a clear idea about the topics and issues related with those courses. They may have no idea about the concepts and methodologies involved in their engineer courses. And they have difficulties to explain the reasons why they have selected these particular courses instead of some others. This initial confuse situation may be a disinclining factor; and it is difficult to know how many students leave the recently initiated studies by that reason. In [7] the authors propose to design initial courses with extensive active learning components in cooperative students teams as an effort to retain those confused students. The same situation may be identified when pre-university students have to select their university studies.

Some different solutions have been proposed in our University to help students to solve this confuse situation as soon as possible: pre-university labs, adaptation courses, classrooms open door day, or talks about the features of different courses. All these solutions have a point in common: the university presents the information about their courses mainly from an institutional point of view. These solutions fail to provide more information about the real activities developed in the classrooms or information directly obtained from others students.

From another point of view, but related to the proposed work, it is necessary to take into account that, all engineering activities and results have to be explained and summarized in any technical document. So, it is not only necessary to learn good competences in technical engineering topics, but it is also necessary to acquire good technical writing skills. Cockrum et al. in [3], propose some ideas of how to design writing courses, to help students to acquire those necessary generic competences.

In this study, we propose to learn writing competences not in a separate subject, but in several subjects at the same time and in combination with each specific subject contents.

Laboratory and autonomous works typically finish with the presentation of a document, which is, in fact, a technical document. In that case, the student, with some minimum requirements proposed by the teacher, writes the document using a free format. The second goal of this work is the coordination of several subjects to propose the same template format for all kind of educational activities. So, not additional documentation must be elaborated by students, it is only necessary to adopt a common document template and some common writing requirements, like researchers when they want to publish a paper.

Seven different subjects have been selected to participate in this work. They have all revealed positive enhancement in both goals: the motivation of first years' students, pre-university students and authors students; and increasing the writing skills of engineering courses.

INITIAL SITUATION

Any technical course is organized in several independent subjects distributed in time. The student is motivated to learn isolated concepts in each subject and it is usually expected that the student will be able to mix those concepts and construct his/her own knowledge. Another important characteristic is related to how the concepts are learned. In traditional education methodology, it is usual to transmit the concepts from teacher to student using oral sessions. The model is changing and the main idea is that the teacher does not control the knowledge, because it is freely accessed through new technologies like internet. Nowadays, the student is in the learning centre and the teacher helps the students to construct their own point of view about the concepts.

These changes in the teaching methodology lead to more individual and in group homework, and cooperative learning activities. Those activities require a lot of time from students and from teachers in tutoring processes. In general, this kind of activities concludes by writing a technical document, which is a valuable element for the evaluation process. Those works and documents are only used for evaluation purposes and, at the end; they are stored in a box or bookcase and forgotten. In that situation, only the students and the teacher know the content of the work, since information is not shared outside of the classroom.

From the motivation's viewpoint, this behavior is not a positive factor: because both the students and the teachers keep in mind that the unique purpose of the work is to evaluate the learning process. But, what if there was a possibility of public diffusion of the work? This new feature may increase the students' motivation to do their best.

Usually, in actual fractioned knowledge courses (divided in isolated subjects), another teachers and students do not know what kinds of activities are developed in each subject, because those activities are made in the classroom with the closed doors. So, students have not a previously clear idea about the subject which is applying for. Nevertheless, that situation may be worst at the starting point of the studies. In that case, they not have sufficient resources, examples or other students' comments to discover what kind of learning activities are carried out in the university subjects.

Another aspect that has to be pointed out in this section concerns the first degree project. In technical programmes, the students must develop an independent work, in which the student should plan, carry out and report a research work. In general, the degree project concludes with a written report of the work and an oral presentation to a group of three likewise selected teachers. The same way as learning activity reports, the degree project reports are collected in the university library and forgotten there. Although, much time has been spent on those reports, they finally (and unfortunately) end up in some university bookcase. Obviously, no all project reports are suitable for public diffusion, but with a good selection, why not award the best reports with a "better life"? Maybe the expectation of a public recognition of the degree project could be a good factor of motivation to do the best.

Writing good reports may be one of the less developed skills in technical courses. Obviously, any student writes a lot of reports, but each teacher uses its own requirements adjusted to the evaluation process, so no common organization or features are shared. In fact, students just adopt the new template without any additional comprehension. No time is spent in learning how to write better reports, how to decide which information is useful and which is not, or in any other considerations about technical writing style. In research environments, reports are continuously used to explain the results of projects, and documents must follow some style if those reports have to be included in a journal. That is the same idea, but applied to student reports.

OBJECTIVES, PLANNING CHANGES AND METHODOLOGY

The proposed learning activity, for increasing the motivation and the coordination between subjects in university programs, is the publication of an annual journal called "enginy@eps". The journal opens one alternative to make classroom and project reports public.

Proposed Objectives

The publication of an annual journal was proposed with the following main goals:

- To introduce a motivation element for the students. A selection of students' works will be published in "enginy@eps". So, those students are motivated to do their best and to expose their works to readers. Furthermore, the readers (students and teachers) will be motivated to participate in the next issue and could help to create an adequate atmosphere between new and last year students.
- To introduce a motivation element for teachers. Without any public exposition of what is done in each course, it is difficult for teachers to make profit of learning activities of previous courses. So, by showing the learning activities that students develop inside the classrooms and during their degree projects, it may be possible to improve the next courses contents. On the other hand, as the students' works are not public, there is not any motivation to change the learning activities. But, when the learning activities results are published, those may be used as technical documents for future learning activities.
- To improve the technical documentation writing skills during the learning process as a multi-course learning objective. The students' papers review process may help to learn better writing and document organization skills. Although a lot of technical documents are generated by students in several courses, the student writing skills are not included as a goal of any technical course.

Courses Planning changes

The initial planning of the subjects involved in this study has been modified in order to incorporate the new learning activity. One of the most important changes is related to the activity perception by students. The proposed changes should be introduced without high increment in the student's work. So, several different options have been used to incorporate the needed changes:

- Without making major changes to the subjects to include this project. In that case, there is an activity which may be adapted easily. An example is when all students have to write a project's documentation or have to perform an experimental project, in groups of a few students. The project is related with the subject topics and each group has to deliver a report with the obtained results. In order to adapt those kinds of activities to the context of the presented study, the students have to write the project report according to the specific format defined by the enginy@eps publication.

- Adapting an existing activity but including, at the beginning of the course, some guidelines, in the form of a paper template. The different sections of the technical document (introduction, objectives, design, implementation, evaluation, conclusions) are briefly described so the students get a better idea of what they should include in each section. They are encouraged to write the Introduction and the Objectives in a simple language, as for a non-expert reader, and then to change to a more technical language for the rest of the paper.
- A new learning activity is included in the course. For instance, developing an information research work. After having introduced the students in the basic general knowledge of the subject, different topics on actual and emerging topics are proposed to them. These topics are distributed among groups of two or three students that have to elaborate on them. As a result of their research, each working group have to write a four pages article, following the journal format, which has to be presented to the rest of students of the course through a short presentation with slides in the classroom. The objective is to evaluate the autonomy of the students to seek information on existing technologies and their ability to transfer their knowledge, as well as to asses the satisfaction that it entails.
- Some previously planned activity is substituted by a new one. Before, the students had to write a homework report, but now, it has been substituted by an oral presentation together with the proposed paper format.

The changes previously described do not only impact on the activity planning, in some cases, they require new elements for the evaluation process. The new methodologies in evaluation techniques have to be adapted because the activity changes do not only modify how students report the activity conclusions, but they also modify how the subject topics are learned by students.

TABLE 1. INITIAL QUESTIONNAIRE

	Question
Q1	I like this subject
Q2	The subject topics are related to my personal expectancies
Q3	Sharing the project results is important for me.
Q4	My effort is enough to accomplish the goals of subject
Q5	I am concerned about others students having better results than me
Q6	I have confidence I will understand the concepts of this subject
Q7	I am motivated to view my work on a public journal
Q8	I am able to write a good paper
Q9	Writing is a hard word
Q10	Value from 0 (not interesting) to 10 (very interesting) the grade of motivation about viewing your name in a public journal.

TABLE 2. FINAL QUESTIONNAIRE

	Question
Q1	Writing the journal paper has increase the motivation for the subject
Q2	The motivation in the university degree has been increased with this activity.
Q3	It is important to write the results of my projects
Q4	This activity has contributed to accomplish the subject goals
Q5	I am not concerned about comparing the project results with others students
Q6	Finish the paper has been important for me
Q7	Writing is a hard word
Q8	Value from 0 (low) to 10 (high) your capacity to accomplish the activity.
Q9	Value from 0 (not interesting) to 10 (very interesting) the learning process developed during the writing activity.
Q10	Value from 0 (not interesting) to 10 (very interesting) the grade of motivation about viewing your name in a public journal.

Additionally, all subject teachers involved in the study have designed two questionnaires to quantify the impact on motivation for writing and publishing activity. The first questionnaire, see Table 1, collects the initial motivation of students when the activity is proposed. In fact, in some cases, the activity is not different from previous years, and only the technical summary format and the idea of possible election for publication are introduced. Each professor, according to the subject planning, has introduced the required changes. Table 1 shows all questions answered by the students when the activity starts. All questions can be answered within the range from 1 point (disagree) to 5 points (completely agree).

The second questionnaire has been filled by the students at the end of other activity, previously to the selection of the best papers for publication. Some questions remain unchanged intentionally and other try to measure how the student has perceived the activity.

Review Methodology and accepted papers

The review process has been organized by the corresponding teacher within each subject, but following some common review criteria. The objective of this process is to select the best and the second best papers which should be proposed to the editorial staff for the final review/accept process.

The review process for each subject has been developed in different ways, depending on the teacher's methodology. Some alternatives are:

- First, all the students had to deliver a first version of the project. After reviewing all the papers, the three best works were selected and the teacher suggested some changes to the authors. Finally, the selected students delivered the final version (camera ready version) and a second review was done to choose the paper that was proposed to the editorial staff.
- After reviewing all the documents, the teacher talked individually to each student, showed them the main errors both in the technical part and in the paper itself, and gave them some advices. Only the best papers' authors were requested to improve the document following the suggestions given to finally propose their paper to editorial staff.
- The different reports presented by all authors were available to all students and the evaluation was performed following a peer-review process where the different groups evaluate the other ones with the help of a template in order to ensure a homogeneous evaluation. The final grade of each project was calculated from the average value obtained from each group. Finally, the best evaluated project was proposed to editorial staff.

In summary, the strength of this academic activity is that it does not change significantly the methodology from the teacher perspective, but it does change a lot the perception of the students about their work and the relevance of having good writing skills. They learn that they should not focus only on the concepts or physical implementation, but they should also focus on communicating the results.

All teachers involved in the study were part of the editorial staff, so finally, all documents proposed were reviewed and accepted by all of them. In order to help the internal organization of the editorial staff, the technical courses were grouped into five different categories: building engineering, computer engineering, electronic and automatic engineering, telecommunication engineering and mathematics. One member of each area was elected as an area chairman with the following functions:

- To promote as much as possible the participation of the subjects associated to the category.
- To manage and coordinate the review process of the papers in the area.
- To maintain the area in communication with the rest of the categories in order to share best practices.

The described staff organization has been introduced as needed and allowed the participation of even subject from any technical courses present in the Universitat Illes Balears.

THE JOURNAL "ENGINY@EPS"

The annual journal called "enginy@eps" was proposed to the university community as a local initiative to promote the activities developed in technical courses at the university. The initiative opens a new space where educational works are shared between all university community members.

At present, the publication process has been performed for two courses, so the results of this study show how this kind of activity, which aims at improving the students' motivation, evolves when the students share their educational works and can read previous published works.

First year: enginy@eps is born

The first edition of the journal published 14 educational works of 9 different subjects from electrical and telecommunications engineering. All papers included were based on laboratory activities or individual research projects following some of the previously mentioned methodology changes in the subject planning.

The first edition of "enginy@eps" included 450 copies; see the cover sheet in Figure 1. The journal was distributed between students and teachers of the Engineering faculty, and some copies were sent to pre-university schools. In fact, two weeks after the presentation day, the copies were finished. That is not a scientific result, but shows how good the new publication was received by readers.

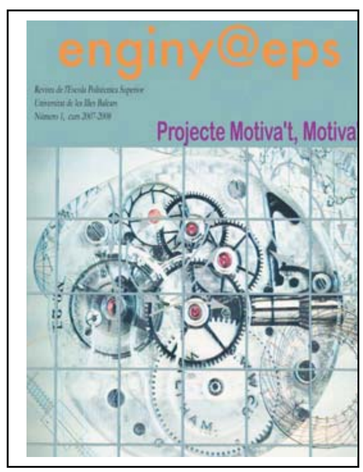

Figure 1. The "enginy@eps" cover sheet of first edition.

In that edition, some aspects employed most of the time and work of the editorial staff:

- Defining a good and easy paper-template to facilitate the writing process as well as the organization of the information for any kind of works.
- Financing the activity with external support.
- Designing the journal image, incorporating the final versions of papers and carrying it to the press.

At the end of that year and as a result of the new journal, new teachers were involved with the project. A lot of new ideas and contributions were received from the university community, promoting the inclusion of others technical courses for the next edition.

Second year: expanding the initial objectives

In the second edition, two new sections were introduced with new initial objectives:

- *Research works*: degree project reports or internal reports about new technologies were considered to be pubished in the journal. The main goals of this section are to contribute in the difussion of students projects and to motivate for reading technical information. This section starts with 6 papers from diferent degree projects, but also from teachers projects.
- *Open Section*: With the aim to contributing to create a collaboration atmosphere among students and teachers, this section publishes diferent opinions about a central topic. The central topic is selected by the editorial staff and different contributions are included: from school managers, from interview with students, from external institutions, ...

Moreover, a new impulse in the design was introduced. The journal now presents a modern aspect, with some information about internal sections on the cover sheet. See the second edition cover sheet in figure 2.

Figure 2. The "enginy@eps" cover sheet of second edition.

The second edition of "enginy@eps" included 900 copies. The journal was distributed between students and teachers of the Engineering faculty, pre-university schools and some copies where sent to other universities and external institutions.

From the point of view of management, an open journal management system [4] was adopted. The new journal management software allows the creation of an electronic edition of the journal, increasing the capabilities of difussion. By the moment, the electronic edition of the journal is used in combination with paper edition, because the journal gains more visibility and impact if it exists physically (in paper).

The impact of the journal's previous edition on students works has been noticed by teachers. When the writting activity was proposed to the students, they had a reference in their mind (last year edition). In fact, some subjects used the last year reports to improve the educational activities in their laboratory or classrooms. Last year edition has been incorporated in technical courses as an additional reference, useful for students who applied to the course, but also, usefully for other courses as an information source.

In the second year of this activity, our feeling is that the journal is a useful means to motivate the students. As soon as they had the previous issue in their hands, they expressed a lot of interest and checked it with attention. Although it may not be measured in objective terms, this is a clear indicator that social recognition is a strong motivating factor, as already stated in the literature [1].

RESULTS IN MOTIVATION

The impact of the journal in the improvement of the educational activities and on maintaining the communication between university communities may be observed in how the journal has been received and incorporated as a new tool for educational purposes. But the goal of this study is on the impact of the journal on the student's motivation.

The results in motivation are obtained from two questionnaires answered by the students at an initial stage of the writing activity and at the end of the activity, previous to the final selection of best paper for publication.

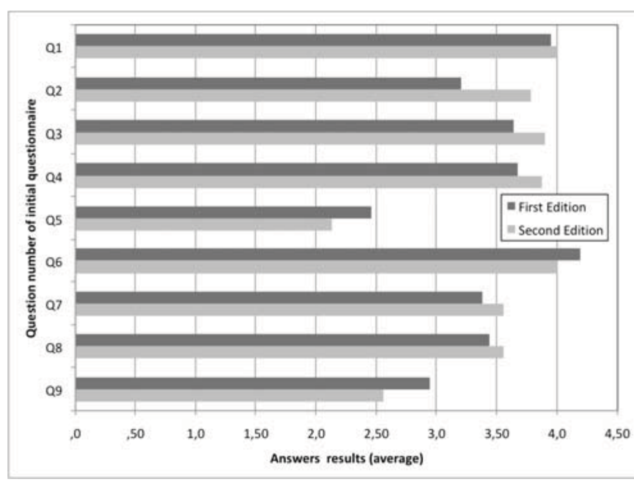

Figure 3. Initial questionnaire results evolution.

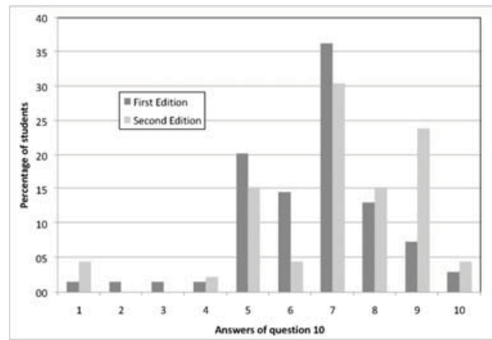
Figure 3 shows the average values initial questionnaire for both editions. It is important to remain that the students answer questions Q1 to Q9 with a maximum value of 5, while the question Q10 can be valuated until 10 and is not showed in Figure 3. Some conclusions can be obtained from the results chart:

- All students agree to consider that they like the contents of the subject and that their effort to accomplish the subject goals is enough.
- Question 3 shows how the students are increasing their interest in sharing the results of their works with other students. While the results of question 5 reveal insouciance by the comparison between students' works. These results are good for this kind of activity, because the external review of the works is a necessary step in the publishing process.
- The positive trend in the interest of students in the publication of their works is reported in the results of question 7. This may be considered an important indicator (activity valuation) of the impact on motivation. Although the values of first and second editions are similar, the number of students involved in the project was higher in the second edition than in the first one.
- Evolution of the questions 8 and 9 answers results may be considered a direct consequence of the first edition impact. While in the first edition writing a paper was considered a hard work, this process is considered less hard in the second edition, perhaps the final goal is perceived as a real fact (previous edition was published previously).
- Finally, the results of question 10, see values in table 3, may be considered a second important indicator (motivation for the activity) of the impact in motivation. The second edition impact in the results may be observed in the increment of the initial motivation.

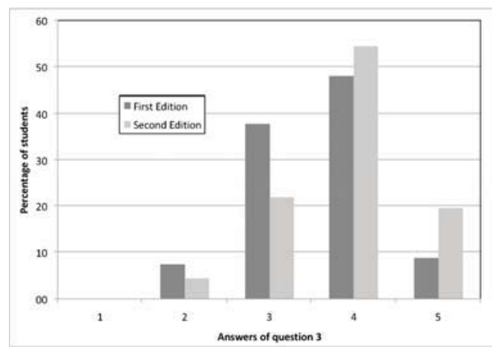
TABLE 3. INITIAL QUESTIONNAIRE STATISTICS

	Average		*Standard deviation*	
Editions	***First***	***Second***	***First***	***Second***
Q1	3.9	4.0	0.7	0.7
Q2	3.2	3.8	0.9	0.9
Q3	3.6	3.9	0.8	0.8
Q4	3.7	3.9	0.7	0.8
Q5	2.5	2.1	1.0	1.1
Q6	4.2	4.0	0.7	0.8
Q7	3.4	3.6	1.0	1.2
Q8	3.4	3.6	0.8	0.7
Q9	2.9	2.6	1.0	0.9
Q10	6.9	7.3	1.7	2.1

In Table 3, it has been collected the average and standard deviation of the initial questionnaire answers. The standard deviation is an indication of dispersion in the answers. As the values of possible answers are integers, a standard deviation lower than 1 indicates that the average is a representative value, while a standard deviation greater than 1 denotes a high dispersion in the answers. Taking into account this observation, only questions Q5, Q7, Q9 and Q10 show a standard deviation greater or equal to 1. The reason of this may be explained by the histogram of answers. In all previous enumerated questions, there are students' answers in all possible answers options. It could be due to the fact that the questions may not have a clear meaning. This comment may be observed in Figure 4, where the histogram of answers values of initial questionnaire question 10 and question 3 are shown.



(a)



(b)

Figure 4. Histogram of answers values of initial questionnaire. (a) Question 10 and (b) question 3.

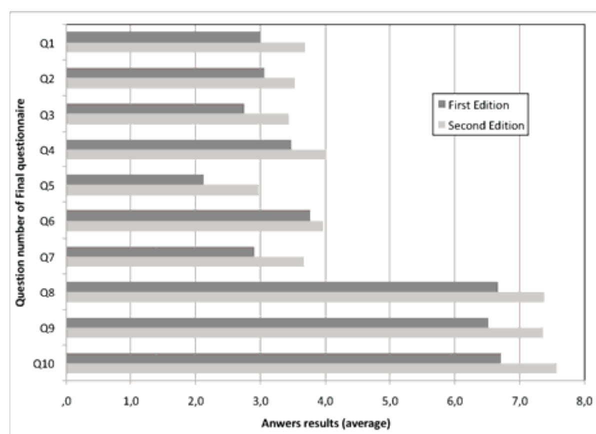


Figure 5. Final questionnaire results evolution.

On the one hand, the information observed from standard deviation may be considered in a revision of questionnaires, as an indicator of which questions must be adjusted, because it is possible that the students did not understand it. On the other hand, a standard deviation high in one question shows some discrepancies with the average answer, and could be studied with more attention.

Figure 5 shows the average values of final questionnaire for both editions. The students answer questions Q1 to Q7 with a maximum value of 5, while the questions Q8 to Q10 can be valuated until 10. From chart of Figure 5, some comments can be obtained:

- All results show a positive impact of the first edition on the second edition results, increasing the first edition results.
- The impact of writing activity has increased the student motivation from one year to the next, as shown Q1 and Q2 answer results. In fact, the importance of this activity, as perceived by student has increased too, see results of question Q3.
- A majority of students believe that this activity has helped to improve the results in the subject, see Q4.
- The importance of comparison has decreased, so the students seen to tolerate better the process of external review, or the publication of their works.
- Although the writing activity has not been considered as a hard work, finally, at the end of the process with the review, the students valuate the task developed as a hard work (question Q7).
- The students' self-esteem is increased, because they are feeling that they are capable to do similar activities again (question Q8).
- The effort of writing in a technical manner is valued positively by the students, while the motivation or expectation to see its paper published in the journal is maintained at the same level as at the beginning of the activity.

- TABLE 4. FINAL QUESTIONNAIRE STATISTICS

	Average		*Standard deviation*	
Editions	***First***	***Second***	***First***	***Second***
Q1	3.0	3.7	1.0	0.9
Q2	3.1	3.5	1.1	0.7
Q3	2.7	3.4	1.1	1.1
Q4	3.5	4.0	0.9	0.6
Q5	2.1	3.0	1.0	0.9
Q6	3.8	4.0	0.9	0.7
Q7	2.9	3.7	1.0	0.9
Q8	6.7	7.4	1.6	0.7
Q9	6.5	7.4	1.2	0.9
Q10	6.7	7.6	2.4	1.4

In Table 4, it has been collected the average and standard deviation of the final questionnaire answers. In this case, only question Q3 maintains a standard deviation high in both editions. The high number of questions with high standard deviation during the first edition could be explained taking into account that the students did not have any copy of the journal, so the activity goals were not clear to all students involved in it.

CONCLUSIONS

This study has been developed in two years and has tried to evaluate the impact on the student's motivation of public recognition using a writing activity. In technical courses there are a lot of students' activities or degree projects which may be used to create a publication. In fact, the process of publication is an educational process, where the own knowledge is compared, shared and discussed with colleges.

The proposed study has demonstrated how the process of writing, reviewing and publishing may help to improve the motivation of students in different areas: personal motivation, implication with the subject activities or as a reference for future students. The activity has been valuated positively by students in both editions, as it is observed in the final results.

The writing process may be a useful educational process, not just for the authors of the best papers, but also for all the students involved in the review process.

The impact on future degree project reports is not evaluated yet, but we believe that, in general, the writing skills will be improved, and this kind of activities allows promotion of non-classroom activities, which may impact in the same way in all courses. Perhaps, theses kind of activities are necessary to learn socio-professional capacities in future engineer courses.

ACKNOWLEGMENTS

This study has been possible with the support of "Institut de Ciències de l'Educació", "Vicerectorat de Professorat i Innocacció Pedagògica", and "Oficina de convergencia i harmonització Europea" from Illes Balears University.

Abstract— **We report on the content and early evaluation of a new introductory programming course "Media Propelled Computational Thinking," (abbreviated MPCT and pronounced iMPaCT). MPCT is integrated into a freshman-level program designed for under-prepared students with interests in a STEM discipline. It is intended to reduce attrition rates by fostering student intuition in, appreciation of, and confidence about basic pre-calculus concepts.**

The MPCT curriculum is problem-driven, with analytical challenge exercises that are intended to motivate inquiry and to illustrate the reasoning used in the STEM professions Preliminary evaluation results are encouraging – students from a wide range of academic majors found MPCT engaging, and report that the course conveyed insight, and decreased anxiety about foundational mathematical concepts.

Keywords-component; introductory computing curriculum, CS0, MPCT, entering students program, CCLI, CPATH.

I. INTRODUCTION

We report on the content and early evaluation of an introductory programming course titled "Media-Propelled Computational Thinking" (MPCT) [5] that is intended to retain students in STEM disciplines by strengthening their understandings of pre-calculus concepts.

At UTEP, MPCT has evolved into variants taught with the introductions to several of the STEM subjects. The original version was integrated into some of the Entering Students Programs (ESP) [4] attended by entering freshmen at the University of Texas at El Paso, a primarily Hispanic-Serving Institution (HSI) serving an economically disadvantaged bi-national urban area on the US-Mexico border. The ESP course is designed to help students develop the skills necessary for academic success, and to assist students in career selection. Consequently, half of the ESP course addresses issues such as study, note-taking, presentation, writing skills, and career guidance. The other half features a technical content module such as MPCT. Its purpose is to present an engaging broad-brush perspective about learning technical content.

Introductory courses for technical disciplines such as computer science can only provide a limited set of activities. One of the main challenges we faced in the design of MPCT was how to use our very limited classroom time in a way that is not only engaging, but that first and foremost improves student readiness for calculus and the challenges of mathematical reasoning. At UTEP, students often have to spend four semesters in remedial and background classes before enrolling in a first course in a STEM major. Consequently, we needed a half-course that could enhance student interest in CS, while simultaneously providing enough mathematical intuition to improve student retention in the high-attrition STEM majors. Trial courses based on outside programs identified some engaging curricula -- especially for students interested in art or in the use of applications to solve specific types of problems -- but none of the programs seemed to have enough focus on pre-calculus mathematics concepts backed by hands-on programming. So we designed our own course, which turned out to require far more work than we had anticipated.

Section II presents the main pedagogical concerns that guided the overall design of MPCT.

The need for an easy-to-use programming environment was also of great concern, since students need to focus most of their time on analytical tasks and algorithm design, and not program syntax. Likewise, we realized that typical programming projects in MPCT had to be very short. Typical assignments are solved with four to ten lines of Python code that includes numerical iteration controlled by for-range statements. To provide students with visceral understandings of program behavior, the output is generally graphical, and involves the direct manipulation of pixels within an RGB image plotted in Cartesian coordinates. Section III presents some of the constructs used to minimize the syntactic difficulties.

The progression of concepts and projects is presented in Section IV. Programming fundamentals are introduced and exercised within lab assignments during the first couple of weeks of class in the context of graphical manipulation such as such as the use of nested for-range statements to enumerate the coordinates of pixels within geometric objects. Subsequent labs first examine the plotting of simple mathematical functions, which are later extended to explore the simulation and mathematical simulation of familiar physical phenomena such as ballistics and resonance.

Section V mentions the adaptation of this education program for other courses at UTEP, and Section VI presents ongoing efforts to evaluate MPCT. A preliminary study indicates increased confidence and interest in pursuing

STEM studies despite MPCT's lack of socially motivated context. Our research plans include a longitudinal study of academic progress that examines the success of students who pursue STEM studies after attending MPCT.

II. THE PEDAGOGICAL APPROACH

MPCT's design is motivated, in part, by observations that deficiencies in, and anxieties about mathematics cause many students to avoid computer science and other STEM disciplines, and are likewise responsible for much of the attrition from these programs. Thus, the key question in designing MPCT is how to foster better mathematics intuition, and how to instill these understandings in an engaging (and hopefully enduring) way. Of course, the results to date, though encouraging, are only preliminary, and much more needs to be done to see if the basic approach can be extended to encompass a more substantial curriculum. Nevertheless, it is not too soon to communicate some preliminary conclusions -- especially when learned from mistakes and occasional failures.

In retrospect, this project has benefitted from a small number of critical design principles. Some of the most important are listed below.

1) Minimize syntactic overload.

Students need to spend most of their time mastering concepts and developing intuition. The syntax of object oriented programming and excessive type declarations can be very time-consuming for beginners.

2) Use a sequence of exercises that present a coherent progression of worthwhile projects.

Since MPCT is intended to use computation to strengthen mathematical reasoning, we designed exercises (coupled with interesting applications) that illustrate increasingly advanced principles in pre-calculus and calculus. Section IV covers the sequence in detail. We also selected problems that are in some sense representative of the issues faced by practicing STEM professionals.

3) Hands-on computing and a see-for-yourself approach to learning is unlikely to succeed unless each inquiry-based exercise is designed with the utmost of care, and tested to ensure that the outcomes match the intentions.

The first version of MPCT used an early exercise that asked students to the graph lines y=ax+b and experiment with the parameter a to see what happens. To our surprise, the overall lesson failed to instill a sound understanding of slope. A revised exercise sequenced through smaller, more carefully structured steps: Fill row 13 of an array; Plot the line y=13, Now treat y as a running sum that begins at 13, and grows by the constant 0.1 from x-value to x-value. Now change the growth constant from 0.1 to 0.5. Here the primitive was slope, and students quickly grasped the idea that straight lines and constant slope (growth) were equivalent. More importantly, they displayed a solid understanding of slopes, and the progression to parabolas based on constant incrementation of the growth rate (slope) was much easier to teach.

III. MINIMIZING EMPAHSIS ON SYNTAX

Programming techniques in early courses should be chosen to minimize cognitive load while maximizing pedagogical value. The focusing of MPCT to introductory computation included a significant reevaluation of the programming interfaces used to support coursework. The original programming interface used the rich object oriented (OO) Java AWT toolbox exposed by the programming framework of [1]. With this approach, even the design of extremely simple algorithms requires fairly complex access code before anything can be programmed. Consequently, the *conceptual* content embedded within our introductory programming lessons were often overwhelmed by the mainly *clerical* task of managing the access and manipulation abstractions for pixels in Java.

This motivated our development of an alternative shallow Raster class described in Figure 1. All pixel accesses explicitly specify row-column addresses. Thus, a pixel location is just a (row ,column) pair of integers represented using a native Python tuple (vector) type, and a pixel color is just a red-green-blue tuple. Algorithms that visit all pixels in a rectangular region can be programmed by a pair of nested loops. As reported in [5], students have little trouble understanding nested iteration in this context.

Constructors
- `Raster((numCols, numRows))`
- `Raster((filename))`

Accessors
Origin is in lower-left corner
Parameters & return values are tuples
- `r, g, b = getRGB((col, row))`
- `setRGB((col, row), (r, g, b))`

Controls
- `setAutoRepaint(state)`
  redraw on every access (default true)
- `setIgnoreOutOfRange(state)`
  silently ignore out-of-range accesses (default true)
- `width, height = getWidthHeight()`
  returns raster geometry

Actions
- `write(filename)`
  save to file
- `repaint()`
  redraw now

Figure 1. Public interface to Raster class

The course begins with by presenting simple code that draws dots and lines. Students adapt them to draw rectangles, triangles, trapezoids and parallelograms by the end of the second class. Figure 2 presents a program sometimes examined within the first two weeks of class that dramatically modifies a familiar cartoon image. The example was selected to illustrate low-overhead programming – *the code does not even require a function definition.*

In order to facilitate projects that plot mathematical functions and leverage students' incoming knowledge, Raster's origin is located in the lower-left corner, and thus column-row addressing directly mimics x-y coordinates within the first quadrant of a Cartesian plane.

```
url = "http:….jpg"
p = Raster(url)
green = (0, 255, 0)
cols,rows =  p.getWidthHeight()
 for col in range (cols):
  for row in range (rows):
     r,g,b = p.getRGB((x,y))
     if r<40 and g<40 and b<40:
        p.setRGB((col,row), green)
```

Figure 2. Program to recolor dark pixels

In short, the simplifications in the necessary code allow the class time to focus on the logic and the algorithms rather than object-oriented hierarchies that provide abstractions ill suited to the problem being addressed. Later projects require the plotting of functions with negative range that are (deliberately) inconvenient to represent with Raster's origin, which is located in the image's lower-left corner. MPCT pragmatically utilizes this inconvenience to motivate the introduction of a `PosNegGraph` class that extends `Raster`. Both `Raster` and `PosNegGraph` are referenced by examples in this paper.

The next section summarizes the curriculum, including example problems in the newly developed modules on mechanical resonance and coupling, and planned extensions of MPCT's pedagogical approach to other courses. Finally, we report on our in-progress course evaluation and adaptations to the evaluation plan in response to MPCT's evolved focus.

IV. Topic Sequence

Figure 1 presents a flowchart of course modules and prerequisite dependencies. A strong–inter-module dependency is represented by a solid line; and a weaker dependency (indicated by a dotted line) indicate an alternate path that permits a course to move more quickly at the cost of removing a particularly engaging presentation of a key concept.

Initial programming exercises are sufficiently short to be conveniently typed directed to the interpreter. The first exercises contain no explicit arithmetic operations, which are gradually introduced to implement increasingly sophisticated computation. The difficulty of reliably typing more advanced programs motivates their storage within files.

The overall program is designed to foster experimentation and to encourage students to review fundamental concepts in algebra and geometry in a way where motivated understanding leads to successful program-generated displays.

For example, A.2 provides a preferred first exposure to nested looping that provides opportunity for students to play with both column- and row- major filling of simple polygons in a dramatic and motivated context. In A.3, students apply their newly gained knowledge of nested iteration to the filling of a rectangular region in A.3, which uses nested looping over both columns and rows to visit every pixel within a rectangular region.

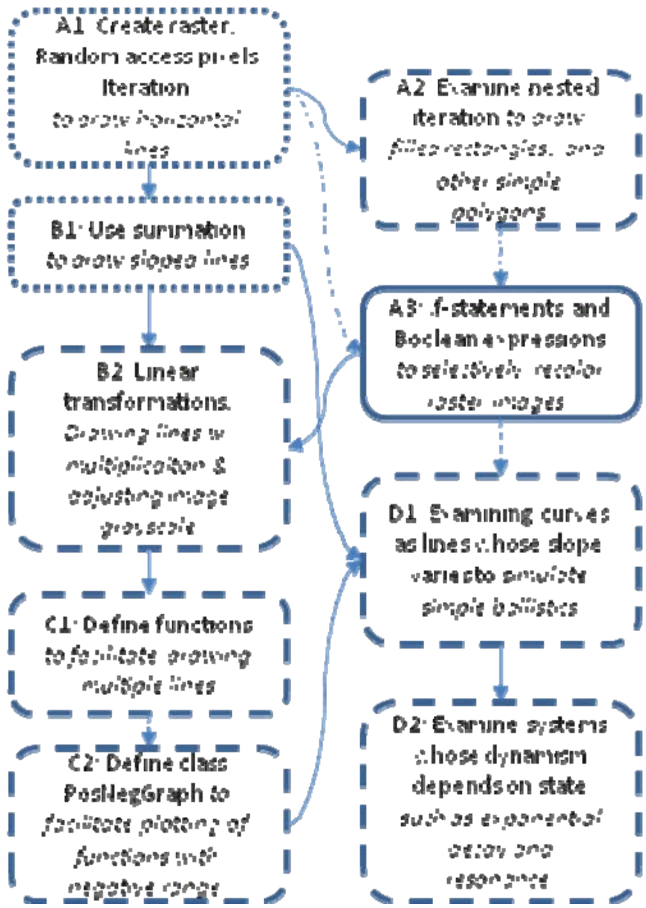

Figure 3. Linkages among course modules

A. *Programming Basics*

In a manner analogous to an immersive language course, students begin to 'converse' in Jython using only three statements to draw a multitude of geometric objects:

- `Raster(size)` – Used to "construct" a computer image:
- `setRGB(pos, color)` – Used to draw a dot:
- `for loops` - Used for iteration.

As described below, these commands allow students to:

- Draw lines as a sequence of dots stacked in a row.
- Draw boxes as a sequence of lines stacked in a column
- Draw triangles, parallelograms, and trapezoids by deriving the inner loop's range from the outer loop's iteration variable.

Module A.1: Create raster, random access pixels, iteration to draw horizontal lines: This introductory lesson exploits Python's interactive mode to permit students to issue single commands to create and manipulate a raster image (represented as a Raster object) and "draw" upon through the column-row selection of individual pixels that are conveniently represented using Python's native tuple (vector) type. The clerical challenge of reliably typing sequences of commands first motivates the storage of a sequence of commands within a file in a manner can be easily repaired or reused using copy/paste. Finally, iteration is presented as a convenient and intuitive solution to the challenge of repeating a single command multiple times while varying a single parameter in order to draw horizontal or vertical lines as is illustrated in the top row of Figure 4.

```
pic = Raster((80,80))
for col in range(20,60):
  pic.setRGB((col, 15), green)

pic = Raster((80,80))
for col in range(20,60):
  for row in range(40, 50):
    pic.setRGB((col, row), green)

pic = Raster((80,80))
for col in range(20,60):
  for row in range(20, col):
    pic.setRGB((col, row), green))
```

Figure 4. Exploration of iteration

Module A.2: Examine nested iteration to draw filled rectangles, and other simple polygons: As illustrated in the lower two rows of Figure 4, A.2 exploits students' familiarity with direct pixel manipulation and iteration presented in A.1 to provide students with an engaging opportunity to playfully tinker with tiny programs that generate filled geometric forms. A.2's engaging sequence of exercises first introduce students to the nesting of loops as an intuitive and simplifyin approach to the clerical challenge of enumerating the location of every pixel within rectangular region and then provide an opportunity to develop intuition about inter-loop interactions.

For example, the first project traverses every pixel within a rectangular region in column-major order, and its immediate successor challenge students to fill the same region in row-major order. Conceptual errors result in easily understood graphical results that are amenable to student analysis and repair. A.2's scope can be modulated by available time and desired learning outcome. Optional lessons examine interactions between inner and outer iteration bounds in order to draw non-rectilinear forms such as triangles, parallelograms, and trapezoids and manipulate iteration stride to enable the drawing of striped patterns. Should the learning priorities include only a superficial understanding of iteration, A.2 can be omitted entirely and the topic can instead be briefly presented in the context of A.3.

Module A.3: If-statements, relational, and boolean operators to selectively recolor raster images: As illustrated above in Figure 2, this lesson uses nested iteration and exploits conditional expressions including relational, Boolean, and grouping operators to conditionally change the color of pixels within a rectangular image. Earlier modules used intuitively named pre-defined constants (e.g. "green") to represent colors. A.3 exposes the graphical system's underlying representation of color as red-green-blue tuples. A raster image is initialized from a jpeg explicity obtained from "the web" using HTTP.

Each pixel location within the rectangular (raster) image is systematically visited using nested iteration. Each pixel's red-green-blue vector is obtained and unpacked into its components using a single getRGB method. An if-statement that contains relational and Boolean operators controls whether the pixel's color-vector is overwritten. Projects challenge students to both experiment with the creation of conditional expressions that select alternate colors and the specification of vectors representing desired alternate colors. Finally, students are exposed to the complexity of automating the detection of forms easily recognized by the human vision system. Optional projects examine simple image processing techniques such as blurring that provide insight into convolutional operations.

B. *Linear systems*

Module B.1: Use of summation to draw sloped lines and the computation of slope: This module examines the nature of linear systems. As illustrated by the top two images and programs from Figure 5, initial projects extend the concept of iteration introduced to draw horizontal lines in A.1 to instead draw sloped lines using summation. A row variable is initialized at column zero. A constant "step size" value is repeatedly summed into the row variable increasing its value at a linear rate that is graphically depicted. Students characterize the effect of various step sizes and initial row values. Later exercises lead students to derive the meaning of their generalization as slope and y-intercept.

As illustrated by the image and program at the bottom of Figure 5, students are subsequently challenged to draw lines that connect designated points (say, to draw a geometric shape). To do this, students must derive the step size from the desired change in row and column using division. We observe that most attending the class can parrot "y=mx+b" as an equation for a line, but nonetheless initially have trouble computing step size; even math-phobic students enrolled in non-STEM programs and are visibly delighted when they derive an approach to determining step size (slope) using division.

Module B.2: Linear transformations: Drawing lines with multiplication and adjusting image grayscale. This module challenges students to generalize their understanding of line generation to the linear projection from an input variable to a dependent output variable. Early projects examine the concept and utility of computing a y-intercept in order to easily compute the row corresponding to any column.

```
pic = Raster((80,80))
…
row = 15
for col in range(0,pic.width):
  pic.setRGB((col, row), green)
```

```
row, step = 15, 0.5
for col in range(0,pic.width):
  pic.setRGB((col, row), green)
  row = row + 1
```

```
first, last = (10, 10), (70, 50)
run = last[0]-first[0]
rise = last[1]-first[1]
step, row = float(rise)/run, first[1]
for col in range(first[0], last[0]):
    pic.setRGB((col, row), green)
    row += step
```

Figure 5. Exploration of line drawing

A particularly motivational project from this lesson examines the grayscale correction of pictures with limited dynamic range. Following a discovery-learning model, students are initially challenged to “improve” the picture’s contrast without guidance Typically students will suggest appliying either linear scaling or constant offsets.

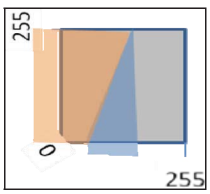

Figure 6. Expansion of image grayscale

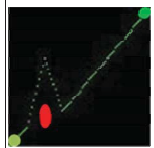
Figure 6, illustrates a composite approach that applies a linear transform that projects the input image’s limited grayscale to a full 0…255 range. The challenge of correctly displaying a negative image permits students to explore the computation of inverse relationships.

C. *Managing complexity using language features*

Module C.1: Defining functions to facilitate drawing multiple lines: Functions are introduced as an approach to reduce complexity through the creation of reusable code fragments. As illustrated in Figure 7, students are challenged to write programs that draw a path using line segments that connected designated start and end points and avoid colored obstacles. Rather than focusing on the path problem, this module provides opportunities to first practice the application of computing slope. Observe that, the body of drawline appearing in Figure 7 is identical to the program at the bottom of Figure 5. In this manner, reduction of the program complexity is achieved by drawing multiple lines with multiple calls to a single function rather than the insertion of repeated code fragments.



```
def drawline(first, last)
  run = last[0]-first[0]
  rise = last[1]-first[1]
  step, row = float(rise)/run, first[1]
  for col in range(first[0], last[0]):
    pic.setRGB((col, row), green)
    row += step
```

Figure 7. Maze and function from C.1

Module C.2: A user-defined class that facilitates plotting of functions with negative range: The linear systems examined previously only have non-negative range. In this module, students are encouraged to examine negative range by translating the image through the adding of a constant to the row value. The repetitive task of translating the image to examine the negative range motivates the examination of a user-defined class that centers and draws the X-axis. As illustrated by Figure 8, the easily understood PosNegGraph class conveniently translates the origin to the middle of the left edge.

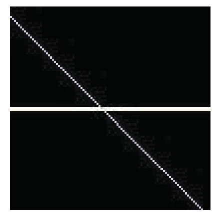


Figure 8. Illustration of PosNegGraph plot

D. *Non-linear systems*

To ensure that students are not intimidated by unfamiliar mathematical abstractions, we prefer to first introduce evolving processes using the simplest-possible generators, and then to guide students into discovering algebraic simplifications they are fully prepared to understand.

The topics sequence through increasingly complex computational themes where all of the physical modeling is based on rates of change or summations (as opposed to integration).

Lab exercises examining non-linear systems extend the summation techniques previously examined to simulate the dynamics of familiar physical phenomena. Exercises mimic the familiar phenomenon of ball bounce and spring resonance, which are frequently poorly understood, even by students who have completed a semester of college physics [6].

Finite differences are computed at each time step and are summed into system state. Longitudinal studies are being conducted to determine if cohorts of students who are first exposed to these concepts through simulation have improved academic success in subsequent courses that examine the same phenomena using calculus.

For problems in mathematics and physics, we endeavor to minimize the level of outside knowledge required, and prefer show how processes evolve at an intuitive level and where incremental changes in the process state can be explained in physical and computational terms -- much like [7].

Math-centric programming projects generally begin with an exploration of the effects of rates-of-change. Afterwards, students are guided to reduce the already familiar summation problems (implicitly a recursive formulation) to closed form.

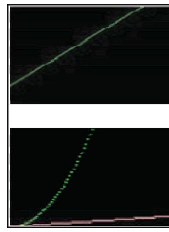
D.1: Examining curves as lines whose slope varies to simulate simple ballistics: Boolean expressions and conditional statements (taught in A.3) should be taught if the simulation of a ball bounce is included in the lesson. The instructor leads a discussion about the similarities and differences between lines and curves and elicits an observation that a curve's slope must vary. Students add the rate variable, and begin to experiment with drawing curves.

The main study concerns curves whose slope changes linearly as shown in the parabola in the bottom Figure 9. Once sufficient time has been spent experimenting with drawing curves, students begin to apply what they have learned to simulating familiar phenomena such as ballistics and ball bounce.

In ballistic problems, objects are accelerated only by gravity. Their trajectory is parabolic. The slope of their trajectory with respect to time corresponds to velocity. The slope of their velocity with respect to time corresponds to acceleration. The mapping of trajectories to parabolas is straightforward: slope corresponds to velocity, and the slope's constant rate of change maps to acceleration. Students first simulate a single "toss," and then are challenged to simulate a bounce as an inelastic collision with the ground, where at each bounce, velocity is reduced by 20%. This leads to an exponential decay in the maximum height achieved after each bounce. The `parabola` program's overlaid plot of position and velocity illustrates both continuous and discontinuous evolution of physical parameters.

As illustrated in Figure 10, students are able to easily examine the effects of varying initial conditions including examples where the slope and rate have different and same initial signs. Finally, the relationship between parabolas and quadratic functions are made concrete through geometric proofs such as depicted in Figure 11.

D.2: Examination of systems whose dynamism depends on state such as exponential decay and resonance. It is interesting that upperclassmen who have attended multiple courses in Calculus are enthralled by the progressive computation of exponential decay illustrated in Figure 12 that could easily be understood by a freshman if presented in an accessible context. We observe that the spring resonator of Figure 13 is accessible to students attending a first course in mechanics. The electrical resonator of Figure 13 is incorporated in an introductory programming course offered to students in electrical engineering in the Spring of 2010 that incorporates the pedagogy of MPCT.



```
row, step = 15, 0.5
for col in range(0,pic.width):
  pic.setRGB((col, row), green)
  row = row + 1

row = step = 0
rate = 0.1
for col in range(0,pic.width):
  pic.setRGB((col, row), green)
  pic.setRGB((col, step), pink)
  row += step
  step += rate
```

Figure 9. Progression from lines to curves

```
def bounce(height=50, speed=0, accel = -0.1):
  pic = PosNegGraph((100, 75))
  for time in range(0,pic.width):
    pic.setRGB((time, height), green)
    pic.setRGB((time, speed), pink)
    height += speed; speed += accel
    if height < 0 and speed < 0:
      speed = -0.8 * speed
```

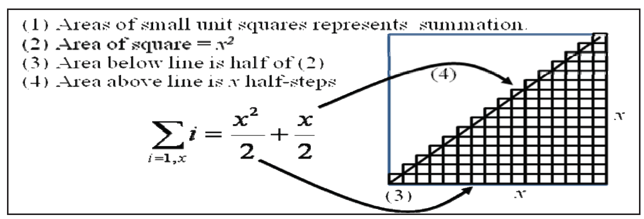

Figure 11.
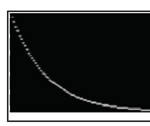
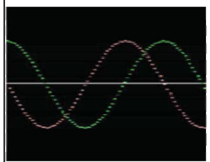
Graphical depiction of linear sums in closed form as a quadratic function



```
i = Raster((80, 80))
row = 80
for col in range(0, 80):
  i.setRGB((col, row), white)
  row = row * 0.95
```

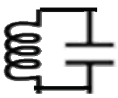
Figure 12. Exponential decay

MPCT completes with an example of coupled resonance illustrating the principle underlying an opera singers' wine-glass shattering trick and the catastrophic failure of the Tacoma Narrows bridge (see Figure 3) in 1940 and the crashes of several Lockheed Electras around 1960.



```
i = PosNegGraph()
pos = 45; speed = 0
springConst = 0.01
deltaT= 0.1
mass = 0.01
for x in range(0, i.width):
  i.setRGB((x, pos), green)
  i.setRGB((x, speed), pink)
  force = -pos * springConst
  accel = force / mass
  speed += accel * deltaT
  pos += speed * deltaT
```

Figure 13. Simple mechanical resonator



```
img = PosNegGraph((300, 100))
V, I = 0, 50.0e-3    # initial conditions
C, L = 1e-9, 1e-3    # farad, henry
for x in range(0, img.width):
  img.setRGB((x, 1000*I), white) # fs=100ma
  img.setRGB((x, V), green)
  dv = (I/C) * dt
  di = -(V/L) * dt
  V = V + dv
  I = I + di
```

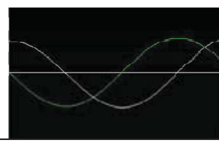


Figure 14. Electrical resonator

MPCT completes with an example of coupled resonance illustrating the principle underlying an opera singers' wine-glass shattering trick and the catastrophic failure of the Tacoma Narrows bridge (see **Photo image courtesy of Ed Elliott www.camerashoptacoma.com. All rights reserved. [8]**

Figure 15) in 1940 and the crashes of several Lockheed Electras around 1960.

Figure 16 illustrates the result of an advanced project that examines coupling when both the oscillator and resonator are tuned to the same frequency. Like the catastrophic failures enumerated above, this resonator quickly accumulates energy from the oscillator.

V. Extensions to Other Courses

A new introductory course titled "Computation for Science and Engineering" in computational science intended for upper-division students of STEM disciplines that traditionally do not include computation such as biology, geology, finance, and math is planned for Spring 2010. This course will introduce programming using examples from MPCT, and then will proceed to implement simulations modeling more dynamic systems in which a sudden action could change the "normal" or expected behavior such as production-consumer markets, investment valuation, predator-prey models, and biological processes.

Two other pilots are beginning in Spring 2010.: A section of an introductory programming course offered to students enrolled in Electrical Engineering will be taught using MPCT's pedagogical approach and will include projects that simulate dynamism in electrical systems. A section of a statistics course attended by students of psychology will also include elements from MPCT with the expectation that the process of constructing simulators of stochastic systems will assist in students' understanding of coupled and independent random processes.

We are also adapting this approach of motivating math from concrete problems to the teaching of algorithms. There, the objective is to use specific problems as a vehicle for teaching algorithms as general methods that can be adapted to solve related problems of interest. We find that by teaching algorithmic schemas to solve "purified" problems, students can follow the reasoning far more easily and can sometimes develop the computational idea themselves. As in MPCT, the layered elaborations are introduced step-by-step to solve increasingly complex problems as described in [9].

VI. Evaluation

More than half of the students entering UTEP intending to study CS are not "calculus ready," as required for CS1. First-attempt pass rates for CS-1 range from 50 to 70%, which surely contributes both to student time-to-graduation and attrition. Thus the need for intervention is clear. During the development of MPCT, several variants of Media Programming were offered at UTEP. In all versions, almost all students demonstrated proficiency at basic programming concepts and passed.

UTEP is a member of the Computing Alliance of Hispanic Institutions (CAHSI), which is evaluating various CS-zero courses offered at multiple institutions serving predominantly Hispanic populations of students. These evaluations include intermittent classroom observations and both pre- and post-course surveys examining preparation, social context, student engagement with the course, interest in further study of computation, and success in subsequent coursework.

In their 2008 report, the CAHSI evaluator measured high levels of both interest and confidence [10] among entering students prior to attending the course, though less than 20% had previously programmed. Post-course surveys of students attending the precursor courses indicate that 25% of the students were not motivated to continue studies related to computer science. This is likely a positive result if the course helped students correct unrealistic expectations about computer science early in their academic careers.

Students who attended a variety of CS-0s (including Media Programming at UTEP and Alice at other institutions) had similar passing rates that were similar to the general population. The mathematically-oriented revisions to MPCT have required several semesters of development and have only recently been implemented – hence no longitudinal data is available yet.

Entering STEM students attended MPCT during the Fall semester of 2008, and non-STEM students attended distinct sections during both the Fall and Spring semesters. The mathematics included in the section was first offered Spring 2009, and therefore was only attended by non-STEM students. A post-course survey of the Spring 2009 non-STEM cohort examined changes in (1) perceptions of knowledge and understandings of key concepts, (2) perceptions of mathematics' relevance to 'real life' scenarios, and (3) attitudes toward learning math concepts in the context of programming.

As described in [11], the preliminary findings from the non-STEM section are encouraging. Although the sample size was too small to draw reliable conclusions, they reflect the instructors' observations of student motivation and engagement. Survey results indicate shifts from low level to higher levels of understanding math concepts introduced in MPCT, positive attitude toward MPCT structure and its intended objectives, and highly favorable perceptions of MPCT's relevance to real-life applications. We expect statistically reliable results from the Fall 2009 cohort, which is much larger, containing more than sixty pre-STEM and twenty non-STEM students.

During the Spring 2009 term, the evaluation was broadened to include instruments that examine changes in interest, self-efficacy and competence related to mathematics. Several open-ended essay questions were included in order to guide the selection of relevant questions for the intended Fall evaluation.

Pre-survey results indicate that in addition to high confidence in programming their programming skill, students have high confidence in their math skills that are inconsistent with their performance in class.

Our longitudinal evaluation will be broadened to also compare the academic success of students in subsequent math courses with the academic success of students who do not attend MPCT.

VII. Conclusion

Continuing evaluation of introductory programming offerings at UTEP targeting pre-STEM students have motivated evolutions in curriculum, course objectives, and evaluation strategies. Interestingly, the resulting course, MPCT, which engages students in a "computational reasoning," integrates both programming and mathematics, is engaging to both pre-STEM and non-STEM students with weak math skills. Results from early evaluation efforts are encouraging and have lead to refinements in evaluation strategy that mirror the course's evolution.

A Tablet PC-Based Teaching Approach using Conceptual Maps

José-V. Benlloch-Dualde, Félix Buendía, Juan-Carlos Cano
Computer Engineering Department - ETSINF
Universidad Politécnica de Valencia, Spain
{jbenlloc, fbuendia, jucano}@disca.upv.es

Abstract— **There are clear evidences that technology can drive major positive changes in the classroom addressing problems associated with traditional lecture-based pedagogy. In particular, the flexibility of Tablet PCs and digital ink has the potential to achieve a wide range of educational goals and promote a more dynamic classroom environment. However, as the possibilities of these educational technologies grow, it seems necessary to consider their role by conceptualizing the knowledge they provide. In this work we propose a teaching approach based on the use of conceptual maps to generate instructor guidelines for Tablet PC-based courses. Our approach combines the instructional domain with the technological one in order to offer practical guidelines to design and develop both lecture materials and active learning experiences, providing a systematic and flexible way to guide the teaching process in a Tablet PC-based learning scenarios. We present a case study on how to implement the approach in a first-year Computer Engineering course reporting the introduction of the Tablet PC in this educational setting.**

Keywords- Tablet PC; Digital Ink; Conceptual Maps; Instructional Design.

I. Introduction

The widespread adoption of slides displayed with a digital data projector has supposed an unquestionable technological change in the classroom. However, it has no essentially modified the lecture model of instruction, which is still prevalent in many of our Computer Engineering (CE) undergraduate courses. It is often difficult to maintain concentration of students for the entire 2-hour lecture sessions, especially when there is a lack of variety in the teaching method. Stuart and Rutherford [1] assessed students' concentration during a didactic lecture and found that ''concentration rose to maximum at 10-15 min. and then fell steadily until the end of the lecture''.

One of the latest trends in instructional technology is the use of Tablet PCs in the classroom. In recent years, Tablet PCs are making its headway into classroom instruction at every level, from primary and secondary school, to higher education. In fact some recognized institutions, such as Virginia Tech, have adopted, since 2006, a mandatory program requiring all first-year students in College of Eng. to own a Tablet PC [2].

Recent research demonstrates obvious advantages of using Tablet PCs in higher education. In fact, there are clear evidences that technology can drive major positive changes in the classroom, addressing problems associated with traditional lecture-based pedagogy [3].

However, we think that any random implementation of educational technology has a low probability of success and widespread adoption. We consider that clear guidelines are required to develop and deploy such new technology settings. As the number and possibilities of Tablet PC and pen-based technology grow, it seems necessary to consider the role of these educational technologies by conceptualizing the knowledge they provide. There are different tools to represent and organize these knowledge items and we have selected conceptual maps [4] as one of the more flexible and powerful techniques to support this process. Concept maps are graphical tools for organizing and representing knowledge. They include concepts and relationships and their use permits modeling mental trees of assimilated concepts to a simple format.

In this work we propose TAGGE (*Teacher Assistance Guideline Generation Engine*), as a teaching approach to generate instructor guidelines for preparing interactive face-to-face courses supported by technology. Based on the learning requirements of a specific educational setting, TAGGE uses conceptual maps to model the instructional domain and the technology domain in order to provide clear teaching guidelines, i.e., the outputs of our approach. These guidelines will then be used by instructors to adapt traditional courses to an active learning technology-based course. The main idea behind TAGGE is, on the one hand, the conceptualization of the instructional and technological domains using conceptual maps and, on the other hand, to relate the instructional domain to the technological issues in order to propose the teaching guidelines.

This paper is organized as follows. Section II reviews the related works using Tablet PCs and conceptual maps to enhance the learning process. Section III presents TAGGE, our teaching approach. Section IV describes the conceptualization of an educational setting example. Section V presents the teaching guidelines offered by the TAGGE approach in this particular context. Section VI describes the teaching context of our case study and presents some preliminary results. Finally, Section VII presents some concluding remarks.

II. Related work

In this section we first present some of the most outstanding works using Tablet PC to enhance learning and to promote student engagement. After that we review some of the fields where conceptual maps have been applied.

A. Using Tablet PCs on Education

The advantages of using Tablet PCs in a classroom have been reported by several studies in the last few years. In [5] authors used the Tablet PC in an upper level Electrical Engineering course for both content development and presentation. Tablet PC was also used in [6] for several undergraduate engineering courses, which clearly showed how it facilitates collaborative and active learning, allowing the instructor to spend more time on explaining concepts rather than drawing figures. In [7] classroom instruction using a Tablet PC with standard PowerPoint presentation and whiteboard are compared. The authors reported that Tablet PC-based class presentation showed better attention rate and better comprehension of the material. Tablet PCs are also being increasingly used in secondary school where the overall learning process is greatly improved if they use Tablet PCs [8].

In terms of instructional tools, *Classroom Presenter* [9], developed by the Univ. of Washington, has the ability to enhance the usage of PowerPoint-based slides, allowing students to communicate among themselves and the instructor in real time. *DyKnow* software [10], which has two interoperable programs within it, *Monitor* and *Vision*, is another interesting example. *Monitor* enables the instructor to monitor and/or block unauthorized student computer activities, while *Vision*, fosters interaction through collaborative note taking, student response tools, content replay, and anywhere, anytime access. *WriteOn* [11] is another tool, which can be used together with Tablet PCs to allow annotating on top of any application visible on the Tablet screen.

B. Applying conceptual maps

II. Concept maps have been around for quite some time, and their principles are deeply rooted on well-known learning theories. Their adoption sought to offer an Ausubelian perspective of the knowledge acquired [12] by allowing to externalize mental trees of assimilated concepts to a simple format. In terms of learning approaches, concept maps offer the evaluator great insight and help at detecting misunderstandings and flaws in the learning process strategy. Concept maps were first proposed by Novak [4] a few decades ago. They consist of a very flexible structure that allows users to create meaningful relationships between key concepts so as to improve the processes of learning and knowledge acquisition in general. Since their invention, they have received much attention from researchers and experts worldwide. In fact, concept maps have been used in various areas of knowledge with heterogeneous purposes such as creating cross-language tools [13], thereby simplifying concept translation between different languages, as a tool to enhance web searches [14], in the evaluation process in Computer Engineering Undergraduate Courses using objective metrics[15], or even to improve the public outreach of the Mars exploration mission[16].

In this work we used concept maps in order to model the instructional learning domain and the Tablet-PC technological domain, and thus generating teaching guidelines in Tablet PC-based courses.

III. TAGGE: OUR TEACHING APPROACH

This section introduces TAGGE, our approach to generate teaching guidelines for technology-supported courses. This approach is based on modeling the knowledge items about instructional and technology issues that are part of a specific course. This conceptualizing process will enable the guideline generation in a more systematic and flexible way.

Fig. 1 shows the conceptual framework of TAGGE. It takes the learning requirements attached to a specific course as inputs (e.g., the learning general needs, the learner profile, or the course subject features) and processes them to obtain the guidelines to assist instructors in a particular learning scenario. The basic under TAGGE is the conceptualization of the instructional and technological issues for a given learning scenario (e.g. a course). There are different tools to represent and organize these knowledge items and, in this case, conceptual maps have been selected as one of the more flexible and powerful techniques to support this process. Concept maps are graphical tools for organizing and representing knowledge. They include concepts, usually enclosed in circles or boxes, and relationships between concepts, indicated by a connecting line linking two concepts.

Starting from the conceptual maps representing the instructional domain and the technological one, the processing performed by TAGGE is organized in two steps. First, the learning requirements are fed as inputs to the TAGGE environment. These variables are used to modulate instructional issues such as learning objectives (e.g. getting theoretical knowledge or promoting hands-on skills), course resources (e.g. lecture handouts or lesson scripts), learning tasks (e.g. assignment, project elaboration or portfolio development), or assessment activities (e.g. summative vs. formative strategies). Once the basic instructional concepts have been selected, their relationships with other descendant concepts are searched. The second step starts when concepts located at the technological map are "detected" using relationships coming from instructional "leaf" concepts. These technological-based concepts should be instances of higher class concepts in the map (e.g. Desktop Sharing in a Tablet PC context) which define the category concepts used to generate the teaching guideline. Attached to each selected technological category, several guidelines can be configured as output of the TAGGE system. These guidelines will then be used by instructors to adapt traditional courses to a new technology-supported educational approach.

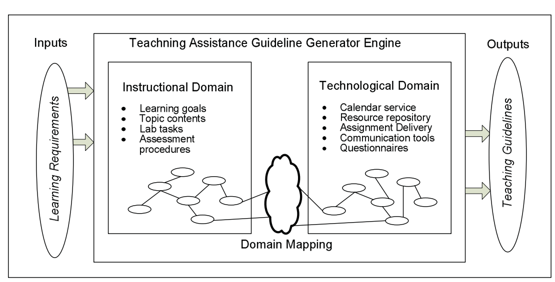

Figure 1. TAGGE. Overview.

Next, we present two conceptual maps which are core elements in our approach. The first one is associated to the instructional domain in a specific educational context, and the second one is related to the Tablet PC domain.

IV. CONCEPTUALIZING THE CONTEXT

In order to illustrate the proposed approach, this section describes a specific context where TAGGE will be applied. On the one hand, Computer Technology, a first-year compulsory course in Computer Engineering has been chosen to describe the instructional domain. On the other hand, Tablet PC devices have been selected as the technological elements in this context. Once both domains have been defined, conceptual maps should be built up in order to organize the corresponding knowledge items.

Fig. 2 shows a conceptual map aiming at describing the instructional model of the course entitled Computer Technology, object of our case study, before integrating the new technologies. Elements located at the top of the map introduce, on the one hand, how sessions are organized and, on the other hand, the assessment strategies. In particular, instruction is organized in face to face lectures, problem-solving classes and laboratory sessions. Instructors take the main role in lectures, whereas both problem-solving and laboratory sessions are focused on the student activity. The lower levels of the map describe the general goals of the different sessions as well as the specific resources that they use. Additionally, this part of the map provides information about what kind of skills students should improve in the different sessions, such as cognitive skills in lectures, communication skills in problem-solving classes or hands-on skills in laboratory sessions. In relation to assessment strategies the map enumerates different approaches that are taken (multiple-choice tests, problems, hands-on activities, student in-class activity). Moreover, it shows some relations with the methodological aspects and how the results may be used.

Fig. 3 depicts a conceptual map that tries to organize the knowledge about Tablet PC technology in a comprehensive manner. In order to better understand the different aspects it covers, we will try to distinguish different areas.

On the top left side of the map, the physical aspects of Tablet PCs are addressed and their main features, such as portability or mobility, are presented. This area also introduces the elements that characterize these devices as a special display screen including a digitizer, and a digital pen, which gives name to a broader family of devices, the pen-based technologies. The three types of Tablet PCs currently available on the market are showed as well: a) slate, b) convertible, and c) hybrid.

On the top right side of the map, different services provided by this technology are displayed, such as presentation delivering, interactive whiteboard, polling, desktop sharing and videoconference. Connected to these services those aspects that may be promoted, are presented as: note taking, collaboration, feedback or communication. This area deals also with specific operating system or software applications related to these devices.

Finally, the map also introduces at the bottom side area the capabilities of digital ink as a key concept in Tablet PCs. In particular, the possibility of using handwritten inputs allows users not only to write in a more natural and free way, but also to mark, to sketch or to draw, among others. In this section, the ability to use a pen to directly write on the surface of a computer screen is also related to the activities that may be fostered, such as: brain storming, prototyping, designing, reviewing, annotating, etc.

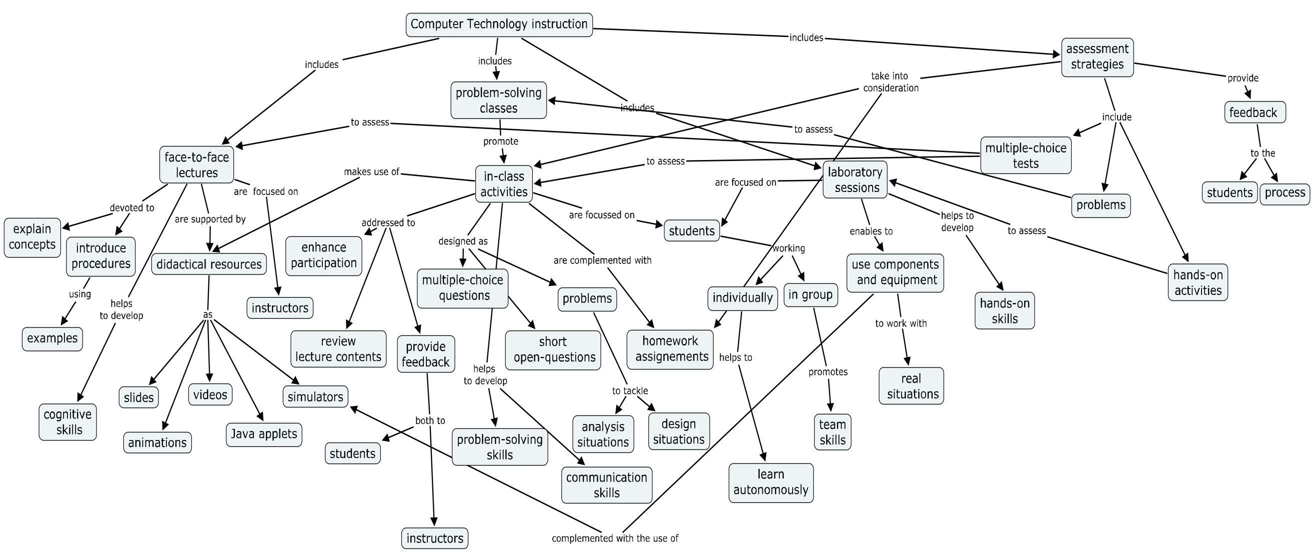

Figure 2. Conceptual map of the instructional domain: Computer Technology course.

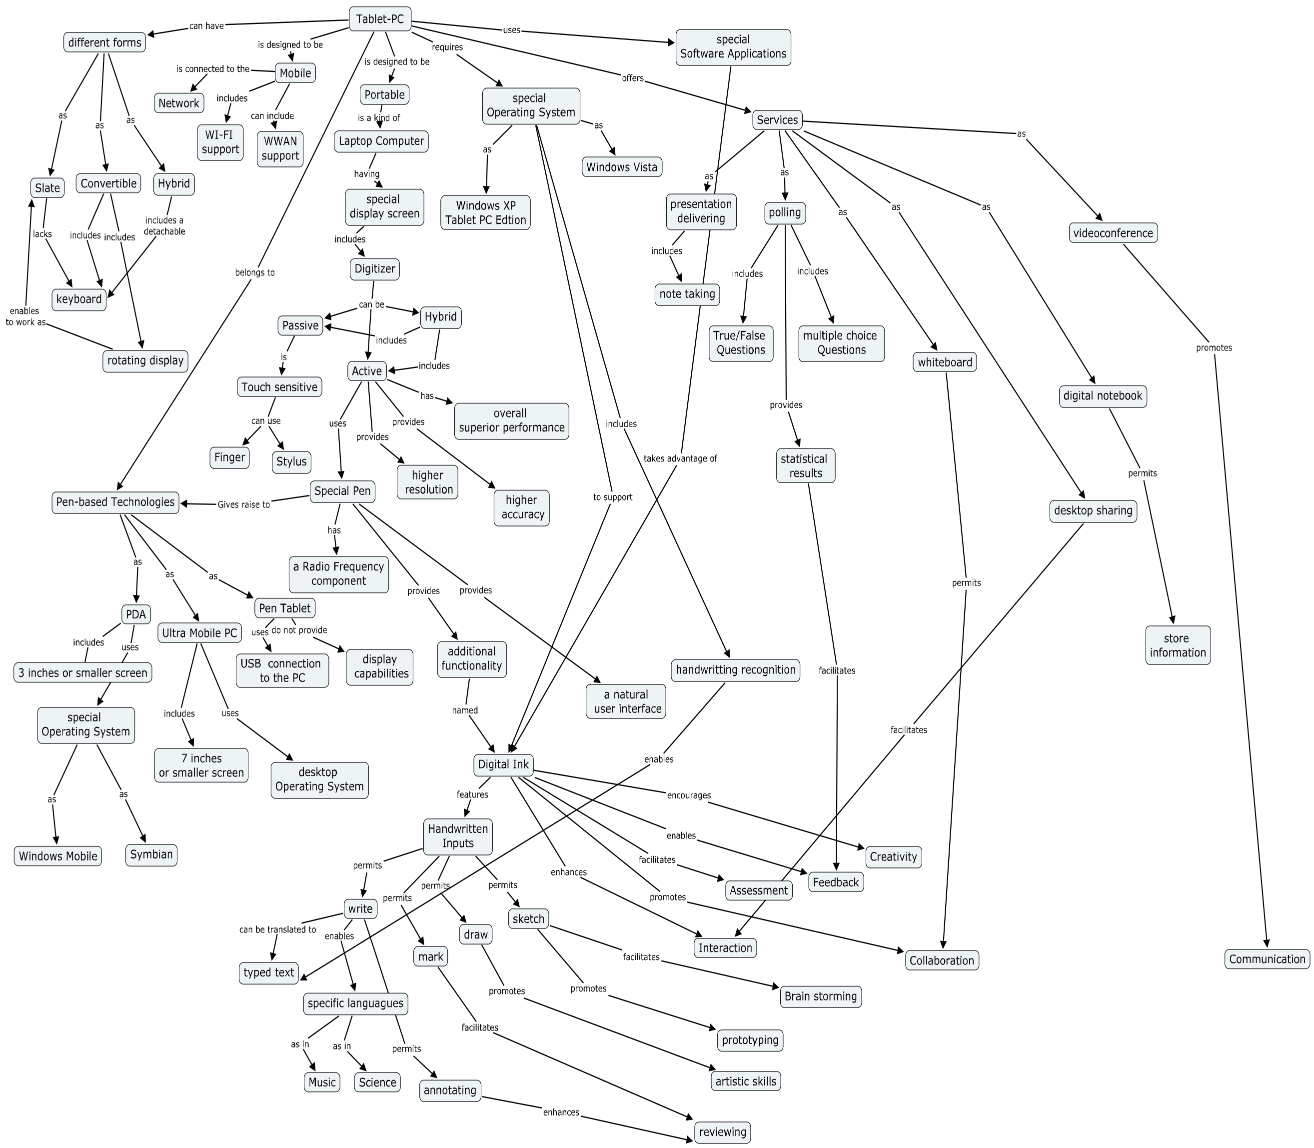

Figure 3. Conceptual map of the technological domain: Tablet PC

V. OBTAINING THE TEACHING GUIDELINES

This section describes the application of the proposed teaching approach to the context example presented in the previous section As stated in the TAGGE description, learning requirements represent the inputs that help to describe the specific context. Concerning the Computer Technology course, over the last five academic years have been observed the following problems: a) pupils' lack of motivation; b) low class attendance rates; c) high course dropout rates; d) low participation and student interaction, and eventually, e) poor students' performance. These issues are also common in other first-year courses. Furthermore, the discipline demands abstract reasoning to understand how semiconductor devices and logic circuits work, problem-solving skills to tackle analysis and design situations, usage of computer simulation tools to help modeling those devices and circuits and additionally, a good knowledge in Physics (more in particular, in topics related to circuit theory).

Once the learning requirements have been set up, the first step of our approach consists in feeding them to our instructional domain in order to decide which are the basic instructional concepts we should focus on. In our particular case, we determine that initially, we should face those instructional factors related to the learner profile, such as engagement, interaction, participation, or feedback; then, we should address the issues related to the discipline itself, trying to obtain a more realistic and motivating approach, by using multimedia resources, computer tools, additional examples, etc. When we try to match these basic concepts to our instructional conceptual map, we find that: a) in-class activities should be emphasized as a way to create more interactive and cooperative sessions; b) those didactical resources that promote student participation should be strengthened, as they could improve both face-to-face lectures and promote autonomous learning; c) assessment strategies should be shaped in order to track learning attainment in a continuous way and also to provide feedback to students and to the process.

The second step of our learning approach connects those basic concepts coming from the instructional domain to the corresponding ones in the particular technological domain. In relation to the Tablet PC domain, it leads us to exploit the inking functionalities and to select which services fit better our instructional issues. In our particular case, we observe that: a) delivering services can contribute to foster student participation and cooperative learning; b) desktop sharing services can help to take the best use of multimedia resources or computer tools and, at the same time, also facilitate the student active role; c) polling services can assist both students and teachers to obtain timely feedback about student attainment and what is better, to facilitate mechanisms to adapt the teaching strategies to the learner's needs.

Finally, teaching guidelines represent the outputs of the process and describe how the technological domain could contribute to fulfill the addressed learning requirements. Table I summarizes the outputs in our case.

TABLE I. TEACHING GUIDELINES

Tablet PC issues	Instructional issues	Learning issues
Presentation delivering services, included in tools as *Classroom Presenter* or *Dyknow*, make use of digital ink functionalities, could be used to:	Increase the instructor's flexibility while lecturing. Facilitate student note-taking. Enable submission of student in-class activity to the instructor and further discussion. Permit archiving of both instructor presentation and student submissions.	Student participation Cooperative learning Enhanced communication with other classmates and instructors Timely feedback to students and instructor.
Desktop Sharing service, as provided by *Yugma*, could be used to:	Engage students in computer simulations introduced as in-class activities. Enable students to assume the presenter role in face-to-face lectures.	Realistic approach of the subject Simulation tools, as PSpice Student engagement
Polling services, also included in tools as *Classroom Presenter* or *Dyknow*, could be used to:	Promote student attainment. Gain knowledge about students understanding related to key course concepts given in lectures. Review misunderstandings and propose reinforcements.	Student self-esteem and confidence Timely feedback to student and instructor
Digital notebook services, as offered by *Microsoft Office OneNote*, could be used to:	Collect all the activities done through the academic year. Review student tasks and provide students with comments and learning recommendations.	Student engagement Student activity tracking Continuous assessment

VI. CASE STUDY & RESULTS

This section reports how the former approach was applied during the spring 2009 semester to Computer Technology (5554), a core course in our Computer Engineering Bachelor, at the Universidad Politécnica de Valencia. The course has 7.5 credits (75 teaching hours), distributed in lectures, problem-solving classes and laboratory sessions. 10 faculty members are involved in the course that the last academic year had an enrolment of 300. Students used to be distributed in 5 lecture groups, 10 problem-solving groups and 15 lab groups.

At present, the course includes two hours of lecture and two hours of problem-solving session per week. In both cases, instructors have a prevalent role whether exposing the contents, supported by a slide presentation, or solving the problems on the blackboard. Several attempts have been made to increase in-class student participation during the last academic years. However, many students are reluctant to present their solutions on the blackboard and what is worst, some declared to drop the course due to the participation demands. As a consequence, these attempts have not significantly improved the overall scores.

In order to apply the approach in this new technology setting, an additional group of just 20 students has been defined. Although this figure could seem very low, it often represents the actual number of students regularly attending to problem-solving sessions.

To measure the effectiveness of the approach, two sections have been compared, the experimental group (20 students) using the Tablet PCs following a 1-to-1 computing approach, and a control group (34 students), following the traditional teaching methods. During all the term we have mainly used *Classroom Presenter*, a Tablet PC-based classroom interaction system that supports the sharing of digital ink on slides between instructors and students to increase the instructor's flexibility while lecturing.

We have used final scores as the main performance indicator, since they were a direct summation of the evaluation of the different activities included in the semester. A 30% passed the course in June in the treatment group while only an 18% in the control group. Other remarkable evidence is that the percentage of students taking the final exam in the experimental group was a 70% while in the control group was only a 29%. Class attendance has also considerably increased: a 60% attended at least 67% of the classes in the experimental group while only a 32% in the control group. Moreover, drop-out rates in the experimental group decreased below 25% while reached almost a 60% in the control group.

VII. CONCLUSIONS

In this work we present a teaching approach that enables the generation of guidelines for technology-supported courses. The proposed approach is based on the conceptualization of instructional and technological issues using concept maps to represent the knowledge provided by educational technologies such as Tablet PC and digital ink. The proposed approach provides teaching guidelines addressed to design and develop both lecture materials and active learning experiences, in a systematic and flexible way. The obtained guidelines have been tested in a case study conducted in Computer Technology, a first-year Computer Engineering course. The results of the test during the spring 2009 semester have revealed a higher degree of students' engagement and an increment in class attendance. We also consider developing computer tools which enable the automatic processing of conceptual maps in order to facilitate the generation of teaching guidelines.

Abstract—**This paper shows a pioneering project in education with the use of cell phones and other mobile devices. The mobile learning environment was developed by Fazion Sistemas and currently is at the Universidade Fernando Pessoa (Portugal). The paper presents an overview of mobile-learning concepts, its barriers, challenges and trends.**

Keywords- m-learning; distance education; mobile application, mobile learning; e-learning; enginneering education.

I. Introduction

Today people are used with mobile phones, and pay to communicate with people whom they like or with whom they work, either through direct conversation or by exchanging messages. In fact, the text messages play a very limited role in communication, either by poor information quality or high costs. While the "idea" of the personal computer largely derived from the look of a typewriter and calculator, usually born in the company, the phone came from the merger of the notebook and telephone, being something very personal.

We must learn from this change - home versus business – and what should be done to enhance phone quality when developing applications. Today, more than ever, businesses are stepping forward to bring people together because people like to relate to each other, regardless of business they do. If a mobile network project can be developed in this format, aimed at relationships, then this is the path. [1]

Currently there are three areas where mobility can bring immediate fruits and strategic importance for organizations, which are "mobile-business", "mobile-commerce" and "mobile-learning", or simply "m-learning".

M-learning can be considered an offshoot of e-learning. But, in fact, considering that e-learning enabled the distance learning using the Internet, m-learning goes beyond by allowing the user access to perform anywhere, even on the move, and the device becomes in fact a mobile repository of information. The concept of education with the use of mobile phones covers a wide range of opportunities:

- learn anywhere and in motion, simply carrying a personal mobile device;
- learn by interacting with different people through social networks, forums, etc.;
- archive and order a wide range of information, using memory resources of the device;
- create, with equipment features, image files, video or text, attaching them to the systems of communication and learning;
- consult various information such as grade, messages, calendars, among others.

This paper does an overview about m-learning and shows a pioneering project in education with the use of cell phones and other mobile devices. The project is at Universidade Fernando Pessoa (Portugal) and the basic system refers to academic information such as calendar, information about the subject, grade and environment forum between students and teachers. Universidade Fernando Pessoa uses a very successful e-learning environment based on the *sakai* collaborative platform [2] and sees it as a natural expansion of e-learning environment towards m-learning.

The m-learning project presents several challenges and barriers to transpose, either on technical or cognitive issues. As an example, there is no standardization on the several mobile platforms or devices, screens vary from device to device and the industry is not worried about data traffic or computation basis when compared to voice traffic and its respective earnings. The cognitive aspects of mobile learning is yet more obscure, as the research on this area is just in its very beginning and depends on new experiments and trials.

The project with Universidade Fernando Pessoa is a real case use and is also object of study and research. The paper begins with an overview of mobile learning concepts and describes the context of the project at Universidade Fernando Pessoa.

II. Evolution of Distance Education - a Brief History

The evolution of distance education can be divided roughly in three different stages: 1) the distance learning, 2) the electronic learning, and 3) the mobile learning phase.

The distance learning stage, abbreviated as d-Learning, begins with the industrial revolution around centuries 18^{th} and 19^{th}. The industrial revolution brings several new possibilities for communication, and one of the most important is the printing facility of large volumes of books, newspapers and other documents. The post service evolved those days, and the expansion of railways, with trains arriving or passing through distant places, got the advantage to take people together or more connected then ever before. The first distance education courses were based on books and correspondence, and people away from large centers could receive materials, study alone and conduct tests and relationships through correspondence. In the United Kingdom the University of London opens its education program in 1840. The concept of distance education evolved until the last century when, during the 1970 decade, the first "Open Universities" opened in Europe (UK, Spain and Germany).

The electronic learning, or e-Learning, comes with the electronic revolution and the internet. The arrival of electronic communications has enabled a new level of access and communication for education, first with the radio live broadcasts of courses, and after the television era came. Then in the nineties arrived the internet network that allows a wide range of new possibilities for communication, especially interactive, which was not possible with radio and television. Learning systems using the internet can provide content, promote discussion forums and chat in real time, show videos and create other possibilities as an entirely new way to educate through the use of web tools. The intensive use of internet was possible due to several facts:

- deregulation of communications, followed by telecom privatization around the world;
- development of personal computers and its popularization in the '80s; computers became easier to use and price came down year by year;
- communication networks have switched from analog to digital; this digitalization allowed the development of new transmission technologies and protocols and conditions to compact more information in a single "packet";
- Internet has become public in the '90s; earlier used by academic or military reasons, then became public and spread out.

After the internet revolution came the wireless revolution that brought the new stage of mobile learning, or m-learning. A personal communications revolution began at the turn of the century when the number of mobile phones surpassed the number of landlines of the traditional telephony. There were 500 million handsets in 1999/2000, and in 2008 there were more than 3 billion mobile lines in the world. Features were added every year, such as photography, music and video in all devices. In these handsets the computing power is already higher than the desktop from a few years ago, with increased memory and sophisticated web browser. Currently there are three times more mobile phones than PCs with Internet access, and we are in an era of global mobility, where 50% of workers spend up to half their time outside the office. The cell phones are personal items, and define a personal style. But the experiences with the use of mobile devices for education are just beginning, and most of them focuses on implementing, literally, the versions of the web to the phone while using the browser, or merely implementing very simple learning objects or small games [3] [4]. An overview about m-learning can be found in [5].

III. Concepts of M-Learning

As a first view, the m-learning can be considered as an offshoot of e-learning, allowing a wide range of opportunities in education. Just like e-learning that has become an entirely new way to teach and transfer knowledge, m-learning is now showing a horizon of new challenges and possibilities. Some of these challenges and possibilities can be described as:

- learn anywhere, everywhere, and in motion - just simply carry a personal mobile device wherever you go;
- learn by interacting with different people, whether in the social community or through social networks, forums, etc;
- archive and sort a wide range of information, using memory resources of the device (the information will be always at hand);
- create, using the equipment features, image, video or text files, and then attach to the systems of communication and learning; this way all participants of the learning network can be knowledge collaborators;
- continuous extended library - information such as grade, messages, calendars, among others, can be always updated and seen.

Devices for this kind of learning are in continuous evolution and going for a technological convergence. Today one can see equipments for training and education varying from common mobile phone to new advances like smartphones, palmtops, pocketPC and several kinds of personal digital assistants.

IV. Challenges of Mobile Education

The main overall challenge is to develop new paradigms to support education on mobile platforms. Paradigms which are different from the ones that emerged from the previous internet era. New wireless paradigms such as:

- collaborative learning – people are now connected all the time and can collaborate in real time, asking, answering, discussing and participating in a very democratic way;
- corporate education – as the workers are more and more on the go and out of office, the corporate education must pass through mobiles;
- collective generation of knowledge – as the device has powerful tools (camera, recorder, text, etc) and is always connected, it should be used to generate knowledge from the field;
- the growing experience of young people with social networks can be turned on an advantage for the mobile-learning.

Another complex challenge is the mobile content authoring. How to develop a new authoring platform for content development, how to solve the markup text for different devices and formats, and how to use the small interface to show text and images are fundamental questions [6].

Existing content in e-learning must be adapted for the new devices, and this should be done by automatic processes. This can generate new business models, like new platforms for m-LMS (learning management systems), and new businesses to interact with existing ones.

The challenge of the mobile features: every year (or month!) new features are built on the mobile devices and this is very exciting. How to fully exploit these new features, such as geo-location, motion sensors, photo and video, to make the educational experience as interactive as possible – that's the defiance to deal with.

V. Barriers to M-learning

Despite the evidence of the wireless revolution and all the possibilities it brings for several areas, there are yet important barriers for de m-learning adoption. Some of these barriers can be described as follows:

- the cost of packet transmission (WAP, GPRS, 3G and other) is yet impeditive in several countries, mainly in poor regions and even in developed countries, maybe due to the business models of telecom operators which are yet focused on voice billing and short message services;
- the size of devices is a problem because the screen is considered small, the keyboard is not practical to text, and there is no uniformity of devices in the industry; some of these problems were surpassed by the touch screen interfaces, but dimension is an usability question to solve [6];
- multiple platforms, multiple operators – each manufacturer constantly launches always new devices with different dimensions and features, and telecom operators have not a standard of data quality transmission or business models, what puts difficulties for developers in general;
- there are only just few experiences in mobile-learning, which are yet incipient and often discontinued [1];
- reactivity and the conservatism of educators – most of them see these kind of technologies as a new problem to deal with, and sometimes prefer old ways which they are used with;
- new technology adoption is a barrier because depends on early adopters;
- the need to produce new content and learning objects could be a strong barrier because teachers and researchers do not have this know how [7];
- despite the huge mobile phone installed base, development of applications for mobiles is still something very embryonic [8];
- owing to the students misuse of mobile phone at schools (for instance counterproductive conversation at classes, ringtones and so on), there is yet a negative image of mobile within the educational environment.

VI. M-Learning Platform Typical Tools

When we think of mobile-learning tools we can classify them into two major groups: 1) access to academic information (schedules, marks, information about educators on the educational institution, etc.) and 2) access to educational content. The second group should consider the use of assessment tools of learning, like the creation of multiple choice questionnaires, and how to associate this kind of testing with confidentiality and safety measures, as well as the correct user ID system at the completion of the assessment.

Considering these two groups we can enumerate the following functions that are typical of mobile platforms:

- alerts and alarms: set indicated to alert on events on determined schedules or agendas;
- direct communication tools: peer to peer possibility of communication between educators and students;
- multiple choice systems: development of evaluation questionnaires;
- educational games: how to make content more attractive to the audience, development of learning objects considering the game designing style;
- records, schedules, evaluation scores: basic tools for access to scholarly information;
- searching tools: words, glossary, dictionary, tools supporting the dissemination of content;
- links to mobisites: how to make content more dynamic and how to find more references;
- instructional videos and audios: use of multimedia resources to enrich the contents and overcome the monotony of long texts;
- tools to capture information: capture in the field and then send to referral groups, encouraging the use of mobile platforms in times of extreme mobility;
- forums and social networks: the approach is fundamental because participation in forums and social networks in the m-learning universe is a way to boost the mobile employment for education. This trend is in line with recent research showing that mobile phone users have the largest networks of contacts [9].

VII. Major Issues for the M-Learning Future

The future of m-learning, its success and time to adoption depends on a series of questions, like portability, capability of interaction with existing educational methodologies and technologies, the device dimension and related features, data transmission quality, social interactivity and user centered applications. Let's exploit these points further.

The portability of applications: mobile-learning systems must search for applications that can be used in a wide variety of devices, in order to democratize access to mobile-learning and be as less as possible dependent on new hardware launchings.

Hybrid educational opportunities: use of mobile-learning systems operates as a complement to formal face-to-face and e-learning education and could be used as an additional teaching method outside of the classroom, as an online bridge between students and educators, allowing quick exchange of information between these actors.

Small size of devices (screen and keyboard): the easiness that younger generations adapt to mobile devices can predict that actual difficulties will be overcome in the same proportion as the devices become more sophisticated and prices go down. Just observing the ease with which young people create text messages on their cell phones and we can glimpse that the small keyboard will not be an obstacle in a short time.

Quality of transmission networks: the enhancement of the quality of transmission network in many countries, the quality of its coverage and even the possibility of ever-increasing use of free Wi-Fi will bring more and more ease of access to information.

Interactivity: one of the biggest attractions of mobile networks is the possibility of being connected to the network all the time and interacting with other people through it. The design of platforms that make use of principles of social networks to disseminate knowledge and not just entertainment is the path to education in the near future.

User centered applications: tools for mobile-learning should be created in the user viewpoint, i.e. the student. The conservatism of educators must be overcome with other strategies, through training and development of tools for "back office" that encourage the use of mobile-learning. The fact is that the applications to be installed on mobile phones should be visually attractive, user-friendly and stimulating for students, and certainly soon a specialty area of design will be established, geared specifically to create visually exciting interfaces for mobile phone screens.

VIII. Case Study: UFP M-Learning Project - Universidade Fernando Pessoa

The project developed in partnership with the Universidade Fernando Pessoa aims to provide students, faculty and staff an innovative way of access to information, as well as a versatile tool for exchanging messages and a real time mode to the promotion of discussions on relevant topics and disciplines.

The mobile-learning application is designed to live alongside with other ways of access to information already available at the Universidade Fernando Pessoa. Among the technology platforms of education available in the institution we can cite the environment of e-learning developed with the *sakai* [2] collaborative learning tool, and the access to virtual office via the Web.

The e-learning environment provides access to documents relating to each discipline. In principle, each student has access to courses that are enrolled in a given period. Within each virtual class is offered the content, the teacher information, the possibility of a conversation environment among students and teacher, which can send messages to students about facts that occur during the school year. Also available is a forum environment, where students can discuss topics of interest related to the discipline on focus.

In the virtual secretary office environment, which is also accessed via Web browser, it is possible for the student to access academic information such as calendar, evaluation scores, financial situation as well as information about the services available in the university.

The mobile-learning application developed by Fazion to University Fernando Pessoa took account of these environments and attempts to build a single application to gather information more meaningful to the daily lives of students, faculty and staff. They can have in their hands palm, even when moving, the information deemed essential to their routine. For this step of the mobile-learning application development Fazion conducted a survey of the most relevant needs and how they should arise in the interface of mobile phones.

The goal of this mobile-learning tool is to allow access and storage of essential information to the user. In the case of the student, the real sense that is possible through the application be directly related to the school year in which he/she is. When updating the information on the agenda, the app shows the information of the subjects the students are to attend at the current school year. Such information, after updated on the device, will remain stored there. When the student does an update on another school year, the previous period subjects will be replaced by new subjects, leaving only the history of the marks obtained before. A major advantage of this application is just the fact of allowing the student to have in one place all information related to his/her grades. The information is available personally in the particular device, without having to login every time one wants to see it.

Another important feature is the ability to send alerts from teacher to students. By accessing the Web Portal tool related to the m-learning app, the teacher sees the list of their students sorted by discipline. This feature is useful for sending last minute alerts, when students are already on the move, for example if a change of venue or time made just before the start of a lesson. In this case sending an e-mail can not work and SMS can be tricky, considering the list of students. With this tool the teacher can ensure the communication with the students in situations of extreme mobility and with just one click.

Also included is the possibility for the student to consult information from the faculty during the school year, and then have in the palm of the hand the information needed to contact them at any time (their agenda at university, phone and e-mail). Information about the core services of the University, like library and department hours as well as phone and email contacts are also included.

To create a social networking environment among student's users of the tool, m-learning app has inserted a forum, which allows the creation of discussions about the subjects taken at the school year, with the teacher's intermediation. The goal of this tool is to encourage the exchange of information among students, especially when they are out of the classroom, providing the questions anywhere and even encouraging reflection on specific topics. This is very interesting to occupy lost times, such as when one is commuting public transport. This forum is also an environment for content exchanging between students (text, music, videos and other docs).

Finally there is a user profile area. The first login to the m-learning app shows the form to fill together with the login and password to access the system. After this initial insertion there is no need to re-fill the login, which ensures quick access to information. This is a slight and important difference to the traditional virtual environment office, where you must reenter your login and password every time access is done.

IX. TECHNICAL ASPECTS OF THE UFP M-LEARNING APP

Java programming language was used to develop the tool with its ME (Micro Edition) architecture, which consists of a collection of specifications and technology created by Sun Microsystems and the JCP (Java Community Process) to develop applications that will run in environments with limited resources, like small devices with low-capacity memory, small display and limited power capacity. The main factor that influenced the choice of language was driven by portability across platforms, enabling the tool to be used for a wider range of users, no matter the mobile device manufacturer or service operator.

As shown in Fig. 1 the architecture of the application is divided into three concepts.

- Service Platform – Platform responsible for communicating and processing of content that could to be provided in a format that a low power processing device could receive and manipulate information easily. The concept of "Web Service" was used for implementation of the platform service provider. The concept of service adds to the m-learning platform flexibility for contents to interact with systems developed on different platforms, exchanging information in XML (eXtensible Markup Language). This characteristic makes it an interoperable platform.

- Web Platform: Tool responsible for managing the content and audit system access. The web tool communicates with the institution software legacy to provide writing and reading content availability on the institution portal. This flexibility provides real-time evaluation scores, class schedule as well as other content and interactions with students.

- Mobile Platform: it is able to communicate with the service platform and do the exchange of information and do the presentation of content and learning objects. As already mentioned, the mobile architecture is based on Java ME, making it independent of operational systems (OS). Through the mobile platform, the user can monitor contents, score and schedule and has the opportunity to ask questions to the teachers and receive public or private notices. The major difference of this approach is that students have access to information, consulting or even interacting using mobile handset, regardless of physical location. Another important factor is that with this approach, the channel or medium of communication between the mobile platform and service platform becomes flexible. User can use any available technology, being able to access the service platform via GPRS, EDGE, Wi-Fi, 3G or other technologies available.

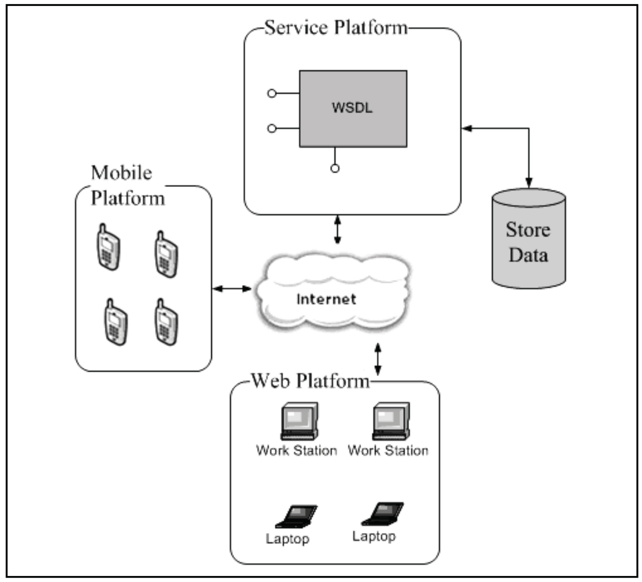

Figure 1. M-learning application architecture.

A. Tools and diagram

The main diagram of the mobile application framework is shown in Fig. 2. It is only illustrative and presents a diagram of the interfaces and flow of screens used in the mobile tool implementation. With this kind of diagram is possible to preview interactions between the User and the device, allowing efforts to design more user-friendly applications.

B. Mobile tool app

The "Beta" mobile version of the UFP m-learning platform allows the students to access information like evaluation scores and agenda of the disciplines to which they belong, as well as relevant information from their teachers and services provided by the university.

Using the mobile handset it is also possible to participate in forums linked to the disciplines, and receive warnings from teachers and sectors of the institution. Fig. 3.a illustrates the main screen of the mobile tool.

Fig. 3.b illustrates the layout used to provide evaluation scores. For future reference the student can obtain the current grade of a particular discipline and store it in the phone.

Through the module "message" the student can receive in the cell phone not only reports but images and texts in various formats (as exemplified in Fig. 3.c).

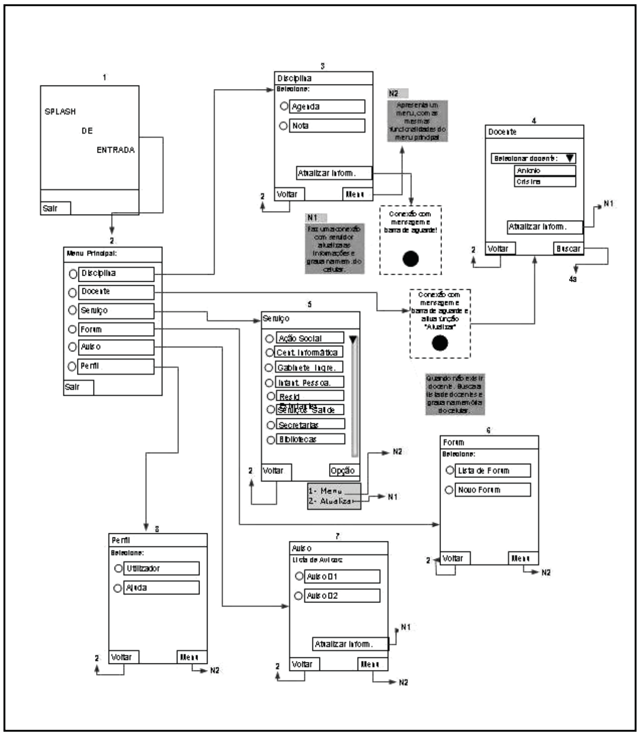

Figure 2. Interface flowchart.

Figure 3. Mobile learning interfaces.

A major differential of the mobile tool is the flexibility given to the user, which permits him to have access to content anywhere and be able to interact with teachers, within the university campus or in any other location. Fig. 3.d illustrates the forum entrance functionality.

C. Web tool app

The mobile learning system application has a web portal that operates as an original authoring tool, responsible for monitoring the content of education as well as handling and sending grades and reminders to students. Through this portal the teacher can interact by sending content or answering questions through the forum features, and sending alerts. Fig.4 illustrates some of the interfaces of the web portal.

At the "forum" module the teacher may add questions or even answer questions from students remotely via the mobile platform. In this module the teacher can create new discussions withim disciplines, encouraging and urging the students to search for knowledge.

At "alert" module the teacher can monitor and send public messages to all students enrolled in his/her courses, or can also send private messages directed to a single student. Through this module teachers can provide content of their disciplines and also notify students of the existence of new content.

The web tool also enables to audit the use of the system, recording date and time of use of both the web tool and the mobile tool. Fig. 4.d illustrates an example of the logs of requests occurring in a given period. Note that through this module it is possible to identify the resources more accessed by a particular class of users, building a customized social network to analyze. The possibilities of monitoring and auditing the connections, and the interaction between the mobile application and the web service are fundamental functions of the system.

X. CONCLUSIONS

Seek for new ways and tools in education is a challenge increasingly compelling. University Fernando Pessoa, from the city of Porto in Portugal, has chosen to look for new technologies to make the art of teaching more interesting and motivating. Since its beginning the organization has chosen to develop tools and methodologies of teaching aligned with the state-of-art of technology. This was the thinking that led to the partnership for the development of the m-learning tool, which represents a differential respect to other higher education institutions globally. Thinking about the student and giving him different forms of interaction with the University is the way to make learning more interesting.

In this sense, the whole process of developing this m-learning tool used as fully as possible the information already available in the university database for conventional forms of web access, and created new options for communication between students and teachers through messages and forums.

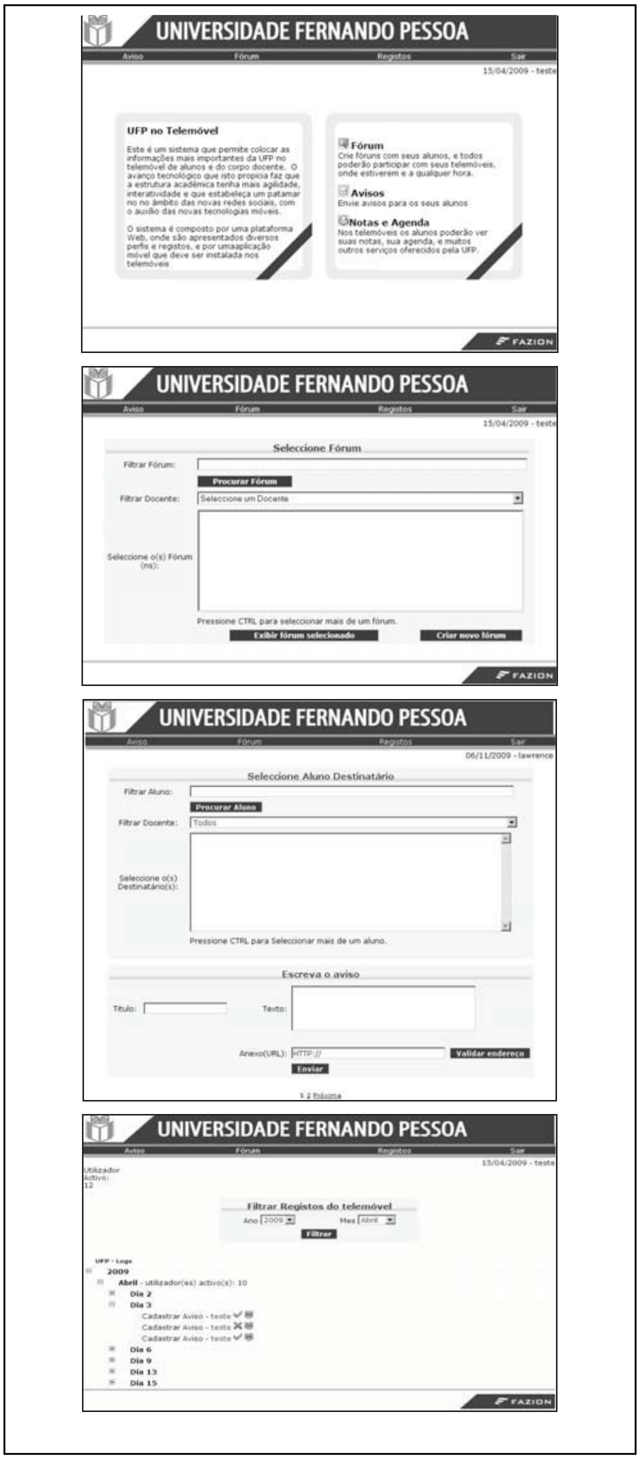

Figure 4. Web portal learning interfaces.

The continuous use of the m-learning tool in the university and the feedback from users will allow new questions and new enhancements, important for the maturation process of mobile-learning as a whole. For instance, engineering courses that require laboratories and other face-to-face classes may be, in parallel, facilitated by new learning objects and relationships that may be available on mobile phones. This new way of educating opens potential applications, especially in the area of interpersonal relationships in online interaction, and provides the experience of knowledge even when outside the traditional educational environment.

***Abstract*—Teaching mathematical intensive engineering based courses to undergraduate Information Technology students poses a great challenge to instructors. In this paper we provide an efficient and effective method for teaching digital and analog modulation to undergraduate students enrolled in an Information Technology program which does not require a strong foundation in mathematics as in the case of an Engineering program. The used approach utilizes Matlab packages, Simulink, and Communication Blockset to simulate analog and digital modulation techniques avoiding the derivation of any mathematics formulations and without coding. A survey that was distributed to Information Technology students who were taught using this approach showed a high level of satisfaction in understanding all modulation concepts.**

Keywords: Matlab; Modulation; Simulink, Communications Blokset

I. INTRODUCTION

Matlab is a numerical computing environment and a 4th generation programming language. It is a high level language and interactive environment that enables users to perform intensive calculations based tasks very fast. Developed by Mathworks [5], Matlab allows matrix manipulation, plotting of functions and data, implementation of algorithms, creation of user interfaces, and interfacing with programs in other languages. Matlab has been widely adopted for over 25 years in the academic community, industry and research centers. It was originally written to provide easy access to LINPACK and EISPACK software packages [1-4]. The Matlab software provides the users with a large collection of toolboxes and modules for a variety of applications in many fields of interest.

Simulink [6] is an interactive graphical tool that was added to Matlab to make the modeling and simulation of various systems as easy as connecting predefined and designed building blocks. Simulink contains many block sets that are used in almost all applications such as the communication block set and the signal processing block set.

Research using Matlab/Simulink has been conducted for many years in academia, industry and also military. Many researchers have published papers using Matlab/Simuling for simulating particular systems. For examples, the authors in [7, 8, 10, 11] used Matlab/Simulink to model components and performance of various wireless communication systems. Others have utilized Matlab/Simulink as a research tool for army and military based applications [13, 14].

Matlab has been used as a teaching aid in many subjects such as mathematics, physics, heat conduction, control systems, mechatronics, mechanical design, circuit design, communication theory, random processes, electronics and many more disciplines and applications [4, 5, 9, 12, 15, 16].

In this paper, we provide an efficient and effective method for teaching digital and analog modulation techniques to undergraduate students enrolled in an Information Technology program which does not require a strong foundation in mathematics as in the case of an Engineering program. The used approach utilizes Matlab and Similink blocksets to simulate analog and digital modulation techniques. To assess the degree to which Matlab/Simulink helped students to understand the taught concepts, a survey was distributed to students and the results were analyzed using Statistical Package for the Social Sciences (SPSS [25]) and presented in this paper.

The rest of the paper is organized as follow: In section 2, analog and digital modulation techniques are introduced. Section 3, discusses the use of Simulink and the communication toolboxes available in Matlab to study modulation techniques. Section 4 shows the results of the students' survey, and section 5 concludes the paper.

II. ANALOG AND DIGITAL MODULATION

In general, modulation is used to give the transmitted signal properties which are best suited to the transmission channel or environment. Specifically, modulation is the process of imparting the source information onto a band pass signal with a carrier frequency, f_c, by the introduction of amplitude or phase perturbations or both. This band pass signal is called the modulated signal and the base band source signal is called the modulating signal [4]. At the receiver end a mean to translate the higher frequencies back to the audio range is implemented and this is called demodulation.

A. Amplitude modulation (AM)

Audio signals at most occupy the frequency range 0-20 KHz (minimum 15 Km wavelength). This range of frequencies is too low to transmit directly as electromagnetic radiation, particularly due to the prohibitive sizes of the transmitter and receiver antennas which would be required. Antennas must have lengths of the order of the wavelength of the EM radiation of interest. Higher frequencies permit much more effective and practical transmission; however, these lie outside the audio range. For example, AM radio broadcasting occurs at frequencies of the order of 1 MHz.

In standard AM, the audio signal is shifted in amplitude by adding a DC component and then multiplied by a sinusoid at the carrier frequency, f_c. The carrier frequency is much higher than the audio frequency band. We consider a mathematical description of amplitude modulation. Following the nomenclature of Couch's textbook [4], let the audio message signal be m(t), where m(t) is band limited to "W" Hz, and let A_c be the message amplitude (or gain).

Let $\omega_c = 2\pi f_c$ be the carrier frequency in radians per second where $f_c >> W$. Then the amplitude modulated signal *s(t)* can be expressed as

$$s(t) = A_c[1 + \mu m(t)]\cos(\omega_c t)$$

$$s(t) = A_c \cos(\omega_c t) + A_c \mu m(t)\cos(\omega_c t)$$

The constant, μ, is selected such that

$$-1 < \mu m(t) < 1$$

The students shall understand very well the above formulas and they have to write codes using Matlab to draw the following curves depicted in Figure 1.

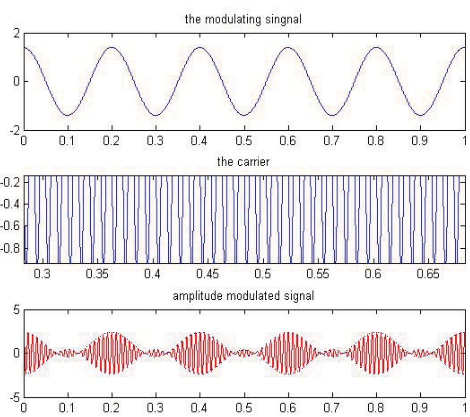

Figure 1: AM modulation using Matlab code

Figure 1 depicts the audio signal, the carrier, and the amplitude modulated signal. This result is a coding the above formulas of AM using Matlab codes which is not easy for the non engineering students.

B. Frequency modulation (FM)

Frequency modulation encodes the message, *m(t),* by making the instantaneous frequency deviation about f_c proportional to *m(t)*. Frequency Modulation is a special case of *Angle Modulated* signaling. In angle modulated signaling the complex envelope is:

$$g(t) = A_c e^{j\theta(t)}$$

Note that this is in *polar form* so we can immediately say what the *amplitude modulation is R*(*t*) and the *phase modulation is simply θ(t).* The amplitude modulation is:

$$R(t) = |g(t)| = A_c$$

The phase modulation is simply *θ(t)* and for angle modulated signals is a linear function of the modulating signal *m(t).* For FM the phase is proportional to the integral of *m(t)*:

$$\theta(t) = D_f \int_{-\infty}^{t} m(\sigma)d\sigma$$

Where the frequency deviation constant D_f has units of radians per volt-second. So the frequency modulated FM signal is:

$$s(t) = A_c \cos\left[2\pi f_c t + D_f \int_{-\infty}^{t} m(\sigma)d\sigma\right]$$

The bandpass signal is represented by:

$$s(t) = A_c \cos\left[2\pi f_c t + D_f \int_{-\infty}^{t} m(\sigma)d\sigma\right]$$

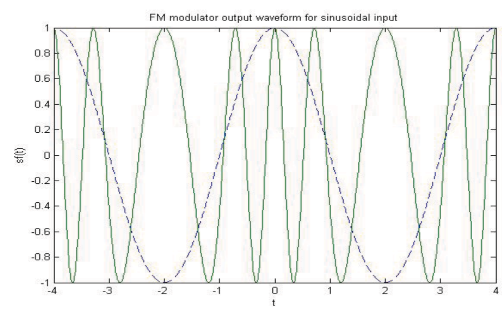

Figure 2: FM modulation

Figure 2 illustrates the Programmed FM modulation using Matlab codes.

III. Analog and Digital Modulation Using SIMULINK and Communication Toolboxes

A. Simulink

Simulink, developed by The MathWorks, is a tool for modeling, simulating and analyzing multi-domain dynamic systems. Its primary interface is a graphical block diagramming tool and a customizable set of block libraries. It offers tight integration with the rest of the MATLAB environment and provides scripting capability. Simulink is widely used in control theory and digital signal processing for multi-domain simulation and design.

Simulink is integrated with MATLAB, providing immediate access to an extensive range of tools for algorithm development, data visualization, data analysis and access, and numerical computation. The Key Features of Simulink include: [6]

- Extensive and expandable libraries of predefined blocks.

- Interactive graphical editor for assembling and managing intuitive block diagrams.
- Ability to manage complex designs by segmenting models into hierarchies of design components.
- Model Explorer to navigate, create, configure, and search all signals, parameters, and properties of models.
- Ability to interface with other simulation programs and incorporate hand-written code, including MATLAB algorithms.
- Option to run fixed- or variable-step simulations of time-varying systems interactively or through batch simulation.
- Functions for interactively defining inputs and viewing outputs to evaluate model behavior.
- Graphical debugger to examine simulation results and diagnose unexpected behavior in designs.
- Full access to MATLAB for analyzing and visualizing data , developing graphical user interfaces, and creating model data and parameters.
- Model analysis and diagnostics tools to ensure model consistency and identify modeling errors.

With Simulink, the user can quickly create, model, and maintain a detailed block diagram of a system using a comprehensive set of predefined blocks. Simulink provides tools for hierarchical modeling, data management, and subsystem customization, making it easy to create concise, accurate representations, regardless the system's complexity. Details on how to create and run simulation models are out of the scope of this paper, for more information on this the reader can look at the following references [6, 17, 18].

B. *Communication Toolbox*

Communications Toolbox extends the MATLAB technical computing environment with functions, plots, and a graphical user interface for exploring, designing, analyzing, and simulating algorithms for the physical layer of communication systems. The toolbox helps create algorithms for commercial and defense wireless or wireline systems, such as mobile handsets and base stations, wired and wireless local area networks, and digital subscriber lines. It can also be used in research and education for communication systems engineering.

The Key Features of Communication toolbox includes [5]:

- Functions for designing the physical layer of communications links, including source coding, channel coding, interleaving, modulation, channel models, and equalization.
- Graphical plots for visualizing communications signals, such as eye diagrams and constellations.
- Graphical user interface for comparing the bit error rate of a system with a wide variety of proven analytical results.
- Galois field data type for building communications algorithms.
- New channel visualization tool to visualize and explore time-varying communications channels.

C. *Simulation of analog modulation*

The students don't have to derive any more the modulation formulas. He/She has just to understand the components of the equation (e.g. AM equations) and start to implement using the Simulink. Figure 3 illustrates the blocks needed to design an AM modulator. The students have to open simulink and drag and drop in the area of work all these blocks. To visualize the modulated and modulating signals, we need to add to the simulator two scopes. Scope 1 shows the original signal before the modulation. Scope 2 shows the modulated signal, it means after the modulation process. The students can also see the modulated signal in frequency domain. They need to drag and drop the Box "BFFT". This Box does the Fast Fourier Transform operation and illustrates the signal in Frequency domain. The students are exempted to know the derivation of FFT formula.

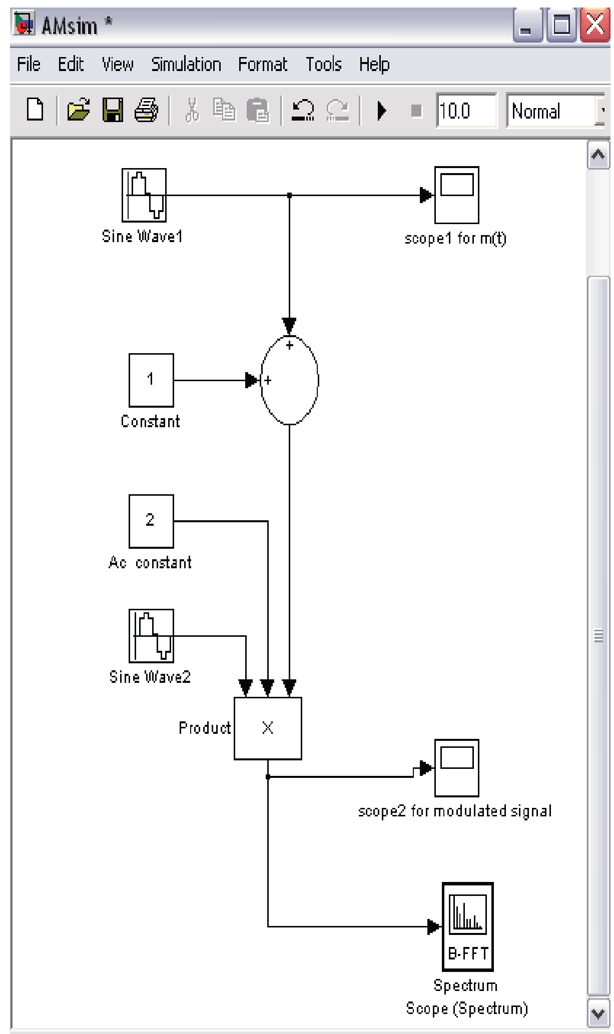

Figure 3: The model of AM modulator using Simulink

Figure 4 shows the audio signal before modulation; it is depicted by the Scope 1.

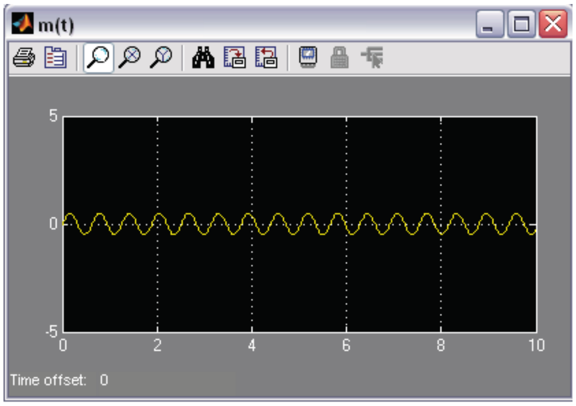

Figure 4: The modulating signal *m(t)*

Figure 5 illustrates the amplitude modulated signal. This signal should be transmitted over the medium.

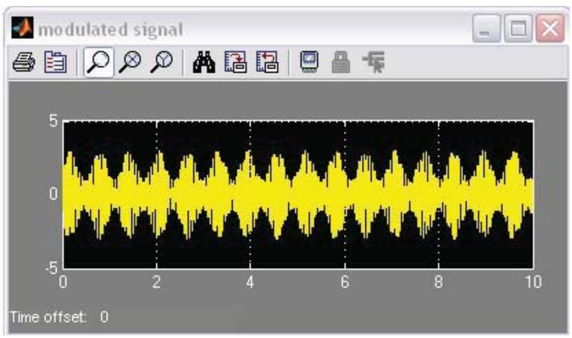

Figure 5: The amplitude modulated signal *s(t)*

The frequency domain spectrum is obtained through a buffered-FFT scope, which comprises of a Fast Fourier Transform of 128 samples which also has a buffering of 64 of them in one frame. Figure 6 depicts the modulated signal in frequency domain.

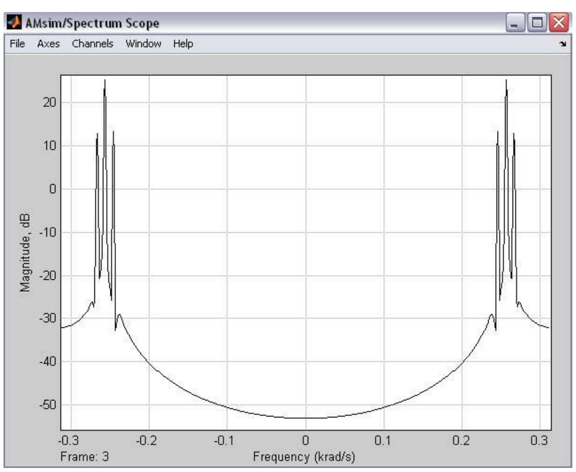

Figure 6: The spectrum of the AM signal *s(t)*

Table 1 below lists and describes the blocks in the Analog Passband sub-library of Modulation by double-clicking on the Analog Passband icon in the main Modulation library, or by typing commanapbnd2 at the MATLAB prompt. For more details, the readers can consult the Mathwork website.

TABLE I. TABLE 1: BLOCKS FOR ANALOG MODULATION

Block Name	Purpose
DSB AM Demodulator Passband	Demodulate DSB-AM-modulated data
DSB AM Modulator Passband	Modulate using double-sideband amplitude modulation
DSBSC AM Demodulator Passband	Demodulate DSBSC-AM-modulated data
DSBSC AM Modulator Passband	Modulate using double-sideband suppressed-carrier amplitude modulation
FM Demodulator Passband	Demodulate FM-modulated data
FM Modulator Passband	Modulate using frequency modulation
PM Demodulator Passband	Demodulate PM-modulated data
PM Modulator Passband	Modulate using phase modulation
SSB AM Demodulator Passband	Demodulate SSB-AM-modulated data
SSB AM Modulator Passband	Modulate using single-sideband amplitude modulation

D. *Simulation of Digital modulation*

Table 2 lists and describes the blocks for digital modulations. Figure 7 illustrates the model for MPSK modulations using Simulink and the Communications block set. The students can vary the parameter “M” and also the Signal to Noise Ratio (SNR) and can easily draw the BER (Bit Error Rate). Figure 8 depicts the results of BER versus the SNR. The student can simulate all type of digital modulations by choosing the adequate Blocks and they can also choose different type of channels. The blocks are respectively Data generator, Modulator, Channel model, demodulator, and the BER calculator. The students are not supposed to know the formula of Probabilities of errors. The model generates a million of bits and can calculate easily the errors.

TABLE II. BLOCKS FOR DIGITAL MODULATION

Block Name	Purpose
M-DPSK Demodulator Passband	Demodulate DPSK-modulated data
M-DPSK Modulator Passband	Modulate using the M-ary differential phase shift keying method
M-PSK Demodulator Passband	Demodulate PSK-modulated data
M-PSK Modulator Passband	Modulate using the M-ary phase shift keying method
OQPSK Demodulator Passband	Demodulate OQPSK-modulated data
OQPSK Modulator Passband	Modulate using the offset quadrature phase shift keying method
M-FSK Demodulator Passband	Modulate using the M-ary frequency shift keying method

M-FSK Modulator Passband	Modulate using the M-ary frequency shift keying method

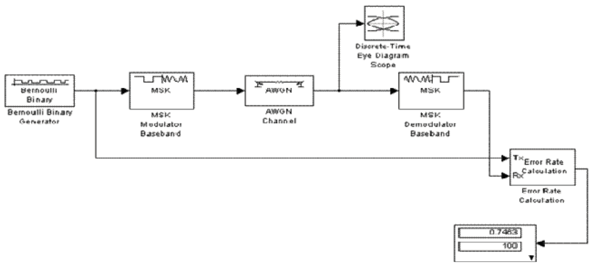

Figure 7: The Block diagram of MPSK Modulations

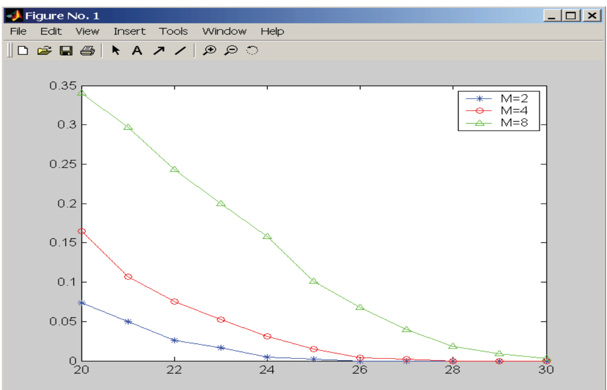

Figure 8: The BER versus SNR for MPSK

Figure 8 shows, for MPSK, as the value of M increase the BER increase. So, MPSK is better in term of BER when the value of M is small.

IV. RESULTS AND DISCUSSION

A 13-item survey was administered to 57 Information Technology undergraduate students. The survey tapped students' reactions to using Matlab with Simulink for learning and understanding digital and analog modulation concepts. The convenience sample of participants responded to the survey, which was based on the following, 5-point Likert scale: 5 = Strongly Agree; 4 = Agree; 3 = Somewhat Agree; 2 = Disagree; 1 = Strongly Disagree. As can be seen from Table 3, students expressed a general consensus towards their agreement of the benefits of incorporating Matlab with Simulink in their course. Most of them, for instance, claimed that the Matlab with Simulink component was very useful for helping them understand the theoretical aspect of the course, thereby increasing their knowledge base of the subject matter.

TABLE III. Descriptive *STATISTICS (N=57)*

Variable	Min.	Max.	Mean	SD
Knowledge before 1	1	5	3.02	1.009
Knowledge after 2	2	5	4.14	.766

Independent Samples T-Tests were run to investigate differences between the 2006 and 2007 cohorts in terms of how they perceive the usefulness of Matlab with Sumilink. As can be seen in Table 4, higher means were observed for the 2007 students. This group of students held more favorable views about the utility of Matlab with Sumilink in their course. For example, compared to their 2006 counterparts, the 2007 cohort felt more strongly that Matlab with Simulink was easy to use (mean = 4.41), helped them understand the course much better (mean = 4.45), and that their knowledge has now increased as a result of using Matlab with Sumilink (mean = 4.55).

A. Internal consistency reliability

A Pearson correlation matrix of the 13 Matlab with Simulink questionnaire items was run yielding a Cronbach's alpha coefficient of .91 (α = .91). The 13-item questionnaire was then subjected to factor analysis using principal axis factoring to extract the underlying factors.

B. Factor Analysis

Data from the 13-item, Matlab with Simulink questionnaire was analyzed using principal axis factoring (SPSS 14.0) to extract the underlying factors. Principal axis factoring is preferred over the principal components analysis method, which is the default option in some statistical programs including SPSS. Since it is assumed that in principal components analysis all variability in an item ought to be used, it is advantageous to use the principal axis factoring method through which the researcher can only use the variability in an item that it shares with the other items [20]. The number of factors to be extracted was based on minimum eigenvalues of 1.0 and minimum loadings of .45 of individual items under each factor. The Kaiser-Gutman procedure, through which only factors with eigenvalues of one or greater are selected, is the most often used method to determine the number of factors [21]. The varimax rotation method produced a two-factor solution, accounting for almost 62% of the total variance (see Table 7). Varimax rotation was employed because it is a type of orthogonal rotation that mathematically ensures that the resulting factors are uncorrelated with each other [21]. This is important since in exploratory factor analysis, the researcher does not know the number and the types of factors that exist, let alone whether or not they are correlated [19].

1) Factor 1: Factor 1 consisted of eleven items from the Matlab with Simulink questionnaire. The following eleven items loaded on factor 1(Table 5):

TABLE V. Eleven items from the Matlab & Simulink Questionnaire

	Loading
My overall attitude towards Matlab with Simulink	0.65
Matlab with Simulink is a useful tool for understanding course content.	0.62
If Matlab with Simulink is available in the future, I will use it to learn more about it.	0.77
Matlab with Simulink is easy to use.	0.66
Most people who are aware of what I'm studying would approve my using of Matlab with Simulink in the future to learn.	0.72
I have experience using computer-based simulation tools	0.64
I like Matlab with Simulink being part of my learning experience.	0.8
I am inclined to use Matlab with Simulink because it increases my ability to interact with the course content.	0.76
I am inclined to use Matlab with Simulink because of its educational benefits.	0.71
I feel comfortable when using Matlab with Simulink to learn course content because it enables me to learn	0.66
I feel satisfied with my learning experience using Matlab with Simulink.	0.76

2) Factor 2: Factor 2 consisted of two items from the Matlab with Simulink questionnaire. The following two items loaded on factor 2 (Table 6):

TABLE VI. Two items from the Matlab & Simulink Questionnaire

	Loading
Before using Matlab with Simulink, my knowledge of course content was:	0.51
Now, my knowledge of course content is:	0.79

In sum, results of the factor analysis portion of this study suggested two components that characterize the School of IT students' perceptions and attitudes towards the benefits of incorporating Matlab with Simulink into the course curriculum. Factor 1 can be labeled "Motivation" since all of the items that loaded onto it are likely to contribute to learners' engagement and motivation in the classroom because of the Matlab with Simulink component. The two items that loaded on factor 2 are strictly related to students' knowledge level before and after their experience with the Matlab Simulink. Therefore, Factor 2 can be labeled as "Knowledge Competence" (See Table 8).

TABLE VII. Principal Axis Factoring (13 questionnaire items)

Factor	Eigenvalue	% of Variance	Cumulative %
1	6.749	51.915	51.915
2	1.305	10.038	61.953

TABLE VIII. Factor Structure

Factor	Label	Eigen -value	Variance	Cumulative Variance
1	Motivation	6.749	51.915	51.915
2	Knowledge Competence	1.305	10.038	61.953

V. CONCLUSION

In this paper, the approach utilizes Matlab packages, Simulink, and Communication Blockset to simulate analog and digital modulation techniques avoiding the derivation of any mathematics formulations. A survey that was distributed to 57 Information Technology students who were taught using this approach showed a high level of satisfaction in understanding all modulation concepts. As can be seen from the survey results, students expressed a general consensus towards their agreement of the benefits of incorporating Matlab with Simulink in their course. Most of them, for instance, claimed that the Matlab with Simulink component was very useful for helping them understand the theoretical aspect of the course, thereby increasing their knowledge based on the subject matters.

Abstract—***Research based approach in education is important for engineering specialties. The implementation of this approach is interesting for students also. The research possibilities involve all level of education process: pupil's interest is higher, average mark of students is increasing; the number of graduate students is increasing with introduction of research-based approach.***

Keywords- Research-based approach, electrical engineering , bachelor program

I. INTRODUCTION

The education in Power and Electrical Engineering is set as priority in many countries, because people have to find ways to substitute petroleum and natural energy recourses, which are decreasing in the world each day, to introduce more efficient and safe approaches to the use of present energy resources and significantly decrease unnecessary losses of energy. In different countries, there are large discussions about the rational use of power resources: gradual transition to bio-fuel, use of hydrogen power in transport systems, development of cars with hybrid transmission and electro mobiles.

The countries of the European Union also have declared the beginning of the power engineering revolution towards the same purposes like the same program in the USA does.

The existing contacts with other universities in Europe allow wide use of Erasmus students exchange programme, especially during the process of final papers preparation, such as bachelor and master thesis. According to statistical data from Ministry of Education and Science the number of students of Riga Technical University studying abroad in 2008 was 89 (table 1). The study programme "Computer control of electrical technologies" is popular at international level, at the present moment five of international undergraduate students are studying at our institute Also students from Latvia are going abroad, for example Vladimirs Skopis and Julija Soboleva the students of professional bachelor program within the frames of Erasmus programme, and now they study in Sweden in King Technology institute / Kungliga Tekniska Högskolan. By financial support for master studies in Germany from German academic exchange centre (DAAD – Deutscher Akademischer Austausch Dienst) this year awarded Armands Senfelds and Edgars Ivanovs .

It is great opportunity to have an experience in international groups, which allows having an international carrier in future. This is a great benefit from Bologna process introduction.

TABLE I. STATISTICAL DATA FROM MINISTRY OF EDUCATION AND SCIENCE THE NUMBER OF RIGA TECHNICAL UNIVERSITY STUDENTS STUDING ABROAD (2008)

Germany	20	Spain	6
Italy	13	Austria	4
Sweden	12	Czech Republic	4
Portugal	10	France	2
Denmark	10	UK	1
The Netherlands	6	Finland	1
Total 89			

The education in RTU covers all steps of academic and professional high education (figure 1) in full time and part time groups.

A leader in Latvia in the electrical engineers education and training is Riga Technical University (RTU), Faculty of Faculty of Power and Electrical Engineering, Institute of Power engineering, Institute of Industrial electronics and electrical engineering and Environmental engineering Institute.

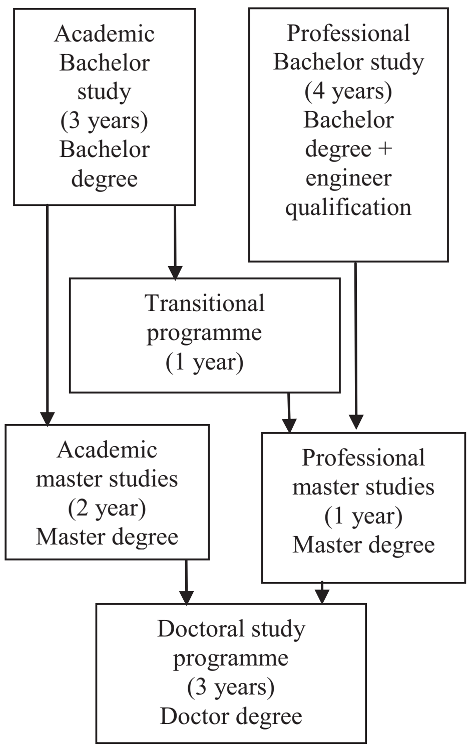

Figure 1. Study levels and education duration for study programme computer control of electrical technologies

Principles of integration of educational process and scientific researches are radical ways of improvement of quality of preparation of electrical engineers education and training in efficient energy production and consumption. The training and research integration principles are presented as efficient way for training of energy-and-sources-saving specialists. Faculty of Power and Electrical Engineering in RTU provides several study programs: Electrical and Power Engineering; Computer Control of Electrical Technologies; Environmental Engineering. Each year more then 250 students enter for the first year studies.

II. Description of education structure

The study programme computer control of electrical technologies is a research based educational programme. Every day research activities are an integral part of the routine work of the staff of the Institute of Industrial electronics and electrical engineering (IEEI). The group of seven senior researchers are realizing research process in the institute. For that branch of activities IEEI has been legally registered in the state as a scientific institution. This allows applying for European structural funds support programs for modernisation of institution research equipment and financing of young researcher's attraction. Based on the research the staff of the Institute proposed sixteen new patents in 2008. During the same period of time in the institute twenty one patents are submitted. The Institute has published four scientific monographies and forty seven scientific publications in proceedings of international conferences abroad. The students of the Institute defended twenty seven bachelor theses, fifteen engineer projects, twenty three master theses and three PhD theses.

The IEEI working strategy is to fulfil the program „Computer control of electrical technologies" in the fields of industrial electronics and electrical engineering with the specializations in power electronics, adjustable electric drive, automatization of electrical technologies and electric transport, to develop scientific investigations in the field of industrial electronics and electrical engineering, realizing the program, which meets the needs of industry and the graduates of which are competitive at the world labour market.

The education in power engineering on one hand covers education in Energy production and transmission as a study program of Electrical and Power Engineering, on the other hand energy consumption and control in study program Computer Control of Electrical Technologies (figure 2) and possibilities of the decreasing of the impact on the environment in study program Environmental Engineering.

Figure 2. Bachelor students are examining regulation theory application for electrical technologies, using computer simulation

The students of study program Computer Control of Electrical Technologies obtain practical skills and theoretical knowledge in control, designing and operation of the computerised electric technical devices. For successful students with good knowledge of foreign languages (English or German), IEEI provides a possibility of partial training abroad.

The level of technology development demands high qualification and effectiveness of education in the field of electrical engineering.

The number of students of different levels and directions of the studies (including the students of evening and extramural department) is presented in table 2.

TABLE II. THE NUMBER OF STUDENTS OF DIFFERENT LEVELS AND DIRECTIONS OF THE STUDIES

Levels of studies, programs and directions	Number of students total	Nr of graduates
Bachelor studies total	180	27
Bachelor studies (B)	56	13
Bachelor studies (C) profes.	124	14
Master studies (acad)	7	0
2 level professional post-bachelor studies (G)	57	23
Students total amount	244	50
Doctoral studies in „Computer Control of Electrical Technologies"	*22*	*3*

Academic studies last three years, during this time the students have basic courses and are to defend bachelor thesis at the end.

During the professional studies the students have in addition practical working experience at industrial enterprises. This industrial practice lasts 6,5 months.

The industrial practice of students (figure 3, 4) is the major part of process of preparation of highly skilled specialists. Practice will be organised in various branches of a national economy at the leading industrial enterprises, firms and establishments of the Latvian republic. According to the program Computer Control of Electrical Technologies, during the industrial practice the student's master practical skills in the work with electric motors and systems, and in automatic control of such systems. Main principles and ways of automatic control, and also possibility of automation of industrial technological process by means of computer management accustom, there is a development of modern techniques, the students receive practical skills in installation and operation of new modern devices and elements in manufacture.

Main areas for research results application are the companies, which produce electrical and electromechanical equipment as well as in designing, process optimisation and service processes, in electrical engineering and technologies supervision and control.

The skills received in the course of an industrial practice, and also materials of any particular production, the device or object of automation, can be used for writing bachelor, engineer or master degree works. The content of practice, and also the terms of it are defined according to the confirmed curricula and programs.

Figure 3. Bachelor students Maris Gureckis, Ugis Sirmelis are studying industrial power drives in Latvenergo division TEC-2.

Practice is provided both for the professional bachelor and master programs. In programs of the professional bachelor "ECO0" the volume of a practical training is 26KP that in a time equivalent makes work at the place of practice within 16 weeks or 26x16=416 hours. Since 2009./2010 academic year this practice, in the programs of day training of students is included in the 6th semester with the volume of 5KP (80 hours), in the 7th semester with 12KP (192 hours), and in the 8th semester with – 9KP (144 hours).

Figure 4. RTU supervisor prof. asoc. A. Ziravecka, Supervisor from industrial partner U. Anitens and student A. Shapovalovs at experimental results monitoring of relay systems Latvenergo division at Jelgava city.

If a student has completed the training under the academic program and starts further training under the master program then he/she is enlisted into the transitive program "EGOB" and in the first half of the year passes practice with volume 14KP, and in the second - with 12KP, completing thus the necessary qualification of the professional bachelor practice of 26KP.

Both in the program of the professional bachelor, and during the transitive master year, the student, mainly, pays attention to gathering of a material for the future engineering project the defending of which provides an obtaining of professional qualification.

The purpose of the practice:

- to apply practically knowledge and the skills received in the course of training under the program of a professional master "Computer Control of Electrical Technologies";

- to get an acquaintance for students with work of the enterprises, and teachers with requirements of the enterprises;

- to involve into the process of formation the organisations-partners, organising practice outside the educational institution;

- to provide cooperation with large, middle and branch small enterprises.

III. Project-based learning methodology

The use of project-based learning (PBL) [1] method is the important methodological issue to get sustainable development of economy in Latvia. The RTU is the main higher education structure in Latvia, according to the total amount of students, so the technical development of Latvia is strongly related to the level of education in Riga Technical University. The PBL introducing in RTU is extremely important, for developing innovations, and technical progress in Latvia.

PBL [1, 2, 3] in general provides complex tasks based on challenging questions or problems that involve the students' problem solving, decision making, investigative skills, and reflection that include teacher facilitation, but not direction. Project Based Learning is focused on questions that initiate students to encounter the central concepts and principles of a subject hands-on.

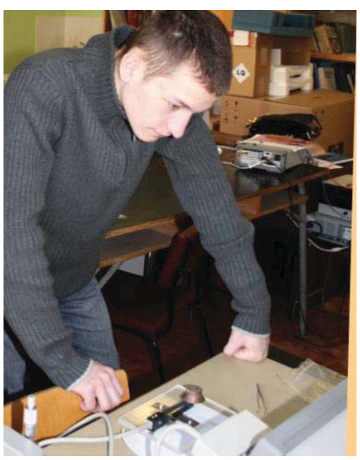

Figure 5. A. Morozovs is now a Bachelor student of study programm Computer Control of Electrical Technologies experiment on material dielectric density measurement in RTU

The main PBL advantages in general [2] are that it: overcomes the dichotomy between knowledge and thinking, helping students to both "know" and "do."; supports students in learning and practicing skills in problem solving, communication, and self-management; encourages the development of habits of mind associated with lifelong learning, civic responsibility, and personal or career success; integrates curriculum areas, thematic instruction, and community issues; assesses performance on content and skills using criteria similar to those in the real work world, thus encouraging accountability, goal setting, and improved performance; creates positive communication and collaborative relationships among diverse groups of students; meets the needs of learners with varying skill levels and learning styles; engages and motivates bored or indifferent students. The main problems of introducing the PBL in RTU are changing the way of thinking of academic staff and students, talking about technical problems to solve it.

IV. Project-based learning methodology application

The project based methodology application within the frames of study programme Computer Control of Electrical Technologies starts before studies in RTU. IEEI has cooperation agreements and experience to involve in research process also pupils from secondary schools. Pupils during annual project week make research, using RTU facilities, equipment and staff consultation. During the project realisation Riga Ukrainian 12th school pupil Aleksandrs Morozs made a research in dialectical features of materials and used RTU staff experience and facilities. Now he is the 1st year student of the considered programme (figure 5).

TABLE III. The number of applications for the 1st year full time program in 2009

Study program	City	State financial places	Priority	Number of applications
REBO0	Rīga	20	1	25
			2	48
			3	8
RECO0	Rīga	35	1	38
			2	15
			3	11
VEBO0	Ventspils	3	1	2
			2	5
			3	1
LECO0	Liepāja	6	1	7
			2	4

There is also quite a large difference in pupil's interests in academic and professional studies. The tendency of last 3 years is that application amount of professional study programme is higher than in academic programme Tables 3 and 4). In code of programme REBO0 means: is Riga Electric Bachelor (Academic) O Computer control study programme 0 number of group; in other code RECO0: C means Bachelor (Professional). L and V means education place in Latvian cities Ventspils and Liepaja.

TABLE IV. THE NUMBER OF ACCEPTED STUDENTS FOR THE 1ST YEAR FULL TIME PROGRAM IN 2009

Study program	City	State financial places	Priority	Number of registrations
REBO0	Rīga	20	1	8
			2	20
			3	3
RECO0	Rīga	35	1	18
			2	7
			3	1
VEBO0	Ventspils	3	1	2
			2	3
			3	1
LECO0	Liepāja	6	1	2
			2	4

Main advantage in pupil's questionnaires is a possibility to have practical skills and choose place of future job during practice time.

This thesis was used during pupil's attraction seminars from 2005 till 2008.

The practical experiment in education means have been shown in pupils attraction seminars in secondary schools and this approach allows to attracts "technically minded" pupils.

Figure 6. Students at factory REBIR (Rezekne, Latvia)

The research based approach education means not only writing thesis, but also visiting industrial companies. During the studies students take part in various cooperation projects with industrial partners. The first steps for Bachelor students are visiting the partners and preliminary introduction into industry specific field and organization (Figure 6).

The next step is to choose an industrial partner for practice. All the work during practical time including the tasks of the students and their reports about the practice is organized in the way that it brings scientific benefit for the industrial partners. The RTU facilities for experimental work and specific research is of huge interest not only for day time students, but also for part time students, which mainly starts their education after colleges and many years of experience at industries companies.

As the result of research students annually have RTU scientific conference in April. Every year the best students' works are nominated in RTU senate, and one student from each section will be named and receive gift. It is the first time, when the Cinder's named scientific organization activity is focused on RTU that means each year the interest in researchers, students and companies is increasing. This year, conferences are organized in computer control of electrical technologies, intelligent electrical transport programming and intelligent electrical transport modelling section. There were more then 57 students and Riga State Gymnasium pupils' scientific works results presented.

Figure 7. Student A.Braufmans is defending his bachelor work demonstrating physical results

The use of the project based approach allows adding also Bachelor and engineering projects with practical application (figure 7).

During the studies students also have been involved in research projects, the involved students are specially pointed as a criterion for support of RTU internal annual research projects. Also international cooperation projects mainly at doctoral studies level, but also some bachelor students are involved (figure 8).

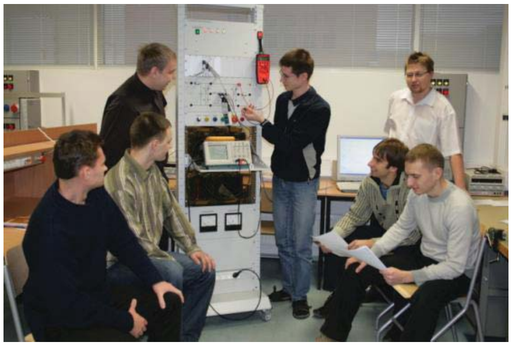

Figure 8. Students during the period of school for post-graduate student

V. AWARDS

The best students' works annually are nominated at various competitions. Industry partners and state organisations support best student's research.

Figure 9. Prof. I. Rankis (standing the fourth at the right), prof. L. Ribickis (standing the fifth at the right) at the ceremony of winners awarding of organized by Siemens competition „Werner fon Siemens Excellence Award", M.sc.ing. M. Pletnova (sitting the second at the right) and Dr.sc.ing. A. Vitols (sitting in the middle).

Many students within last three years have received a special prize in honor of Werner fon Simens for the best master and doctor's thesis in the sphere of the exact and technical sciences. Many students IEEI have been awarded with this honourable prize: A. Vitols (Figure 9) for doctor's thesis „Research of the power-electronic converter for bidirectional energy flow of traction substations", O. Krievs for doctor's thesis "Investigation and development of control systems for active filters of power electronic converters" I. Rodionova for doctor's thesis "Investigation of the effectiveness of AC electric trains direct current electric drives"; M. Pļetņova for her master thesis " Main Tasks and Realization of Automation of Oil Products Storage and Transportation ", A. Vilks for master thesis " Investigation of Possibilities to Improve Electric Magnetic Compatibility of Thyristors Regulated Reactors ".

IEEI students regularly participate and are being awarded in competitions of degree works which is organised every year by the Riga Dome, the Latvian fund of formation, the Latvian association of electroenergetics and power builders, company Latvenergo and ABB Ltd.

VI. CONCLUSION

The application of project based learning approach in electrical engineering studies is the main instrument to reach acceptable level of specialists and, as a consequence, of industry in Latvia.

The research possibilities involve all level of education process: pupil's interest is higher, average mark of students increase; the numbers of graduate students are increased after introduction of research-based approach.

At least seven activities should be continuously realized for the successful organization of the engineers and other specialists educational and training process: education should be continues, from school, the young researcher centres should be supported, the competitions and other pupils attractions should be used to attract people into engineering science; attraction of talented pupils and explanation for teachers should be made continuously; students' scientific conferences should be organized; competitions with significant prizes should be organized for pupils and students.

The analysis of case study at IEEI, which is a leader in RTU in project-based learning application, shows that such strategy application could give a two times increasing of the number of students at the program that in its turn increases the flow of financial resources of the institution more than two times as well as it can significantly improve the quality of education and the range of students' and further specialists' knowledge and skills.

Abstract— **This paper presents a teaching approach for an undergraduate course of project management under the learning by doing paradigm. The course experience as a whole is presented, including planning aspects for all scheduled activities, are provided later. The definition of the project is provided, as well as its specific details for practical project work, the main educative instrument of the course, in order to bring out the most relevant aspects of the approach. These include improving the learning process by means of a collaborative model and details of the assessment process that make continuous improvement possible. Detailed research to evaluate the effect of students' previous work experience of this learning model is also considered in this paper.**

Keywords-project management skills; collaborative groups; interdisciplinary groups; engineering education; learning by doing formatting.

I. Introduction

This paper presents a 'learning by doing' approach related to a course in the project management of engineering projects, which is offered in the final academic year of the Industrial Engineering Degree at Universidad Politécnica de Madrid.

The teaching approach involves a combination of several topics in an endeavour to reinforce the learning process itself. These topics are:

- Practical work focused on managing a real project, mainly in its beginning stages (preliminary scope of the work, feasibility analyses, technical and tactical scope of the work, design, documentation and customer presentation).
- Competition among teams of students.
- Transforming theoretical course material from a time-oriented presentation to a practical presentation of contents that enables them to become of direct use in practical work.
- Combining different roles and responsibilities within each student team in order to improve the learning process that results from internal discussions in which students adopt different roles.

The subject of the project was chosen to ensure that:

- Several disciplines are involved.
- Different solutions are possible.
- Integrative solutions must be found in order to present a coherent solution to the customer.

The teacher has two different roles in order to foster student learning from the training. The first role is that of an external consultant to the student team. The second role is as a customer representative, who is able to negotiate (i.e., make decisions or agree to compromises on behalf of the customer), if required.

For much of prehistory, educational methods were largely informal. Children imitated the behavior of others or modeled their behavior on that of their elders, learning through observation and play. In this sense, the children were the students, and the elder was the teacher. A teacher creates the course materials to be taught and then puts them into operation. Pedagogy is usually defined as the different methods by which a teacher can teach. It is the art or science of being a teacher, generally referring to strategies of instruction or style of instruction.

There are several methodologies available for teaching engineering courses, but, according to ANECA [1], the agency in charge of monitoring the educational system at the university level in Spain, more than 90% of engineering courses uses a delivery strategy based on lectures. The purpose of a lecture is to clarify information for a large group in a short period of time. Lectures require a great deal of time for preparation and need to be supported by various audio-visual materials. The lecture is an instructor-centered methodology.

Although the lecture strategy has such advantages as productivity in content delivery and its suitability for specific topics like project management, it also presents difficulties. These difficulties are related mainly to the knowledge, which has a high degree of practical application, and specific context skills, such as leadership skills, negotiating skills, etc., which are usually perceived by students to be abilities that are acquired or developed outside of school. In addition, students of engineering greatly prefer technical content to managerial content, which they perceive to be potentially useful, but provided only after they have completed the educational process. All of these elements serve to strengthen students' passive attitude.

In order to manage this context, some particular improvements have been designed [2], implemented and tested. They were motivated by a desire to foster a greater engagement of students as well to reinforce the learning process itself [3]. These special add-ons included the immediate use of most of the theoretical components presented, team competitions, team work, and negotiation [4].

As described later in this paper, this study can be viewed as the construction of an applied learning environment [5] under a paradigm of learning by doing [6] in which concepts and tools are required to develop practical work in a competitive context. A convenient conceptual framework is provided before theory class is runned under a discussion approach. The purpose of a discussion is to solicit student participation and involve the student in content transmittal. Discussions are usually limited to small groups and require considerable time. However, the discussion method requires little audio-visual support. It promotes understanding and the clarification of concepts, ideas, and feelings. There are numerous variations. The discussion method can vary from a teacher-centered approach to a student-centered approach. Examples of specific methods that can be employed include role playing, debates, panel discussions, reviews, supervised study, brainstorming, buzz groups, idea incubation, tests, show-and-tell, worksheets, conferences, and interviews. In this particular teaching approach), a role playing approach was usually selected, although the relatively high number of students to manage was a challenge. An additional reason to use the role playing approach is that students must become very accustomed to these concepts for immediate practical application in competitive practical projects. In creating a suitable environment in which to use the acquired knowledge, specific asynchronous events that impact a project's lifecycle are introduced [8].

All scheduled activities need to be estimated in terms of student effort in accordance with ECTS criteria. Satisfying this requirement for the project management course produced the following distribution, assuming duration of 14 weeks per course (Table I).

TABLE I. DISTRIBUTION OF STUDENT EFFORT IN THE PROJECT MANAGEMENT COURSE

Task	In class effort (Per week)	Out of class effort (Per week)	Total effort (Per course)
Reading course material	0 h	2 h	28 h
On line quiz relative to theoretical reading material	0 h	0,25 h	3,5 h
Class discussion	1 h	0 h	14 h
Individual work	0 h	1,5 h	21 h
Software practical class	0,5 h	0 h	7h
Practical project Development	0,5 h	5 h	63 h
Public presentation	0,05 h	0,1 h	2,1 h
Test	0,25 h	1h	17,5 h
Total	2,3 h	8,85h	156,1h

Like the time distributions of other courses and, because the course has been given a grade of 6 ECTS and one ECTS means 27h at Universidad Politécnica de Madrid, the total time available is 162h. This includes a float of 4% as a safety factor since the estimate was based on averages.

Investigating the outperformance of teams according to their internal structures [7] was of additional interest. In order to investigate the effect of previous work experience in developing the real project, two different teams were created, the first consisting entirely of young students who had no previous work experience and the second consisting of students who possessed significant previous work experience.

An additional interest for this research is to measure the instructor's effort. In such way, specific activities for theoretical learning processes and practical ones are presented (Table II).

The rest of this paper is focused on presenting the relevant aspects of the development of a practical project, as the latter is the driving force of the PBL approach chosen. Firstly, previous experiences in teaching project management by use of a 'Project-based learning' methodology is recalled, as this is the easiest way of identifying innovations to include in the learning approach presented here. This is the objective for section II.

Later, the project definition and implementation details are presented, bringing up the most relevant aspects of the experience, like details of assessment of the process to make continuous improvement possible or improving the learning process by a collaborative approach. This is the goal of section III.

The next section is dedicated to a discussion of the results of the experience, including learning planning, learning development, a comparison to classical lecture-based learning models and an overall score. Also discussed is how these results are transformed into learned lessons as feed-back. Finally, the last section presents the main conclusions and future plans.

TABLE II. DISTRIBUTION OF INSTRUCTOR'S EFFORT IN THE PROJECT MANAGEMENT COURSE

Task	Theoretical effort (Per week)	Practical effort (Per week)
Preparing and updating course materials (syllabus, quiz and case studies)	3h	
Class discussion	1h	
Scoring four individual assignments	4h	
Test definition and evaluation	1h	
Practical case definition		1h
Monitoring the project evolution and reporting		2h
Scoring the practical work including public presentation		2h
Individual mentoring	3h	3h
Total	12h	8h

II. PROJECT-BASED LEARNING AND COLLABORATIVE TEAMWORK IN PROJECT ENGINEERING

There is a shift in emphasis in engineering education from professional skills to process skills [9]. These skills include problem analysis and problem solving, project management and leadership, analytical skills and critical thinking, dissemination and communication, interdisciplinary competencies, intercultural communication, innovation and creativity, and social abilities. PBL has proved to be an excellent method for development of new forms of competencies [10][11].

Research has shown that students retain minimal information in the traditional didactic teaching environment and frequently experience difficulty in transferring the acquired knowledge to new experiences [12]. A PBL environment enables students to draw upon their prior knowledge and skills, brings a real-world context to the classroom, and reinforces the knowledge acquired by both independent and cooperative group work [13].

PBL is a model in which learning opportunities are organized around projects [14]. According to the definitions found in PBL papers, projects are complex tasks that are based on challenging questions or problems that involve students in design, problem-solving, decision making, or investigative activities. They give students an opportunity to work relatively autonomously over extended periods of time and culminate in realistic products or presentations [15] [16] [17]. Other defining features of projects that have been found in the literature include authentic content, authentic assessment, teacher facilitation without direction, explicit educational goals [18], cooperative learning, reflection, and incorporation of professional skills [19].

Several criteria define what a project should have in order to be considered an instance of PBL [20]. The five criteria are centrality, a driving question, constructive investigation, autonomy, and realism. The first criterion is that PBL projects must be central, not peripheral, to the curriculum. In PBL, the project is the central teaching strategy. Students encounter and learn the central concepts of the discipline by means of the project. The second criterion is that PBL projects must be focused on questions or problems that "drive" students to encounter the central concepts and principles of a discipline. The definition of the project (for students) should be so crafted that a connection is formed between activities and the underlying conceptual knowledge that one might hope to foster [21] [22]. The third criterion is that projects must involve students in a constructive investigation. An investigation is a goal-directed process that involves inquiry, knowledge building and resolution. Investigations may take the form of design, decision-making, problem-finding, problem-solving, discovery, or model-building processes. However, in order to be considered as a PBL project, the central activities of the project must involve the transformation and creation of knowledge (by definition: new understanding, new skills) on the part of students [23]. The fourth criterion is that projects must be student-driven to a significant degree. PBL projects incorporate a good deal more student autonomy, choice, unsupervised work time, and responsibility than traditional instruction and projects. Finally, the fifth criterion is that projects must be realistic and not school-like. Projects should have characteristics that give them a feeling of authenticity to students. These characteristics can involve the topic, the tasks, the roles that students play, the context within which the work of the project is carried out, the collaborators who work with students on the project, the products that are produced, the audience for the project's products, or the criteria by which the products or performances are judged. Reference [24] was the first to make a distinction between academic challenges, situation challenges, and real-life challenges. PBL incorporates real-life challenges where the focus is on authentic (not simulated) problems or questions and where there is a possibility that solutions will be implemented.

In PBL, the project is the central teaching strategy. Students encounter and learn the central concepts of the discipline by means of the project. There is a longstanding tradition in schools of "doing projects," incorporating "hands-on" activities, developing interdisciplinary themes, conducting field trips, and implementing laboratory investigations [25].

Research on PBL can be undertaken to: (1) make judgments about the effectiveness of it (collective evaluations), (2) assess or describe the degree of success resulting from implementation or performance of Project-Based Learning (formative evaluation), (3) assess the role of student characteristics in PBL effectiveness or appropriateness (aptitude-treatment interactions), or (4) test a proposed feature or modification of Project-Based Learning (intervention research) [20]. Moreover, there are at least three traditions from which PBL research and practice seem to emerge. They are: (1) Outward Bound wilderness expeditions [26] [27], (2) postsecondary models of PBL [22] [28], and (3) university-based research in cognition and cognitive science applications [29] [30] [31].

The inclusion of real-world problems in engineering education reinforces concepts and improves learning in ways not available with traditional lecture methods or predefined case problems [32]. Students develop problem solving skills, project management skills, communication and teamwork skills, and a sense of professionalism from such experiences.

III. EXPERIMENT AND ASSESSMENT PLAN

A. Project definition

The learning approach presented here concerns the development of a real engineering project by groups' competitive assignments. The main purpose of *playing to manage projects* is to move on from simply learning contents by heart to understanding, discussing and sharing in order to learn from experience.

The project proposed is multidisciplinary and unifying. Students come from nine different specializations: industrial management, manufacturing, energy, electronics, chemistry, construction, materials, mechanics and electricity. Each team member plays a different role, according to his/her specialization, skills or preferences. Each group appoints a project manager who has the authority to assign responsibilities and acts as the team spokesperson to communicate with the project's owner(s). The professor will play two different roles during the process – that of the project owner's representative who is ready to make decisions when required and also as an external consultant during the project follow-up meetings.

Each team will study the fundamental notions of Engineering Project Management and apply them to actual cases. Students will be required to define the scope of the project, assess its technical and economic feasibility, prepare a schedule and budget, and assume responsibility for cost management, conflict management, documentation management, follow-up controls, quality management, communication management, and, finally, completion of the project and the main conclusions.

In this study, the project owner is a European investment trust that is highly committed to the preservation of nature and the avoidance of any negative impact on the environment as a result of its investments.

Following an exhaustive analysis of the different investment opportunities, the trust has decided to embark on the construction of a non-hazardous industrial waste management plant. This new plant will be located in a highly industrialized area and will address the potential demand of nearby companies for waste disposal services. The project owner would like to see an analysis of the different alternatives for the construction of the plant, bearing in mind that the plant will be operated for a minimum of fifteen years and a maximum of twenty five years.

The strength of the proposed solution will be considered in the final assessment, as well as its conformity to existing legislation and the potential for waste treatment (the higher the better). Both the cost of the complete solution and its operating expense must be included in the budget. Finally, the engineering fees also must be included.

With regards to methodology, the students have at their disposal the theoretical materials needed to cause the project to move forward. In this learning experience, theory is subordinated to the requirements of practical sessions, both in sequence and content. The learner studies the contents and completes a questionnaire about the subject before a lecture or a project meeting takes place. For each knowledge area, the student submits an individual assignment about planning the scope, preparing an offer or taking a stance on a current topic in Project Engineering. All of these activities have been assigned specific time "costs" that count towards the final evaluation of the subject.

Two project teams were created for the case study that is under consideration, the teams are populated by ten to twelve members in order to have a fit management workload. Each project team represented a different consulting firm that had been asked by its client (the lecturer) to undertake an assessment of the project. In this context, the students apply the project management methodologies and techniques that they learned during the course to enable them to make a sound proposal that meets the client's terms (in time, resources, etc). The technical quality of the proposal, excellence of the presentation of the offer to the client and the team's performance in managing the project will count towards the final evaluation of the subject.

This participative model shifts the active role to the student, given the fact that he is the one who needs to solve the problem after he has validated his approach. Once the simulation of this collaborative, multidisciplinary model has been completed, it becomes clear that the proposed learning dynamics promotes the development of diverse knowledge competencies required to manage engineering projects: reach management, time management, resource management, cost management, communication management, risk management....In addition, the model fosters the development of collective skills, such as teamwork, conflict resolution skills, negotiating skills, leadership skills, self-control, creativity, commitment, motivation, etc. In short, the model permits the student to put into practice those skills that a project manager should possess. Finally, the student's impressions of this learning model with regards to planning, development and assessment are presented, as well as the methodology, resources employed and changes proposed to enhance the usefulness of the subject.

B. Development of the learning experience.

Each project team must meet for half an hour each week during which time the project manager reviews the work performed during the previous week that the plan had required. Also, tasks for the current week are agreed upon and scheduled.

All team participants must claim their hours spent in execution of assigned tasks. The project manager is responsible for managing the work to be done and reporting the hours used by all team members - 600 in this particular case. The efforts spent can also be reviewed. The limited time available for the weekly team meeting reinforces the need for skill in conducting meetings and leadership.

The Work Breakdown Structure, as well as internal deliverables (e.g., documents or products created by the team) are freely determined by the team itself with the only constrains being the total effort available and final products to be provided as a result of the work. This particular design improves the creativity and reinforces the contribution of the interdisciplinary groups to the common project, even when the interests that the students have in the project differ.

The role of the teacher is perceived to be that of an external consultant-agent, due mainly due to the effort expended in maintaining both profiles (consultant and owner representative). The specific management of the owner representative is an issue for team leaders. Team members' week-by-week progress in their work is the result of a combination of effort, use of their technical skills and the growth of group competencies (e.g., leadership, teamwork). This is an excellent way for monitoring the development of these competencies.

This approach puts emphasis on an active role for the students who must present a solution for a problem, after discussing it to assure them that it has been well thought out. During the learning experience, specific knowledge is applied by the students and various skills are reinforced, such as scope management, time management, resource management, communication management, both formal and informal, and risk management. The proposed approach also improves group competencies like teamwork, conflict management skills, self motivation, negotiating skills and competitiveness.

In order to evaluate the dynamic capabilities for quick answers by the teams, specific asynchronous events are introduced. For example, this might be an environmental regulation change that affects the project under development or a customer crisis that precipitates a sudden reduction in the size of the investment budget, which necessitates a significant change in the size or scope of the project. Such unexpected issues force the team to manage the situation by redefining the scope of the work, re-planning the work to be done or adjusting the previous plan It is an excellent way to see how the team manages a situation that can lead to loss of motivation, frustration, contempt for the customer or renewed motivation, or any combination of these elements, in order to win the competition. There is a possibility of observing a direct relationship between the attitude of team managers and internal team atmosphere. Obviously, there is a relationship between the team's internal atmosphere or morale and its productivity and the quality of the products that it delivers.

As the team needs to work in a multidisciplinary way, and nearly all team members have specific schedules due to their other engagements, it is appropriate to provide tools that allow for easy group work activities. To aid teams in this approach, a model [33] site was established, although teams are free to adopt other approaches, such as specific Google-groups. The model system provided is configured as group courses arranged in such a way that the contributions of one team are concealed from the members of other teams. These additional tools contribute towards improving members' skills for technological uses in the execution of projects.

The approaches carried out by the teams differ greatly. The team consisting of young students who lack professional experience invests a great deal of effort in devising the right scope and formulating logical alternatives. It functions as a real team with discussions, a common vision of the solutions and high commitment to project objectives. The other team, which consists of students who have previous professional experience, adopts a more individualistic approach. Only matters of coordination are handled at team meetings. The scheduling of individual tasks is conditioned in great degree by the experience of the participants. Significantly less time is given to developing the team. The homogeneity of people in teams and tasks was observed. It is noteworthy that some team members divided their attention between their employment and their studies. This makes it much more difficult to develop the team in ideal fashion.

IV. RESULTS AND FEED-BACK

A confidential survey was carried out during the last course week. Several groups of related questions were reviewed and scored on a Likert scale 1 to 5 (from fully unsatisfactory till fully satisfactory). As it is allowed to no answer some questions, 0 values mean no answer to that specific question. One chapter of the survey takes into account particular aspects related to the concerned methodology.

It becomes clear (Figure 1), that students prefer to read by themselves and to get their own feedback prior to attending a common discussion (answer X7_1) or to provide their own opinions in personal essays (answer X7_3). There is agreement in having an opportunity to develop a real project solution (answer X7_4), as well as activities like negotiation role plays (answer X7_5). Finally, greater support for the methodology used was obtained than for the more classical methodology, which is based on theoretical concepts plus some individual practical tasks, each of which is two hours in duration.

In addition to considering the feelings of students in regard to methodology, resources, services from teachers, the learning process and learning planning, a specific evaluation of the quality of the product was conducted.

X7_1. I agree with reading class material before the class and use that time for concept discussion.
X7_2. I agree with using the theory as a toolbox for development of practical projects.
X7_3. I agree with individual tasks that allow me to express my own opinions.
X7_4. I agree with the development of a practical project.
X7_5. I like to perform specific tasks like negotiation simulation.
X7_6. I like to learn specific software tools for project management.
X7_7. Overall, I prefer the current methodology, instead of the classic approach, which is much more oriented to lectures.

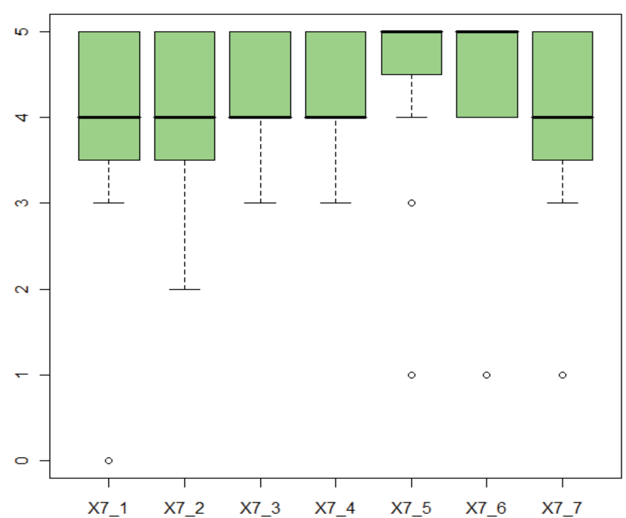

Figure 1. Boxplot of specific aspects of methodology.

From a technical point of view, both solutions were far removed from the professional viewpoints, due mainly to a lack of specific knowledge of the specific field. This can be used to introduce the subject of technology transfer solutions or, at least, to visit different solutions related to current problem. Another problem is the great differences between real costs and estimated costs for most cost categories. As most of the time was consumed in defining the problem and identifying alternatives, there was not enough time spent on the task of cost analysis.

A common strategy that the teams employed was to attempt to keep the owner's agent far from their design and solutions. The main drawback of this strategy is that, since the customer was not involved in intermediate decisions, the risk of a failure to fulfil customer's expectations becomes higher as the project nears its end. This was an important lesson that was learned.

By far, the most important problem identified by the students concerns the amount of time that the teams spent, although the number of hours claimed individually is consistent with the initially planned time (600 hours in this particular case).

Another specific problem not identified directly by students, but reported by teachers, is the project manager's lack of skills (i.e., the student acting in that role usually had more interest in technical questions than in managerial matters). This unfocused management normally leads to wasted efforts as the Work Breakdown Structure is produced later and there is no close tracking. A visible effect is a lower rating for teachers in practice classes (Figure 2).

It becomes clear that students are more comfortable with a fixed environment. They assign a lower rank to a noisy environment (Q3), (i.e., practical sessions where there is less structure and where time is managed by a project manager without the benefit of a plan provided by the teacher (see in Figure 2, answer for X6_3 against those for X6_2 and X6_4).

X6_1. There are enough teachers
X6_2. Teachers of theory do good work
X6_3. Practical class teachers do good work
X6_4. Overall, I agree with the performance of the teaching team

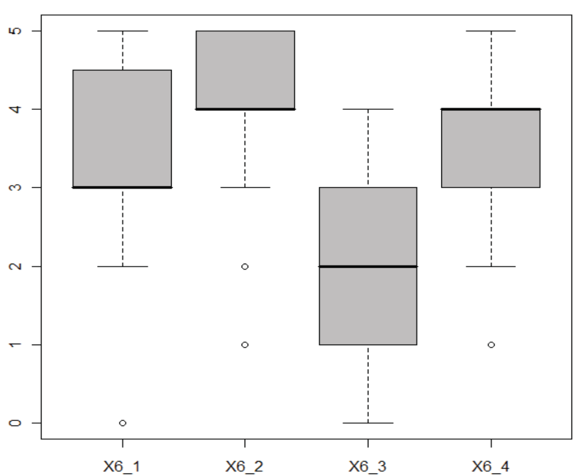

Figure 2. Boxplot of the perceptions of teacher performance

V. CONCLUSIONS AND FUTURE PLANS

As demonstrated, PBL is a method of instruction that challenges students to learn how to work cooperatively in groups in order to seek solutions to real world problems. These problems are used to engage students' curiosity and initiate the learning of the subject matter. PBL prepares students to think critically and analytically and to find and use appropriate learning resources (see Figure 3 below and particularly the answers to X4_5, X4_6 and X4_7).

This provides students with an opportunity to prepare for a professional life by practical training in coordinating a work group and working effectively as a member of a team. The independent research and learning aspects of the PBL provide the students with the skills necessary to identify, research and fill in the missing knowledge for the types of problems that they may encounter during their professional lives.

The purpose of this practice was not only to enable students to acquire technical knowledge, but also to open their minds and see what engineering project management is really about.

This experience has demonstrated that project-based learning is an effective way to effect student learning in the subject area of project management. In addition to detailed technical knowledge and performance skills, successful project management requires engagement, motivation, creativity and understanding. Interdisciplinary team projects offer many learning opportunities related to complex problem-solving, conflict resolution, and decision making, among others. The opportunity to develop these skills often is unavailable to students until they become employed. Introducing students to such experiences earlier can foster the development of these abilities.

X4_1. The real effort expended equals that of the theoretical one.
X4_2. The evaluation is consistent with the rules presented at the beginning of the course.
X4_3. The evaluation processes measure knowledge correctly as well as competencies.
X4_4. The evaluation components are coherent with the activities scheduled.
X4_5. I learned concepts, tools and techniques that are new and valuable to me.
X4_6. I learned to do things related to this matter that are useful and completely new to me.
X4_7. Overall, I support the evaluation system for this course.

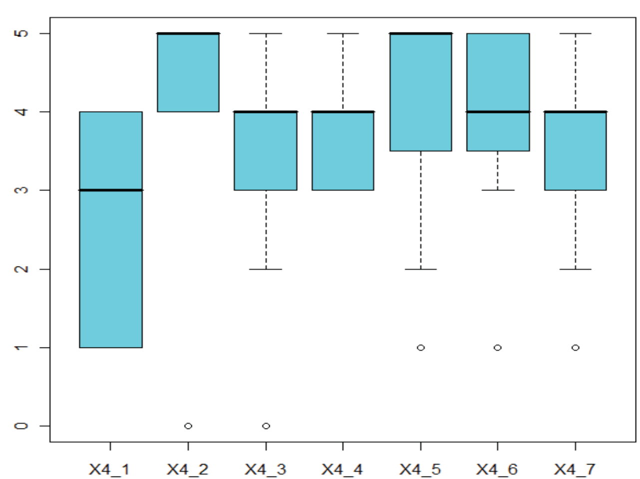

Figure 3. Boxplot of learning opportunities

A comparison of inexperienced and experienced students also reveals aspects that require special management. Young students are much more reluctant to make practical assumptions that are not directly related to specific mathematical formulas. In contrast, the students who possess previous work experience make assumptions naturally. However, because of their individualism and empowerment, they require a much more experienced manager. Management that has strong leadership attributes is clearly required here to avoid providing various fragmented solutions to the customer, instead of one well-focused approach.

When the project manager fulfills his role, the solutions provided are more practical than those generated by inexperienced students. This analysis supports the relevance of work experience as an additional skill provider to formal knowledge with an impact on student performance. When the project manager doesn't fulfill his role, the risk of project failure is much higher than in the other case. This is also a lesson that was learned, demonstrating its relevance for the profession of project manager in real life.

The perception of both the students and teachers is that the learning approach tested was valuable and more productive than lecture-oriented approaches, despite the fact that it required greater effort than the classical method, in which most of the effort is spent as examinations approach.

This does not mean that the learning approach presented is in an optimal state because, according to the lessons learned, there are improvements to consider making to the lessons. The easiest improvement to implement would be to design some 'gates' for practical projects to help project managers to have individual goals to refer to concerning the progress desired.

One issue is the number of class students as some scheduled tasks are class size-dependent, including the blended learning tools.

These tools were rated as very relevant for both students and teachers as they make possible direct feedback from an individual's reading, as well as an individual's work. Also, they make non-synchronous work possible by means of common repositories, forums with email alerts and many other useful tools.

The experience could be adapted to other courses by changing the project area to one that aligns with the subject of the course concerned. Our immediate plan is to complete the experiment by comparing the work of the teams. The following step will be to study and measure how technical information about project management improves the execution of practical work. In order to accomplish this, specific objective measurement looking for effectiveness of this learning approach will be established. Also, scalability characteristics will be analysed by running the approach with nearly two hundred students integrated into sixteen different teams.

Abstract—**Mechanical/Industrial Engineering students at Higher Technical School of Industrial Engineering (ETSII) of Technical University of Madrid (UPM) receive an in-depth knowledge of mechanical design and manufacturing processes, but the increasing interaction with other engineering branches, induces the need to integrate concepts which allow students to make an integral design of new products, and thereby facilitate their subsequent integration into multidisciplinary engineering teams in industry.**

Complex engineering projects are usually carried out by the assimilation of different work teams, which could even be located geographically distant. Collaborative Web environments are proven to be ideal knowledge repositories, as it has seen in Academia and in Industry. The work here presented reproduces the organization of actual engineering projects, and brings it into the classroom.

This new way of developing Project Work documentation and discussion has helped students become self-directed learners who internalize specific topics from different subjects, programmes and courses with their own interests, and has been considered as an easy alternative to promote active learning, not only in this area but in other courses.

Project were launched in the engineering disciplines, each offering possibilities for the application of specific skills in the following courses: TEC -Manufacturing Technology-, CAD -Computer Aided Design-, SIM -Simulation in Mechanical Engineering-, and FAB -Fabrication / Manufacturing. TEC and SIM are applied in the Mechanical Engineering programme at ETSII, while FAB is part of the Industrial Engineering programme; finally CAD is voluntarily employed by students in different semesters and programmes. The new approach is oriented towards inducing collaboration within multidisciplinary teams.

This paper describes the experience of collaboration among students and teachers in order to develop multidisciplinary projects, and to reproduce as closely as possible, the team's integration into a company environment. A new methodology based on student interaction and content development in a Wiki environment has been developed. The collaborative server has allowed creating an "out-of-the-classroom" active discussion forum for students of different teams /topics, and to compile an important "project work" portfolio. This experience has been very satisfactory for students and teachers, who have participated with enthusiasm due to the exit of the well-distributed work and the easiness of use of the selected platform (Wiki). The quality of the developed projects has been dramatically improved due to the integration of the results provided by the different teams.

Keywords: Project Based Learning; Active Learning; Collaborative Work; Multidisciplinary Approach; Wiki Environment, Teaching Mechanical Engineering

I. Introduction

Mechanical/Industrial Engineering students at Higher Technical School of Industrial Engineering (ETSII) of Technical University of Madrid (UPM) receive an in-depth knowledge of mechanical design and manufacturing processes. The increasing importance of the electronics, hydraulics, pneumatics, etc. in this field induces the need to integrate multidisciplinary knowledge which will allow students to make a whole design of new products and thereby facilitate their subsequent assimilation into multidisciplinary engineering teams in industry.

The use of project-based learning that allows students to participate in complex projects was already reported quite a while ago. Examples of these experiences can be found in many areas, with a positive evaluation in the case of learning in engineering.

The main objective of this experience has been to design a set of projects to be developed by students, mainly in the area of automated engineering, where students have to work in cooperative groups of three and have to integrate their results with groups from three other different subjects. They used a Wiki server to share and prepare their work content. This server integrates the information available from all projects with the following advantages:

- "Out-of-the-classroom" discussion with the ensuing improvements in students' ability to conceptualise.
- A simple, homogeneous compilation of the documents contributed by students.
- The chance to improve knowledge in other areas of interest.

The use of collaborative WEB environments is now commonplace in university education [1] [2]. The new technology platforms such as Blogs, Wikis and RSS feeds are proving to be invaluable educational tools that satisfy the constructivist theories of active learning [3]. Some experiences are specifically oriented towards teaching in Engineering and many are suited to collaborative work [4][5].

Some authors emphasise creating case study portfolios to promote an efficient understanding of concepts by students [6]. These case studies give rise to different ideas and have been proven to be an ideal mechanism for stimulating conceptualisation.

The Wikis are an excellent environment for a knowledge repositories and many experiences have been developed in teaching [7] [8] and in industry [9].

The use of Wikis helps improve students' reasoning abilities and their interaction with Wikis, and can be done outside the classroom as previous experiences have shown [10], where work on a collaborative project is considered as a way for students to add to the knowledge acquired in theory classes.

II. PROJECT DEVELOPMENT

A. *Team organization*

This educational initiative has been applied in four topics directly affecting 110 students working in different subjects and another 44 students that set the work for the students in each group of independent students.

The wordings for these works were launched with their particularities for the different subjects comprising the experience:

- TEC: Manufacturing Technology. (Code 1463).
- CAD: Computer Aided Design. (Code 9004).
- SIM: Simulation in Mechanical Engineering. (Code 1461).
- FAB: Manufacturing. (Code 1684).

TEC and SIM are topics in the Mechanical Engineering curriculum at the ETSII and are taught in the sixth semester while FAB is part of the Industrial Engineering programme taught in the eighth semester, and finally CAD is a free choice subject. Students in these subjects have carried out application projects for years but with this new experience, they are moving towards collaboration between disciplinary teams in different subjects. A collection of manufacturing cells was proposed to be worked on from four different points of view, to study and analyze them, and subsequently four different team approaches would be embraced to be solved in each of the previously mentioned topics.

This project carried out by students is shown in Figure 1 from four points of view reflected by the typical topics of these subjects and, therefore the tasks to be solved are seen from four different approaches.

Groups of three students were selected for each project and topic except for CAD which were two-student teams. Initially the teacher and students set the boundaries of the project for each topic.

The teachers involved in this experience organised fortnightly coordination meetings in order to coordinate course content timetables. Figure 2 shows an example of a problem in handling an automatic packaging machine. The difficulty of the projects proposed is uniform, but the work sequence and other specifications must be set in advance for each topic.

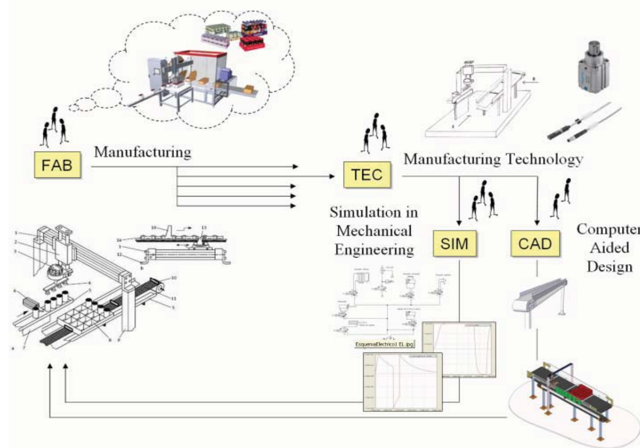

Figure 1. Four different teams for each manufacturing cell project.

Ten different types of manufacturing cells were designed. The cells proposed are shown in Table I:

TABLE I. MANUFACTURING CELLS

Manufacturing cells	Acronym
Parts manipulation in injection molding process	DPPMI
Machine to make pipe ending bezels	MBFT
Panel manipulation	MP
Can packing machine	EL
Saw cutting unit	US
Quality control for trays	CCB
Glass sheets positioning	PC
Tubular parts feeder	APT
On demand storage feeding unit	AM
Adhesive application station	AA

TABLE II. WORK EXPECTED FOR EACH TEAM:

Teams	Function
FAB	Manufacturing process selection and planning
TEC	Process simulation in the manufacturing cell
SIM	Design, drawing and drafting for the manufacturing cell
CAD	Design, drawing and drafting for the manufacturing cell

B. Publication and development on the collaborative Web

When each team has defined their particular area of contribution, the collaborative Web begins its task, which is basically to integrate all the information from student contributions and show it to the other teams with the purpose of enhancing the overall quality of the results produced.

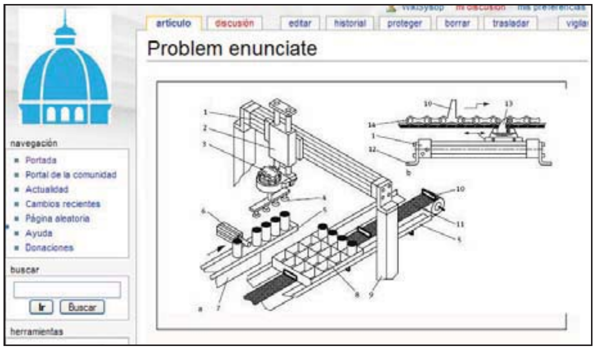

Figure 2. An example of the type of project proposed. A can packaging machine (EL). The project was provided by the teacher.

To facilitate an exchange of experiences and communication among the team members assigned to developing each manufacturing cell for the different topics. Once a week they could use a collaborative classroom, where the 11 members from the different topics that had designed the manufacturing cell could exchange information face-to-face or solve problems that could not be sufficiently clarified by the Wiki.

Figure 3 shows one of these inter-group exchange classes in which the different teachers from the four topics involved answered any query and realized how the projects were progressing.

Figure 3. Team coordination meetings

In the FAB and TEC topics, the rest of the students worked to provide the main groups with information (Figure 4).

Manufacturing Cell (11 students)			
CAD Group (2 students)	MEC Group (3 students)	FAB Group (3 students)	SIM Group (3 students)
	Subgroup 1 to n	Subgroup 1 to n	

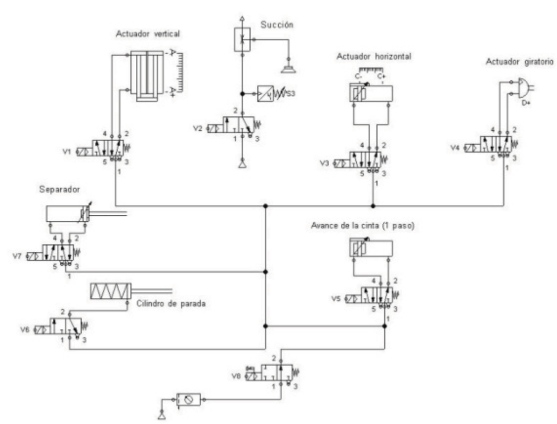
Figure 4. Organization of the work groups

Figure 5. A preview of the wiki space for a work team; solution provided by one of the CAD teams about the can packing machine shown in figure 2.

Figure 5 shows a solution to the formulation of the problem set in Figure 2 by the CAD team, chosen for publication in the so named WikiFab collaborative Web (acronym of Wiki Fabrication) [11]. MediaWiki 1.11 was chosen for its simplicity of configuration, its popularity (it is used in Wikipedia) and its powerful Wiki functionality.

In this Wiki, students must perfect the different issues set in the project. The discussion page contains everything related to working sequence and the starting conditions, such as the parts references provided by the manufacturers or the various design changes (Figure 6). All this information is discussed not only by the team members themselves but they also can receive comments from the members of other teams.

It is important to mention that the recommended format for offering solutions is a graphic format. This forces students to train their synthesis skills to express the objectives of their models through schematic outlines or diagrams. In another of the machinery stations, Figures 6 and 7 show different approaches to the proposed project model and the solution adopted respectively. The discussion page currently allows interacting with the teacher and other team members to be able to discuss the details of the proposed model.



(a)

(b)

Figure 6. Different approaches to the project. (a) from the Manufacturing Technology subject TEC, (b) from the Manufacturing subject FAB.

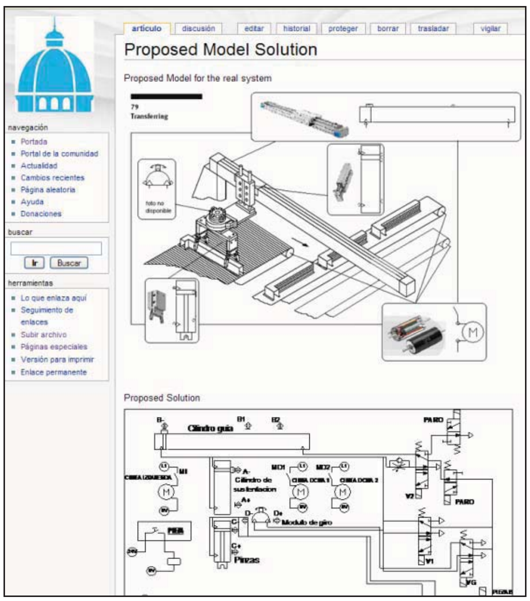


Figure 7. Solution for the proposed model

III. RESULTS

Every week, the students involved had to fill in a set of reports to evaluate team progress, interaction with other members and the problems they found in the assimilation of the project. These evaluation reports were prepared using Google Docs forms. Teachers use these reports to detect bad team behaviours and delays in the teamwork process.

Two general checks were also made midterm and at the end of the semester to evaluate satisfaction and the evolution of competencies.

A. Influence on the marks of the subjects involved

Figure 8 shows the average mark attained for TEC, CAD, SIM and FAB by students who took part in this experience (Project Based Learning PBL) and those who did not. It can be seen that there is difference between the two groups in the different topics as well as in the progress of the competencies developed.

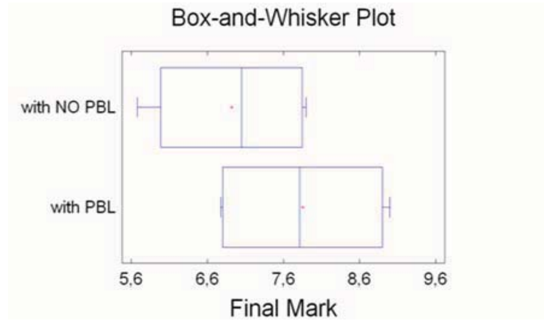

Figure 8. Comparison between students that follows the PBL method

B. Follow-up checks

Two checks were made midterm and at the end of the semester to evaluate student satisfaction. The questions contained in the survey were scored on a scale of 0 (zero) to 5 (completely in agreement). The questions were as follows (Table III):

TABLE III. CHECK QUESTIONS

Question Number	Question
Q1	Select your subject.
Q2	The 'multidisciplinary' work method is preferable to classic 'teacher-delivered lectures'
Q3	I think my work assessment method is correct
Q4	The teacher recognises the extra effort required to do work outside the classroom
Q5	The effort made to take part in the project is worthwhile. It would be a mistake not to take part in this experience.
Q6	Would you recommend it to a friend?
Q7	Score the WikiFab enviroment
Q8	I have improved my ability to work in multidisciplinary teams
Q9	I can estimate work execution times more accurately
Q10	I am more precise in the work I do
Q11	I have improved my ability to work with different teams by having to exchange information .
Q12	I have more leadership ability

Q6 has no numeric answer, the responses could be 'Yes', 'No', or 'I don't know'.

C. Statistical analysis

The results of these surveys were analysed statistically, obtaining the findings described below. 154 students answered the surveys: 23 students were enrolled in the CAD subject, 53 students applied in FAB topic, 28 students were working in SIM and 50 students in FAB.

Figure 9 reflects how at the end of the semester the scores for satisfaction showed a perceived improvement in competencies, although not in a major way, since from the start of the programme students perceive a positive improvement in their competencies. The multidisciplinary method used compared to the traditional one is scored favourably (Q2).

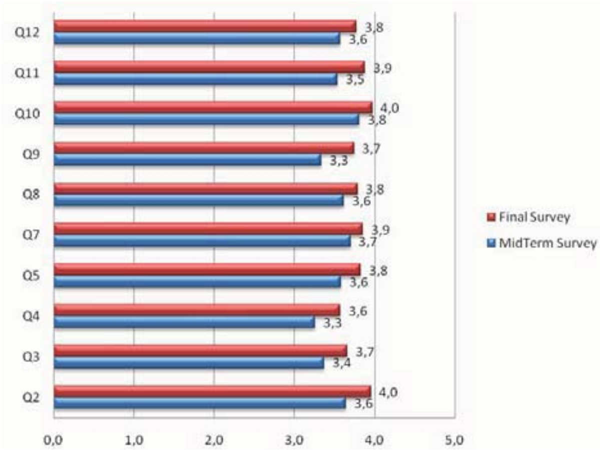

Figure 9. Mean of the questions results for Q2 to Q12

It can also be seen that there are no important deviations in the sample taken (Figure 10):

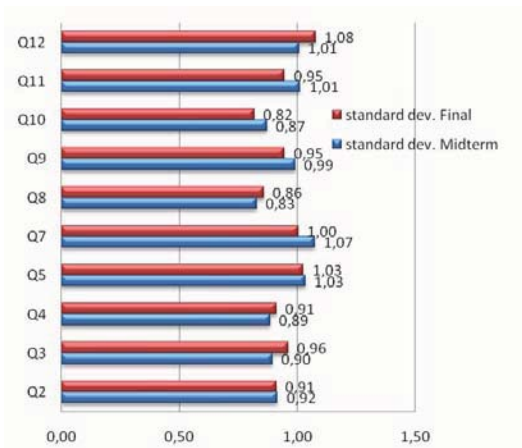

Figure 10. Standard deviations for Q2 to Q12 results

Regarding question Q6 "Would you recommend it to a friend?" the following results were obtained. It can be seen how in midterm students are doubtful of the benefits of the programme. However, at the end they are satisfied (Figure 11).

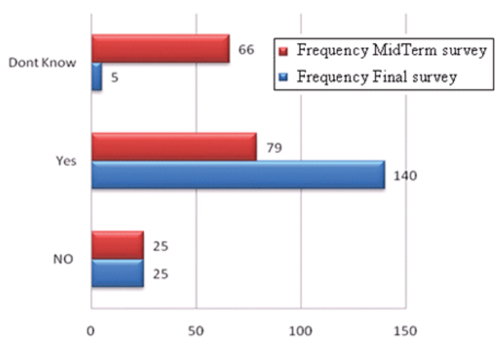

Figure 11. Histogram corresponding to Q6 results.

Chi-square test were made and 'P-value = 0' (< 0,1) so we can reject the hypothesis that rows and columns are independent at the 99% confidence level.

Therefore, the observed value of Q6 (fig. 11) in the midterm survey is related to its value for its subject.

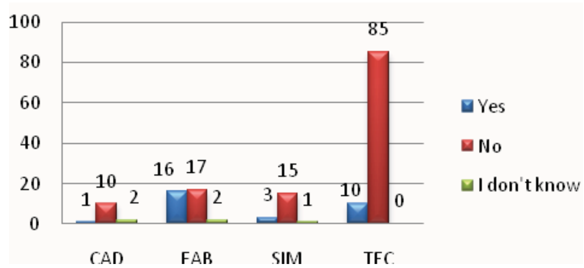

Figure 12. Q6 results in the midterm survey

This Q6 question was studied in the final survey again obtaining a clear correlation with the topic's students belong. Performing the Chi-square test, Since the P-value = 0,0056 is less than 0.01, we may reject the hypothesis that rows and columns are independent at the 99% confidence level. Therefore, the observed value of Q6 in the final survey case is related to its value for the applied subject.

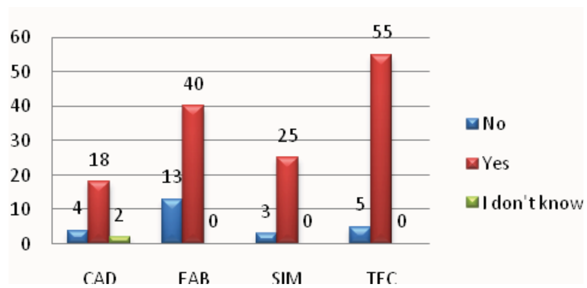

Figure 13. Q6 results in the final survey

D. *Analysis by subject*

An ANOVA analysis was made of the different student opinions regarding the topic they were studying. These findings refer to the final survey conducted in the semester.

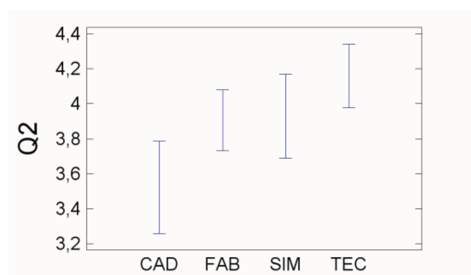

Figure 14. ANOVA(means and 95,0 Percent LSD Intervals) of Q2 results

The response to Q2 shows discrepancies between the CAD and TEC groups (Figure 14). We use the Student t-test to know if the groups are or not are homogeneous.

The responses to Q3 and Q4 show a homogeneous distribution for all groups. The response to Q5 shows discrepancies between the FAB and TEC groups. The FAB students do not positively score the extra effort required compared to multidisciplinary work.

On the other hand, these students are from the Industrial Organization specialisation and are not purely Mechanical Engineers (Figure 15).

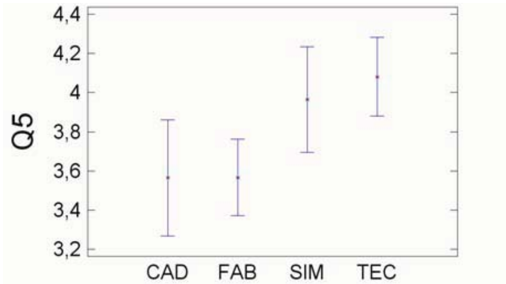

Figure 15. ANOVA (means and 95,0 Percent LSD Intervals) of Q5 results

However, question Q7 did show more disparate performance as Figure 16 shows. The SIM and TEC students score it very positively, which was not the case with the other groups.

The SIM students found the Wiki to be a very useful environment for developing their work and the TEC group, moreover, was driven by a teacher who was highly enthusiastic about its use and deployment.

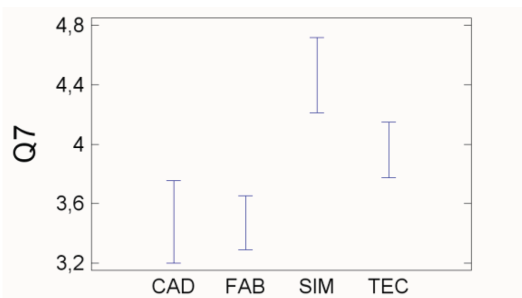

Figure 16. ANOVA (means and 95,0 Percent LSD Intervals) of Q7 results

The CAD students did not perceive any improvement in their work in multidisciplinary teams (Q8) compared to the other groups (Figure 17).

The TEC and FAB groups considered they had improved their time calculation estimates for jobs (Q9) better than the other teams (Figure 18).

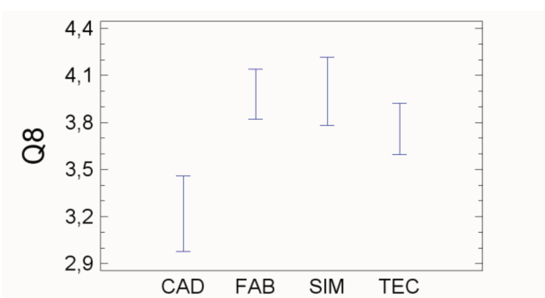

Figure 17. ANOVA (means and 95,0 Percent LSD Intervals) of Q8 results

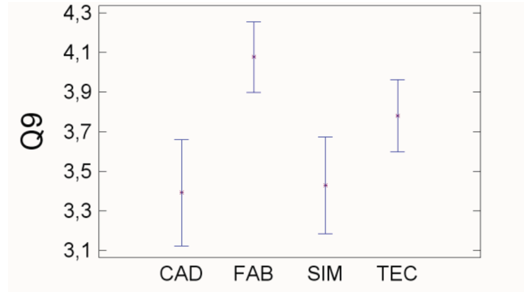

Figure 18. ANOVA (means and 95,0 Percent LSD Intervals) of Q9 results

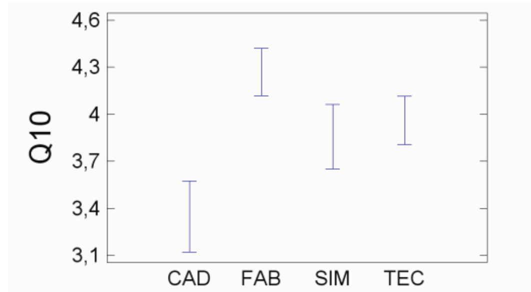

Figure 19. ANOVA (means and 95,0 Percent LSD Interv.) of Q10 results

Regarding Q11, the ability to exchange information was compared to other teams. All the means were above 3.5 points with the FAB teams giving the highest scores (Figure 20).

The FAB teams best score leadership ability (Q12). The CAD teams do not consider they have improved their leadership abilities (Figure 21).

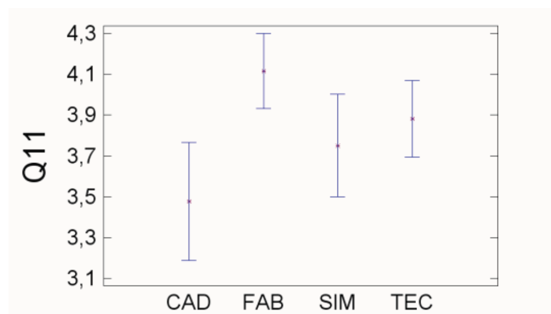

Figure 20. ANOVA (means and 95,0 Percent LSD Interv.) of Q11 results

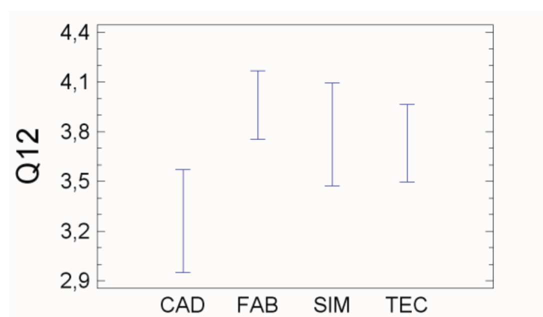

Figure 21. ANOVA (means and 95,0 Percent LSD Interv.) of Q12.results

IV. CONCLUSIONS

We have presented an experience for a large number of students involved in four topics from two different specialisations related to the Mechanical Engineering course of the Industrial Engineering degree. The use of a collaborative Web environment has made it possible for students to work in multidisciplinary teams. Students analyse, reason, discuss and decide on the solutions that their companions keep suggesting until completion of the project. This project has enabled students to approach a problem from four different points of view and mould them to the opinions of the other contributions from different subjects.

This new way of carrying out the project in this paper and its subsequent discussion has been very enthusiastically received by the student body and the teaching staff who consider it a simple alternative for promoting collaborative tasks between different groups.

The Web structure will let a major set of automated manufacturing case studies to be collected in a homogeneous format that may well become a virtual reference space in this area.

A Project-Based Learning Approach to Teaching Power Electronics

Difficulties in the application of Project-Based Learning in a subject of Switching-Mode Power Supplies

Diego G. Lamar, Pablo F. Miaja, Manuel Arias, Alberto Rodríguez, Miguel Rodríguez and Javier Sebastián
Departamento de Ingeniería Eléctrica, Electrónica, de Computadores y Sistemas, University of Oviedo
Power Supply System Group
Gijón. SPAIN
e-mail:gonzalezdiego@uniovi.es

***Abstract*— This paper presents the introduction of Problem-Based learning (PBL) in a power electronics subject at the University of Oviedo (SPAIN) by means of two practical projects: the design and construction of a Switching-Mode Power Supply (SMPS) prototype and the static study of a dc-dc converter topology. The objective of this change in the traditional methodology of the Power Electronics course is to foster the application of the knowledge acquired by students in theory classes. PBL is known to be a motivating, problem-centered teaching method that brings the real professional world closer to the student. For this reason, the lecturers considered PBL to be the most suitable methodology to obtain the desired results. The underlying methodology, task planning and assessment of these projects will be presented. Furthermore, the influence of the introduction of PBL in practical sessions versus the traditional teaching method will be discussed. Finally, the lecturers' reflections and conclusions regarding the application of PBL in this subject over the last two years will be presented.**

Keywords- Proyect-Based Learning (PBL), significant knowledge, power electronics, switching mode power supply, practical sessions.

I. Introduction

It is well known that electrical engineers are recognized for their contributions to technology and for their improvements to global conditions. This is due to the fact that their main skill is the application of mathematics and scientific knowledge to the real world. However, traditional practical classes in Electrical Engineering curricula may obviate this fact because they are seen by students as a mere requirement without any interest in the real world. Therefore, the main skill involved in electrical engineering (the transfer of acquired scientific knowledge to society) is not enhanced because students do not see the real application of the work carried out in practical sessions.

On the other hand, the overall current aim of the Bologna Process is to create a European Higher Education Area (EHEA) based on international cooperation and academic exchange that is attractive to European students and staff from other parts of the world [1]. This means that all the undergraduate and masters degrees in Europe must have the same structure. In Spain, this change in the structure of university degrees is being employed to change the traditional methodology used to teach. Taskplanning and methods must now focus on student learning. Therefore, we must use active teaching methodologies to obtain significant student learning as opposed to mechanical learning. Significant learning goes beyond just understand-and-remember and even beyond application learning. In other words, students build their own knowledge on the foundations of their prior experience and know-how [2].

Taking into account the aforementioned motivations, a team of lecturers at the University of Oviedo (Spain) introduced the Project-Based Learning (PBL) methodology in a subject called "Sistemas Electrónicos de Alimentación" (Power Supply Systems) in the academic year 2007/2008. This subject, part of the final course of the Telecommunications Engineering degree, deals with Switching-Mode Power Supply (SMPS) and power supplies systems. The objective of this experience is to foster the application of the knowledge acquired by students in theory classes. In other words, the goal is to put into practice all the concepts regarding power electronics acquired during the entire course. For this reason, the lecturers proposed two projects to students: the design and construction of a SMPS prototype (boost converter) and the static study of a dc-dc converter topology.

First, this paper presents the methodology and task planning for the two projects. Second, the results of the application of PBL over the last two years will be discussed. Then, the lecturers in the subject present the main difficulties of the application of PBL after two years of experience. Finally, proposals aimed at improving the application of PBL for the current course and the conclusions will be presented.

II. Objectives of our experience. Why PBL?

Bearing in mind the main goal and the motivation underlying this experience, the lecturers in the subject gave them the form of more specific objectives. They were contextualized within the subject's requirements and were formulated as competencies which the student must have acquired by the end of the course:

1. To provide students with the fundamental concepts of SMPS and to prepare them for advanced study and research in this area: basic topologies, power supplies systems, passive components (inductor, transformer and capacitor), semiconductors, etc.
2. To learn how to search for, classify and analyze technical information about power electronics equipment and component datasheets and to be able to identify suitable sources of information about switching power supplies..
3. To provide laboratory experience to supplement theory in switching power supplies and to promote the application of theoretical concepts.
4. To provide students with the ability to propose solutions to problems and to enhance the critical reasoning needed to choose the appropriate solution in accordance with specific criteria.
5. To enhance other transversal competencies within the Telecommunications Engineering degree course such as the ability to write technical reports properly and to develop the ability to speak in public.

Having defined the objectives of the subject, the lecturing team had to select the most suitable methodology to obtain these goals. We chose PBL due to the fact that this methodology prompts students to encounter the core concepts and principles of a discipline while managing a specific task (project), thereby enabling the application of acquired knowledge [3,4]. Furthermore, PBL goes beyond the relationship between knowledge and thinking, helping students to both "know" and "do". In fact, this methodology focuses on “doing something” and “learning on the way”. The main characteristics of PBL from the point of view of student learning can be summarized as follows:

1. PBL is student-centered and focuses on their main competencies. Students design the process for reaching a solution. Therefore, they focus the task around their main concerns and skills. In fact, the end product is a reflection of themselves. For this reason, students have no problem spending a lot of time implementing their projects.
2. PBL helps students to solve problems by themselves: self-management, project management and critical knowledge are enhanced. As they program their own work, PBL thus permits frequent feedback and consistent opportunities for students to learn from experience. Self-assessment takes place continuously during project development.
3. PBL recognizes the capacity of students to do important work and their need to be taken seriously by placing them at the core of the learning process. It engages and motivates bored or indifferent students. PBL is designed to establish a student’s commitment to the task to be done.

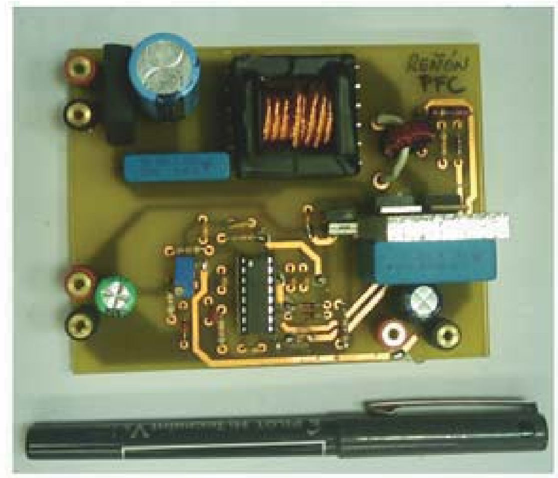

Figure 1. Switching-Mode Power Supply (SMPS) prototype made by a student.

4. PBL creates positive communication and collaborative relationships with lecturers and other students. PBL can help the lecturer to create a high-performing classroom in which the group (the lecturer plus the students) forms a powerful learning community focused on achievement, surpassing oneself and contributing to the community.
5. PBL includes the development of high-order knowledge and high-order competencies. Thus, PBL seeks significant learning.

Within a multidisciplinary educational context (i.e., Electrical Engineering, Telecommunication Engineering, etc.), PBL appears as one of the most interesting instructional strategies. In brief, the PBL strategy aims to engage students in authentic real-world tasks and open-ended projects that can increase motivation for most of them. For this reason, in recent years some authors have used PBL in their Electrical Engineering degree classes [5-7], in particular in their practical sessions [8-9].

III. METHODOLOGY APPLIED IN PRACTICAL AND PROBLEM-SOLVING SESSIONS

Two projects were introduced in the practical and problem-solving sessions of a SMPS subject forming part of the University of Oviedo Telecommunications Engineering curriculum.

A. Design and construction of a Switching-Mode Power Supply (SMPS)

An experimental prototype of a SMPS was designed and built in the practical sessions (7 sessions of two hours and 1 session of 1 hour) of the subject by each student. The assessment of this project focused on the student-learning process that becomes practical know-how. The end product (Fig. 1) was only evaluated as a part of the process. Therefore,

Figure 2. Laboratory student desk and devices to develop the practical sessions.

the application of the knowledge obtained in the theory classes is the goal of this project and the goal of the assessment.

At the beginning of the course, each student was assigned a laboratory desk with all the devices and instrumentation needed to develop the project. In the first session, students familiarized themselves with all the material. The rest of the practical sessions were divided into design sessions and building sessions. In the former, students had to design a part of the SMPS. In latter, students had to build this part. At the beginning of all these sessions, the lecturer briefly explained the concepts of the work to be done. All the lecturer's explanations have to be brief and to the point and have to drive student learning. After that, the students developed their part of the project with the lecturer acting as a mere facilitator, redirecting all the technical problems that arose during the session. At this point, the interaction of the students among themselves and with the lecturer is very fruitful because positive communication and a collaborative relationship is created. Moreover, as the sessions progressed, the lecturer raised challenging issues or questions that led students to in-depth exploration of authentic, important topics related to this part of the project. Student reflection regarding these issues was very important. All the concepts proposed at the beginning and all the questions raised during the class were carefully planned in each session. In the final session, students experimentally presented their SMPS prototype.

The lecturing team took special care with respect to the student-learning process. For this reason, tutorial classes were proposed to students when deficiencies in their knowledge appeared. Sometimes it was necessary to review and clear up concepts presented in classes.

B. Static study of a dc-dc converter topology

The second project undertaken by students was the static study of a dc-dc converter topology. The objective of this project only focused on obtaining theoretical knowledge.

The theoretical model to develop this static study was explained during theory classes with basic dc-dc converter topologies. Mid-course, a different project was proposed to each student. It is the lecturing team's belief that students have sufficient knowledge at this point to tackle a high-order problem. This project was the static study of a non-basic converter topology. In this case, the student role was authentic PBL: students were engaged problem-solvers, identifying the root problem and the conditions needed to obtain a good solution. They were also pursuing meaning and understanding, as well as becoming self-directed learners.

During the rest of the course, the student developed this static study in parallel with theory sessions in which the lecturer established similarities between the problems which had been solved during the course and the project to be developed. Yet again, a specific time for reflection was proposed by the lecturing team. For this reason, all the solved problems presented in the problem-solving classes were carefully planned after the project was launched. Finally, the project was presented as a MATLAB spreadsheet. In this project, tutorial classes were also fundamental.

IV. ASSESSMENT OF TWO PROJECTS

A. Design and construction of a Switching-Mode Power Supply (SMPS)

The assessment of this project was planned differently from a traditional one. The lecturing team wanted to assess the learning process instead of the end product: in this case, a SMPS. The lecturer responsible for the practical sessions drew up a report on each student in every practical session. Thus, continuous assessment was carried out. The lecturing team thought that this project was particularly well suited to be included in a continuous assessment scheme in order to evaluate the main competency that students have to acquire: namely, application of the knowledge acquired in theory classes. Also, students presented a report with a thorough explanation of the tasks carried out during practical sessions. An experimental presentation and verification of the prototype was also conducted with the idea of promoting oral expression and public presentation in the final session.

The practical session reports drawn up by the lecturer, the final report on the SMPS design and the experimental presentation of the prototype were used by the lecturers to assess this project. This project counted for 30% of the final mark for the subject.

B. Static study of a dc-dc converter topology

The students presented a MATLAB spreadsheet (Fig. 3) with the solved static study of the proposed topology at the end of the course. They explained their solution to the lecturers and answered their questions with the idea of assessing the design process they had implemented. In this case, the goals of this assessment were to evaluate the ability to propose solutions to problems and to enhance critical reasoning to choose the appropriate solution. The fostering of oral expression and presenting in public were additional competencies likewise assessed in the presentation and defense of this project.

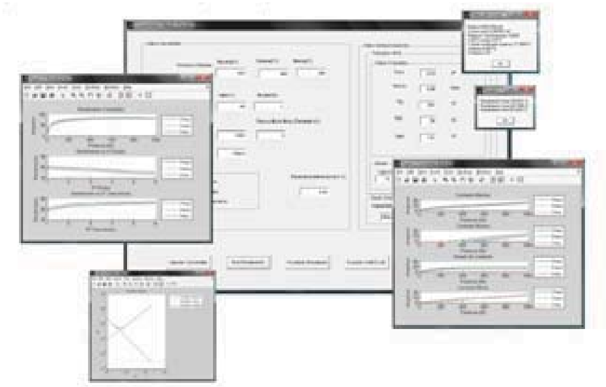

Figure 3. Example of a spreadsheat programed in MATLAB.

The project was assessed by means of a report on the presentation of the spreadsheet drawn up by the lecturer. This project counted for 20% of the final mark for the subject.

At the same time, a traditional exam was sat to complete the assessment of the subject, counting for 50% of the final mark.

V. Student Surveys

At the end of the course, the lecturing team conducted a survey to ask students about the PBL methodology introduced in this subject. The results of this survey are shown in Fig.4. The main topics in this survey focused on the development of the main student competencies that the lecturing team wished to improve via this experience, the improvement of other skills and a general assessment of the subject.

As can be seen, students positively rate the improvement in their ability to solve problems, to apply the know-how acquired in theory classes and in their ability to make decisions. In fact, the opinion of the students can be summarized in a student comment that was common in all surveys:*" I enjoyed working in a power electronics laboratory developing the design of a converter very much. It is very interesting to solve real problems and to face challenging activities like this project"*

Other skills that students improved were reflected in the survey as positive issues: namely, the ability to search for and to assimilate information on their own, oral expression and writing technical reports.

Finally, the experience of this subject was also positively rated. As can be seen in Fig. 4, the students appreciated the planning time and the assessment of the subject. They were also very satisfied with the work carried out in the two projects forming part of the subject.

VI. Lecturers' reflections after two years. The dificulties of PBL aplication.

It seems logical that the assessment of this experience (the application of PBL) does not depend solely on student opinion. For this reason, the lecturing team established periodic interviews and meetings with students throughout the course. The results of this experience were thus deduced taking into

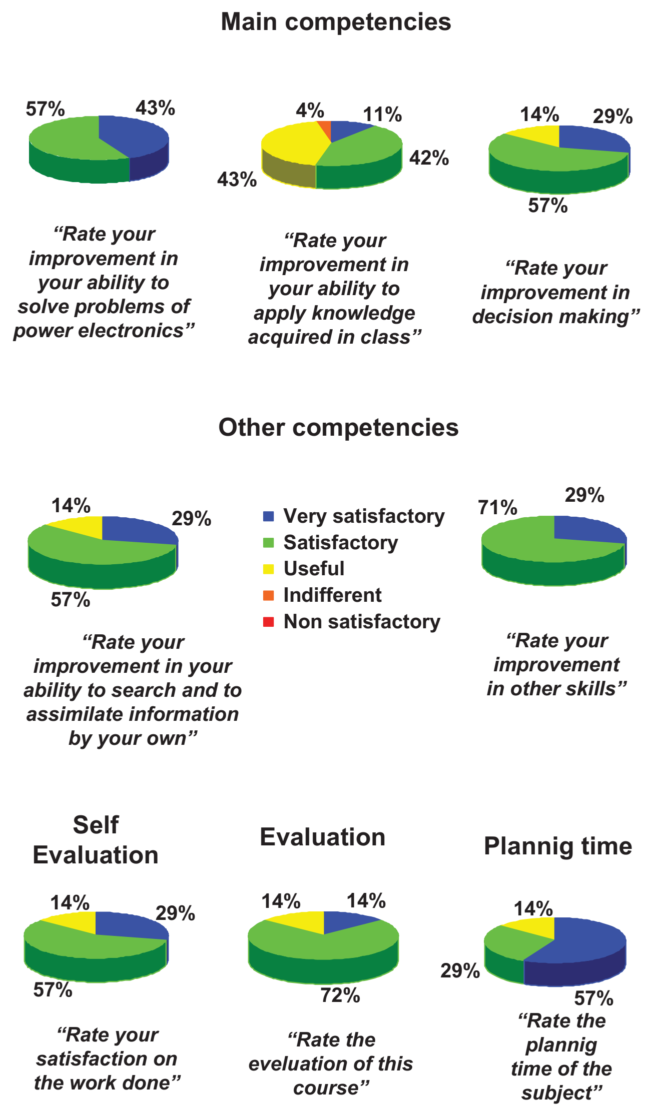

Figure 4. Student survey scores

account the surveys, meetings, interviews and final marks obtained in the subject. These results made us reflect on the application of the PBL as a new learning methodology. We conclude that the application of the PBL is neither straightforward nor easy. Including PBL in a subject curriculum presents a number of difficulties. We summarize our main reflections in what follows:

A. Student exam results were worse than their projects. Are we evaluating the learning process appropriately?

The results of both projects were very satisfactory from the technical point of view. All the students designed and built the SMPS prototype and obtained a certain benefit from the process, while the proposed static study was correctly developed. However, the results of the theory exam were worse

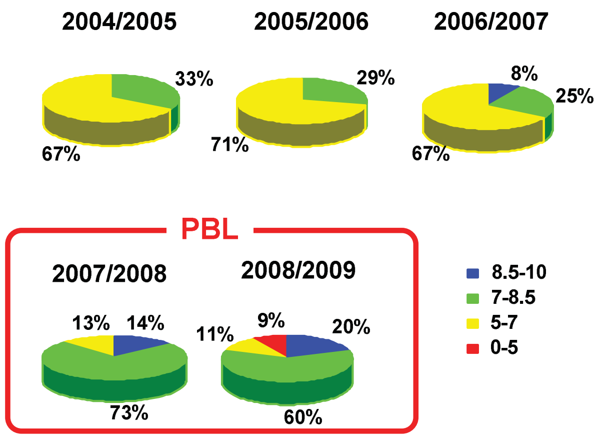

Figure 5. Marks obtained in the subject.

than expected. There were some mistakes in basic concepts developed in theory classes. We found that students apply acquired knowledge in practical projects as a "small recipes" in order to solve specific problems in project execution. Furthermore, they use a "blind" trial-and-error system to tackle the problems that arise in the projects. In both cases, although students solve their difficulties during the execution of the project, they do not acquire an overall view of the subject and significant learning is not achieved. These results lead us to think that we did not suitably assess the student learning process. We made a mistake: we assessed the results of both projects (the SMPS prototype and the MATLAB spreadsheet) but did not assess the student learning process. This fact is reflected in the final marks obtained in the subject. The marks for the last two years are better than the previous years when PBL had not been introduced in the subject. Figure 5 shows the marks obtained by the students in the last five years. Students fail if they get less than 5 marks out of 10. These marks are grouped in four intervals, which represent the qualification that is given to the student. As can be seen in Fig. 5, although most students passed the subject, the percentage of those who obtained the highest marks has increased significantly with the introduction of PBL in the subject. These results are due to the fact that the qualifications of the projects of the last two years are better than those of the practical sessions in the subject in the years 2004/2005, 2005/2006 and 2006/2007. However, the exam marks are equal to or worse than non PBL courses.

In order to improve the assessment of the student-learning process during the practical sessions, we intend to include rubrics in the present course (2009/2010). These rubrics will replace the report drawn up by the lecturer on each student in every practical session. These rubrics have been designed to carefully assess the main competencies to enhance: to promote the application of theoretical concepts and to provide the student with an ability to propose solutions to problems and to enhance critical reasoning. Also, this assessment methodology (the rubrics) will be applied to qualify the final report of the SMPS design, the MATLAB spreadsheet, the experimental presentation of the SMPS prototype and the defense of the static study. In this case, we wish to assess other competencies: the ability to write technical reports properly and the improvement in speaking in public.

B. *Is the exam the greatest enemy of PBL?*

Traditionally, PBL plus exam is a bad combination in a traditional course where the exam possesses the greatest weighting with respect to the final mark [10]. To implant PBL in a course requires a new perspective of the role of the exam.

According to our experience, the exams done by students are a continuous source of frustration to lecturers because the marks obtained by former are worse than the expectations of the latter. This is due to the fact that student projects, developed during the course, are generally very good. This fact may suggest that the subject should be only assessed by means of projects. From our point of view, however, all the efforts made during the course cannot centered around PBL. In fact, we only apply PBL in our subject to enhance a number of student competencies principally the application of technical and scientific knowledge acquired in theory classes. For this reason, we use theory classes to provide students with a broad view of the main concepts in the subject and to foster in them prior reflection before practical sessions. Therefore, we are convinced that theory classes are fundamental and we wish to highlight this conviction. As a consequence of this, the exam is necessary. Perhaps we have to rethink the role of the exam, bringing it more in line with the projects developed in the subject or planning the projects more in accordance with the exam. Another possibility is to plan an exam that ensures the basic concepts of the subject that students must have acquired.

C. *We all have to accept that mistakes are necessary to learn*

Student motivation was not constant throughout the two projects. The lecturing team expected student motivation and dedication to be very high when tackling real projects. This appreciation was however mistaken. The students were highly motivated during the first sessions. However, they have to master high-order reasoning as projects of this kind evolve. At this point, the students were found wanting in terms of their knowledge and the application of basic concepts acquired in theory classes. As a consequence of this, student motivation declined. Moreover, lecturer despair likewise increased. This situation (drop in motivation) was repeated during the project.

After two years of applying PBL in our subject, we must bear in mind that this is a normal situation in PBL and does not constitute a drawback. Lecturers and students have to accept that errors are necessary in order to learn and to apply acquired knowledge. It is very important for lecturers to make students aware of this fact in order to motivate them when problems arise. The motivation of both students and lecturers as the project evolves is like a "roller coaster". In some situations, the passengers (lecturers and students) might wish to get off the roller coaster. However, we have to keep up our motivation and that of our students in order to achieve the ultimate goal of PBL: significant learning.

D. The time spent on PBL. A real change for lecturers and students

First, lecturers need to be aware of the dedication that PBL requires. Monitoring, driving and implementing the work undertaken by students require time. The time spent on these activities is greater than the time spent on traditional learning methods. This is a new scenario that lecturers have to assume.

On the other hand, students have to plan their time during project implementation. It is normal for students to encounter problems in managing their own time, as they traditionally work on tasks planned by the lecturer. In each practical session, students only have to solve one planned problem. If students do not complete their tasks then they can redo this practical session at the end of the course because each practical session is self-contained. The problem to solve now is the project. The project presents a number of problems during its implementation and now the problems that arise presented are different for each student. The presented problems depend on the strategy used by the student to tackle the project. This situation seriously upsets student planning. Common student comments in practical sessions are: "it is too much work to develop in practical sessions", "we have to work a lot before practical sessions", etc. However, all students carried out the work planned by the lecturer in practical and problem-solving sessions and presented their assignments on time. Furthermore, surveys revealed that the time spent by students to prepare and develop both projects was less than the time scheduled by lecturers. These reflections show that students are not comfortable managing their own time.

E. The application of PBL requires aninvestment in resources and facilities

If a new active methodology is applied instead of traditional methods, then the facilities to develop this new methodology also have to change. Therefore a inversion in this methodologies has to be done [11].

The lecturing team is aware that this experience can be carried out because the number of students enrolled in our subject is low. "Sistemas Electrónicos de Alimentación" is an optional subject in the 5th year of the Telecommunications Engineering degree with an average of 12 students per course. For this reason, practical sessions of 6 students can be planned in our research laboratories to implement the SMPS project. However, this current year we have 30 students enrolled in our subject and so had to equip a new laboratory to develop the SMPS project. In this case, practical sessions of 10 students have been planned with two lecturers supervising the group in each session. As can be appreciated, PBL requires an investment in resources and facilities.

VII. CONCLUSIONS

Our experience in the application of PBL in the subject: "Sistemas Electrónicos de Alimentación" has been extremely positive for us and for students. However, we conclude that the introduction of PBL in our subject is upsetting for both parties. It implies difficulties which we are still solving after two years of applying PBL: facilities, assessment of the learning process, etc. We hope that the results obtained each year serve to improve the application of this methodology.

On the other hand, this methodology is appropriate to achieve the objectives proposed at the beginning of this experience. Students are motivated with this new scenario because they tackle and solve real problems in their projects. We have to benefit from this new atmosphere to guide students to significant learning. It is a great opportunity!

***Abstract*—There are many learning management systems all over the world. But these conventional E-learning platforms aim at students who are used to work on their own. Our students are young (19 years old – 22 years old), and in their first year at the university. Following extensive interviews with our students, we have designed GE3D, an E-learning platform, according to their expectations and our criteria. In this paper, we describe the students' demands, resulting from the interviews. Then, we present our virtual campus. Even if our platform uses some elements coming from the 3D games world, it is always a pedagogical tool. Using this technology, we developed a 3D representation of the real world. We also propose a process of a lecture on the Programmable Logic Controllers (PLC's) in this new universe. GE3D is a multi-users tool, with a synchronous technology, an intuitive interface for end-users and an embedded Intelligent Tutoring System to support learners.**

Keywords-component: virtual campus, Technology-Enhanced Learning, learning systems platforms, engineering education, Intelligent Tutoring System, Multi Agent System .

I. INTRODUCTION

There are so many learning management systems (LMS) all over the world, that to choose one is difficult. Among them, Moodle is the one mostly used [1]. Five years ago, our university decided to implement it for all syllabi. Until now, it is a statement of fact that this tool is at best underused or at worst unused. There are many reasons explaining this lack of interest. The most important are the learner's loneliness, the lack of ergonomics and the way it is used: like a bookcase or a set of compartments for documents. This platform must be an exchange and communication area, supporting knowledge acquisition by links established between end-users, belonging to the same interest community. The subject taught and the students' profiles are decisive factors in the choice of the shape and functionalities given by the LMS. In order to explore the expectations of the students, their way of life, their uses of Internet and their computer equipment, an assessment of their needs was conducted. Following the results obtained and according to many studies on the value added by three dimensional environments (3D) in e-learning [2-6], we have designed GE3D, a virtual campus with the SCOL technology [7].

Finally, we will focus on the lack of the individual tracking and the communication with the learner, which generate a risk of disinterest and eventually desertion. For Carr [8], the desertion rate is over 10 to 20% when compared to face-to-face classroom learning. How can we prevent this risk in the knowledge acquisition process? The intelligent tutoring system (ITS) embedded in GE3D, based on a multi-agent system (MAS), provides solutions. It allows a more accurate interactivity, keeping the learner in touch.

II. SURVEYING THE NEEDS OF THE STUDENTS

The students were surveyed for their expectations and criteria for a learning system platform [9]. They are young undergraduates (19 years old – 22 years old). There are more boys than girls preparing this technological diploma (Department of Electrical Power and Industrial Computing). 220 students were surveyed for the report.

The students are playing 3D games (90%), by network (55%). The majority of students have personal access to internet (68%), with a high speed connection (50%). This connection is often used: every day (37%), from one to several times per week (33%). The time spent for each connection is: 1 hour (26%), from 1 to 3 hours (29%), and more than 3 hours (17%). They use the connection at first for entertainment then for communication and finally for work. They communicate with an instant messenger software (e.g. yahoo messenger) (62%) and by e-mail (74%).

After the general questions, we asked them for the qualities of a "good web site". The first quality is quickness, followed by the content, and then the clarity. A lot of our students (69%) know the web site of the university, but a large number (72%) does not know the Moodle platform and more do not use it (85%). For our students, a LMS must be in addition to the traditional courses (85%), instead of a unique and complete solution (9%). For knowledge acquisitions, they consider facing the teacher as essential (62%). For them, IT isolates people rather than getting them closer, and improves communications rather than deteriorating them. In their expectations of an ideal numerical campus, our students want first to get their time schedule, then complements of the traditional courses, then more exercises and the old exams with the solutions. They want a "hot-line" with the teachers and a communication area with them, a simple but quick web site, and finally they want to access simultaneously with other students on the site.

Following this survey, a first 3D virtual campus prototype was presented to the students, with the topic concerning Programmable Logic Controllers (PLC's). We can summarize the results of the second interview by the following:

- They want a serious 3D environment for classrooms, without anything likely to disturb them.

- For the practical area, they want a room with an industrial look. They want to see the PLC's with an operative part. They want to interact with the system by pressing buttons and observing what happens. In this area, they want to realize something by themselves.

- They do not want a sophisticated avatar for their own representation in the 3D. They just want a simple shape textured with their photo on it. This way, they can recognize who is here at the same time. They think that a human shaped avatar does not give additional information in this virtual world.

- The audio component is essential, but reserved for the teacher. During a session, students put questions by text in the chat module and the professor answers by audio to all the students.

Now, taking into account all the students' recommendations, we will present the final version of a virtual campus for students.

III. GE3D: A SOLUTION

The choice of a virtual campus rather than a traditional LMS (e.g. Moodle) is obvious for the students in the Department of Electrical Power and Industrial Computing. They are experts in playing 3D games on network. According to their expectations and our criteria, we have designed GE3D, with the SCOL technology. The choice of that technology was driven by the specifications: Web3D technology, open source to allow our own developments, platform independent, with client-server architecture.

A. *Description of the 3D world*

In the first area (Fig. 1), we can find in the 3D part a mail box to send e-mail, a board for the time tables, a board for the assessment marks, a board for the system help, a clock to be on time, a door to access other areas.

Figure 1. Entrance of the virtual campus

Figure 2. Amphitheatre with an avatar

In the lower part of the window, we can find on the left the numbers and the names of the connected people, several functions for login, for choosing a representative photo for the avatar, for a private chat between two users and a general map of the site. Under the blue scrolling banner announcing the last news, we can find a public chat available for all the users.

Fig. 2 shows the amphitheatre where synchronous presentations can be done. On the right is a large screen on which videos, slides or drawings can be sent by the teacher. Learners take place on the seats in front of the screen. Only the teacher can use the audio line. In the lower part of the window, we can see the public chat where students ask questions to the teacher.

The next room (Fig. 3) shows the industrial part of the site. Here is a SIEMENS PLC, the same used by our students in our department. A simple actuator is presented here by a cylinder and its Sequential Function Chart (SFC) programme. This 3D environment allows the users to undertake activities in a synchronous way. For example, when one student activates the SFC, the rod of the cylinder moves according to its evolution cycle. At the same time, all the connected users can see synchronously the cylinder movements and the SFC evolutions. Other simple exercises are available in the same room. If a student can complete with success all the exercises, then he can access videos of five more sophisticated industrial processes made with a commercial software [10-11]. In addition to the videos, the student gets the specifications of each industrial process. When they have prepared their own programs of the process, they come back to reality in the real PLC's room where they can test them. As always, if they meet some difficulties, they can get help from peers, teacher or intelligent tutoring system (ITS) through the chat.

Having described the resources available in GE3D, we will now explain how to fit them in a pedagogical scenario.

B. *Pedagogical scenario*

A typical structure of a course on PLC's could be the following:

Figure 3. Industrial area in GE3D

1. An appointment is given to all the students at the amphitheatre.
2. Before entering, the students download lecture notes with gaps they have to fill during the lecture.
3. During the presentation, the lecturer can use the screen to upload notes or slides. He can also use a white board and a microphone for the audio. Meanwhile the students complete the lecture notes and put questions through public chat if needed. The teacher answers the questions by audio for all the students.
4. After the lecture, the students answer an online multiple choice question test. In case of success, they can access the industrial part of GE3D. If they fail the test, they replay the recorded lecture.
5. In the Industrial room, the tutor demonstrates how to use the equipments and explains what he is expecting from the learners. He leaves the students working by themselves but remains available to answer the questions.
6. When the students complete all the given exercises, they can download specifications and videos of a complex industrial process simulator.
7. After programming the process the students can join the teacher to validate their program on real PLC's.

The interviews further revealed that although students can collaborate with each other in GE3D they demand more contact and communication with teachers. In this regard, with the aim of helping tutors and students, we have developed an intelligent tutoring system (ITS) in GE3D.

C. Intelligent Tutoring System to prevent students from giving up

The three main parts of the Intelligent Tutoring System (ITS) are (Fig. 4):

- Four Human-Computer Interfaces (HCI) in blue.

- Three knowledge parts in green.

- A four layers hierarchic multiagent system (MAS) in red, developed with Jade [12].

The MAS inside this ITS is based on previous works with the hypothesis that some parts of the MAS are generic; i.e.

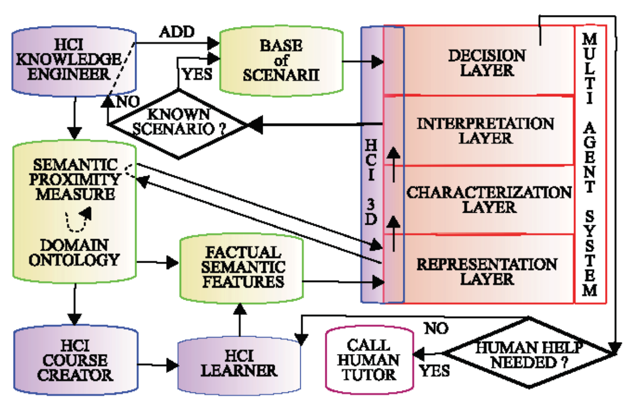

Figure 4. Architecture of the Intelligent Tutoring System

knowing the domain ontology and therefore the structure of factual semantic features (FSF), which are domain specific, the three lower layers of the MAS (representation, characterization and interpretation) are independent of the domain. Previous works were applied to crisis management in an oil plant [13] and emergency logistics [14] with this MAS.

The representation layer receives data from the learner as FSFs. Each agent of the representation layer (factual agent: FA) keeps this atomic datum. Then the given FA computes internal indicators. Those indicators reflect the importance of the FSF in the whole representation. At any time, all FAs represent a snapshot of the situation. From a dynamic point of view, variations of these internal indicators represent the evolution of the situation. The ability to take into account this dynamic point of view is the reason why we choose MAS paradigm [15].

The structures of FSFs are extracted from the domain ontology [16]. The knowledge engineer defines a semantic proximity measure used to compare FSFs included into FAs. Related FAs according to this measure belong to the same semantic group.

The characterization layer clusters the FAs of the representation layer. This partition is a synthetic description of the current situation.

Using this synthetic description, the interpretation layer looks for similar scenarios in the database. If not recorded, the knowledge engineer can add this situation. Depending on the scenario, decision layer chooses either calling a human tutor or a non-human tutor or adapting the learner's course.

IV. CONCLUSION

In 2010, the way our students use IT is not the same compared with the 90's. Addicted to their mobiles they send SMSs all day long. Competing for growing their Facebook relationship and experts in playing video games, they do prefer to stay at home facing their laptop instead of experimenting the real world with its real residents.

Building new systems for distance learning, we have to take into account these behavioral evolutions. Thus, we have designed GE3D. In addition to the above reasons we can notice that real actuators are too expensive. Furthermore, we cannot imagine beginners in PLC's training with a real complex industrial process. These good reasons justify our stand to use virtual equipments in GE3D world.

Unlike video games, where the efficiency of 3D renderings and physics engines counterbalance the weakness of the scenarios, the content must remain more important than the packaging. The pedagogical scenario described in this paper and implemented in GE3D can be easily modified. Its architecture can combine lectures, learning through projects (i.e. collaborative learning), learning with and from the peers (i.e. cooperative learning) and learning by problem solving.

Students prefer to learn by doing, on their own initiative and without being under the teacher's pressure. Nevertheless, they demand immediate help and attention from a tutor. The ITS implemented in GE3D is the facilitator for students and tutors to accomplish this.

Our next goal is to expand GE3D into a clustered Web server to increase the number of connected people and to raise the reactivity of the system.

Abstract—**The transportation of a campus classroom and/or laboratory into a three dimensional virtual representation has changed remote learning, specially in engineering education. Our first collaborative virtual environment, a proof of concept, provides full functionality of one physics experiment, though there are still some performance issues to be resolved.**

The next step for integrating TEALsim and iLabs in Sun's Project Wonderland is porting our system from Wonderland's version 0.4 to 0.5. Our goal is a system redesign in order to support adding flexibility to multiple physics simulations. The performance improvements in Wonderland 0.5 will allow a large number of avatars in our future scenario, where they will be able to run even more physics experiments, through a new 3D user interface.

Keywords-collaborative immersive environment; virtual worlds; Project Wonderland; iLabs; TEALsim; physics experiments, remote labs, visualization.

I. INTRODUCTION

In the past few years, especially due to the increasing availability of faster and robust hardware and software, 3D environments have become common technology. Virtual laboratories, scientific visualizations, and some collaborative work approaches are just some of the successful fields of 3D graphics applications.

One essential term is Virtual Environment (VE), which is a computer generated spatial environment, where the stimulation of diverse human senses gives the user a feeling of being immersed. Immersion means how deep the user is emotionally involved within a specific virtual environment [1].

Nowadays, a great research challenge for educational technology professionals is to build technology that not just supports the learning process, but also connect students and educators in a way so they can easily cooperate, even when both parties are geographically spread.

Our first collaborative virtual environment provides full functionality of one physics experiment. This environment results from the integration of internet-accessible physics experiments (iLabs) combined with the TEALsim 3D simulation toolkit in Project Wonderland [2]. Students and educators, represented as avatars, within this environment can remotely control experiment equipment, visualize physics phenomena generated by the experiment and discuss results. This environment was developed following the Technology Enabled Active Learning (TEAL) classroom idea to support social interactions, encourage student's active learning and interest, in an environment that fosters conceptual change [3].

This study explores the process of conversion of the TEALsim simulation package to the rendering engine jMonkeyEngine (JME), which is the graphics engine used in Project Wonderland version 0.5. Additionally, we have built a Wonderland cell class that can dynamically load TEAL simulations into Wonderland by the end of the research project. This will provide a collaborative environment similar to the current 0.4 version, but using the new graphics engine.

Furthermore, we implemented an automatic generation of the simulation's controls in the Wonderland environment either as buttons, sliders and other control elements within the 3D space or as elements in the Heads Up Display. These controls will provide the standard Java event handling model.

Therefore avatars have the ability to directly interact with TEALsim elements, including moving elements and activating sensors. Changes in the environment would be updated in real-time.

Finally, based on the latest research, this paper outlines the future research directions and challenges to overcome.

This research has been partially supported by the Austrian Marshall Plan Foundation.

II. Related Projects

A. iLabs

An iLab stands for an internet-accessible experiment that can be reachable remotely at any time over the internet. Compared to conventional laboratories, iLabs are available 24-7 and are easily shared. Since they provide access to unique remote resources, they are less expensive and complex than conventional labs. Users can access these online laboratories from around the world through a single standard administrative interface. In engineering education, iLabs enrich the scope of experiments students have available to them in the course of their academic careers [4].

B. TEALSim

TEALSim, the TEAL simulation system is designed as a framework for authoring, presenting and controlling simulations in a variety of domains. It was developed by the Technology Enabled Active Learning (TEAL) Project at Massachusetts Institute of Technology (MIT) [3]. Among others, the objectives of this project are to increase student's conceptual and analytical understanding of the nature and dynamics of electromagnetic fields and phenomena, and also foster student's visualization skills.

Figure 2 illustrates an example of how TEALSim is very useful in electromagnetism helping students to visualize and process phenomena. During the Force on a Dipole experiment, TEALsim enables students to see the invisible magnetic field lines, which of course are not visible in real settings. This visualization behaves according to changes in simulation input values made by students, giving them a better understanding of electromagnetic fields. Such visualizations allow students to make abstract ideas concrete. [3]

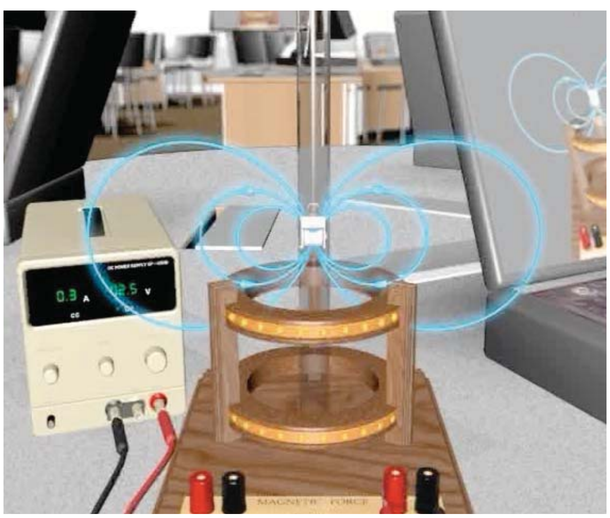

Figure 2. The *TeachSpin*™ apparatus from the Magnetostatics Session.

C. Project Wonderland

Project Wonderland is a toolkit for building 3D virtual worlds, which has been developed by Sun Microsystems Laboratories [5]. Based fully on 100% open source Java technology, Wonderland is extensible so developers and graphic artists can extend its functionalities to create new collaborative 3D virtual worlds. Wonderland also supports a high level of communication via highly immersive audio and enables desktop application sharing, among other features.

In the new redesigned version 0.5 of Wonderland, JMonkey Engine is one of the supported rendering engines. In the Wonderland project, jME helps us to specify 3D objects in a scene [5]. This concerns an object's size, appearance and how they are related to each other. Not just computer graphics operations such as lighting and texture can be done through jME, but also complex techniques like particle systems.

MTGame is a Multi-Threaded Game engine build on top of the jMonkey Engine scene graph [6]. Its main purpose is 3D graphics content processing and rendering. MTGame extends the capabilities of jME offering a fully parallel processing model and a fully featured rendering system, which supports all major rendering techniques. Besides that, three plug-able systems are included: picking and collision, physics and an input system for some input devices. So basically, MTGame is a library for scene graph management and concurrency management.

Animations and other changes, which happen in wonderland scene graph over time, are managed by MTGame. Developers can use MTGame to animate various 3D Object attributes like position, color and lighting. Further information about MTGame will be explained in the next session.

Besides the gain in performance, another important feature of version 0.5 is the possibility of embedded Swing components for user interface development in world. By creating a swing-based interface, we can interact directly with the experiment instead of interacting with a LabVIEW application through VNC viewer.

D. jMonkeyEngine

Due to the lack of graphics engines written in Java, the open source jME was built. jME is an Application Programming Interface (API) dedicated for high performance scene graph based graphics [7]. The feature list of jME is extensive and includes embedded integration of Java Applets and SWT (Standard Widget Toolkit). jME Desktop System is responsible for the rendering of Swing components in jME scenes.

III. Collaborative Virtual Learning Environment

A. Overview

In CLVE students are represented as avatars, through them users communicate with each other, cooperate with other students or educators to solve common physics problems and experience physics experiments. This Virtual Environment extends the real studio physics classroom in many ways in order to support students understanding of physics concepts.

Students are able to interact with a remote experiment through a 2D LabVIEW front panel, for example changing experiment input parameters such as amplitude or frequency. This panel has been presented via the graphical sharing desktop system Virtual Networking Computer (VNC) until now since the LabVIEW application is running remotely in the computer wired to the experiment.

Synchronously, a 3D visualization of the simulation is generated from the input and output values in the experiment equipment. For instance, in the case of the Force on a Dipole Experiment, shown in Figure 1, students are able to compare the generated magnetic field lines with the real physical experiment, which is streamed in real time through a video camera. The network camera is provided by the iLab ServiceBroker.

Due to the lack of support of swing components in the 0.4 Version of Wonderland, a button was developed to start the virtual representation of the experiment and synchronize with the real hardware.

Furthermore, a whiteboard was added to the environment to use for post experiment discussion results. Textchat functionality is also provided. These tools give students the ability to interact with each other during the experiment and discuss results of their work, as it is in a real face-to-face collaboration.

B. TEALsim Architecture

TEALSim was designed according to the principles of the classic design pattern Model-View-Controller [8]. Many classes contribute to the functioning of each of these modules. While the simulation engine represents the Model, the user interface represents the Control. The viewer and renderer constitute the View. A simulation consists of the combination of these three modules with the collection of simulated objects and user interface components specific to the simulation. All simulation elements are JavaBeans and implement the TElement interface. Interfaces provide the basic functionality of the component, leaving the customization for its implementation.

A typical basic Electromagnetic simulation will include a simulation engine, a viewer, which by default is a Java3D viewer, UI elements and other objects being simulated. TSimulation interface describes the requirements for a complete simulation and brings all these components together.

Like any other object in the world, a simulation must implement the TElement interface, which describes the most basic functionality for objects in the world. Graphical elements, control objects and physical objects such as point charge implement this interface. A TSimulation class is responsible for the entire logic in a particular simulation. All the components in the simulation are managed by instances of a class that implements the TFramework interface. SimPlayer, is an implementation of TFramework, that loads a TSimulation object and presents it to the user either as a 3D desktop Java application or applet.

The third basic component is the SimEngine, the simulation engine. Basically, SimEngine performs three actions in a loop. First, it computes variables for the current time step, then updates simulation objects to reflect these new values. Completing the loop SimEngine informs the renderer of any visual changes to the simulation. This corresponds to the main application thread for a TEALsim simulation.

The Viewer represents the rendering engine, displaying 3D simulation elements on the screen. It also manages the user interaction with the rendered images. The interface TViewer defines rendering properties and tasks including camera controls, visual effects and also maintains a list of rendered elements. Each of the rendered elements is responsible for updating the portion of the scenegraph that represents its current position and state. These were considerations for the major architecture components in TEALSim.

C. Incorporating jME in TEALSim

Basically, three TEAL packages should be redesigned: scene graph, render, and geometries.

As Java3D API, jME is also a scene-graph based rendering engine. A scene graph organizes the data in a tree structure, normally spatially. In the case of the jME, scene graph nodes can be called either Nodes or Geometries, depending if we are considering an internal node or a leaf node.

Node's relevant information, like transforms have to be considered during the integration, because Java3D uses different utilities classes. Java3D fundamental types are slightly different than jME ones. These are Matrix,Vector and Quaternion.

Vector3f, Vector2f, Quaternions, Matrices are in jME float because LWJGL only supports float. That is, our double precision values handle the application side and are converted to float at the scene graph level.

Besides other minor changes, we start to substitute Java3D native geometries through jME fundamental shapes: box, cone, cylinder, sphere, tourus.

A factory method is used to facilitate the rendering engine migration. This method just instantiates an object. They are useful here because we can leave the concrete implementation of the conversion to the factory method. In the simulation we didn't know whether to create Java3D or jME instances. Instead we can use "render" and leave the instantiation of implementation to a factory method.

D. MTGame

Although jME is a robust scene graph based rendering engine, it does not provide everything necessary for rendering 3D real time simulation in Wonderland.

MT Game is a full performance Multi-Threaded Game engine, which fulfills this need and also takes advantage of new multicore client systems. In the API hierarchy, MT Game sits on top of the jMonkey engine scene graph and the Wonderland 3D client sits on the top of MT Game.

It extends the JME features by providing a fully parallel processing model and its rendering system supports all major rendering techniques. Besides that, it offers plugable systems including picking and collision resolution and an input system for processing not just mouse and keyboard events but also other devices. In addition, we use MT Game collada model loader to import our models into Wonderland.

MT Game is designed following a component model; this enables us to dynamically add new features to new models with almost no programmer intervention. All data will get into the system through a component. In this model our base object is called the Entity object, which is simply a container object for components that are responsible for the object visual and behavior. These components are created and managed by Managers. The Worldmanager object provides the access to all four Managers in the system: Render Manger, Input Manager, CollisionManager, and Physics.

E. User Interfrace Considerations

As relevant as the graphic engine are the interface controls. Several studies have shown that not well-planned navigation, complex user action models and annoying conclusions normally slow performance in the real world in the same manner that a 3D interface does [9].

This is the reason why we redesign the environment to integrate TEAL in Wonderland. Figure 3 shows the top view of our new environment. We always keep in mind to give the user in the virtual world fast situation awareness through effective overview of the simulation and we are always engaged to provide a meaningful feedback for user actions.

The controversy over 3D versus 2D interfaces is also present in Virtual Worlds. In scientific visualization we consider 3D as necessary to the number of tasks involving continuous variables, surfaces and volumes. However for other applications, a better strategy would be to explore variable relationships in two coordinated diagrams to discover trends, outliers or gaps.

Usability testing is more than essential for successful user interface design. So, for the development of a new prototype, which will integrate all the simulations from the TEAL project, we considered findings of our latest evaluation of the proof-of-concept [10]. In this study, we could compare how effective it is to be immersed in a 3D environment for educational purposes in traditional settings, specially related to understanding physics concepts.

Figure 3. The redesigned Collaborative Virtual Learning Environment in Wonderland integrated with TEAL Simulations

We start by grouping some high level objects together. 3D Simulation visualization, the interface controls and the camera were placed next to each other to provide the students an effective overview of the situation. This organization allows students a rapid visual search of any item. We have noticed that by doing so, students could accomplish their tasks with a reduced numbers of movements and clicks, thus reducing navigation complexity. Figure 4 illustrates this organization.

By the time of the development we were not sure about the implications of implementing either 2D HUD (Heads-up Display) or 3D interfaces in Wonderland cells. On one hand, a 2D version could boost performance and remove clutter to the plan view display. On the other hand, 3DUI can look similar to real world objects leading to a highly immersive environment. Our buttons can appear raised or depressed. Students normally enjoy these interfaces, according to the students preferences documented during the evaluation. In the cognitive domain we believe that students would easily recognize and memorize these objects because they improve spatial memory use [11].

Simulation elements in TEAL can communicate with any other element in the world since all objects must implement TElement interface. Its functionality includes support of Routes and ProperyChangeEvents. In such a manner, simulation objects can communicate with UI components. A property of a simulation object can be manipulated if we connect a UI element such as a slider. In our simulations, the Wonderland swing provided API is wired to the TEAL simulation objects.

Project Wonderland HUD consists of 2D windows, which appear above the 3D scene and they are not shared with other in-world users [5]. They can be either visible or iconified. We developed customs HUDComponents (HUDButtons) using the Java(™) Swing GUI toolkit to control and change some parameters of the simulation. To display the HUD component the user should select the simulation check box menu item. Since the Wonderland client core itself uses Swing to implement HUD, both are local GUI only and not shared among the users.

Parallel to this implementation, we use the Wonderland API to create 3D objects and make them react to user input events. This interface can be manipulated by multiple Wonderland users, instead of HUD, which can only be presented to one user. For the Force on a Dipole we developed a set of buttons to control the amplitude and frequency parameters and to turn on and off the simulation and the coil on the top corner. The great advantage of having 3D interfaces is that these buttons are shared among the other Wonderland clients. By organizing all the buttons next to the experiment, we avoid the unnecessary visual clutter caused by the larger VNC panel.

To define how big the 3D buttons are and how they look, we use the jME API. For the dynamic behavior of the 3D objects, such as the button animations we use MT Game processor objects. In order to display 3D interfaces we create a RenderComponent. Otherwise nothing could be displayed. Buttons can only react to user input when they are "pickable".

To make them pickable we need to attach to their nodes a collision component. Every time users press the button, the simulation opens a data socket to the lab view application. The TEALsim simulation engine receives the data through the socket channel and sends it back to update simulation objects to reflect these new values. As we mentioned earlier also part of the simulation engine rule is to inform the viewers rendering engine if there is any visual change necessary to be made. Having this 3D interface near the visualization minimizes the number of navigation steps for students to accomplish their

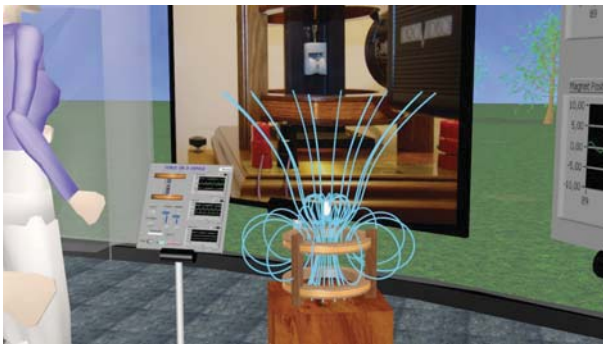

Figure 4. The redesigned Force on a Dipole Experiment in Wonderland

tasks in this environment. This also makes the environment more game-like, being dynamic and enjoyable for students and educators.

F. TEALSim & Wonderland Integration

The integration of TEALsim with Wonderland will not significantly change the process of creating simulations, but will provide Wonderland modules and cells that implement the TEAL framework. These modules will provide simulation engines that run within the Wonderland environment, render engines that execute in the Wonderland client, and manage the communication between the server and clients. In Wonderland a module is similar to a plug-in, just by including the TEALsim module and specifying the top level Java simulation class, it will be in your world.

As we mentioned, the TEALSim rendering engine is implemented as a Java3D based Viewer, which also handles the explicit rendering of the scene. Since Project Wonderland in its version 0.5 uses jME as its main rendering engine, we considered also a redesign of the TealSim 3D viewer. For many reasons, the viewer is tightly coupled to the SimEngine. Every time a simulation object has changed, the simulation engine has to inform the Viewer. Additionally, each of these elements has an associate visual representation, now as jME geometry. In the other way, when the user manipulates a visual object in the viewer, this should report back to the simulation.

IV. CURRENT STATUS AND FUTURE WORK

We plan to finish the TEALSim integration into Wonderland at the end of the Summer 2010. A stable version of this module should be running by April 2010. Depending on time and the level of integration of the game engine at this time, we will start to experiment with the NPC avatars or semi-autonomous tutors, making them intelligently react according to data stream.

Additionally, we are involved in the development of 3D interactive games, where students should be able to understand how magnetic forces and fields behave in nature.

V. CONCLUSION

This research investigates the learning benefit for students and educators by using avatars in virtual worlds for collaboration and educational undertakings. We strongly believe that CLVE plays an important role converging collaborative technologies and tools such as video, graphics and real time simulations.

Such a game like design, keeps students interest even though they are physically remote. Combined with peer cooperation, the real time visualization helps students fully understand the dynamics of electromagnetism [2]. More and more, students and educators are agreeing on the additional value of CLVE as an educational tool, fulfilling students and educators needs for an environment for remote communication and collaboration. Once the students see the same behavior at the same time, it is easier to cooperate on misunderstood concepts. Other than 2D applications, here users could explore our 3D space analyzing TEAL simulations from different locations in the room.

Moreover, the combination of a collaborative learning environment with internet-accessible iLabs is a less expensive solution for educators, because both are based in open source technology and sharing of resources. Some of the experiments and simulations could be very costly in traditional settings. Both are easy to use and are intuitive.

We are also planning to evaluate the different user interfaces approach considering student's cognitive process, relevant features and entertainment. Through such a study we can polish our design and generate new guidelines.

These are the first steps integrating TEAL Simulations in our collaborative virtual learning environment. We will continue to research ways CLVE can increase even more its pedagogical value fostering the learning process. Scientific collaboration may happen in the future primarily in Virtual Environments.

ACKNOWLEDGMENT

We thank the Center for Educational Computing Initiatives (CECI) at MIT for hosting and supporting this research. We also thank the faculty, staff and students involved in the TEAL Project and the team of developers from Sun Microsystems. Special thanks to Mark Bessette for Figures 3 and 4 and Tina Scheucher. This research has been partially supported by the Austrian Marshall Plan Foundation.

Learning Dynamics and Control in a Virtual World

Ali Abbas
School of Chemical and Biomolecular Engineering
University of Sydney
Sydney, Australia
ali.abbas@sydney.edu.au

Abstract— **Virtual worlds can support learning processes by providing visual aid that deals with the complexities of real life problems. Increasingly useful is the online use of virtual worlds and the associated technical and social interactivity. This paper describes the development of a virtual world in Second Life environment for dynamics and control learning, and outlines the use of this virtual world as a learning space in the elective course Process Systems Engineering. The outcomes based on lecturer's experience as well as on evidence from student feedback are reported and recommendations are made for the use of virtual worlds in Engineering education going forward.**

Keywords- virtual world; Second Life; learning; dynamics; control; education.

I. INTRODUCTION

The online classroom is becoming increasingly relevant in the modern connected world. For the purpose of experiential learning, i.e. laboratory and experimental based activities, many educationalists have developed online courseware targeted at experiential education. Some examples are given, for Chemistry laboratory education [1-3, 5], surgery [10], biology [10], physics [1, 2, 4], Chemical Engineering [6-8] mechanical engineering [6, 7, 9], and electrical engineering [6, 7]. The educational challenges are being met by clever utilization of information, communication and data management technologies. Most existing virtual labs take advantage of the simulation, connectivity and internet technologies but to date have the following limitations:

(1) they remain simple in nature with limited features,

(2) in almost all developments the laboratory is presented in a 2D interface,

(3) offer low usability levels, i.e. students cannot see facial expressions and get body language cues.

(4) offer low or no interactivity between the user and the virtual plant,

(5) offer low levels of scalability, i.e. limited number of students can use a particular virtual instrument at any one instant, and

(6) the simulations used are offline in many cases,

This has led to a high demand for online interactive multi-media environments that serve the goals of teaching and learning. Internet-based virtual worlds like 'Second Life' (SL) serve such a purpose very well. These environments allow students and teachers to interact with each other and with software agents through motional avatars, providing an advanced level of a social educational network service combined with general aspects of a metaverse, i.e. not limited to the physical classroom. Students can explore virtual classroom space, meet other students, socialize and participate in individual and group classroom activities. These virtual worlds have generally been well accepted by Internet users, indeed well embraced by the younger generations. Such immersive virtual spaces are flagged as highly advantageous for teaching and learning, particularly because virtual reality can help deal with the scope and complexity of real world problems where traditional classroom and laboratory settings create limitations. Educationalists are therefore adopting these to aid in delivering courses and improve aspects of their teaching and learning. This now has become an active field of research that looks into the way students learn in these environments and to measure the levels of improvement to the learning experience.

This paper (a) describes the development of a virtual world in SL for dynamics and control learning, (b) outlines the use of this virtual world as a learning space in the elective course Process Systems Engineering, (c) reports on the outcomes based on lecturer's experience as well as on evidence from student feedback and (d) makes recommendations for the use of virtual worlds in Engineering education going forward.

II. VIRTUAL WORLDS

A. *Virtual Worlds and Pedagogy*

There are several virtual world environments currently accessible to the public including Active Worlds [11], Second Life [12], There [13], Worlds.com [14] amongst others. A comprehensive list along with reviews of these virtual worlds can be found at [15]. While all these differ in their look and feel, they are all driven by avatars – i.e. by online manifestations of self designed to enhance interaction in virtual space [16]. While these environments have been overly used for social interaction and online gaming, educationalists have been quick to realize their value for teaching and learning, particularly because of the avatar interactions which emphasize a learner-centered education. At the same time there is the recognition of the enormous pedagogical challenges evolving due to the rise of virtual worlds. An important aim for the teacher is to initially understand learner behavior and how learning interactions occur in these up-and-coming environments.

The primary hypothesis from our pedagogical point of view is that "learning is enhanced using 3D virtual worlds". Successful implementation of a virtual laboratory is expected to enhance enormously the levels and ways experiential engineering and science learning takes place and will invite many other academics to assess their experiential teaching and learning strategies and to follow suit towards improving the effectiveness of their instruction with virtual avatar-based online classrooms and laboratories. The use of fully immersive 3D virtual spaces as environments for student interaction and learning are compatible with the following learning rationales:

- Constructivist learning: Learners participate in active problem solving with emphasis on the active role played by the learner to acquire new knowledge and concepts.
- Cooperative learning: Students learn most from their peers (and not from the teacher). Here students interact and cooperate with their peers on problem solving tasks.
- Situated learning: Learning is contextual and is embedded in a social and physical environment.
- Project-based learning: Real-life problems as learning tasks within a project setting (as described by the learning situation in Section III) enhance learning particularly when these are formed within multidisciplinary teams of students.

To begin to assess the primary hypothesis and to understand how students would benefit from learning in virtual worlds, our first objective is therefore to develop a virtual learning space to be inhabited by students learning process Dynamics and Control. The development of such a virtual classroom and associated laboratories is done in SL. This is described next.

B. Process Dynamics and Control and World Development

Arguably one of the driest and more challenging subjects to teach in the Chemical and Biomolecular Engineering curriculum is Process Dynamics and Control. The topics covered can be abstract and less motivating and typically result in students not making a connection between the fundamentals and physical implementation. Process Dynamics and Control is taught as a third year undergraduate module in the School of Chemical and Biomolecular Engineering and also inside the elective course Process Systems Engineering.

The principal aims of the Process Dynamics and Control module are to (a) understand the different dynamic behaviours exhibited by different processes in the Chemicals industry, and (b) to understand process control fundamentals to regulate the said processes. To this end, the virtual learning space was developed to provide a representation of a realistic process learning environment complete with several learning spaces (Figure 1). These include a lecture room shown in Figure 2 and collaboration/meeting rooms shown in Figure 3. A control room is built (Figure 4) to represent a realistic control room environment in a chemical manufacturing process. This is the brain centre of the chemical plant where operators monitor and control the process variables like process temperatures and flows via computer terminals. 3D visual representation of important chemical processes are built and distributed in four different laboratories positioned around the control room. Figure 5 shows a typical process (Mixing tank) in one of the four laboratories alongside an integrated slideshow. Figure 6 is from the distillation column control laboratory showing the visual capabilities possible inside the virtual world.

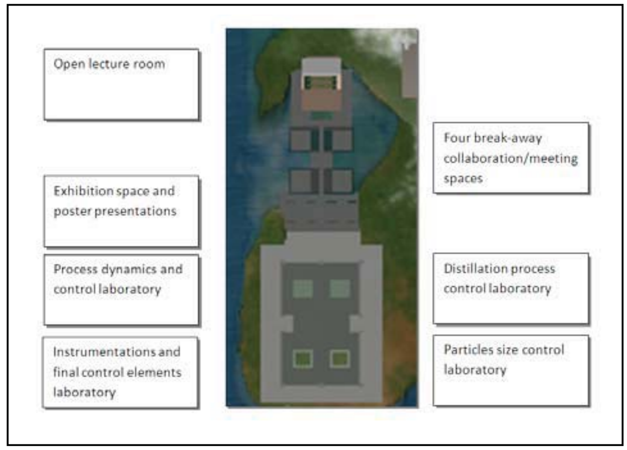

Figure 1. Aerial view of the virtual world developed for Process Dynamics and Control learning. Shown are the different learning areas including (from the top down) a lecture room, collaboration spaces, exhibition space, the four breakaway laboratories. Not visible is the control room positioned between the four laboratories and shown in Figure 2.

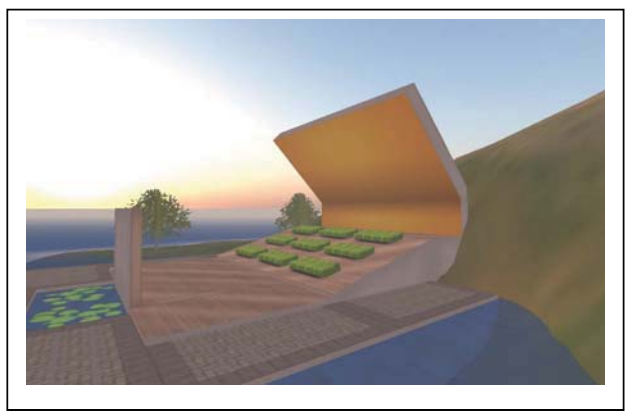

Figure 2. The virtual lecture room.

Figure 3. The virtual meeting/collaboration room.

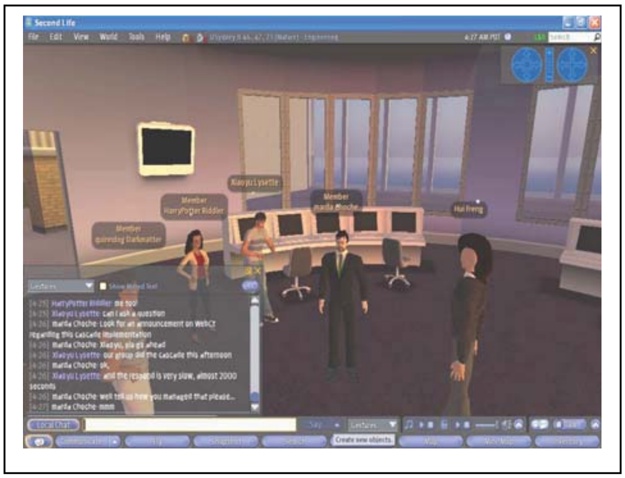

Figure 4. The virtual process control room. Student avatars can walk around, interacting with the lecturer (standing in the middle) and other students as well as with the control panels to operate virtual plants.

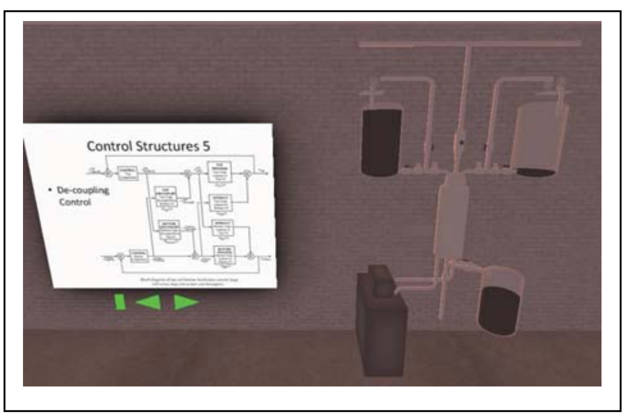

Figure 5. A virtual mixing tank (right) alongside an integrated slideshow (left).

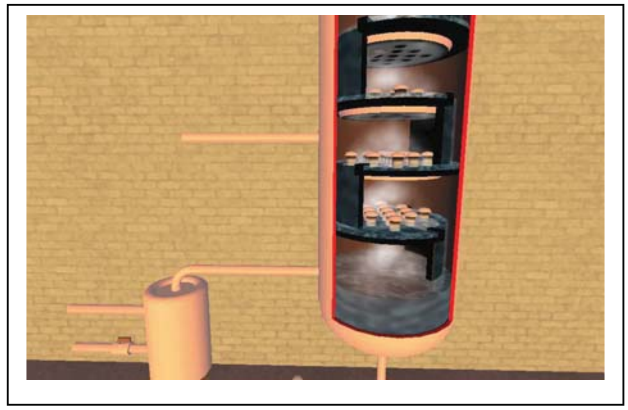

Figure 6. A virtual distillation column demonstrating visualisation capabilities inside the virtual world. Shown are the Column internals including the trays through which vapour rises contacting the liquid falling down on top of the trays.

III. LEARNING SITUATION

This section describes the use of the developed virtual world (presented in Section II) to support learning in the Process Systems Engineering unit of study delivered in the August Semester of 2009. The unit of study covered conventional as well as advanced control strategies in a project-based setting around the mixing system presented in [17] and shown in Figure 5. The project description as given to students is adapted from the "Temperature and Level Control in A Mixing Tank" problem in [18]. Students were required to work in groups to solve the project and prepare two reports – one mid-semester report and one final semester. Information on SL and the virtual space was distributed to the students early in the semester and it was left up to the students to register on the SL website and to create their avatars. While the use of SL in this unit of study was not made compulsory, it was continuously encouraged. Two SL consultation evening time slots were allocated during the week to provide students specific times for raising questions outside classroom hours. Student feedback was continuously gauged during consultation times while an end of semester questionnaire was used to obtain formal feedback.

IV. QUESTIONNAIRE AND STUDENT FEEDBACK

A. Questionnaire

The questionnaire was prepared aimed at gauging the extent of usage of SL in the unit of study as well as to understand what students thought of the environment. The survey questions are shown in Figure 7.

Questionnaire on using SL in Process Systems Engineering course.

Please provide some anonymous feedback on the use of SecondLife (SL) in the Unit of Study CHNG5001, in order to help us improve future course design. Thank you for taking the time to provide this feedback.

1. **How long have you spent in a country where English is a main language?** (please circle)
   - *a) Less than 2 years*
   - *b) More than 2 years and less than 5 years*
   - *c) More than 5 years*
   - *d) Most of my life*

2. **Did you use SL consultation times during this unit of study?** (please circle)
   - *a) Never*
   - *b) Yes, only once*
   - *c) Yes, more than once but less than 5 times*
   - *d) Yes, more than 5 times*

3. **If you answered (a) or (b) in question 2, what are the reasons for your answer, i.e. for not using SL consultation times?**

4. **If you answered (b), (c) or (d) to question 2, Please rate the following statement:**

Consultation in SL was beneficial for my learning (please circle):

Strongly Agree *Agree* *Neutral* *Disagree* *Strongly Disagree*

5. **Would you recommend using SL in conjunction with any future courses?** Yes No

6. **What are the best aspects of using SL in this course?**

7. **What are your suggestions for improvement?**

Figure 7. Questionnaire used to evaluate usage of SL in the unit of study.

B. Student Feedback

There were 24 students enrolled in this unit of study and the response rate to the questionnaire was 92%. For Q2, 23% said they used SL consultation times more than once during this unit of study. For Q4, 36% (i.e. strongly agreed with agreed responses) said SL was beneficial for their learning. This shows a lower level of usage than expected and also a lower level of accepted as indicated by the low positive response of Q4. However, it is interesting that for Q5, 67% still recommended using SL in conjunction with any future courses.

Question 1 was placed in the questionnaire to understand the relationship between competency in spoken English and usage of SL. This provided an interesting result when this was viewed in relation with Q5. Of the students who said they have spent 5 years or less in a country where English is a main language, 80% recommended using SL in conjunction with any future courses, while students who said they have spent more than 5 years in a country where English is a main language, only 25% recommended using SL in conjunction with any future courses. This rather expected result showed that students who lack competency in spoken English regard SL as a valuable tool for their learning.

Several questions in the questionnaire were open-ended allowing students to express their views in writing. The main reasons for not using SL consultation times were found to be due to technical limitations with computers (video card memory requirements in particular) and networking (Broadband internet required for comfortable downloading), which could explain the low response obtained for Q4. Several positive comments were received in reply to Q6. These included:

"User feels more free to ask questions."

"We don't feel the pressure of face to face interaction, & can develop our question more focusly."

"Availability beyond class hours is always beneficial."

"I can see a future in online/virtual learning. It is very convenient and one day can be optimised to allow operation of plants at home or overseas even,…."

In reply to Q7, recommendations were made around improving technical abilities of computers as well as a number of students commenting that SL should not be used solely and should not replace the real classroom, a view shared by the author.

C. Lecturer's Feedback and Remarks

The author (lecturer) found the use of SL to be a pleasant experience. It provided stimulation and raised the level of interest in the project at hand. Students moved from initially seeing SL as a fun tool to later in the course seeing it as a valuable and useful consultation tool. This was evidenced by the fact that they would be logged on and waiting on several occasions for the lecturer in SL and wanting to ask questions.

The development of the laboratory came at a cost to virtual world building consultants. This was not a cheap exercise. It is envisaged that a typical laboratory with standard tools and objects would arrive at a cost of about $5,000-$10,000. Consultants fees vary depending on quality of work as well as on requirements and one could easily end up with a much larger bill. Several advanced requirements could be incorporated and are continuously developing. It is envisaged that once the SL learning curve is overcome, several ways to optimize the cost could be worked out. Teaming up with others, for instance, to build a space could become a worthwhile exercise. Having said that, one is warned not to invest heavily upfront in development. A slow approach is useful. Virtual worlds and related technologies are continuously evolving and newer environments are surely set to be released in the future which could make other environments obsolete. Will Google for instance do something about this and create its own virtual world? This would, considering Google's dominance across the Web, be set to have a disruptive effect. It is though a development to look forward to.

There are current limitations in using SL. This was restricted in this unit of study to consultation times and student-student interactions. The use of realistic process simulations, while ideal, is still limited and any useful solutions are still far off in the future. It would be of interest to interface SL virtual plants with simulation engines as well as with real plants. This would allow a higher level of interaction between the student and the virtual processes. The author is currently exploring ways to attack this problem.

There are interesting aspects of interaction with students in SL. Several students were observed to show a higher level of confidence in asking questions in SL and raising discussions. This aspect was regarded as important. Considering that SL provides voice chat as well as written chat, there is envisaged to be no disadvantage to students towards learning to speak the new language. The lecturer however would need to encourage voice chat.

Finally, it is not the intention of the author to replace the real physical laboratory with a virtual one, and this should never be any educationalist's goal. Rather, the virtual laboratory is a complementary environment that support and deepens learning. So, it is not a question of whether one should be using virtual worlds for education or not, but rather, how does one use such for education. For example, it would be very useful to have the student visit the virtual laboratory the night before the physical laboratory exercise is scheduled. Going through the virtual laboratory and the learning materials associated within it inside the virtual world provides the student with a confident approach and a leap ahead in learning prior to the lab.

V. Conclusions

This paper presented and discussed the development of a virtual world in SL for learning Process Dynamics and Control. Various aspects of the environment were discussed highlighting the features it offers from the pedagogical point of view. The successful use of SL in the unit of study Process Systems Engineering was described. Feedback from students was collected through a questionnaire which showed students to have a mixed view about the use of virtual worlds. More than 90% of students who have spent 5 years or less in an English speaking language recommended the use of SL.

The primary hypothesis that "learning is enhanced using 3D virtual worlds" could not be categorically confirmed, however, the new experience gained showed a tremendous level of possibilities for engaging and stimulating students.

Several recommendations for using virtual worlds in the educational context were presented, importantly, (1) not to invest too much and too quickly into building inside these environments due to the rapid pace the technology is moving at, and (2) to ensure that the physical laboratory is not replaced by the virtual one.

Acknowledgment

The project was funded by the University of Sydney TIES Large Grants Scheme.

Abstract— **Research and development in design of games for education focus on understanding better what features of games can be inherited to further motivate students and simultaneously improve learning outcomes. Since, a common design standard is not available for educational games solutions are usually carried out by an ad hoc process. In this paper, a novel approach to design this kind of games is presented taking into consideration key features of the most successful massively multiplayer online role-playing games (MMORPG). The proposed design incorporates fun and learning through the key ingredients of MMORPGs that make them 'addictive' keeping the players constantly motivated. Our main contribution is to suggest design issues that should be taken into consideration when designing educational games.**

Keywords: Educational games, Virtual worlds, Motivation

I. Introduction

The use of educational computer games in teaching has received significant attention for increasing motivation and for enabling other types of learning experiences than those offered by traditional teaching methods. Despite the fact that this approach is mainly used in the area of lower education [1], more often higher education schools and universities adopt similar teaching methodologies [2]. In designing any learning game, it is all too tempting to simply graft academic content onto existing forms. While this approach may work, many believe that in any academic discipline, there are elements that are fundamentally game-like. An educational game should put players in touch with what is fundamentally engaging about the subject, should help them build a scaffolding of core concepts, and should motivate them to go deeper. The main features of games that could be applied to education are already identified [3] as: lessons that can be practiced repeatedly until mastered, monitoring learner progress, closing the gap between what is learned and its use, personalization of learning, and clear goals. In addition, modern video games may develop higher order thinking skills such as problem solving, strategic thinking, analysis, planning and executing, resource management, multi-tasking, and adapting to changing work scenarios.

One of the potential roles of video games in education is recognized as effective learning paradigms [4]. For example, discovery based learning is an approach to learning that highlights learner's active exploration of a subject. The use of computer games for military training is a reality [5]. Research is needed to advance games for learning. These research need to determine how (1) to design learning games to deliver positive learning outcomes, (2) to develop tools to automate the process of developing games for learning, and (3) to propose methods and techniques to assess the knowledge and skills learners acquire from educational games. This paper addresses the above research problems, providing a novel educational computer game design based on the characteristics and the features of a role playing game.

The structure of the paper is as follows. After this introduction, we examine, in Section 2, the evolution of games for learning, the motivational aspects of learning end education, as well as basic design concepts of online multiplayer games. This leads us to propose, in Section 3, our approach where we present modeling framework based on existing massively multiplayer online role-playing games (MMORPG). In Section 4 we demonstrate our approach giving a design example on framework for educational games we are developing. In Section 5 conclusions are drawn.

II. Previous Work

The problem of designing educational games has been considered in the past [6 – 10]. Based on studies on learning procedures using games and psychological theories of motivation and learning, we combine them in the designing of educational games. In this section, we give an overview of these fields, emphasizing their critical aspects.

A. Background of educational games

Mayo in [4] suggested that video games may teach science and engineering better than lectures exposing potential to address many drawbacks of modern educational systems. It has been found that effective learning paradigms are supported by specific kinds of video games and improve learning outcomes. In [11] Bransford et al found that video games stimulate chemical changes in the brain that promote learning. Mainly it was found that playing video games stimulates dopamine release, which is a chemical precursor to the memory storage process. Further research on video games indicates that an online educational game gives teachers the ability to reach students where they live, with compelling video games that can deliver educational content would increase the time spent on learning. Also, it has been noticed that the development of educational games that integrate learning with video gaming technologies is increasing.

Few of the potential roles of video games in education are recognized as effective learning paradigms and collaborative tasks. Discovery based learning is an approach to learning that emphasizes learner's active exploration of a subject.

In educational games, story can be used to structure the players experience to achieve educational objectives. Example includes Storytelling Alice programming environment [10] for creating interactive 3D virtual worlds. While there are numerous efforts that games can be applied to learning, relatively few attempts can be found where principles of learning and motivation theories were explicitly followed a priori in design.

Computer games are used for training purposes by the army, companies and institutions. Defense Advanced Research Project Agency developed a universal, on-demand training wars program (DARWARS) as a lightweight training simulation. Airplane simulators are widely used to train pilots, racing games are provided e.g. in formula 1 to increase driver's performance. Furthermore, they may be utilised for research and evaluation of particular scenarios or conditions e.g. driving under the influence of alcohol.

B. Motivation in learning process

The human's social development is driven by needs for competence, autonomy, and association. High degrees of motivation require satisfaction of natural psychological needs and are directed towards what people find interesting or important. According to [12 – 15] the Self-Determination Theory (SDT) gives the following classification of motivation:

Intrinsic motivation – refers to doing an activity for the inherent satisfaction of the activity itself;

Extrinsic motivation – refers to the performance of an activity in order to achieve some separable outcome;

Amotivation - denotes the absence of motivation.

Motivation leads to the activation of efficient cognitive strategies for long-term memory issues like monitoring, elaborating, or organizing information. On the opposite, amotivation decreases memorization and personal development. Motivation appears to be a key asset to get actively involved in the learning process.

C. Multiplayer Educational Gaming

Games can be effectively applied in many learning contexts. They can engage learners in ways other tools and approaches cannot, and their value for learning has been established through decades of research. MMOs in the entertainment sector have been seen to attract and retain players; counting millions of active subscriptions to MMOs worldwide, [16].

Over the past decade, the interest in educational gaming has grown and the research that has been conducted to bring games into the classroom have advanced our understanding and led to a more widespread acceptance of educational games. As research indicates, it will become more common to see MMOs offering immersive, engaging experiences in a variety of disciplines. It will still require effort and thought to create appropriate spaces and design compelling problems, but the very nature of MMOs lends itself to use by many people, spreading the benefits to many students.

Another aspect of MMOs that is of value to the educational community is the types of activities they make possible. These games offer opportunities for both discovery-based and goal-oriented learning, and can be very effective ways to develop team – building skills. It is possible to design activities that cannot be completed by a single player; a group must work together to strategize, develop a solution, maximize the various talents of the team members, and execute their plan in concert to succeed.

Examples of massively multiplayer educational gaming applications across disciplines include the following:

•**Study foreign language and culture**. MMOs offer the opportunity for virtual concentration, not only in a visual or design sense, but also in reading, writing, listening, and even speaking. A world based on an ancient or modern culture could include quests that require players to read instructions, listen to non-player-characters speaking clues, and write their own responses or answers, all in a foreign language and in a setting that allows them to feel what it was or is like to be part of that culture.

•**Develop leadership and management skills.** Even in non-educational MMOs, leadership and management skills come into play. Research has shown that players who take on the responsibility of leading a guild (group of affiliated players) or a raid (smaller group of players who team up to complete a specific objective) develop skills which are transferable into their lives at work and at university.

•**Practice strategy and apply knowledge competitively**. Multiplayer games offer an opportunity for students to practice what they have learned. For example, free online games allow players to make business deals and build up their net worth.

III. Proposed Apprpach

In our approach, we are reusing ideas from MMORPGs inheriting all the available multimodal user interfaces combined with techniques used to increase the students' motivation and the learning outcome. In this section, we give an overview of the three main design areas of an online Virtual University.

A. The University: In the virtual community, each university would be responsible for designing facilities (e.g. virtual labs, virtual campus etc). These facilities would be utilized either by the employed lecturers or they may be rented by other educational institutes.

Universities would be able to establish collaborations with other institutions exchanging facilities and even more tutorials and assignments (quests). These collaborations could be either bidirectional or not depending on the established agreement, see figure 1.

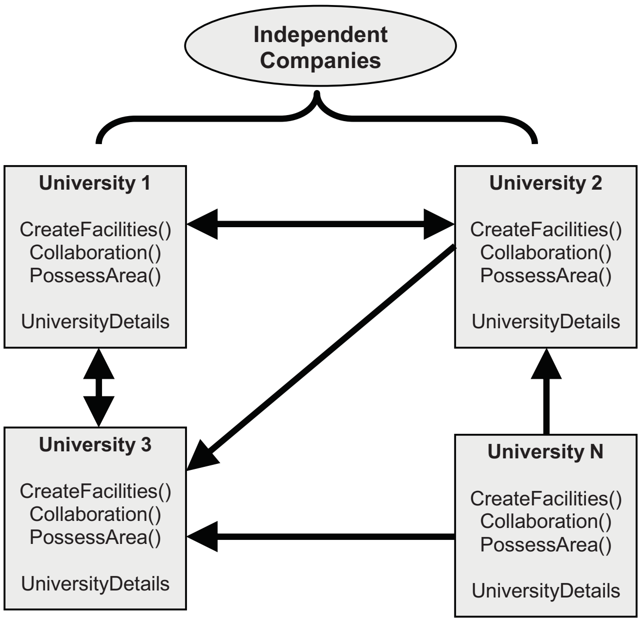

Figure 1: Diagram of established collaborations between institutions exchanging facilities, tutorials and assignments.

Third party companies could be employed by the institutions to design and implement virtual labs and facilities, building for example a virtual lab for dentists or engineers or music studies. Also, the virtual labs may be based on other educational games such as the Immune Attack [6] that is a PC-based single-player video game combining a realistic 3D depiction of biological structure and function with educational technologies for teaching immunology.

B. T*he Lecturers:* Each lecturer, creating an avatar, would be locating in the campus supplied by the affiliated virtual university. The avatar would be able to provide a set of 'quests' e.g. assignments, exercises and tutorials that may or may not require the use of the available virtual labs. For example, a lecturer teaching electronics may provide an exercise to implement a circuit using the virtual electronics lab and so on. Quests may be for individual students or for groups either from the same course or not. Tools would be provided to the lecturers in order to design and upload their 'quests'.

The second responsibility of a lecturer would be to correct and mark assignments that have been designed by lecturers over the entire virtual academic community of the same field assuming that marking instructions would be provided be the assignment's original creator. The marking procedure would be similar to the one used in conferences. Therefore, a list of topics of interest would be created for each academic avatar and based on these topics the appropriate course works would be assigned for marking.

C. T*he Students:* The first time a student logs into the system would be asked to create an avatar, confirm his affiliation and select a path ('race') e.g. medicine, computing, etc from the list provided by the university. Then a course ('class') would be chosen and the student would be ready to join the virtual university. Based on their path and course students would have access to a set of assignments, virtual tutorials either from their university or other institutes if collaboration has been established. A variety of assignments would be available (e.g. for one person, a group, with or without time limits etc) providing at the same time several options. When the students complete the coursework they return it to the lecturer's avatar from where they initially obtained it, ranking also the quality of the assignment, the available tutorials and the virtual facilities. The coursework would be automatically transferred to more than one randomly selected lecturers from any university for blind marking. According to their marks students gain points and move to the next level having access to more advance exercises ('quests'), facilities and tutorials.

Some additional features that could be integrated into the virtual university are the property ownership and prices both virtual and real provided to students with the best performance. Regarding the first feature, students may own a room in campus or share a house with classmates. Functionalities to decorate their rooms would be available. Useful tools or equipment may be parts of the virtual prices. Also, in-game visual displays can be used to broadcast such events including virtual interviews of the best students. The real prices can be scholarships, money or opportunities for further studies or collaboration with companies.

Another feature that will be integrated will be a talent system. Based on the results on their quests students may obtain talent points for example in mathematics, history etc creating a more unique character with specific expertise and capabilities.

D. *Companies*: Virtual stands of companies could be integrated into the Virtual University world, either for job advertisement that may include interview tests or as a research partner providing facilities and 'quests' to students. Companies would not be part of the assignments marking but it will be optional to join the students' evaluation system.

IV. DESIGN EXAMPLE

In this section an analysis of the proposed design is presented. The main classes and their relationships are shown in figure 2. The proposed game design is consisted of three main classes representing the University, the Lecturers and the Students. Companies are not integrated in the current version of the system. The key functionalities and properties are presented for each class. A university is consisted by lecturers, students and facilities with a set of courses to be provided. Each course includes a list of available modules with students and lecturers registered to them. This relationship would provide access to the corresponding 'quests' set, designed by the lecturers related to that particular module.

Regarding the platform that is used for the implementation of the proposed Virtual University, research was conducted and

157 students participated. According to the statistical analysis 70.18% of the students prefer to play MMORPGs on a PC, 15.79% on Xbox360, 14.03% on PS3 and with 0% on a Wii or a portable device. Also, 80.70% of the students would prefer to play the game on a system with nice graphics and with just 19.30% to prefer a web based approach with low quality graphics but higher mobility (e.g. player would be able to login form any system, computer, laptop or mobile, without any software installation to be required). Based on the above analysis C# and XNA were suggested as implementation tools providing the option to implement a game simultaneously for both PCs and Xboxes360 without sacrificing any graphics quality.

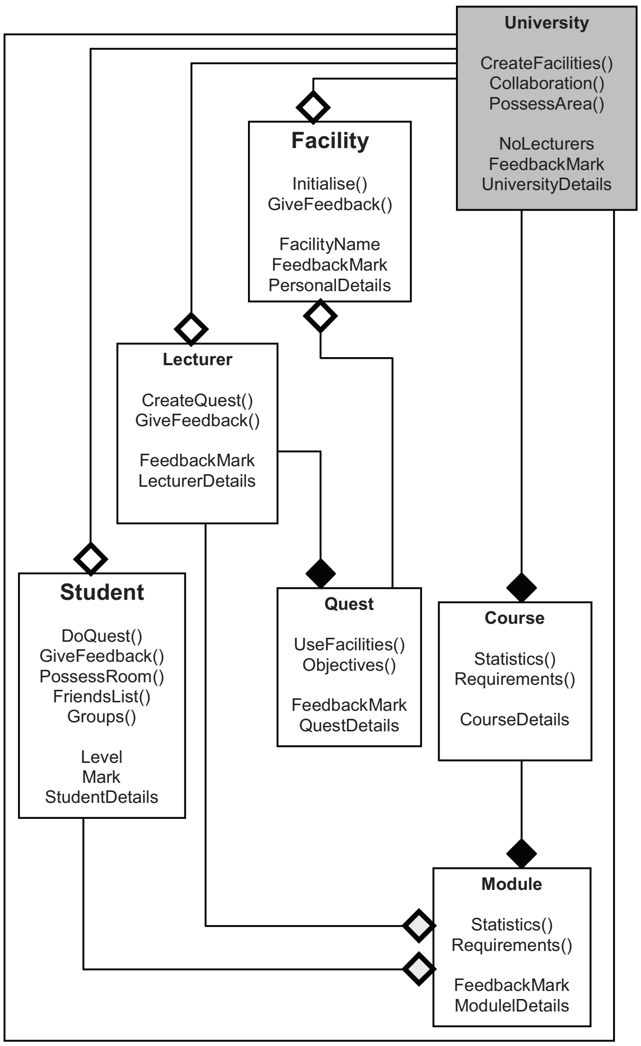

Figure 2: Main class diagram of the proposed Virtual University MMO game.

Based on the preliminary research MMORPGs were considered that provide more educational features compared with other types of games. In more details 42% of the students considered the MMORPGs above the average on an educational scale from 1 to 5. MMORPGs were regarded as high educational games by the 18% of the students and 40% below the average. Regarding other type of games, simulators (e.g. for airplanes and cars) and brain testing games were also considered as educational but for specific applications.

Significant emphasis is given on group quests either including students from the same course or not. From the analysis it was obtained that almost 60% of the students consider the group quests as the most important feature of MMOs, with the leveling concept coming second at 21%. The variety and the constant updating of the quests were selected by 12% of the students and the remaining was the graphics and the AI.

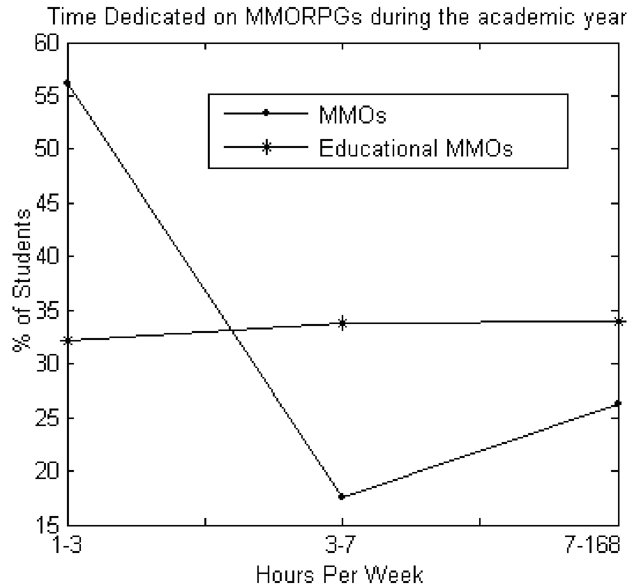

Figure 3: Percentage of students versus the hours dedicated on gaming per week for MMOs and educational MMOs.

During the academic year more than 56% of the students spend less than 3 hours per week on MMOs, almost 18% between 3 and 7 hours and more than 26% is spending above 7 hours. This trend is changing if the MMO game was part of the education with a significant part of students to dedicate more than 3 hours per week, see figure 3.

V. Conclusion

In this paper we propose a design for a virtual academic community based on the principles and the characteristics of a role playing game. The proposed design would provide lessons that can be practiced repeatedly until mastered, monitoring learner progress, closing the gap between what is learned and its use, and clear goals. In addition, the proposed video game design may develop higher order thinking skills such as problem solving, strategic thinking, analysis, planning and executing, team working and multi-tasking.

Abstract—**Increasing globalization and opportunities for engineers around the world to work or study anywhere mean challenges for universities wanting the best students as well as for the companies wanting for the most skilled staff. The social and economic conditions of the country where the student has studied have an impact on his level of knowledge though the attained degree is similar in all countries. It is not enough to use scores as a base for decisions. Some tests for software courses, English language etc. exists. Now the challenge is to design and implement a common test to analyze the knowledge of the student/ test taker and certify him in performing laboratory work and operating electronic instruments. A solution to overcome the problem of recruiting companies in this global market as well as the universities to select the meritorious from worldwide would be by implementing a Common Electronics Lab Operation Test. A test with the operation of the equipment in electronics laboratory has importance as test takers are tested in their knowledge with practical equipment using simulated and remote labs which are identical to the operation of real. The testing system is proposed to be developed using latest remotely operated real labs.**

Keywords-knowledge Engineering; testing;

I. INTRODUCTION

Thousands of students are graduated with a bachelor degree in Engineering/Technology from universities worldwide every year. Increasing globalization make engineers work or apply for master studies anywhere in the world. This makes it necessary to evaluate the technical skills of the engineers. There are a wide range of universities worldwide where many of the students attain the same qualification at the end of their course but their technical skill might not be equal. This motivates to establish a common knowledge level for all electronic bachelor degrees worldwide. There are a number of exams available for testing theoretical knowledge. A survey of such tests and the reasons for testing practical skills is explained in the next section. Section III illustrates the present and future trends in laboratory facilities. The Proposed system of assessment defined in section IV is a solution to evaluate the practical skills of the students and its implementation part is described in section V.

II. PRESENT WAY OF TESTING SKILLS FOR ADMISSION TO HIGHER STUDIES IN DEVELOPED COUNTRIES.

At Present for assessing the student's knowledge for master studies many universities consider GRE, GMAT, and TOEFL/IELTS. IELTS/TOEFL is used to test the skill of the test taker to speak in English as a foreign language [1]. These tests help the student to develop the test takers speaking as well as essay writing in English language [2]. This test is necessary as the student from a different geographical place has a local language and his adaptability to sustain in other country is to be analyzed. GMAT measures the verbal, math and analytical skills of the student which is really required for a MBA admission [3]. GRE General Test which is considered as an admission criteria for many Engineering courses in some of the developed countries analyzes student's verbal and quantitative ability [4].

GRE subject tests are available to test the knowledge in 8 specific fields of study such as Physics, Math, and Computers etc. These subjects are multiple choice questions [5]. The GRE subject test is a good solution for analyzing the technical knowledge but it does not consider the practical ability of the engineers to develop experiments. This exam does not use any simulated environment for testing the test takers practical knowledge.

GRE General Test has nothing to do with the students Engineering discipline or his technical competence in his field of study. The score in this test is based on high English vocabulary and math.

Many industries have a grading scheme which applies for applicants depending on their scores. This hurdle has been overcome by many software industries which have implemented certifications for instance CCNA [6], ORACLE, DBMS, Lab View, etc.

III. PRESENT AND FUTURE TRENDS OF LABORATORY FACILITIES IN EDUCATIONAL INSTITUTIONS:

There is a vast development in the field of technology which has its impact in the field of education. In Electrical Engineering education from many years traditional laboratory equipment are being used such as oscilloscopes, function generator's, multlimeters, components, breadboards etc. In the coming years the traditional laboratories all over the world will be offered online (most of them at present are replaced by the simulated lab benches) which is really a good trend [7]. This helps the experimenters to analyze and understand the behavior of the circuit in a better way and gives the possibility to experiment as he likes by just making a circuit of his interest, adding the components from the components palette provided by the software and run to check its output. This decreases cost, increases time flexibility for making experiments and better research capabilities by analyzing circuits with many options, individually or by a group [8].

IV. DEFINING THE TEST:

A certifying test in electronics laboratory has very high importance as it does not contain theory or a multiple choice question like many other examinations. Here the test takers will be tested in their knowledge with practical equipment. The test taker can clear this exam if and only if he has sound knowledge in using the laboratory equipment. In this proposed exam there are three levels of knowledge testing, Basic, Advanced and Professional.

A. *Description of the proposed levels of the exam*

Basic level: Here the test taker is checked with his knowledge in basic circuits. His practical knowledge is tested by giving the circuits with errors and asking him to correct the circuit to generate output.

Advanced level: Here the test taker has to configure the circuit by him. His practical knowledge is checked in configuring the circuits himself and generating output.

Professional level: In this level the test takers are asked to correct the circuits and also configure them. The level of complexity increases.

B. *Syllabus for the proposed tests:*

Basic level: Any test takers with a passion towards electronics and his interest towards developing electronics can take this exam. In general this part of the exam focuses on the characteristics of diodes, transistors, oscillators, Rectifiers, operation of Oscilloscope and Function generator etc.

Advanced level: This level has an eligibility condition that the test taker has a qualified bachelor's degree (Electronics) or he has cleared the basic level in this exam. This part of the exam focuses on clippers, clampers, gates, OP AMP, characterizing LED's and timers etc.

Professional level: This level has an eligibility condition that the test taker has a qualified bachelor's degree (Electronics) and cleared the advanced level of the proposed exam. This part focuses on overall syllabus from prior two levels including with Flip Flop, shift registers, logical operations such as converting of ASCII to BCD vice versa and micro controller programming.

These tests provide the test taker with an assessment to his knowledge in operating the electronic laboratory equipment. Passing this exam gives electronic professionals the chance to prove their practical knowledge in operating electronic instruments and expertise.

V. IMPLEMENTATION OF THE PROPOSAL:

This approach of testing can be done using simulated and remotely operated real work benches. Primarily let us consider the reasons whether to use a simulated approach as a solution for this proposed exam or a remotely operated real lab.

Simulated labs already exist from long time based on mathematical calculations. These labs are virtual and made up of software simulations during the last decades simulated labs are encouraged in Engineering education due to the fact that the traditional labs are costly to implement and maintain and also due to the belief that they can replace the real labs [9].

Real labs are indispensable in Engineering Education as a means of developing skills to develop with physical process and Instrumentation. Remote labs have proven valuable for a more efficient exploitation of laboratory resources and can be shared among participants form different places. Having the remote experiments ready all the time, the remote lab concept also provides a tool to sustain the shift towards a student – centric teaching approach, which is more and more relevant in higher education, nowadays [10].

In this proposed assessment of practical knowledge using real labs, the authors are considering 5 real labs such as VISIR, REL, WebLab-Deutso, iLabs etc and a brief description of their functioning is given as follows. One good example of remotely operated real lab is ―VISIR System" developed by the Open Labs, BTH [11]. The only difference between this remotely operated real lab and traditional lab is that the student can not feel the instrument by touching it. Virtual front panels of the instruments in the laboratory are displayed on the student's computer screens which make the students feel as if they are using traditional laboratory.

1) Brief description of the open labs electronics laboratory in BTH, Sweden

Here we can find all the resources needed to make electronic experiments, right here in the browser. As shown in Figure 1 all the basic equipments such as oscilloscope, multimeter, function generator, power supply and a number of electronic components are supplied where it is possible to build circuits on virtual breadboard [12]. The circuits built on the local client software are sent to the server and the measurement is done on the real equipment and the measurement results are displayed [13].

Figure 1. VISIR system developed by BTH,SWEDEN

2) Brief description of the WebLab-deutso in University of Deutso, Spain

WebLab-Deusto is an open-source distributed Remote Lab continuously developed at the University of Deusto. It makes possible to do real experiments with FPGA, CPLD, PIC microcontrollers, etc to a certain group of users through any computer network, such as Internet. The experience of using the experiments remotely is exactly the same as using them in a traditional laboratory. The Figure 2 below shows a webcam image of the CPLD being operated remotely and its display to the experimenter [14].

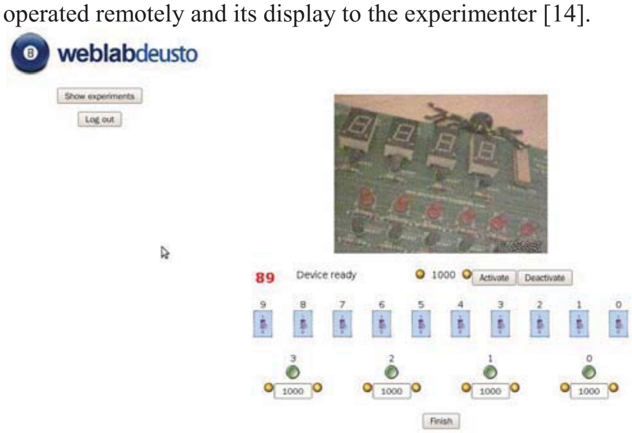

Figure 2. Web cam image of the remotely accessible lab developed by WebLab-Deutso.

3) Brief description of the iLabs in MIT, USA.

iLabs provides an open portal to selected remote laboratories and is developed at the MIT University, USA sponsored by Microsoft Corporation. It makes possible to do real experiments with Microelectronics Device Characterization, Dynamic Signal Analyzer, Microelectronics Device Simulator, etc to a certain group of users through any computer network, such as Internet. The experience of using the experiments remotely is exactly the same as using them in a traditional laboratory. The vision of iLab is to create a worldwide network of shared laboratory instruments and educational materials [15].

4) Brief description of the Remote Electronic lab and Remote Lab for E-Learning in Microprocessors.

The ―Remote Electronic Lab” (REL) is a system for carrying out electronic experiments via the Internet in the context of distance education. It is based on remote control of real laboratory instruments. Figure 3 displays the image of the electronic instruments that are connected to the server to operate remotely.

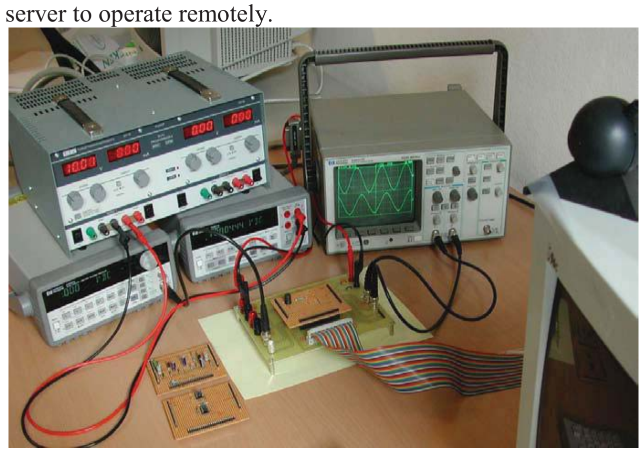

Figure 3. Remote Electronics Lab at CUAS

The Figure 4 consists of a microprocessor remote lab which was developed for the presence learning and teaching as the starting point. The mock-up was used to implement Problem Based learning methodology in both undergraduate and master subjects [16].

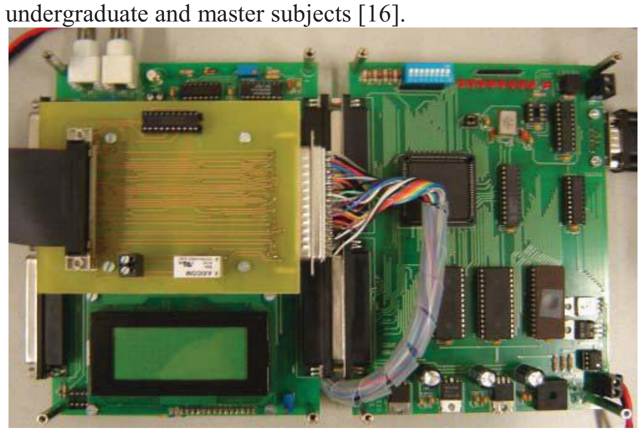

Figure 4. Web image of a Micro Controller that can be accessed remotely

In face to face learning environment users in remote are allowed to download their own code, monitor and control the registers, memory contents, executing the program and reading the display output for example pressing a key on the keyboard and observing the response of different switches.

This exam can be implemented by the engineering associations such as IAOE ―The International Association of Online Engineering" & IEEE ―Institute of Electrical & Electronics Engineers" combined together formulate syllabus for different levels of certification. Depending on the qualification of the test taker as electronics engineer the level of certification is assigned (for instance bachelor or master etc.) The syllabus in general is the course curriculum the student has studied for attaining the degree.

VI. ADVANTAGES

International online laboratory skills testing exam will be a valid and reliable indicator of true skills in electronics laboratory for education, professional accreditation and is very helpful in succeeding as a professional in the electronics laboratory for experimenting with the electronic equipment and provide measurable benefits to the employer. This type of exam or certification helps the test taker to differentiate him with others with the similar qualification in the present global market as well as improve his practical skills.

For E-Lab professionals each certification level signifies a benchmark of experience and expertise recognized with the electronics industry. The proposed certification exam validates the ability of the test taker to install, configure, operate, and troubleshoot with the electronic equipment, including implementation and verification of connections to various electronic components. Earning certification adds credibility to test takers expertise in using the electronic equipment. For organizations and hiring managers, certification can be a credible prerequisite to identify the expertise for hiring, promoting, and outsourcing decisions. This test certifies that that the test taker is technically competent to handle with the electronic instruments so as to promote sustainable society.

VII. CONCLUSION

The concept of evaluating skills of individuals from different countries and providing opportunities based on their knowledge exists since long time and now is the time to extend it to the electronics engineers. This proposed test brings valuable knowledge outcome from the students, rewards to electronic professionals and the companies employing them, the universities admitting them and Research oriented institutes to access the applicant's knowledge in the area of Electronic design and implementation. The fruit of knowledge grading through individual subject related examinations which is presently enjoyed by many software companies should not be limited to their industry itself but to be extended to other core fields such as electronics, mechanics, chemical, electrical, etc. This test enhances skills of electronic professionals which is a benefit for both the employee and employer. Through this paper the authors try to get it to the notice of the engineering organization worldwide that the time has come to develop qualitative engineers and to promote sustainability.

ACKNOWLEDGEMENT

We would like to thank the research teams of VISIR, iLabs, WebLab-Deutso, REL, Remote Lab for Microprocessors Lab, for their support in sharing the valuable information of the research going on the real lab and their working possibilities. We would like to thank Associate Prof. Ingvar Gustavsson for encouraging us in writing this paper and supporting us all through.

***Abstract*—This paper describes a integrated computer-based learning system improving engineering teaching and learning of complex technologies. It combines a tutorial with a virtual laboratory and a self assessment tool to achieve a self-learning system. The tutorial is a hypermedia document linking different concepts of Electronics technology and combining them with a virtual laboratory. This virtual laboratory is made up of a set of virtual experiments with a user-friendly graphic interface and interactive simulated electronic instruments relating practical and theoretical concepts. The self assessment tool combines a test with each experiment of the virtual laboratory. The whole system matches the constructivist theory and constitutes an interactive computer-based complex tool.**

Keywords-component; integrated learning system; computer aided learning; virtual laboratory; self assessment too;.

I. INTRODUCTION

Engineering teaching and learning has turned very difficult because present technological solutions including many interrelated concepts tend to become very complex [1] [2]. Consequently some engineering education experts [3] [4] claim that it is necessary to develop new education methods using information technology tools to improve teaching and learning. Using these methods it is possible to combine theoretical and practical activities [5] [6] in order to learn technology synthesis methods using actual products as working examples [7]. There is also a general agreement about the need of new teaching and assessment strategies to enhance competence-based learning [8]. The whole system matches the constructivist theory [9] [10] [11] [12] and constitutes an interactive computer-based complex tool enhancing competence based learning.

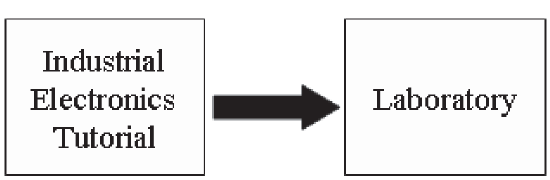

Figure 1. Learning process of complex technologies at present

At present, complex technologies learning comprises two steps. First, the students learn theoretical concepts attending lectures and studying a tutorial book and second, they perform a set of tasks in a laboratory. However, this process has several drawbacks:

- Tutorials included in a book do not give enough information about the dynamic behavior of the different types of circuits and systems.
- Students have insufficient knowledge about commercial components, assembly techniques and measurement instruments. Assembly errors and component damage are common during laboratory classes.
- Students do not know if their knowledge about theoretical concepts is good enough.
- Students have no experience on testing different components behavior.
- It is not suitable for asynchronous distance learning

This paper describes a computer-based system improving the engineering education process. This system is called "integrated learning system" because it combines three subsystems (see figure 2):

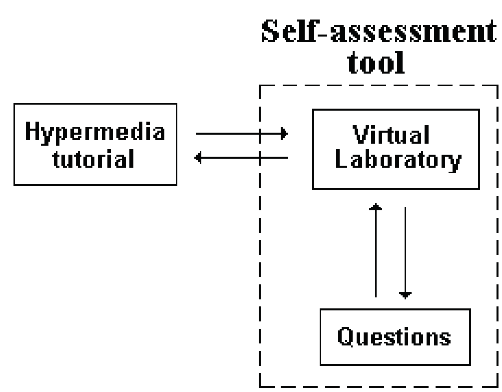

Figure 2. Hypermedia integrated learning system block diagram

A. Ttutorial

It is a hypermedia learning system structured into chapters, sections and subsections. The different subsections are associated with one or more virtual experiments through a user-friendly graphic interface and some interactive simulated instruments relating practical outcomes with theoretical concepts. The student can execute each experiment at the point indicated in the tutorial after studying the corresponding theoretical concept.

B. Virtual Laboratory

There are several kinds of virtual laboratories with different application purposes. The virtual laboratory of the integrated learning system comprises a set of virtual experiments. Each experiment is a pedagogical interactive simulation using just a few computer resources and can be integrated with some other software application.

C. Self-assessment tool

This is a computer tool combining one or more tests with each experiment of the virtual laboratory. In each case the student selects what he thinks is the correct answer and the system does not provide the solution but shows him the experiment outcomes, giving the possibility of verifying his answer. In this way he can learn from his mistakes [13].

As an example an "Electronics Integrated Learning System" has been developed including a virtual laboratory and a self assessment tool.

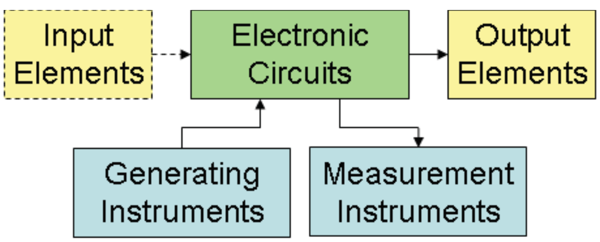

Figure 3. Block diagram for of the interface of the virtual laboratory of the Electronics Integrated Learning System

II. VIRTUAL LABORATORY

The Electronics Virtual Laboratory has the following characteristics:

- A user-friendly graphic interface.
- Interactive simulated instruments with a functionality similar to that of the actual instruments.
- Relates practical with theoretical concepts through a selected set of experiments.
- Each experiment is a pedagogical interactive simulation using just a few computer resources and can be integrated with some other software application.
- Provides destructive experiments which are not possible when using actual electronic devices.
- It has self-test capacity.
- It is scalable to add new performances.

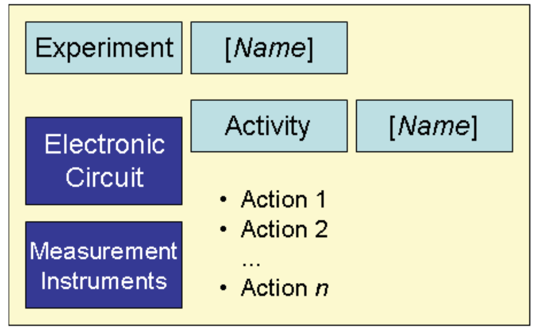

Figure 4. Block diagram of the experiment user interface

The user interface includes the different instruments used in the actual laboratory. These instruments are connected to some suitable test points. Figure 3 shows the block diagram for the user interface of the electronics virtual laboratory, including generating instruments, measurement instruments, input and output elements, and the electronic circuits under test.

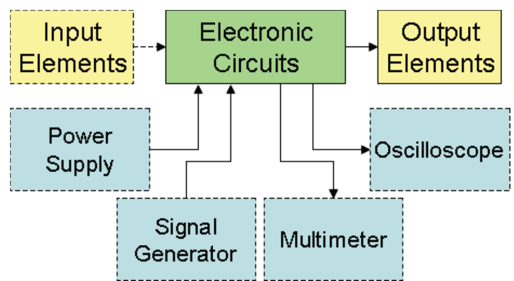

Figure 5. User interface block diagram of the Analog Electronics Virtual Laboratory

Each experiment includes the description of the activities to be accomplished by the student, as shown in figure 4.

The main parts of Electronics are Analog and Digital Electronics, and a Virtual Laboratory has been developed for each one of them.

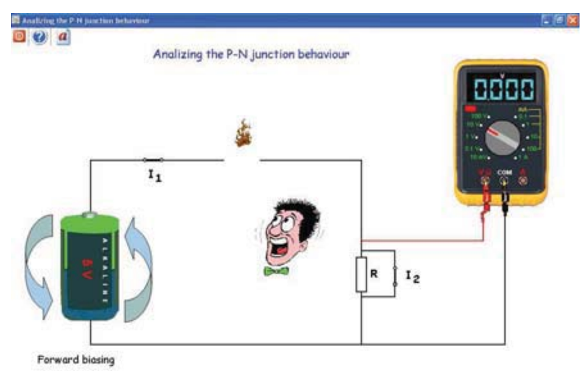

Figure 6. PN junction destructive experiment behaviour using a multimeter

A. Analog Electronics Virtual Laboratory

Figure 5 shows the user interface block diagram of the analog electronics virtual laboratory experiments including a signal generator, a power supply, a multimeter and an oscilloscope. All the experiments use a power supply, and depending on the characteristics of the experiment, one or more of the other three available instruments.

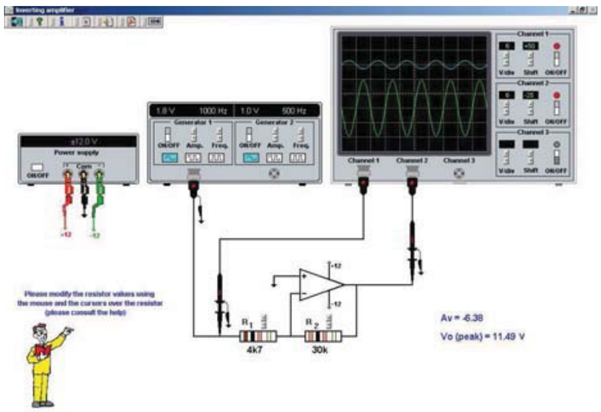

Figure.7 Inverting amplifier experiment using a signal generator and an oscilloscope

The multimeter is used in the experiments where only DC signals are involved. As an example, in figure 6 shows the experiment analyzing the behaviour of the PN junction. This is a destructive experiment where the user can verify what happens when the PN junction is directly biased without a current limiting resistor.

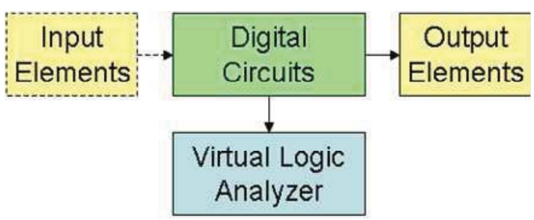

Figure 8. Digital circuits virtual experiment block diagram

The oscilloscope is used when the experiment includes time varying signals. The student can select the type of waveform, the frequency and amplitude of the signal generator output and the scope main parameters. He can also change the resistor standard values using the mouse. As an example, figure 7 illustrates the experiment analyzing the behaviour of an inverting amplifier.

B. Digital Electronics Virtual Laboratory

The digital electronics virtual laboratory (see figure 8) has an interactive graphic user interface including a digital circuit and a virtual logic analyzer to visualize the evolution of the different input and output signals.

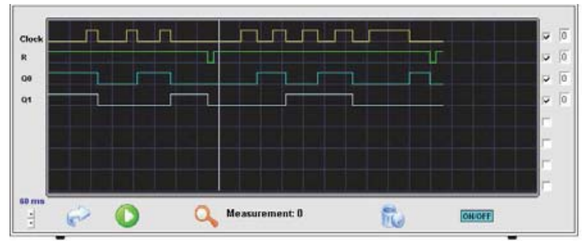

Figure 9. Virtual logic analyzer interface

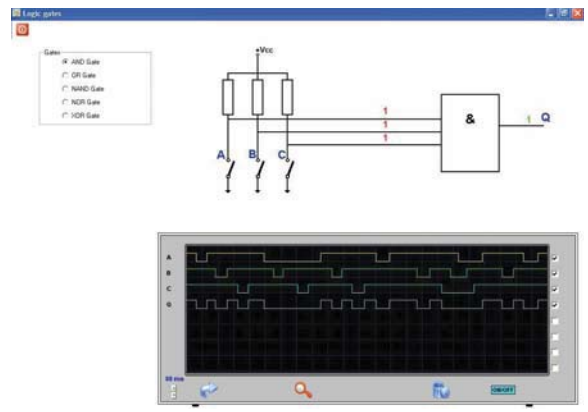

Figure 10. Experiment of the different logic gates

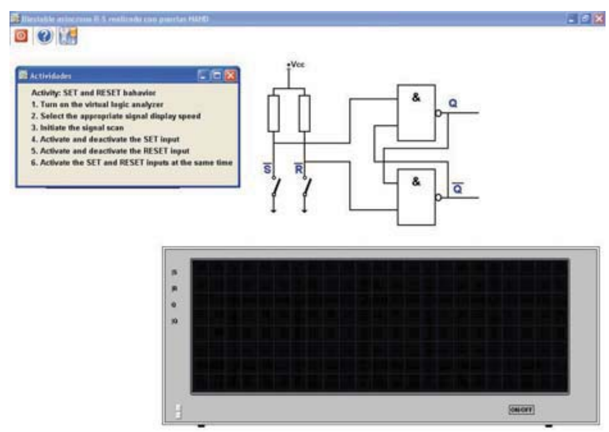

Figure 11. Student interface of the experiment "R-S latch with set priority"

The virtual logic analyzer (see figure 9) has 8 channels. It works like an actual logic analyzer, including user programmable signal display speed. Signal display can be stopped at any time. In this situation, when the user clicks on the magnifying glass a cursor facilitates signal level reading on any point of the virtual logic analyzer screen. The virtual logic analyzer is a suitable tool to analyze the behaviour of the different combinational and sequential circuits. Figure 10 shows the experiment describing the behaviour of the different logic gates. The student can select the type of gate and the logic level of the inputs. Figure 11 shows the R-S latch behavior including its activity description.

III. SELF ASSESSMENT TOOL

The analog and digital virtual experiments can be used by the professor in the classroom but to become a useful tool improving the user self-learning capacity they must be combined with an assessment tool.

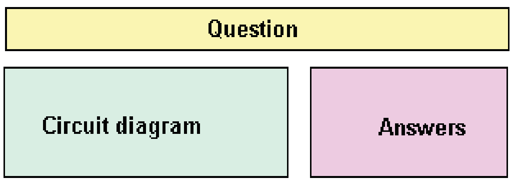

Figure 12. Assessment tool user interface block diagram

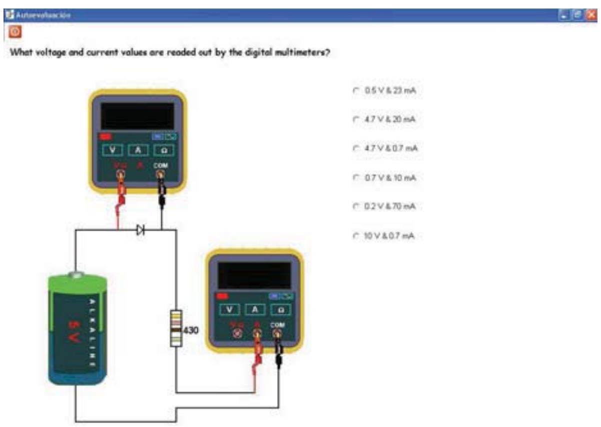

Figure 13. Example of the user interface of a self assessment question

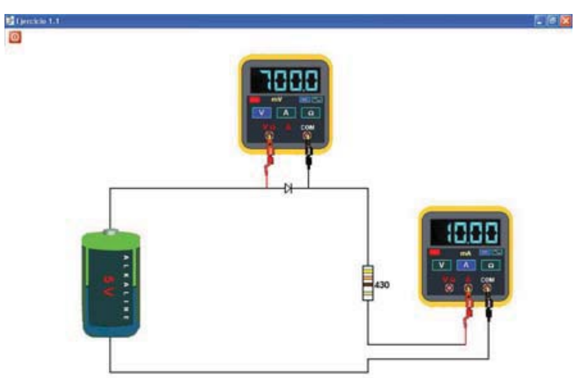

Figure 14. Eecuting the experiment after answering the question

As shown in figure 13, after studying the hypermedia learning system combining the tutorial and the virtual laboratory, the student executes the self assessment tool. This tool is a set of multiple choice questions. Figure 12 shows the self-assessment tool user interface block diagram combining one experiment schematic, one question and the list of the possible answers. The student must select the answer that he thinks is correct. The tool does not give him the correct answer but it presents the experiment asking him to execute it to verify if the answer is correct. In this way the student has the opportunity of executing the experiment before giving the definitive answer. This process constitutes a double assessment using not only the question but also the experiment.

Figure 13 shows, as an example, one question about the semiconductor diode. Answering this question the student demonstrates his expertise about the semiconductor diode behaviour when it is forward biased. The student must choose one of the possible answers and then the tool executes the correspondent experiming. In this way the student can make voltage and current measurements again to verify if his answer is correct in the same way as in an actual laboratory (see figure 14).

IV. CONCLUSIONS

The integrated learning system described in this paper is an enhanced active learning rich environment [11] increasing the self learning capacity of students. The virtual laboratory is structured as a set of learning objects and it can be combined with different tutorials. The self assessment tool can also be integrated with some interactive learning management system such as for example Moodle.

***Abstract*— In the last years, the field of education has advanced boosted by the introduction of Information Technologies. However, these advances have occurred to a lesser extent in the support of evaluation and assessment of students' learning, even when the improvements in evaluation would enhance the whole learning process. In this paper, the processes involved in assessment in engineering university learning are identified, described, reviewed and analyzed in order to ensure fast feedback to the students. A method for evaluation called eXtreme Learning is introduced which builds upon highly granular and continuous evaluation, integration of evaluation within the general learning process and fast feedback of evaluation results to students. At the same time, the method keeps some principles of traditional learning considered mandatory for its application in university education, as they certify the level of knowledge of the student.**

***Index Terms*— e-Assessment, educational methods, computer assisted assessment.**

I. Introduction

The integration of Information Technologies has contributed greatly to the advancement of the majority of educational processes such as information gathering, cooperative learning, distance education, housekeeping, etc. In contrast, the support of evaluation and assessment of students' learning has received less attention by the research and practitioners community.

In the rest of the paper, a model of the activities typically involved in university learning evaluation are presented; then we perform an analysis on such process in order to improve the feedback to students. A series of experiments in real university settings has been done, whose results are discussed. As a consequence, an evaluation process called eXtreme Learning is introduced, which allows applying fast feedback loops into the traditional university learning process. At the same time, the method keeps some principles of traditional learning considered mandatory for its application in university education, as they certify the level of knowledge of the student.

The method relies on the application of well-known principles of pedagogy, such as choosing the proper granularity for each learning activity in contents and students' effort, ordering the knowledge acquisition following a logical path, enforcing the gathering of key knowledge, putting the knowledge into practice (particularly adapted to engineering education), evaluating the core concepts, converting the evaluation into a learning experience, and performing additive marking. Also, the role of e-learning technology is discussed, as the method, having a cornerstone on fast evaluation, cannot be applied without the proper technical support.

This article describes the results obtained in the application of the proposed method to a first course in computer programming in engineering syllabus over two different semesters. The specific characteristics of the subject impose additional requirements as students must face different studying conditions and context, while keeping at the same time the motivation for the kind of studies they have chosen. The application of the method has been maturing for a number of years as the selection of the proper granularity and sequence of learning contents was guided by a "trial and error" strategy. Then, we applied the method in the computer programming in the first course of Telecommunication Engineering in Universidad Politécnica de Madrid (UPM), for two different semesters, over a large set of students on a real setting. The control group exhibited better levels of success (percentage pass/total of students) and better learning results (marks over the whole subject) in the two semesters.

Outcomes from the experiences provide hints about the usefulness of the approach. Also the potential problems and drawbacks in the application of the approach are discussed.

II. Educational Assessment

In order to track the outcome of the learning process it is necessary to evaluate student's process. This is achieved using a wide range of methods for evaluating students performance and attainment including formal testing and examinations, practical and oral assessment and classroom assessment among others [1][2].

The role of evaluation activities in the university education has been analyzed as far as the second half of XIX century, by the philosophical school of K. F. Krause. At that time, throughout all Europe there is a strong interest on pedagogy at university that identifies the concept of traditional exam as one of the key elements to be replaced or complemented by other evaluation methods (such as continual evaluation), in order to improve students motivation and get closer to the actual knowledge [3].

As regards evaluation, pedagogues usually distinguish between summative and formative assessment [4]. The first is usually applied once the learning period has been completed, is driven by the academic staff, can be verified and marked,

Manuscript received November 6, 2009. This work was supported in part by the Vicerrectorado de Ordenación Académica y Planificación Estratégica from Universidad Politécnica de Madrid (UPM) under grant "XL-TIC".

validating that the knowledge /objectives have been obtained. On the other side, formative assessment is applied continuously, and intends to help the student improve the learning, providing feedback and recommendations on his own taken process.

Some tendencies try to conciliate both approaches; among them, “Authentic Assessment” [5] focuses on the acquisition of competencies and the evaluation of this achievement. Thus, evaluation must be a planned integrated process related to professional competences. However, up to our knowledge, no formal efforts have been performed in order to combine summative and formative assessment into a single method that gets the best of both and avoids the problems they face.

In traditional evaluation process –at least in the university education-, whose goal is to qualify or certify the level of knowledge of the student at the end of a learning time, only summative assessment is applied, consisting of a final exam at the end of the teaching semester. This evaluation method has been used extensively due to some of its characteristics: it allows comparison in the group of students as well as the checking of a knowledge threshold, it is cheap in organizational terms; it is predictable in methods, secure and fair. It is also mandatory by legal conditions in some universities.

The traditional evaluation process has been improved in the last years by the introduction of the “continuous evaluation” approach, in which the evaluation activities are performed throughout the learning period (not only at its end). These processes bring the advantages of formative assessment for improving the quality of student learning. Its application allows for: increased feedback to the students about their learning process, increased motivation, feedback to the staff about the quality of teaching, consideration of evaluation activities as learning (it is also formative) [6]. It is a difficult method, as many times the evaluation gets uncoupled from teaching and from learning, it is time consuming, it may be unplanned, increases housekeeping overhead in the learning process, and it may put strong pressure to students, which is clearly undesirable to retain them inside the academic environment (the “retention problem” refers as the capabilities to keep students focused on the syllabus they have chosen), as stated in [7].

However, the incorporation of formative assessment into course assessment presents several challenges to improve the formative capabilities of the process, such as the adaptation of learning objects to the characteristics and context of each student; or the consideration of learning paths, defined as the sequence of consumption of learning objects by the students. This sequence defines a path or trajectory of navigation on the set which can be defined in the learning planning activities, chosen by the student, or explored by social algorithms. In any case, there is an optimal trajectory, and the actual one that must be compared with the ideal in order to know the quality of the learning process, qualify the student, and suggest corrective actions. All this can be considered as a control loop, and as such, a fast feedback and an adequate response to deviations make the system stable. On the technical side, some of the outcomes related to this theory are: the definition of learning paths, the algorithms to adapt these paths to each student, and the resources for the evaluation of the knowledge.

The usage of Information and Communication Technologies (ICT) on evaluation is increasingly growing, leading to the concept of e-assessment as the study of the usage of computers and related technology within the assessment process. It has many advantages over traditional (paper-based) assessment, as it automates most of the repeatable tasks non depending on human judgment, such as getting the answers provided from students, storing them, marking or communicating results [8]. There are some successful systems supporting e-assessment based on forms or questionnaires, such as WebCT.

Particularly useful are those systems which integrate evaluation into the general learning process: learning Management Systems (LMS), also known as learning platforms. They are based on a Web server providing software modules for administrative and tracking processes on a learning system. These kinds of systems also ease distributed collaborative learning from prepared activities and contents; both in synchronous and asynchronous way, based on Internet services. Students follow the lessons, perform the scheduled activities, communicate with professors and other students, and produce statistical and marking records. Some LMS are Blackboard, Moodle and Claroline .

However, being powerful tools, LMS are usually devised for its usage in distributed settings with students spread across a region. Computer security measures, such as the usage of password authentication are in place. But ensuring the student gave answers to evaluation questions without help is still a process requiring human intervention (traditional examination in a certain place in which the student gets reduced communication capabilities is the best example). There are some evaluations that provide legal effects and therefore security and reliability must be preserved; so far these are performed purely in the summative mode without the help of ICT infrastructures.

III. Evaluation process

Therefore, we focused our efforts on the integration of formative and summative evaluation in the context of university education; particularly for engineering degrees which are regulated by law. So, for university education that follows the French-European model (university degree habilitates for a professional title or profession), the student must fulfill a series of competences; and this fulfillment must be assessed by certified staff –a kind of governmental agents. The administrative and legal effects of university education expand those of simply learning: knowledge must be demonstrated and evaluated in practice. In Spain, some branches of engineering follow this model, so the professional activity is regulated, and its access is also specified and controlled.

In the presented context evaluation must meet several requirements:

- Formal education (we define it as any kind of education part of a certified program that produces legal effects, ranging from kindergarten to university), requires validation and verification activities. To produce a legal effect (passing the course) it is necessary to get a proof that the required knowledge and competence have been acquired.

- Evaluation must be normative, as the levels of competence (learning objectives) the student may get should be described in a clear manner, also specifying the different degrees in which the objectives can be covered.
- Evaluation must be precise so it is possible to infer the coverage of these levels of competence by the student from the results of evaluation (examinations, assignments). For this purpose it must also be objective, meaning that no external conditions may affect the results of the evaluation, such as affective bias from staff towards students.
- Evaluation must be secure. This is the main detrimental factor for a greater adoption of e-assessment tools and techniques. Security relates to the authentication of students, non cheating, non plaguing, control of the processes, etc. For this purpose, face-to-face examinations are still a powerful evaluation tool.
- Evaluation must be fair for comparison between students. Even in the engineering university studies we are presenting, and despite the fact that the key point for students in each subject is the pass/no pass decision (all mandatory subjects must be passed to get the degree); each student is given a final mark in each subject. Individual marks or the aggregate results are used for comparison of graduated students by some engineering companies.
- Evaluation must also help in the learning process, helping each student to get knowledge about his/her level of competence and guiding the selection of optional subjects. During the learning period in each subject, availability of in-the-middle, continuous or formative evaluation results helps the student to focus on the issues he/she would require more effort. It is also a motivational agent.
- Finally, the academic and physical conditions in which the evaluation is performed, as regards the evaluation technique, the time for evaluation, the place and space it is performed on, the availability of consulting material, the text of questions, etc, must be handled with care to get the aforementioned goals but at the same time be realistic within the restrictions in staff and costs universities face.

Face-to-face examination must still be part of the process. Nonetheless, evaluation will be more efficient the more continuous it is; besides, it will be more focused the narrower the context of application. In continuous evaluation schemes, a formative approach can be supported. In this situation, processes and technical infrastructure play a fundamental role reducing the cycle execution total time, improving learning through a fast feedback, and adapting learning to students' pace.

Traditional university education has been mostly driven by summative evaluation activities, performed at the end of a long learning time period (year, semester). This is a one-shot process, focused on the legal effects (pass, fail). It has been shown that evaluation and assessment activities have a strong impact in the overall learning process as their main goals are: give students a mark and ranking, help and motivate them by a quick and continual feedback, drive the syllabus development and also to contribute to analyze the teacher performance.

However, we think traditional methods provide poor feedback to students. It has already been empirically demonstrated that at least in ICT (technological disciplines related with communications and computers) teaching knowledge is mainly acquired by means or practical work. The main drivers for student's motivation are learning-by-doing, and the formative role of mistakes [9] [10].

Because of that, in the last years we perceive a movement inside traditional education, evolving from the "one shot process", quite similar to the traditional waterfall software development process, to "continuous evaluation" models. These models perform several iterations in the course time span, including learning and evaluation in each cycle. However, the number of cycles is limited by the complexity of the whole assessment process. The process is composed by many activities, and involves professors, teachers, and university officers. Each step must also be performed with the required security, controlling agents' communication, detecting forgery and copies, as well as storing the documental proof of the evaluation.

Next, a generic process for evaluation is presented. It has been obtained from our experience and the observation of the different examination methods that are followed by the university staff; while the process does not consider evaluation based on the pure observation of the student behavior, other evaluation type of activities, such as the evaluation based on the delivery of homework or project results (in Project Based Learning approaches) could also be accommodated to this model. Figure 1 shows the five activities currently performed in legally binding (paper based) university examinations. There are five tracks, of which third and fourth affect to the quick feedback to the student.

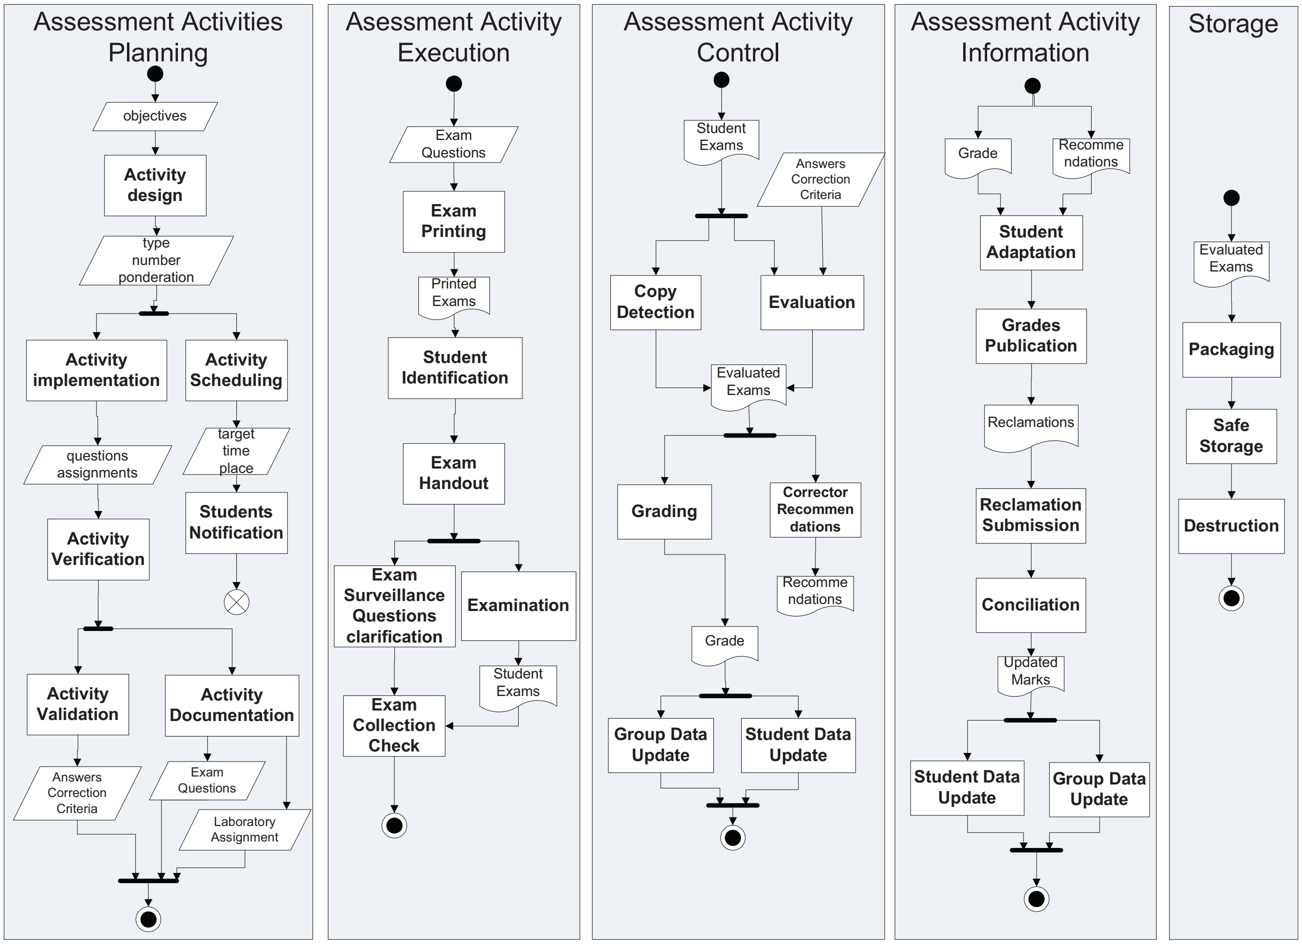

Figure 1 The Assessment Process

1. Development of the evaluation activity. Deals with all the actions required to prepare the examinations ensuring the questions or assignments are accurate and suitable. These activities are performed by the academic staff in a secure mode. They can be made in advance even before the subject period so they do not put an additional burden on academic staff.
2. Execution of the activity. Active participation of each student is required at this point, as he/she performs the examination under objective conditions.
3. Marking which implies evaluation of answers and grading, and constitutes the largest effort to be performed and therefore the highest delay in the feedback to students.
4. Information to students of their performance levels and grades. Also conciliation activities may take place at this point if the student feels in disagreement with the final mark. Review and conciliation activities are regulated by internal norms in our university, but these regulations are only applied for final examinations.
5. Storage of results as any other legally binding document should be safely stored for 5 years.

It is interesting to note that all the activities affect the overall qualities of security, reliability and validity –we call these cross-cutting concerns. It is also worth noticing that so far marking and feedback to students are operations whose effort depends at least linearly to the number of students, hindering the application of methods that imply several examinations, and producing in general poor results as regards the time of feedback.

As it has been mentioned before, these activities are suitable to be automated, but on the other hand a purely computer based approach may not meet the security requirements that legally binding evaluations hold. That is why we approach the problem of evaluation as a mix of purely asynchronous computer based evaluations (in its application to Computer Science I these are programming assignments), with synchronous paper base exams, performed several times during the semester.

The assessment activity development is the first subprocess. Only the academic staff participates in it, and its overall intent is to completely define the assessment activities that will allow measuring the students' fulfillment of the course objectives. The process starts by analyzing these objectives. Depending on the characteristics of the subject, the students' profile, the organizational context and the estimated relevance and criticality of each specific part, the teacher will prepare a high-level design of the subject assessment. By analyzing the objectives, a preliminary definition of the amount of assessment activities, its relative weight to the final mark, and the nature of each type of assessment (written exams – with problems, short and /or long questions - individual or group assignments and laboratory practices) will be performed. Once these activities have been defined, they can be integrated to the overall course planning, scheduling them over the semester, and, if necessary, performing room reservations for its execution. At this point, they can be notified to the students in order to allow a reasonable preparation interval.

In parallel with the organizational tasks, the academic staff will "implement" each activity, defining the specific questions or assignment specifications that will constitute each assessment activity. Once defined, these questions must be reviewed, in order to ensure they are appropriate to the objectives they are intended to assess. This verification should if possible be applied by a different teacher than the creator, in order to provide a broader perspective. Finally, the activity must be properly documented, obtaining the final enunciate of the exam questions, assignment specifications and support material. At the same time, the activity must be validated, in order to define the expected answers and the associated correction criteria. This way, the activities have been completely defined.

The next sub-process is the activity execution by the students, under the teacher surveillance. At this point there are some variations depending on the activity kind. We will describe a written examination, as it is the reference model for any other assessment activity. Prior to the examination time, the teacher must print the physical exams. At the examination room, after verifying the identity of the students, they will be handed out the paper, and the students will start the examination. Over this process, teachers watch over the students and clarify the exam questions. After the scheduled time, the teacher collects the student exams and checks they are formally correct. On an e-Learning context, these activities can also be carried out, as long as the identity of the students is assured.

On a later stage, the teacher proceeds to the marking sub-process, where student answers are evaluated with the reference of the correction criteria, detecting potentially copied answers from different students. Once the evaluation is complete, the academic staff will obtain two results: first, if it is possible to define recommendations to the student, based on the wrong answers and the nature of its mistakes. Second, marks must be obtained from the correctness of the questions. With that information, both individual student data and group data will be updated by the teacher.

Once the marks have been assigned, the teacher will adapt the grade and the specific recommendations to the student, in order to improve the quality of the provided feedback. Once prepared, the complete information will be published to the students, which will have an open time frame to submit any reclamation they consider appropriate to the notified marks. For each reclamation there will be a conciliation process where the teacher and student will review the exam evaluation, and, if the reclamation is deemed right, will update the student mark. Finally, individual and group data will be updated with the changes from the accepted reclamations.

After the assessment has been completed, it is the teacher's duty to ensure that a proper storage is applied to the student proofs. This way, the student exam answers or assignments (either physical or digital) will be safely stored over a set amount of time (stated by the legal normative) and will be destroyed after that interval has passed.

On the light of our requirements for university evaluation, and the observation and formulation of current evaluation processes, we concluded that: it would be feasible to integrate summative and formative evaluations in our environment, this integration would need for several short cycles of assessment in which the feedback of results to students should be very fast, additionally e-learning technologies would help in supporting automatable tasks as much as possible. We performed some experiments in order to check these hypotheses.

IV. Experiments

We have applied the principles of frequent and rapid feedback to students through continuous, formative assessment to a particular subject from the Telecommunications engineering Master degree offered at UPM (which holds learning topics from Electrical Engineering and Computer Science). The specific subject where the experimental techniques were applied is "Fundamentos de programación", a mandatory part of the first semester of the first course of Telecommunications studies which is very similar to "Computer Science I" in other countries. The subject is allocated 47 hours teaching spread along the semester. The subject neither has formal prerequisites nor depends on other subjects –whereas several subjects in the following courses depend on it. This subject has been chosen for experimentation because it offers specific characteristics that make it suitable for improvements in the evaluation process:

- The subject holds both theoretical (knowledge) and practical (operational) competences. Its learning process requires a proactive and practice-oriented effort from the student. As there are few computer programming subjects in the degree, students must obtain a minimum level of proficiency so they can apply programming concepts in later subjects with no more formal learning, despite it is in the first course. Operational contents require a higher level of interaction between student and teacher than pure cognitive contents.
- It builds design competences; students must be able to analyze computer programs, but they must also be able to design or create small programs. This is the first real experience in engineering they get, which requires the student to create his/her personal problem solving process.
- It is offered to freshmen students; so the typical problems of retention of students, wrong selection of studies, adaptation of their study mechanism, and anxiety appear among them. The subject must cope with those factors offering additional motivation as being in the very first semester most of the subjects are on basic (non applied) disciplines such as Mathematics or Physics.

For several years the academic staff has been adjusting both the amount of lessons and its sequence, organizing the subject following an "objects first" approach [11]. Table 1 specifies the topics dealt with, the order in which they are presented, and the time (in minutes) allocated to each of them for the lectures. In this table, the time allocated for the introduction and basic definitions may seem controversial as these definitions do not provide operational capabilities, but they are intended to serve as a "training time", allowing students to get a feeling on the subject –it is the very first semester in the university-.

TABLE 1 SUBJECT LECTURES TIME ALLOCATION

Lesson	Contents	Time(min)
1	Introduction: basic definitions	240
2	Simple classes, objects, references	240
3	Primitive types, operations, arrays	360
4	Methods in classes	240
5	Sentences and simple algorithms	300
6	Classes	240
7	Inheritance and interfaces	360
8	Collections (simple data types)	240

Another key factor which impacts the course organization is the large number of students, ranging from 350 to 500, split into 3 to 5 separate groups. This presents practical difficulties in order to organize the contents of the subject, perform teaching, and include the proper evaluation mechanisms. With these factors in mind the teaching staff agreed to follow a hybrid approach for the summative assessment, shared by all the groups. This way, a quarter of the final mark was assessed from the results of continuous evaluation (performed independently at each group), with the remaining 75% being determined by the final exam, common to every group. This ensured the formality of the process.

In the first semester of course 2007-2008 the first experiment on evaluation improvement was performed. In order to check our hypotheses, we made an effort to apply a large number of assessment cycles over the teaching period, and provide the feedback to students from each of them in a short period (less than 48 hours). This way, we performed a total of 12 assessment activities over 15 weeks (almost one evaluation a week), switching between programming assignments (that could be submitted through the Web) and written exams with short questions (which were performed in the university rooms following the evaluation process presented in Figure 1). The specific contents for each test were very limited, whereas the degree of difficulty was growing incrementally. For all the cases we published the reports before 48 hours from the evaluation.

At the end of the four-month course we validated our approach with the students by means of surveys and by checking marking results against the students from the remaining groups, which were not involved in the experiment. As the marking for each student was primarily determined by the final exam, common to all of the groups, the comparison of the results allows checking the usefulness of this approach to continuous evaluation. The analyzed group had 97 students, whereas the remaining four containing 328 (group composition being assigned at random). Marking results comparison shows that the pass rate was 5% better than the average overall mark, with the absolute grades improving an 8%.

On top of the raw results, further reflection was done over the experience, including the results of the student survey performed at the end of the semester. While the experience was overall positive, there was room for improvement over the implementation. Student feedback informed that the amount of continuous work felt very pressing, and was not directly tied to the final qualifications. In addition to that, it was not only costly for the teacher but also in our impression detracted time for explanation because of allocating so much time to pure evaluation. We believe that the number of continuous assessment cycles was excessive hence hampering the usefulness of this approach, and experiencing diminishing returns when compared with the required effort. These factors guided the evolution of the process for the second experiment.

In the second year of application (first semester of the course 2008-2009) the number of students in the control group was slightly smaller (89), but the same number of groups (5) remained. Based on the previous conclusions, when planning this new execution of the experiment we opted for reducing by 25% the number of continuous assessment activities (from 12 to 9). Table 2 summarizes the assessment activities carried out over this experiment, including information about the weight these activities had on the final grade, the kind of activity (written-programming lab), and the examination contents. In addition to the assessment definition, estimated effort for the execution, preparation and correction-notification time, are presented (in minutes). As it was shown in Figure 1, the preparation time is the time spent by the staff preparing the evaluation and correctors; execution time is the time actually taken by the students in performing the evaluation activity; and correction and publication includes the time to scan and upload written examinations, and for practical assignments the time spent by professors in building and publishing the listings, as well as performing manual inspection of the solutions given by students that did not perform correctly by the automated evaluation system (in these kinds of activities, time spent on erroneous answers turns to be the dominant factor).

TABLE 2 ASESSMENT ACTIVITIES FOR THE SECOND EXPERIMENT

Activity	Week	Weight	Contents	Execution time	Preparation time	Marking time
Exam 1	6	0.25	Short questions: objects, references, expressions, arrays	30	30	240
Lab 1	7	0.18	Simple classes, basic types, operations	60	30	240
Exam 2	9	0.85	Short questions: Methods, classes	45	30	240
Lab 2	10	0.18	Sentences, simple algorithms	120	30	240
Lab 3	11	0.18	Arrays	120	30	360
Exam 3	12	0.25	Regular exercises: classes, interfaces, arrays, sentences	60	30	240
Lab 4	13	0.18	Interfaces, inheritance	180	30	360
Exam 4	14	0.25	Question marks, regular exercises: interfaces, collections(data structures), algorithms	60	30	240
Lab 5 (opt)	15	0.18	Design	240	30	240
Final exam	16	7.5	Full contents	120	360	360
Total		10.0		915+120	270+360	2400+ 360

After applying the same validation in this second iteration we noticed an improvement in the results, which are shown at Table 3. Each column lists the statistics from one of the groups, with A being the subject of the experiment. For each of them group size, average mark and percentage of students passing the course is shown. It can be seen how both the average mark (over 10.0) and especially the pass rate (with 5.0 being the threshold) were significantly improved over the rest of the groups as well as the increased difference when compared to the previous experiment.

TABLE 3 RESULTS FROM THE SECOND EXPERIMENT

GROUP	**A**	B	C	D	E
SUBMITTED	**89**	58	47	49	67
AVG MARK	**6.06**	5.53	4.98	5.68	5.65
PASS/SUBMIT	**74**	47	53	49	60

V. Discussion: the XL method

The presented experiments show the results of applying a set of improvements to traditional evaluation activities which we propose to name “eXtreme Learning” (XL), in analogy to the software development methodology eXtreme Programming [12]. We have found this name used by some UK pedagogic communities [13]. It is also a commercial name that offers services to K12 (pre university) students and organizations. In both usages of the term, it seems to be oriented to the primary and secondary school context. They move the principles and values of XP (eXtreme Programming) to the domain of learning and teaching, but so far they seem to be focused on the first value of XP: communication. For us, XL is a wider method, consisting primarily on the adoption of multiple fine granularity learning cycles in university education. It serves students to control their learning trajectories, providing incremental, fast feedback, integrating summative and formative evaluation.

From the results of its two initial applications we have obtained a set of conclusions which we believe can be extended to other implementations of this approach.

The first key aspect for a successful application is to find the right level of granularity for the activities. There must be a sufficient number of them, in order to provide a focused and frequent feedback to the students. On the other hand, a too large number of tests can lessen the effectiveness of the process, as students can feel overwhelmed by the load of examinations, the time for introducing the new concepts is reduced in concordance, as well as imposing unnecessary load to the teaching staff.

Applying this technique does not only affect the design of the assessment activities, but also influences the course planning. Subject contents must be structured in a sequential development, with each new concept building only over the previous ones. Course contents should be well defined and individually testable. The combination of these factors, will allow focusing only on the tested concept in each of the assessment activities, improving the quality of the feedback provided to students.

As regards the design of the evaluation activities, there are two factors which should be taken into account. Continuous evaluation activities should assess the different types of competences to be obtained from the subject (base knowledge, skills, design capabilities...). In addition to that, it is advisable to select types of activities which can be efficiently evaluated (e.g. short answers / questionnaires instead of long problems), in order to enable a quick feedback process. From the data received by the surveys, we believe that less than 48h is a good threshold value to optimize the usefulness of the provided feedback.

Clearly, from the previous point it can be concluded that e-assessment tools are a great fit to this approach, as they help reduce the required effort for marking, although as it was mentioned before, they do not completely remove the need for manual checking. In addition to that, the security and legal concerns impede to adopt them as the only mechanism, so face to face examination must still be the predominant summative assessment technique.

Finally, we will briefly discuss the relationship between the specific characteristics of the course subject to the experiments and the XL approach.

As regards the suitability for freshmen students, we believe the formative assessment capabilities of this approach can be critical to help them have a smoother transition from their previous learning habits to the steep requirements of the university education. This is not as critical for students from higher courses, as they have already developed the required learning skills.

Another important factor related to these experiments is the high number of students per class, which did not allow providing personalized feedback and learning paths for specific students. However, as rapid feedback informs the students on their continuous progress, it does enable them to take a proactive role where, after looking at the results of his personal progress she/he can request individual lessons (tutorial) to the academic staff. Regarding group size it must also be mentioned that the required effort from the teacher increases linearly with the number of students (and is multiplied by the number of cycles), so it can turn out to be very costly in the presented context.

VI. Conclusions

Over this article we have presented the XL method, applying the eXtreme Learning approach to a traditional university context. Bare bones, our interpretation relies on the execution of lots of assessment tests (both written examinations and practical exercises), corrected and marked quickly, so the student can get a fast feedback on his/her learning process.

Before applying this technique to our context of work we have first analyzed how the domain-specific requirements impact the assessment process. This way, both the formal and security constraints of engineering degree education and the challenges of adapting the subject to freshmen students have been identified. In addition to that, the general assessment process has been described, with an emphasis on the potential techniques for minimizing the complete time required for its execution, which is the only way to provide rapid and frequent feedback to students.

We have defined and implemented this approach for two consecutive years to a first year subject from the telecommunications engineering degree, with several improvements for the later iteration. In our experiments we have found that this fast feedback improves students’ motivation, enhances the quality of learning and reinforces the active role of students in learning.

However, it must be noted that there are several factors which have to be considered before applying this approach to other contexts. First of all, on a traditional university context, the method cannot substitute, but must complement instead the traditional, legal evaluation methods. In addition to the organizational context, it is vital to find the right degree of granularity for the evaluation, and ensure the distribution of course contents allows applying highly focused low-coupled tests.

As future work we plan to increase the role of e-assessment tools in the process. From our experience the availability of an

IT infrastructure that eases the correction, communication and publication activities can substantially reduce the teacher effort, greatly increasing the applicability of this technique. In addition to that, we also plan to improve the quality of the feedback generated by the automated correction system for non-correct submissions, in order to provide personalized feedback to the students.

ACKNOWLEDGE

We want to acknowledge for the support to this work to the Deputy Director for Graduate and Master Studies in ETSIT-UPM, the chair professor of "Fundamentos de Programación" and the rest of the academic staff that helped us in the experimentation.

Abstract— **This paper presents the experiment of a mixed summative-formative evaluation in an asynchronous distance higher education context. In the experiment, performed in the distance course of Total Quality Management, Industrial Engineering, University of Guadalajara (Mexico), students are guided to formultate questions on specific topics. Student-generated questions are evaluated through an ad-hoc quantitative tool, specifically designed for the purpose: the four-criterion Observation Matrix. The experiment shows: (1) that it is possible to improve the Higher Education evaluation process and formalise students' skill in a more thoroughly way than with traditional evaluation; (2) how the student-educator interaction in a distance learning environment can be enriched through the mixed assessment**

Keywords: mixed formative-summative assessment; distance learning; continuous improvement in higher education; quantitative assessment tool

I. Introduction

Student questioning is a strategy to promote higher-order thinking and to improve learning [1]. Koch and Eckstein [2] showed that students who were taught to generate their own questions achieved more learning outcomes than students who used only teacher's questions. In 1992, King [3] found that training students to generate specific questions and then attempt to answer them is more effective than training in other study techniques. Foos et al. [4] showed that generating potential test questions while preparing for an examination is a very effective technique leading to high performance. Besides, students' questions are a precious source of information on the critical issues in a course [5]. Biddulph et al. [6] and Dori and Herscovitz [7] suggest including question generation in the formal evaluation process. This could be reasonably considered one the aspects of the Darwinian evolution of the learning and teaching paradigm.

Recently, Bergman [8] performed a multistage formative assessment experience realised with Ph.D. students, consisting in formulating "good" questions in areas determined by the examiner [8]. Bergman concluded that this reverse-question evaluation model resulted very interesting for it brought to light learners' "hidden" skills and for the different perception of the evaluation conditions it could lead to by reversing the classical role of questioner and answerer.

Inspired by Bergman's research, Ciancimino and Cannella [9] ran a mixed summative-formative assessment pilot experiment at University of Palermo (Italy). The experiment consisted in planning and realising a two-stage examination within the Business Process Modelling course of the MSc in Management Engineering. Students had to generate written questions about topics of the course selected by the educator. These questions were subsequently answered by the lecturer and become the core of formalised class debates among students, mediated by the educator. Unlike in Bergman's experiment, in the pilot test at University of Palermo the examiner utilised an assessment tool specifically designed for the purpose: the Observation Matrix. This Observation Matrix allowed the educator to assess the students' questions on the basis of a list of binary criteria. A value of 1 in case of compliance of the criterion or a value of 0 else has to be assigned to each of the criteria established during the experiment design: pertinence to the assigned topic, terminology used to formulate the question, level of complexity, multidisciplinarity approach. From the comparison of results of the traditional examination and of the reverse-question evaluation model a number of cases presenting an opposite trend was observed. The experience showed that some of the students that achieved a high mark in the classical exam were low-performers in the reverse-question evaluation. As well, other students had an excellent mark in the reverse-question evaluation but were low-ranked in the classical exam. The pilot experiment provided the educator with a significant feedback, useful for a strength/weakness analysis of the course and for a better organisation of the topics in the course.

This paper presents the experiment of a mixed summative-formative evaluation in an asynchronous distance higher education context. In the experiment, run in the distance course of Total Quality Management, Industrial Engineering, University of Guadalajara (Mexico), students are guided to formulate questions on specific topics. Student-generated questions are evaluated through the ad-hoc quantitative tool, specifically designed for the purpose, namely the four-criterion Observation Matrix [9]. To the authors' knowledge, it is reasonable to consider this experiment the first attempt to evaluate student-generated questions through a distance learning platform.

The experiment shows: (1) that it is possible to improve the Higher Education evaluation process and formalise students' skill in a more thoroughly way than with traditional evaluation;

(2) how the student-educator interaction in a distance learning environment can be enriched through the mixed assessment.

II. Design of the experiment

The mixed reverse-question evaluation was developed through a referenced technique for designing and executing examination processes: the Four Processes Architecture [10]. This theoretical framework defines four phases, each of which defines a specific process within the examination, from the learning outcomes selection to the final evaluation of examinees. The phases of Four Process Architecture are summarised in the followings.

(i) Activity Selection: consists in selecting and sequencing tasks to be accomplished by the students. The lecturer of the MSc distance course of Total Quality Management selected three topics from the programme of study: (a) Origins and Evolutions of Quality Management, (b) Statistical Tools for Quality Management, and (c) Total Quality Control. During the six-month course, the students were required to accomplish the routine weekly activities (reports, questionnaires, numerical problems), and monthly verifications. At the same time, each two months the mixed reverse-question model was adopted for the three topics.

(ii) Presentation process: is responsible for presenting the task to the participants. The mixed reverse-question evaluation model was presented to the students during the first month of the course as part of the formal evaluation of the course. Students were required to generate one question for each of the three topics selected in the phase (i) of Almond's framework. On the Moodle platform modality and scheduling of the exam were detailed, including explication of the evaluation criteria and examples. Exemplars of "good" and "bad" questions, chosen so as to illustrate what distinguishes high quality from low [11], were also showed to students, in order to provide a general reference of the level of performance they were required to reach.

(iii) Response processing, has the objective to provide evidence about the participant's current knowledge, skills and abilities. This process was aimed at evaluating the student-generated questions according to the criteria presented in Section 3: pertinence, terminology, level, multidisciplinarity. In this phase the educator recollected the questions and performed a preliminary analysis on their characteristics with reference to the identified criteria. At the end of each mixed reverse-question evaluation session, the educator completed a document in the Moodle distance learning platform for each student with a qualitative evaluation of the questions, including a detailed commentary on their performance and advices on how to improve it. As well, in the same document the educator answered the student's question.

(iv) Summary Scoring: consists in converting the qualitative observations into a numerical value representative of the evaluator's beliefs about the participant's knowledge, skills, and abilities. In this phase the educator filled the Observation Matrix for each student (fig. 1).

OBSERVATION MATRIX				
Student name:				Student ID:
Course:				
Questions	PERTINENCE	TERMINOLOGY	LEVEL	MULTIDISCIPLINARITY
1	___	___	___	___
2	___	___	___	___
3	___	___	___	___

Figure 1: Observation Matrix

The resulting data were gathered in a spreadsheet file and the evaluation of each question was obtained through equation 1. The average value of the assessments of the three questions was the final grade in the mixed reverse-question evaluation.

III. Evaluation Criteria

In the literature, student-generated questions were categorised and assessed differently, but with a shared emphasis on higher-order thinking skills [12]. Dori and Herscovitz [7] created a quantitative method to obtain a single numerical value, indicative of the level of complexity of students' questions. Marbach-Ad and Sokolove [13] developed empirically an eight-level taxonomy to categorise students' questions for increasing order of thinking. Chin et al. [14] classified students' question during laboratory activities in wonderment questions and basic information questions. In Barak and Rafaeli's research [15], quality of question was assessed both by educators and students: students assigned a value within a numerical scale, teachers evaluated on the basis of the cognitive level required to formulate the question, on the basis of a modification of the Bloom's et al. taxonomy of learning domains [16]. Bergman [8] evaluated students' questions through a pass/fail methodology.

In this work, the evaluation of student-generated questions is structured according to a multi-dimensional quantitative method: the PTLM (Pertinence, Terminology, Level, Multidisciplinarity) model. Each question is assessed with the following binary criteria:

(a1) Pertinence: relevancy of the formulated questions to the assigned topic. It is evaluated whether the question has precise and logical connection to the topic.

(a2) Terminology: appropriateness of the words chosen by the student to formulate his questions. Syntax and vocabulary of technical terms used are evaluated.

(a3) Level: extent in approaching the topic. This facet of performance was included to take into account the level of detail of the student's question. It is evaluated whether the question is trivial or if it expresses a significant meaning reflecting the deepening of analysis involved in the reasoning.

(a4) Multidisciplinarity: expansion of the range of subject areas included in the question. It evaluates the ability to connect knowledge from other areas to the topic.

For each dimension the examiner assigned a value 0 if the minimum level is not achieved, 1 if the question satisfies the criterion. The result of the evaluation for each question is a value between 0 and 4, successively normalised to 1 (Equation (1)).

$$C_j = \sum_{i=1}^{4} a_i \bigg/ \sum_{i=1}^{4} i \qquad (1)$$

The final grade for each student in the mixed reverse-question evaluation is computed as the average value of C_j, $j=1\ldots3$.

IV. Results and Discussion

This section is dedicated to present and contrast result from the traditional evaluation and the mixed reverse-question evaluation of the thirty students of the Total Quality course of the MSc in Industrial Engineering at University of Guadalajara (Mexico), academic year 2008.

The first result of the experience was that the degree of interaction between students and educator significantly increased. Moodle sessions increased up to 37% with respect to the previous courses average. Students were enabled to generate questions within a formalized framework, which provided a further stimulus to express their doubts and perplexities. This incentive can be considered particularly significant in a limited interaction context as an asynchronous distance learning environment.

The numerical values resulting from phase (iv) of Almond's framework [10] are reported in Figure 2. Grades of the traditional evaluation and of the reverse-question evaluation are compared. All grades are normalised to 1.

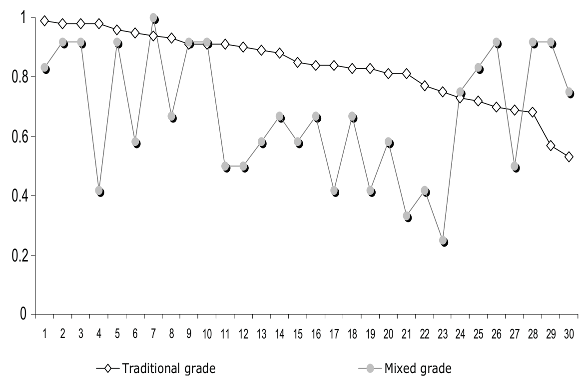

Figure 2: Traditional grade and mixed grade

From Figure 2 it is possible to identify three groups, distinguished by differences in the relative grade on the two evaluations. The first group students (from 1 to 10) performed well both in the traditional and the mixed reverse-question examination, the second group (11-23) performed in the traditional exam better than in the reverse-question, while for the last (24-30) group a better performance in the reverse-question was observed; observation 4, 6, 8 and 27 are exceptions.

In particular, comparing group 2 with group 3, an opposite trend between performance in traditional exam and performance in the mixed reverse-question examination can be noticed. Besides, the grade in the mixed reverse-question examination of students which are low-performers in the traditional one (group 3) is higher in absolute value than the grade in the mixed reverse-question examination of students from group 2.

Figure 3 shows the percentages of accomplishment of the four criteria of the mixed reverse-question evaluation.

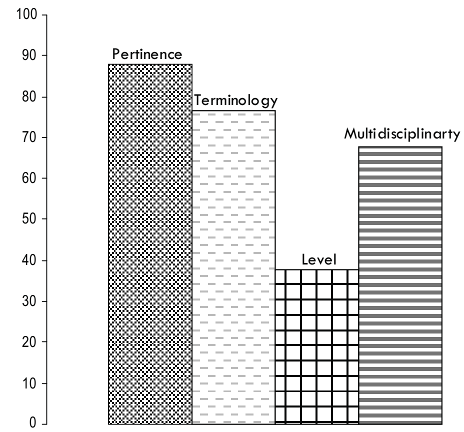

Figure 3: Percentages of accomplishment of the four evaluation criteria

Figure 3 shows that the level criterion was accomplished only by the 38% of questions, the pertinence by 88%, the terminology by 77% and the multidisciplinarity criterion by 68%.

Jointly analysing Figure 2 and Figure 3, a significant difference can be noted between the average grade obtained by students in the traditional examination, 83%, and the percentage of accomplishment of the level criterion. The level criterion is assumed to reflect the deepening of analysis and the understanding of the topic. The relatively low average accomplishment of this criterion could be symptomatic of superficial understanding of the course topics by the majority of students. The difference between traditional tasks and student-generated questioning could be indicative that the learning strategies aimed at succeeding in a traditional examination are not always sufficient when an additional effort is required for creative conceptualisation, which is a fundamental component of problem solving capability. From the comparison between traditional exam and the mixed reverse-question evaluation it is possible to hypothesise that the majority of students involved in the experience has had difficulties in converting their knowledge in capacities and competences.

Results from the experience underline that the mixed reverse-question evaluation method provides the educator with a structured feedback tool, which can release information about students' achievements in terms of learning, abilities and capacities. Furthermore, the comparison between traditional grades and mixed reverse-question evaluation grades are a concrete element for the educator to perform a structured strength/weakness analysis of the course.

From these reflections two main conclusions derive:

(1) Adopting a formative exam and formalising it within a structured framework capable of releasing quantitative information can represent a concrete tool to improve the learning system, as it provides information that is complementary to the classical feedback coming from a traditional exam. The effort for developing, improving and validating innovative tools is a priority for the scientific community. From this perspective, improving the Observation Matrix was reconfirmed as one of the main objectives of the experiment. In this experiment the educator provided a list of suggestions and observations, whose synthesis is presented in Appendix.

(2) The results of the experiment confirm the need for improvement of the higher education system auspicated by the European Community. There is the need to re-think and restructure the student-educator interaction and to enrich the teaching methodologies, in order to balance theoretical knowledge and practical capabilities and competences. Adopting mixed formative-summative evaluation methods can facilitate the conjoint development of the three learning outcomes established by the European Community: knowledge, skills and competences.

V. Conclusions and Future Research

This paper presented the experiment of a mixed summative-formative evaluation in an asynchronous distance higher education context. In the experiment, performed in the distance course of Total Quality Management, Industrial Engineering, University of Guadalajara (Mexico), student-generated questions were assessed through an ad-hoc quantitative tool, specifically designed for the purpose: the four-criterion Observation Matrix. The experience showed: (1) that it is possible to improve the higher education evaluation process and formalise students' skill in a more thoroughly way than with traditional evaluation; (2) how the student-educator interaction can be significantly increased through the mixed reverse-question evaluation method.

The limitations of this study also represent opportunities for future research in the formative-summative assessment field. For example, use of language and writing style could be further elements of student-generated question evaluation, regardless the use of technical terms. Furthermore, as answering the students' doubts resulted more interesting and helpful for teacher and students than mere numerical (summative) evaluation of the criterion fulfilment, this could be formally included in the reverse-question evaluation model. Another point regards the improvement of Observation Matrix. It would be desirable to have intermediate score between 0 and 1. By doing so, the evaluation of fulfilment of criteria could be more informative than the pass/fail scoring.

Aknowledgment

The authors wish to thank the students that participated to the experiment for their commitment and their precious feedback. The research was accomplished while the authors were at the University of Seville as visiting researchers and PhD students, funded by the Italian Ministry of University and Research and the Mexican Council of Science and Technology.

Abstract— **NUCLEO is an ongoing research project that aims at developing a MUVE (Multi-User Virtual Environment) platform for collaborative learning, which uses a role game and a virtual fantasy world to stage a problem-based collaborative learning strategy. The project has four main objectives: (1) to stimulate a change of attitude among students towards studying, forcing them to change their passive listener role to a more active role; (2) to increase students' motivation by adjusting the visual features and the interface of the environment to the peculiarities in the way members of the net generation interact with contents and process them; (3) to help to develop communication skills, teamwork abilities and soft skills in our students, while at the same time they acquire the knowledge and technical abilities included in the subject curriculum; (4) to integrate the platform into an e-learning management system application as a way of centralizing the data management, while at the same time offering the chance to combine it with the use of other instructional strategies that can be applied to wider contexts. This paper introduces the reference framework under which the NUCLEO system has been developed, along with the specific model designed to fulfil the objectives mentioned above.**

Keywords-Computer supportted collaborative learning, Virtual Larning environments, Problem Based Learning.

I. Introduction

Traditional learning strategies are generally based on the revision of contents carefully structured by the teacher and on solving series of exercises organized by themes following an increasing level of difficulty. Also, they usually rely heavily on textual static content with few interactive features. Several analysts [5],[11] sustain the hypothesis that young people today are reluctant to focus their attention on this sort of content format, because of the way the process and interaction with contents has been deeply affected by their everyday exposure to multimedia and ICT devices.

These factors, along with several other related problems, such as, for instance, increasing dropout rates at all education levels, have led the educational community to try new ways of learning, particularly those that seem closer to the aesthetics and the high level of interactivity the net generation seems to prefer, such as educational videogames.

However, this kind of approach doesn't seem to fully satisfy any of the stakeholders in the educational process so far. On the teacher's side, learning with games drags on, is often centred on wrong motivations (i.e. winning instead of acquiring knowledge), and achieving specific learning objectives becomes a difficult task. On the students' side it is generally believed that educational content diminishes the pleasure of playing to a considerable extent.

Moreover, other than a few exceptions [8], most of the game based learning approaches have been developed with no regard to the tools for managing the whole educational process that presently have the highest level of acceptance among educational institutions: Learning Management Systems (LMS). We consider this a big mistake. Not only because it would be recommendable to pay off the huge investments made until now, or to take advantage of the advancements concerning the standardization process of many of LMS features (contents, run time environments, sequencing, learning strategy design, profile management, exams), but also because LMS are wide scope applications that comprehensively manage the whole learning process (in many aspects unreachable by necessarily more limited applications such as videogames). The fact that their interfaces and interaction mechanisms not longer seem to be fully attractive to the net generation does not invalidate their functionality. From our point of view, the goal is rather to complement their functionality with richer modes of interaction, while taking advantage of the developments and the advances already achieved.

The NUCLEO e-learning project has been under development and testing during the last three years in actual academic learning courses in the Electrical Engineering Faculty at the University Complutense of Madrid. It contributes to the research of new ways of learning in the following aspects:

- It seeks to promote a change of attitude among young learners in such a way that they have to abandon the passive role they play throughout their training.
- We look for an effective learning process targeted to achieving specific curricular objectives, and designed to be attractive to the current generation, as well as

increasing motivation by applying the formats and interaction modes the "digital natives'" prefer, and reaching a compromise between learning and amusement which reasonably satisfies both parts implied (teachers and students).

- It promotes the development of team work, leadership abilities, and communication skills in the students. Traditional learning strategies are mainly focused on developing students' technical abilities and knowledge acquisition, while today's job market demands a wider range of personal abilities, among which those related with handling work coordination within a team are specially valuable.
- It achieves integration into an LMS, on the idea that the tools developed under the proposed reference framework can be complementarily used with other learning strategies, designed and managed through an LMS. Therefore we obtain a twofold benefit: we increase cost effectiveness, on one side, and we increase the pedagogical range and the target audience of the application on the other side.

The rest of the paper is structured as follows. In Section 2 we introduce the reference framework in which the NUCLEO system was developed. This reference framework is conceived as the baseline model for developing e-learning teaching approaches targeted to complying with the learning needs of a particular population context in a particular situation, and for integrating such approaches in an LMS. In Section 3 we introduce the specific framework developed for the NUCLEO e-learning system, which was benchmarked at the experimental level with extraordinarily promising results relating to the first three objectives mentioned above. Finally in Section 4 the experimental results obtained so far are briefly presented together with some conclusions as the outline for our future work.

II. A REFERENCE FRAMEWORK

The reference framework we propose in this section identifies the main components and interfaces for the development of e-learning solutions targeted to a specific situation, while allowing its integration with an LMS. We depart from the hypothesis that there are no absolute models for teaching and learning, but instead one application will work better or worse at reaching certain learning objectives depending on the targeted audience (social context). Therefore we consider it important to hew closely to a comprehensive system that allows for managing different strategies and solutions, and provides a centralized database in order to maintain continuous learning processes.

At its highest level of abstraction, the framework is organized into five components (see Figure 1):

- *Underlying pedagogical stream*. Its choice will condition the remaining layers, since it is related to the concept itself or the nature of learning, which is to say:

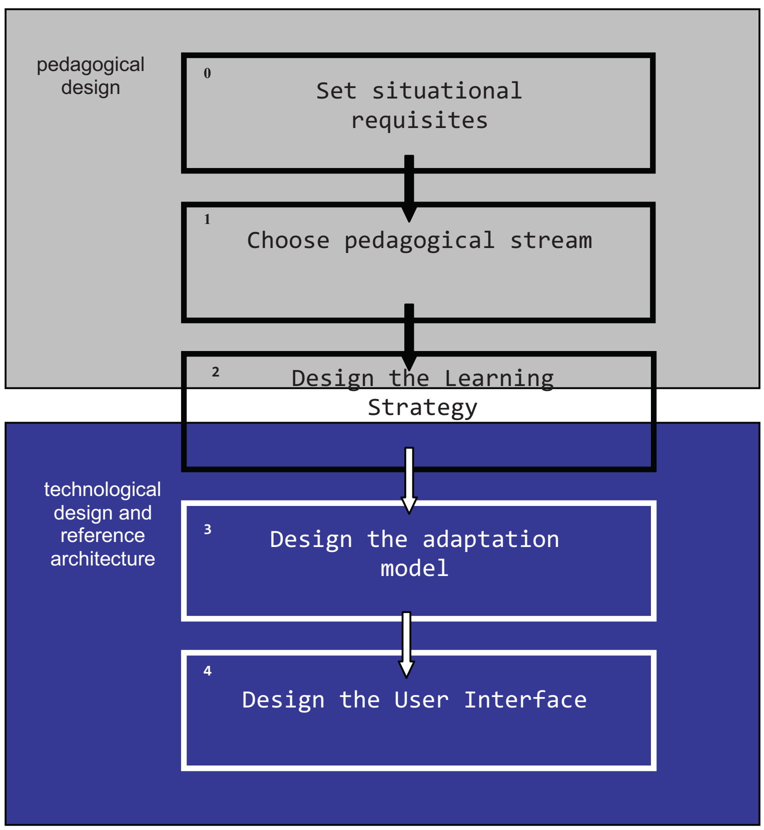

Figure 1. Reference framework used for designing NUCLEO system

what the meaning of learning is and how to achieve it according to a series of generic principles.

- *Learning strategy*. A learning strategy is a particular specification about how to undertake a learning process. It is in the strategy where all the elements in the learning process are defined as well as the way in which they are executed. The definition of a strategy is conditioned by the underlying teaching approach as well as by the definition of the adaptation processes (which in some cases affects all or a part of the elements in the strategy).
- *Adaptation*. Adaptation is the learning system ability to customize certain aspects of the learning process in terms of certain student characteristics (including previous knowledge, preferences, limitations, personality, learning styles…), founded on a series of predetermined rules. The pedagogical stream has influence over the adaptation layer's existence (since from cognitivism onwards all streams consider that each individual reacts in a different way when he/she is placed in a learning context), and the learning strategy determines what, how and the terms of what the adaptation must achieve. In turn, the adaptation process itself also has influence over the strategy, determining which specific aspects must be modified. Therefore these two layers are interrelated.
- *User interface*. The user interface for an e-learning system is the way of communication and interaction between the learning strategy layer and the student. In other words, the interface is the main element for the staging of the learning strategy.
- *Interface with the LMS*. The interface with the learning management system acts as a mechanism for exchanging information between the situational application and the LMS. The situational application is specifically conceived for a particular context. The LMS is in charge of managing all the processes and data implied in a comprehensive context supporting the continuous learning.

III. USING THE REFERENCE FRAMEWORK FOR DESIGNING THE NUCLEO SYSTEM

This section explains the specific model designed for the NUCLEO system, using the reference framework depicted in Section 2, regarding what we have defined as "situational requirements", which are as follows:

- *To whom is the tool targeted*? At a first stage of the project development, the tool is targeted to the current university population, which belongs to the so called "net generation". The students that belong to the current generation are used to accessing information in a discontinuous way, jumping from one subject to another, and they would rather use multimedia digital formats than textual printed ones; they prefer interactive hypermedia contents to static ones; multitask working is easy for them, and they are used to being permanently connected with their peers (e.g., through instant messenger tools). They also feel uncomfortable if they do not obtain quick feedback and immediate responses.
- *What is the application context?* Our tool is mainly targeted to higher education in strongly practical content domains.
- *What are the learning process objectives?* We pursue three main objectives: driving students toward the development of skills for team-work, communication (soft skills), and problem-solving; promoting a change of attitude among students that turns them into active learners; and increasing motivation, while trying to attain learning specific goals included in the subject curriculum.

A. Underlying Pedagogic Rationale

Taking into account our situational requirements (namely, turning students into active actors concerned with their own learning, and promoting the development of skills for real problem solving in complex situations, along with soft skills), we have opted for an approach strongly rooted in the socio-constructivist pedagogic stream [12], [16]. Specifically, we use a problem-based collaborative learning system, or PBL ("Problem Based Learning"), whose original scheme was developed more than thirty years ago by Neufeld and Barrows [9]. This sort of strategy has been often implemented in collaborative e-learning environments or CSCL environments (Computer Supported Collaborative Learning or sometimes Computer Supported Cooperative Learning), even though tools included in CSCL cover a wider set of applications that can be sustained by different pedagogical approaches [13].

While in traditional environments tutors are responsible for providing and organizing the information and providing students with contents in a structured way, in PBL environments the students acquire knowledge during the process of solving complex collaborative problems. Therefore, the tutor role changes from being the sage on the stage to being a guide in the process of finding a solution. He provides hints and encourages the students to seek the information and knowledge sources. In spite of the unquestionable pedagogical values socio-constructivism in general and PBL in particular provides [6], it is not easy to implement PBL, especially in a non face-to-face setting. Three of the main reasons are:

- The tutor must do a comprehensive follow-up of students, leading them and giving them clues and feedback, tasks that considerably increase his/her teaching load, since he/she is forced to conduct and supervise the steps of many small groups.
- The effectiveness of a collaborative learning process is highly related to group dynamics. The success of the educational experience relies deeply on the capacity to handle effective coordination among the members of the work group. In extreme cases, being part of an ineffective team, whose members do not establish suitable collaborative dynamics, can be frustrating and end in withdrawal [1].
- The creation of social bonds among participants seems to be the one of the keys to establishing effective collaborative dynamics. Nevertheless, it is not enough

to form the groups and to provide the students with some support for communication in order to develop the appropriate dynamics [4].

In the NUCLEO system the remaining situational layers (the learning strategy, the adaptation model and the user interface), are designed with the aim of establishing an effective model of collaboration that will lead to a more effective learning process, while at the same time reducing the tutor´s teaching load.

B. Learning Strategy

As already mentioned, the learning strategy used in NUCLEO follows the classical scheme for PBL approaches, according to which students must collaborate in small groups to solve complex, ill-structured, real world problems. The difference is that in NUCLEO the real world is a "fantastic" one. Problems are embedded in a game narrative, and solving them is part of the game. Instead of trying to disguise the educational aspect inside the game, as is most commonly done in some game based learning approaches, we have turned the whole learning setting into a game, on the idea that playing and solving problems share many features [14].

The baseline metaphor leads the students to a fantasy world in which they play the role of warriors trained to face a threat against their civilization. During the training, organized in teams, they will have to confront "assigments" simulating real danger situations, in order to reach the grade of "Paladins" for which they compete individually and in groups, with the aim of obtaining the best score (the idea was inspired by the book "Ender´s Game" by Orson Scott Card). Once this setting is introduced, we proceed to test the students by placing them in an active role, so that they are considered candidate warriors for the Paladins corps, and it is on their shoulders that the survival of the civilization lies.

As in any classical PBL method, groups have to solve a practical case. In NUCLEO assignments represent practical cases in the domain of knowledge that follow the narrative of the baseline metaphor. Hence, they must be solved by a team in which concrete functions and responsibilities are assigned to each individual by means of his/her role (teams as well as roles are determined by the adaptation model).

C. Adaptation

The adaptation model in NUCLEO aims at improving the team's efficiency, which produces a comprehensive improvement in the learning process and a lesser teaching load for the tutor. With this objective in mind, we are using two combined strategies:

- *Formation of heterogeneous teams*. The aim is to avoid the grouping of the students with the most effective learning strategies together, while leaving the less effective ones on the same team, which would bring about the subsequent impoverishment of the whole learning process [10]. We use the framework proposed by Vermunt to distinguish the students with the most effective learning strategies [16] from the ones with weaker strategies, in order to place at least one strong student in each group, since one of the principles implicitly assumed in collaborative learning is that students learn from each other.
- *Assignment of functional roles*. The roles are assigned to each student by means of his/her profile according to Vermunt's model, which is initialized and maintained through a user-modelling process.

The adaptation cycle follows the same cycle the learning strategy does: in every mission teams are reconfigured, and roles are reassigned. It is performed directly in the Moodle LMS. We have developed an automatic grouping manager tool

Figure 2. Air perspective of Dragon Island.

that it is installed as a plug-in in the LMS.

The group manager takes the result of the Vermunt Inventory of Learning Styles as

D. User Interface

Many studies have shown that the user interface is a key feature to attract the students' attention and interest [7]. An attractive interface may encourage students, while increasing effectiveness of learning. Besides, it may contribute to developing students' ability to perceive, organize, integrate and remember information. On the contrary, an unsuitable poorly designed interface may have an influence in lowering student's interest and even in withdrawal. As mentioned above, the kind of interface chosen for NUCLEO, as well as its design, is oriented to bringing the learning environment closer to the net generation's preferences and peculiarities. But that is not our only objective. We also pursue the student's identification with his/her avatar, the immersion atmosphere and its positive influence in establishing social bonds to improve the collaboration scheme and foster the sense of belonging to a community of practice. And finally, our third objective is to provide the setting and narrative for turning the typical PBL setting into a game, thus contributing to the student's immersion in the story.

NUCLEO also provides 3D settings to stage the two existing levels of social interaction: collaboration among members of the same group occurs inside a ship, while intragroup interaction among all participants in the course takes place in the Dragon Island, a space station with different areas linked to different educational functionalities (see Figure 2).

In addition to this, to foster the sense of competition, student avatars acquire differential features in terms of their intellectual achievements, and individual and team scores are public, as it has been observed that one of the most powerful incentives for the players in MMORPG (Massive Multiplayer Online Role Playing Games) environments is the social recognition by the community of users [2].

E. Interface with LMS: a bridge between MUVES and LMS

The use of digital games and Multi-User Virtual Environments (MUVEs) as educational tools has drawn significant attention [3]. Digital games engage users with challenges that take place inside immersive narratives using realistic artificial scenarios, where students can formulate hypothesis and test them in the virtual world. Hence digital games are an ideal channel to promote relevant educational aspects such as problem-solving skills or analysis and reflection.

Nevertheless, as recent research reveals [15] most of the educational gaming approaches present a lack of balance between educational value and fun, which is the game essence.

Also, the use of digital games and MUVEs has some drawbacks that have not been totally addressed yet. For instance, digital games and MUVEs are rarely fully integrated

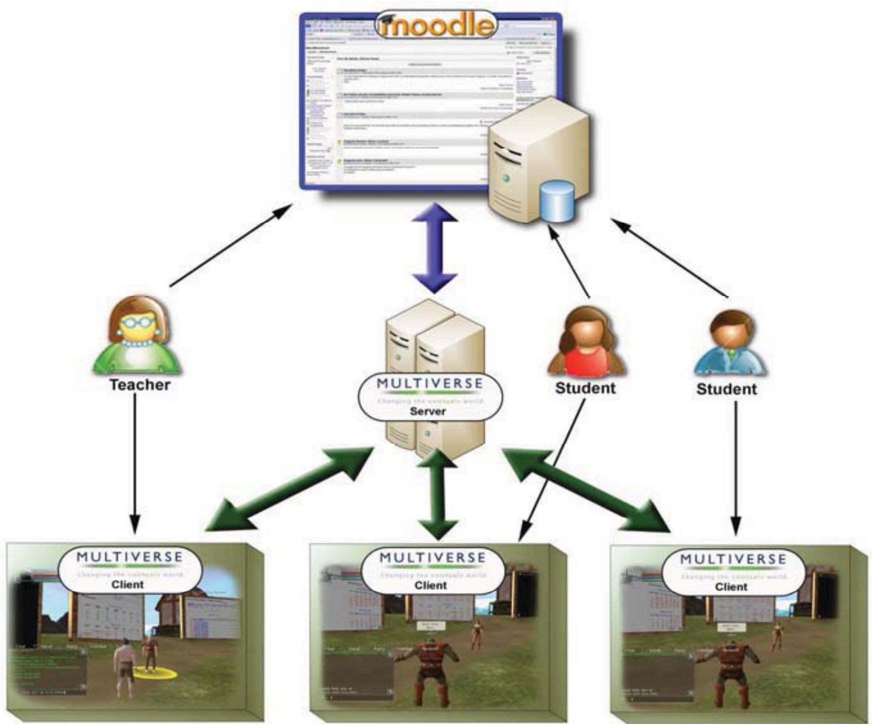

Figure 3. Reference architecture for the NUCLEO framework

in the educational infrastructure and behave as "black boxes". Thus it is impossible to get any instructionally relevant information about the course of the game-based learning experience, such as students' performance for assessment or keep a persistent student historical record.

These issues could be addressed by taking advantage of the already deployed e-learning infrastructure. Many educational organizations are using modern LMS not only for distance learning but also as a complement for traditional lectures (an educational trend usually known as blended learning or b-learning). Those LMS (e.g. Moodle, Blackboard-WebCT, Sakai, etc.) are not only content repositories, but rich web-based systems, that provide instructors with tools to track and evaluate the performance of the students, keep a record of each student or to promote communication and collaboration between students (i.e. collaborative learning). Thus a synergy between educational gaming and e-learning could bring together the benefits of both worlds.

This is precisely one of the key issues where the NUCLEO project aims to contribute. NUCLEO is an instructional framework that integrates a 3D MUVE with an LMS (Figure 3 shows the reference architecture). NUCLEO is conceived to be used as a plug-in application over an LMS, therefore, services, tools and data are managed in a centralized way at the same time that simplifies its integration in the educational infrastructure.

IV. BRIEFING OF EXPERIMENTAL RESULTS AND CONCLUSIONS

The significant hypotheses on which the framework proposed in Sections 3 and 4 is based have been benchmarked at the experimental level during the 2007-2008 and 2008-2009 academic years in three different settings of higher education. So far, we have obtained rather promising results because dropout rates have dramatically lowered compared to the previous years in which a traditional pedagogical strategy has been applied (see Figure 4 and Table 1).

STATISTICAL DATA FOR DROPOUT RATES FOR THE 2005-09 PERIOD.

Academic year	Pedagogical approach	Students enrolled	Students attending the exam	Dropout rate (%)
2005-06	Traditional	115	43	62.61
2006-07	Traditional	110	33	70
2007-08	Traditional	38	13	65.8
	NUCLEO (Mundo Nucleo)	22	20	9.09
2008-09	NUCLEO (Mare Monstrum)	54	45	16

In addition, in 2008-09 students filled a satisfaction questionnaire to collect their opinion over different issues related to the system, including what was the perceived effect of using a virtual world as user interface as a motivating factor. The question was: "In your opinion, has the 3D virtual world GUI affected your motivation?". 51% of the students thought the MUVE was a positive motivating factor, while 41% thought it caused them a delay in their learning duties and was unnecessary. The rest considered the virtual environment as neutral in terms of motivation.

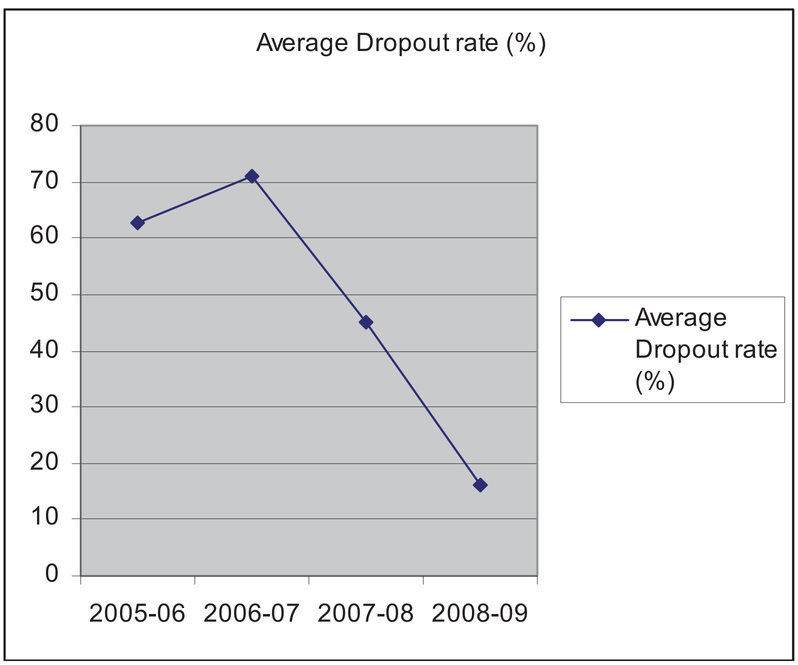

Figure 4. Evolution of the dropout rates through 2005-2009 period.

Even though this evaluation is just a starting point, and more practical research has to be performed in order to establish final conclusions, taking as a base the results obtained in our experiments, we can extract the following conclusion: Fantasy and gaming are powerful motivators, but representing them in immersive 3D multi user interface, with powerful graphics, does not seem to be as important as the gaming or the learning strategies themselves.

During the actual academic year more research is being performed in order to get a more concluding result. Potentially, we consider that this sort of environments would increase its benefifts when teaching less structured subjects, in which it is much more difficult to formalize knowledge and therefore to acquire the skills pursued (e.g. in working-team management and leadership skills). We think it opens a wide field of uses for business training.

Next steps in the project are to obtain a more complete MUVE, easier to install, with improved teacher support and to extend its usability for other knowledge domains different from programming courses.

Abstract— **Communication skills development is one of the main goals of engineering education. We propose an integrated student-centered collaborative learning environment for developing communication skills, using project-based learning methods and peer assessment. In our learning environment, projects are assigned to small groups of students under teacher supervision, documented in a wiki-editing tool and presented during a public poster session. By combining wiki entries and poster presentations, we intend to facilitate students (1) to gain access to the project of their peers and share their results, (2) to analyze and comment critically the project of their peers and provide them with feedback, and (3) to enhance their writing and oral skills. Previous experiences encourage us to promote this integrated learning environment. Wiki environments allowed students to improve the quality of their projects and to develop a critical attitude towards their projects and the projects of their peers. The poster session was found to be more dynamic than traditional oral presentations. Students got engaged in a more open and critical manner with the project of their peers, and students presenting their project had the chance to improve the quality of their presentation on the fly, by presenting their work several times in the duration of the session. In future courses, we will implement a learning environment that combines both wiki-based and poster session approaches. We expect that the implementation of both approaches will help to develop the communication skills of engineering students.**

Keywords- communication skills; collaborative learning; wiki; poster session; project based learning.

I. INTRODUCTION

One of the main goals of engineering education and higher education in general, is to enhance students' communication skills, which comprise abilities such as reflection, critical thinking and analyzing, writing and oral skills, and teamwork. Engineering curricula sometimes include courses that are specifically devoted to developing communication skills. Another common approach is to develop them as transferable skills and create in any course, irrespective of its contents, a learning environment that promotes reflection, criticism, analysis and bidirectional communication between the teacher and the students, and among students themselves.

A successful way of enhancing communication skills is by organizing students in groups, which are assigned specific tasks or projects. Group projects are being increasingly used in higher education in general, not only because they facilitate the intellectual and social dimensions of education, but because they mirror industrial approaches to problem solving [1]. Group projects promote discussion between the members of the group, i.e. intra-group communication. In addition, presenting projects in oral sessions further enhances communication skills at inter-group level and serves as a basis to disseminate students' work among their peers. Finally, group project approaches, in both intra-group and inter-group dimensions, open up the possibility of peer assessment, which constitutes an interesting experience for critical thinking and analyzing [1]. Nevertheless, in certain cases as for example, when there are a large number of students, achieving agile dynamics in the classroom when using group project approaches can be difficult. In this scenario, disseminating the work of each group and collecting feedback from their peers can be problematic, and oral presentations can be lengthy and passive.

Communication skills development can benefit from the use of web-based collaborative environments. The emergence and rapid proliferation of web-based collaborative environments, notably the Wikipedia [2], has revolutionized the traditional models of understanding the nature of knowledge itself, and has promoted the creation of global knowledge communities. As an inevitable consequence of this knowledge revolution, web-based collaborative environments have entered the classroom too, mainly in the form of a wiki. A wiki is simply an on-line editing tool that allows its users to create, comment and navigate a collection of documents, which are also known as entries. Web-based collaborative environments have been implemented for different purposes in the classroom. Some authors have emphasized the use of wikis and similar tools as repositories of shared knowledge [3] [4]. Taking the constructivist paradigm as a basis, other authors have highlighted the opportunities that wiki environments offer in education [5]. Reflective learning and critical thinking can also benefit from wikis [6] [7]. Finally, wikis allow coordinating group projects on a global scale [8].

In this paper we propose an integrated student-centered collaborative learning environment aiming at enhancing communication skills. Specifically, this environment promotes the development of fundamental abilities such as writing and oral skills, critical thinking, analyzing and teamwork by using project-based approaches, wiki-based environments, poster presentations and peer assessment. The rest of the paper is organized as follow. In Section II we describe the design of our integrated learning environment. In Section III, we present the outcomes of previous teaching experiences that included some of the fundamental components of our proposal. Finally, Section IV conveys our conclusions.

II. Learning Environment

Communication skills comprise a collection of abilities, which include reflection, critical thinking and analyzing, writing and oral skills, and teamwork. We propose a learning environment to enhance communication skills that can be implemented in an engineering course, irrespective of its contents. We form our approach based on constructivism. According to this paradigm, the best way that people can learn is by means of constructing knowledge itself. The main features of constructivism are the following [9]:

- Knowledge is constructed through reflective abstraction.
- Cognitive structures facilitate learning.
- Cognitive structures are in continuous development.

Taking constructivism as our starting learning theory together with student-centered teaching approaches, the basic ingredients that form our learning environment are two, namely project-based methodologies and peer assessment. By organizing students in project groups we seek to facilitate students to construct knowledge, to engage students with the subject matter of the course, to promote discussion among peers in the same project group, i.e. to promote intra-group communication, and to stimulate teamwork. Peer assessment favors reflection, critical thinking and analyzing, and peer communication.

In order to create a learning environment that integrates all these elements coherently, we propose to implement two strategies to promote communication, documentation and dissemination of knowledge in both the writing and oral dimensions. The strategy for enhancing writing skills uses a wed-based collaborative tool, namely the wiki. The strategy for enhancing oral skills consists of a poster session during which students present in public their projects. They are described hereafter.

A. The writing dimension: Wiki environment

A wiki is an on-line editing tool that allows its users to create, comment and navigate a collection of documents that are known as entries. By extension, this collection of documents is sometimes referred to as wiki as well. With respect to their accessibility, wikis can be either of three categories. Wikis are public when any user can gain access to their contents and modify them. They are semi-public when any user can gain access to their content, but only authorized users can modify them. Finally, they are private when only authorized users can access and modify their contents.

Wikis possess the following interesting features. Firstly, since many users can edit their content they are suitable for *collaborative* applications, in which users collaborate to create knowledge. Secondly, public and semi-public wikis are visible to anyone, and therefore their contents can be *shared*. Finally, any authorized user can *revise*, *discuss* and *modify* the content created by other users. If we accept the constructivist paradigm together with student-centered approaches, these three features can make of a wiki a useful tool for the classroom:

- Projects or in general assignments that are documented by means of traditional editing tools, such as handwriting and computer text editors, usually reach the teacher and hardly a few students. On the contrary, an assignment edited in a wiki can reach the whole class no matter how large the number of students. Therefore, assignments can be shared and any student can benefit from the work of their peers.
- When the documentation of a project reaches all in the classroom, everyone can participate in the process of critical analyzing, discussing and providing feedback. Additionally, wikis provide with the necessary tools to revise and discuss each project. In other words, wikis' features facilitate peer assessment and inter-group communication.
- As opposed to other knowledge repositories such as books, that too many times are perceived as absolute and definitive, the use of a wiki can make the process of constructing knowledge transparent to students.

In summary, wikis constitute an interesting tool that provides a framework for students to construct knowledge critically and to enhance communication skills.

B. The oral dimension: Poster session

Public oral presentations constitute an excellent opportunity for students to develop their communication skills and stimulate inter-group interactions, reflection, and critical thinking and analyzing. When the number of students is limited, it is doable to promote an environment in which everyone participates. However, when the number of students is large, the most common situation is that at any time one group presents their project while the rest of the classroom act as a passive recipient. In these cases, attention is lost quickly and only the most active students from the audience participate, relegating the rest to a second plane. As a consequence, the scope of public oral presentations is greatly reduced.

Public poster sessions can overcome these difficulties while still enhancing communication skills. During a poster session, every group or only a few groups present their projects simultaneously in different stands that are distributed on the same physical space. In the same poster session, students can play both the roles of audience and presenters. Furthermore, students distribute themselves spontaneously forming small groups around a single project and as a consequence, personal interactions are greatly promoted and the average level of students' participation increases.

Another advantage of poster sessions is that students presenting their projects can increase the quality of their presentation during the session, since they present their projects several times in the whole session. This feature constitutes an interesting opportunity to promote self-reflection in students, who will try to analyze their own performance every time they present their project and will try to repeat those positive features and correct the negative ones.

III. PRELIMINARY RESULTS

For the past two years in our department, we have implemented in three courses a wiki environment using the free and open web-based software MediaWiki [10], and we have put into practice the experience with a poster session in another course. Results have been overall very positive and have encouraged us to propose the integrated learning environment that was described in Section II.

The first course that implemented a wiki environment last year was devoted to wireless technologies and involved senior engineering students [11]. The aim of the wiki approach was to enhance students' understanding of the industry sector of wireless technologies and its professional opportunities. Students were organized in small groups consisting of two or three members that were assigned the project of investigating the industrial sector of one wireless technology. They were told that the aim of their projects was to help them and their peers to understand each industrial sector by collaborating. Thus, project assignments were presented to students as a common goal, in which each group investigated one particular sector for the common benefit. Projects were documented in the wiki and course evaluation took into consideration both contents created in the wiki and a final oral presentation. Nevertheless, the possibilities of the wiki environment were not discussed in the classroom, no common format for each wiki entry was outlined and no ways of interacting between groups were considered. In other words, students were free to make the use of the wiki that they thought was the most suitable.

Students considered that compared to classic paper alternatives, the process of elaborating a wiki had been very positive and confirmed that the wiki approach had allowed them to learn about other projects, whose entries they visited regularly. Additionally, students said that the visibility of their projects had been a stimulus to increase the quality of their projects and had favored some spirit of competition among different groups. In summary, they benefited from sharing their projects and they were encouraged to be more critical about their work and their peers'. Nevertheless, we observed that they did not use all the expressivity that the wiki offered and as a consequence, wiki entries resembled a *virtual* version of classic assignment with the only difference that they were accessible to everyone. For instance, they did not link their projects to other projects and they did not attempt to develop a document structure other than linear. The degree of inter-group interaction was also observed to be more limited than initially expected by teachers.

We have tried to overcome the problems encountered last year by enhancing the role of the teacher in coordinating the wiki environment. Once again, we have implemented the wiki environment in the same course for students to document their projects [12]. However, this year we have outlined a common standard for entries elaboration. Even when this initiative limits students' freedom to use the wiki, we consider that the advantages of creating a common language and specifying basic rules overcome its limitations. Specifically, we have succinctly specified a common format for each wiki entry, including aspects such as extension and organization, use of references and use of images and intellectual property. Furthermore, we have devoted one session to discuss how to use our wiki environment, notably introducing non-linear document structures, and we have coordinated the interaction among students in the following way. Two deadlines have been established. In the first deadline, a preliminary version of each project must be available in the wiki. After this deadline, and during a week, students have to read their peers' projects and provide them with feedback to improve their assignments. Based on the feedback from their peers and from the teacher, the final version of their project must be available for the second deadline. After that, projects are presented in public. To date, projects have met the first deadline and students have provided their peers with feedback on their projects. Compared to last year's initiative, we have observed a noticeable increase in the quality of the wiki, which we attribute to the efforts to clarify the uses of our wiki. Students have said that reading their peers' projects has helped them to understand and learn about other technologies. Furthermore, the first deadline has given them the chance to reflect on their own work and some have confirmed that they will adopt some solutions found in other projects. Additionally, students have critically commented their peers' work, and they have said that the comments on their projects will definitely allow them to increase their quality.

The implementation of a public poster presentation in a course on digital image processing was very successful. Following project-based approaches, students were organized in groups consisting of two members and they were assigned one project. This initiative took place in a single session and there were altogether 15 groups. The session was scheduled as follows. During a time period of two hours and a half, teachers approached each group to evaluate their project. During evaluation, it was necessary that both members be there to explain their project and answer various questions. Meanwhile, in the rest of the groups one member had to stay at their stand to discuss it with their peers while the other could approach their peers' stands to know and discuss their projects. Halfway through the session (approximately after an hour and 15 minutes), group members would exchange their roles.

With this initiative, teachers achieved increasing students participation. Students commented in turn that the discussions that originated were open and lively. Interestingly, students agreed that repeating the presentation of their project several times gave them the chance to reflect on their exposition and continuously improve it. In fact, teachers observed that the best presentations were the last ones, probably because of this spontaneous self-improvement process. In general, compared to traditional oral presentations the poster session increased the motivation and enthusiasm among students. The success of this approach is that it facilitates that students remain active for the duration of the session, while in traditional presentations their attention span is limited to 10-15 minutes. Additionally, it allowed other students and teachers from other courses to attend and participate.

IV. CONCLUSIONS AND FUTURE IMPLEMENTATIONS

In this paper we have proposed an integrated student-centered collaborative learning environment for developing communication skills. We adopt a constructivist approach according to which, the best way of learning is by constructing knowledge. The main ingredients of our learning environment are project-based methodologies and peer-assessment, and we propose two strategies to put our method into practice. The first one is a wiki environment, and it is used to document projects, enhance writing skills and facilitate content sharing, reflection, discussion, inter-group communication, and critical thinking and analyzing. The second one is a public presentation based on poster session, and allows us to enhance oral skills, promote participation, inter-group communication, and critical thinking and analyzing.

We have implemented both mechanisms for the past two years in different courses and the results are very positive. Our previous experiences have allowed us to reflect on their outcomes and to improve their practical implementations. In the future, we will implement in other courses our integrated learning environment, by combining both wiki approaches and public poster sessions in a coordinated manner.

***Abstract*—This paper analyzes new trends on the use of technology in engineering education having as main source the Horizon Report. We discuss and analyze the predictions of this source and also other different views of the current situation in the use of technology based in the previous forecasts and the experience in distance, on-line and on-class engineering education.**

Keywords: Technology enhanced learning; engineering education; service-oriented learning.

I. Introduction

Everyday technology is having a more important role inside the engineering education just as new technologies are part of the day-to-day learning. And those technologies are implied in the learning process everywhere and in every different learning model (in the traditional on-class system as well as in on-line or distance models, which have everyday more in common in their evolution).

In the last 10 years we have had an impressive new use of technologies inside the learning process as well as communication and Internet technologies impacted previously in the last part of the 20th century. The Horizon Report (HR) [1], a work from The New Media Consortium and the EDUCAUSE Learning Initiative (ELI), has been foreseeing since 2004 the impact of the technologies inside the learning process along the world having three temporary scopes: the year of the report (short-term), the next two years (mid-term) and finally, the four years following the report (long-term).

II. Objectives

We will use these predictions from 2004 to 2009 (six Horizon reports) that will cover the period 2004-2013 to analyze the technologies that will have a higher impact in education.

We will also discuss about the technologies not covered in the report and that we believe will also have a great impact in the engineering learning near future. In this process we will keep in mind the expertise from previous engineering technology projects as well as the knowledge shared in different technical conferences that provides a guide of the most used technologies around the class-rooms.

With all this information together we will develop a structured view of the foreseen technologies that will have an active role inside the engineering education process, providing our agreement or not with these predictions. On the other hand, the study will include the not forecasted technologies in the past that have been really used in the practice today. Finally we will analyze the technologies that currently and in a near future could have a great impact in our engineering education.

III. Methodology

The first stage on this research is to gather the technologies identified in each one of the six existing Horizon Reports. These technologies are structured according with the three adoption horizons: short-term, mid-term and long-term.

This work provides information about the technologies that have been identified as the more likely to impact since 2005 to 2014, but with the benefit of a temporal perspective.

The second stage is to create a visual representation of the results, using different colours to differentiate the technologies obtained from the different reports. This work provides an overview of all the technologies involved in the educational environment during the last years and also the most promising technology for the near future.

The third stage is aimed to group technologies according with their similarities and create particular views of each technology group. This work will help to detect where the technology flows are going to and what technologies have finally impacted on the educational environment and on contrast, what others have postponed their implantation or just have never arrived.

Finally, the fourth stage has as main objective to provide comments about what technologies have impacted in the educational environment and do not appear in the research.

IV. Most likely technologies to have an impact on education

According with the stage 1 of the proposed methodology, the following temporal diagram (Figure 1) represents the technologies that Horizon Reports considered as the most promising to have impact on education.

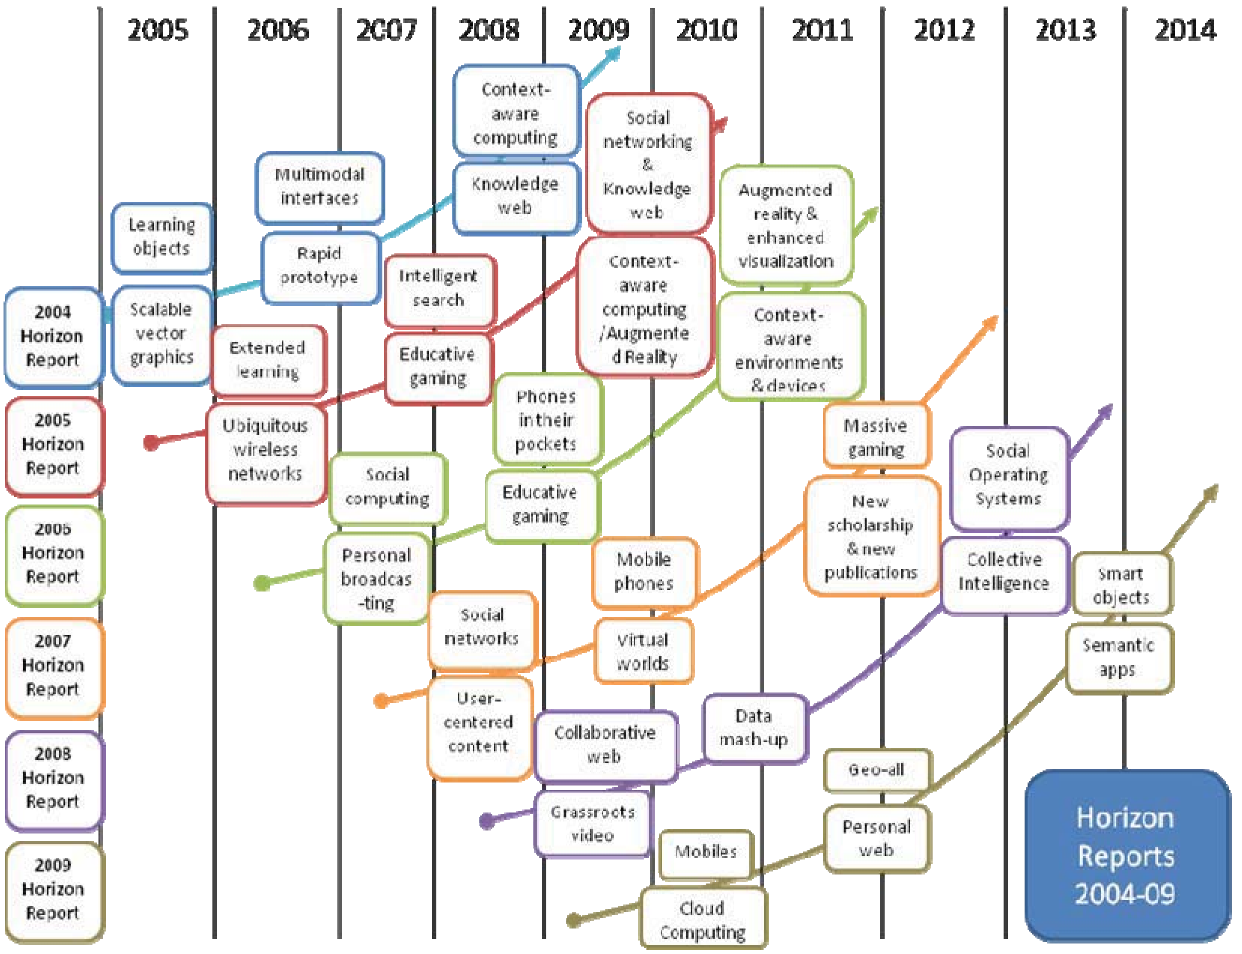

Figure 1. Most likely technologies to have an impact on Education according with Horizon Reports from 2004 to 2009.

In figure 1, each one of the six Horizon Reports is represented in a different colour. And also everyone provides two technologies in each term (short, mid and far) placed in their suitable temporal range.

These technologies can be structured in six technological groups that will simplify next stages. These groups are the following ones:

- Knowledge-Web. It includes cloud computing, which is based on the use of educative services on the cloud. It also includes the called Personal web, which is aimed to reorganize and customize the web according with the preferences of the students. Besides other technologies, in this group it is possible to find technologies that support knowledge representation (learning objects). These technologies are the basis for the arrival of others such as intelligent search engines and semantic-aware applications (understanding of the meaning of the web content); etc.
- Augmented reality. This technology provides additional information to the real world with interactive features. It can be used on both desktop-based computers and mobile devices.
- Social networking. It is aimed to enhance the collaboration and communication among students through moving the social networks phenomenon.
- Ubiquity. It includes smart objects (the Internet of Things within the education environment. It involves technologies such as RFID, QR codes, NFC or smartcards);
- Educative games (both on desktop or mobile computers, helping learners to be immersed in a virtual world that offer them a deeper understanding of the concepts).
- Mobile devices (thanks to new interfaces, location-awareness, broadband connectivity, etc.) and Geo-everything (mainly related to mobile devices);

These technologies will be studied in more detail in the following points, providing a temporal graphic for each one, which will help to analyze the technology flows.

V. KNOWLEDGE WEB

The use of Web-based technologies in education does not suppose any innovative approach. However this research focuses on the arrival of technologies that will support the development of the called 'Knowledge Web' [2]. It is based on three key trends: knowledge representation, mainly through some kind of meta-data or structure language; knowledge generation through collaboration; and personalization of the gathered knowledge (Figure 2).

The first trend was forecasted in the reports for the first time in the 2004 HR, with the arrival of learning objects (forecasted for 2005) and knowledge-web, basically based on technologies such as RDF or RSS (forecasted for 2008-09). The 2005 HR also forecasted it as an important technology to have into consideration, but in this case closely related with social networking (implantation in 2009-10). These technologies are today totally implanted.

The second trend is related with collaboratively creating and sharing knowledge, using the representation schemas previously created. Within this concept we can also find the personal broadcasting, forecasted in the 2006 HR for its arrival in 2007, and based on the idea of a user that will create its own multimedia content that will deliver to others through the Internet (e.g. YouTube-like tools). In addition, regarding also this trend, the 2007 HR included as key technologies for 2008 the creation of user-centred content (the user actively becomes author of the content, not just a listener, as in the case of blogs, wikis or video-web creation). In fact, as this technology was rightly a fact, the 2008 HR saw the impact of more advanced collaborative technologies, as data mash-ups (forecasted for 2010-11). These technologies merge knowledge from different sources (pictures; real state; entertainment, academic or corporate information) into other tools (e.g. maps and social networks) getting an added value from the raw knowledge. The impact of this technology will be considerably more important when the knowledge sources used to mash-up were based in a collective work (as Wikipedia is). This kind of applications are not far to be a reality. In fact, the 2008 HR forecasted its impact on education for 2012-13 (long-term horizon).

And finally, the technologies from the third trend are related to searching and getting personalized knowledge, based on the previous knowledge representation. Regarding the searching, the 2005 HR provided details of the implantation of intelligent search engines (e.g. federated searches, such as Blinkx and Google Scholar or Desktop) in a mid-term horizon (2007-08), which is a totally implanted technology today in the educational environment. This concept is the basis of semantic applications, forecasted in the 2009 HR to impact in a long-term horizon (2013-14). It is based on the idea of systems able to extract meaning from the information in the Web and giving personalized services and information more according with the user's needs.

On the other hand, regarding the personalization, trends seem to tend towards the personalization of the content, services and knowledge that the user receives. It specially reflected in the 2009 HR, which forecasted the impact of the personal web (self reorganization of Web content, using technologies such as RSS or Widgets) for 2011-12.

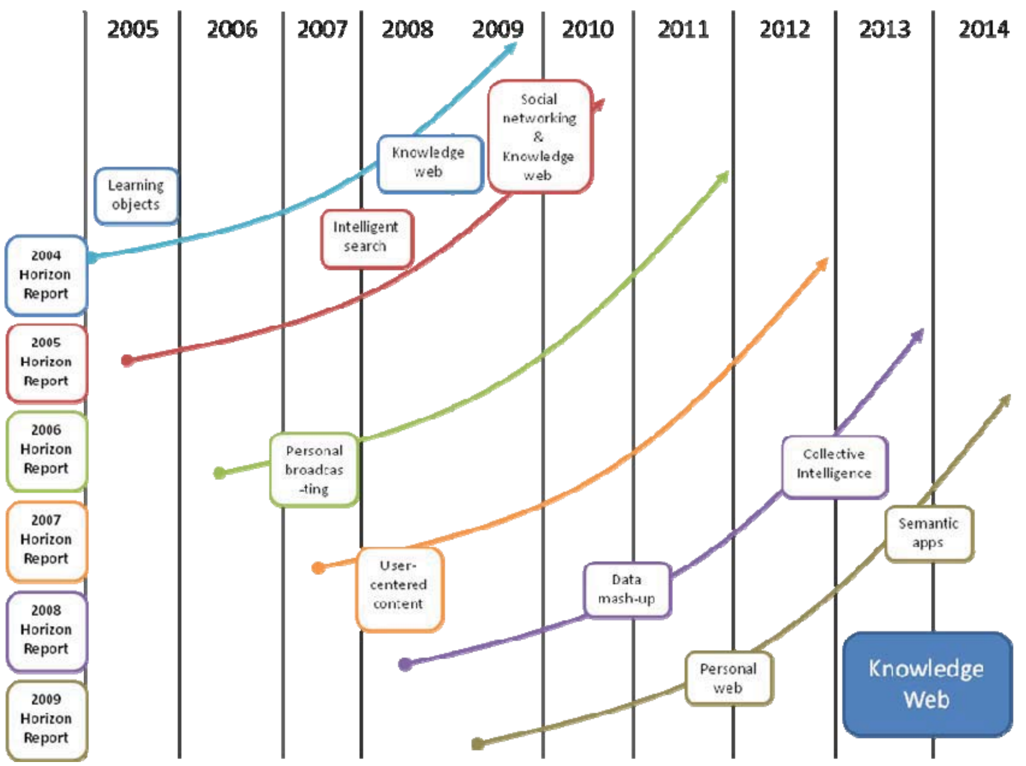

Figure 2. Most likely Knowledge-Web technologies to have an impact on Education according with 2004-09 HR.

VI. AUGMENTED REALITY

Augmented Reality (AR) is a technology that basically merges information or images with video-streaming from a Web-cam [3]. The result is similar to virtual reality but using real-world images in real-time. Some of the many potential revolutionary applications in education are related for example with the study of architecture, art, anatomy, decoration, or in general anything that a graphic, a simulation or a 3D model could improve the comprehension of the concepts. The forecast (Figure 3) in this field started in the 2005 HR, as a long-term promising technology (placed on 2009-10), and the next HR (2006 HR) delayed its arrival one more year (2010-11). Today, it still seems to be far from real implantation. Nevertheless, although any other HR has made any mention to this technology, it is still a promising technology. The proof is that some other technologies, apparently unconnected, are being developed and successfully implanted. As an example, the 2004 HR forecasted the implantation of Multimodal interfaces (i.e. the use of not only keyboard and mouse as input methods, but also others such as motion sensor, location, etc) and Rapid prototypes (i.e. creation of 3D models through CAD, CAT or even X-ray). These technologies are also related to AR, as 3D is one of the basic pieces of information provided, and the use of multimodal interfaces support the interactivity with the simulation just moving around it (motion and location sensors).

Reports also show other examples, such as mobile devices, that were forecasted in the 2007 and 2009 HR to have its arrival along 2009 and 2010.

2007 HR was also focused on user-centred content (forecasted for 2008). This technology is based on the concept that the user is no longer a mere listener, he/she will participate in the creation of any kind of material: videos, wikis, 3D model, etc to be mashed-up in geographical systems. This technology matches the conception of AR, as it is based on providing valuable material over real world images. Therefore, the experience will be more enriching as long as the user has more accessible contents. These two technologies specially converge when we talk about 3D models or information to be placed over a particular location. Along these lines, reports also show that other technologies such data mash-up and geo-all (2008 and 2009 HR respectively) will make its arrival between 2010 and 2012, when in fact, they are quite extended technologies. These technologies are closely related with the previous one because of the need of mashing-up content with location capabilities. Finally, other technology that apparently is not related to AR is Smart Objects, which is partially based on the concept of tags (RFID or QR). This tags support the tagging of our surrounding environment, helping us to provide it some kind of intelligence. This tags are also one of the key factors for AR, due to the fact usually the matching between real world images and computer-based information is through this tags. It means that when the AR system finds one of these tags, it changes it for the desired simulation or information.

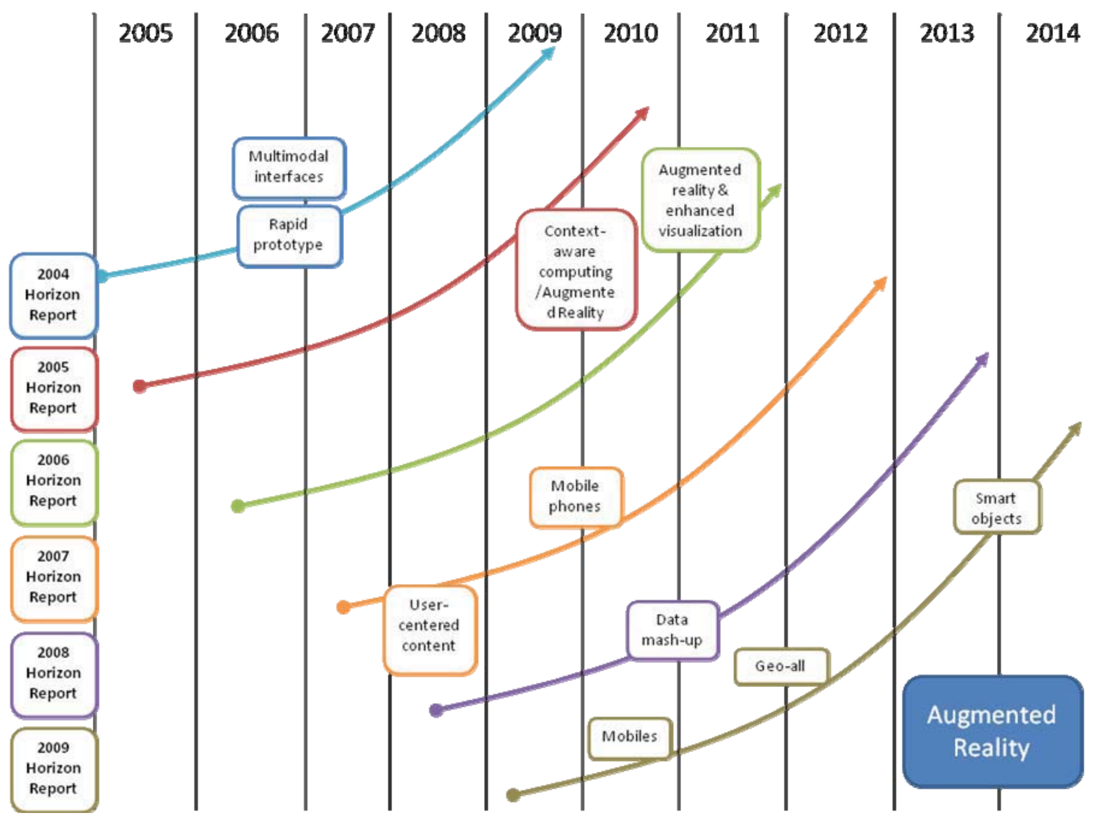

Figure 3. Most likely AR-related technologies to have an impact on Education according with Horizon Reports from 2004-2009.

VII. Social Interaction

The social phenomenon is one of the most promising technologies, as the amounts of technologies of this area that have been forecasted demonstrate (Figure 4).

The 2005 HR already forecasted the importance of the Social Interaction, through the arrival of collaborative tools for communication among students (called extended learning) in a short-term (2006), as it already was a widely implanted technology in other environments. This report also predicted its importance when it forecasted the use of more advanced tools in education, as social networking, in a long-term (2009-10).

The 2006 HR also reflected this fact, focusing on virtual collaboration tools (Social Computing) and broadcasting of user-created content (Personal Broadcasting), such as blogs, wikis, and audio/video based tools (its impact was forecasted for both during the year 2007). This last concept appears in the 2007 HR as user-centred content to have impact in 2008. Moreover this report shows the imminent arrival (2008) of a widely implanted technology in entertainment environments: Social networks. This phenomenon is based on the idea of providing advanced communication tools and the creation of a network of contacts, supporting a totally engaging environment. This report also focuses in a mid-term horizon (2009-10) on virtual worlds, which are the evolution of social networks towards totally immersive environments, where the user plays a role inside a virtual world. This report also describes the impact of Massive Multiplayer On-line Games (MMOG) in a long-term horizon (2011-12). Here the user plays with thousands of other players an engaging on-line game, which is active 24 hours per day. It means that the game goes on, although the user is not connected. In these games, every player has a specific role inside the game. It usually involves the development of complex tasks, such as a pharmacist that has to create pills to sell to doctors, which will use these pills to heal warriors in a battle. These tasks involve the development of many skills and knowledge in a very engaging environment. For that reason, education should not leave it aside of the academic environment.

On the other hand, the 2008 HR is again focused on the use of collaborative systems in a short term (2009), especially those focused on the Web, such as the use of collaborative tools to edit documents in group or sharing videos with a community. In the mid-term horizon (2009-10), data mash-up is introduced as a key technology. It is based on the idea of overlapping information over geographical systems. And finally in the long-term horizon (2012-13) the forecasting focuses on social operating systems, which promulgates the organization of the social networks around people instead around content. The other technology forecasted, in this report and in the same term, is Collective Intelligence based on the knowledge generated from large groups of users, such as Wikipedia or passive search patterns.

In brief, the social networks phenomenon has widely proved its power of engagement, and its capabilities to create collective knowledge [4] from the work of a group, which is more than enough to take it into consideration in education.

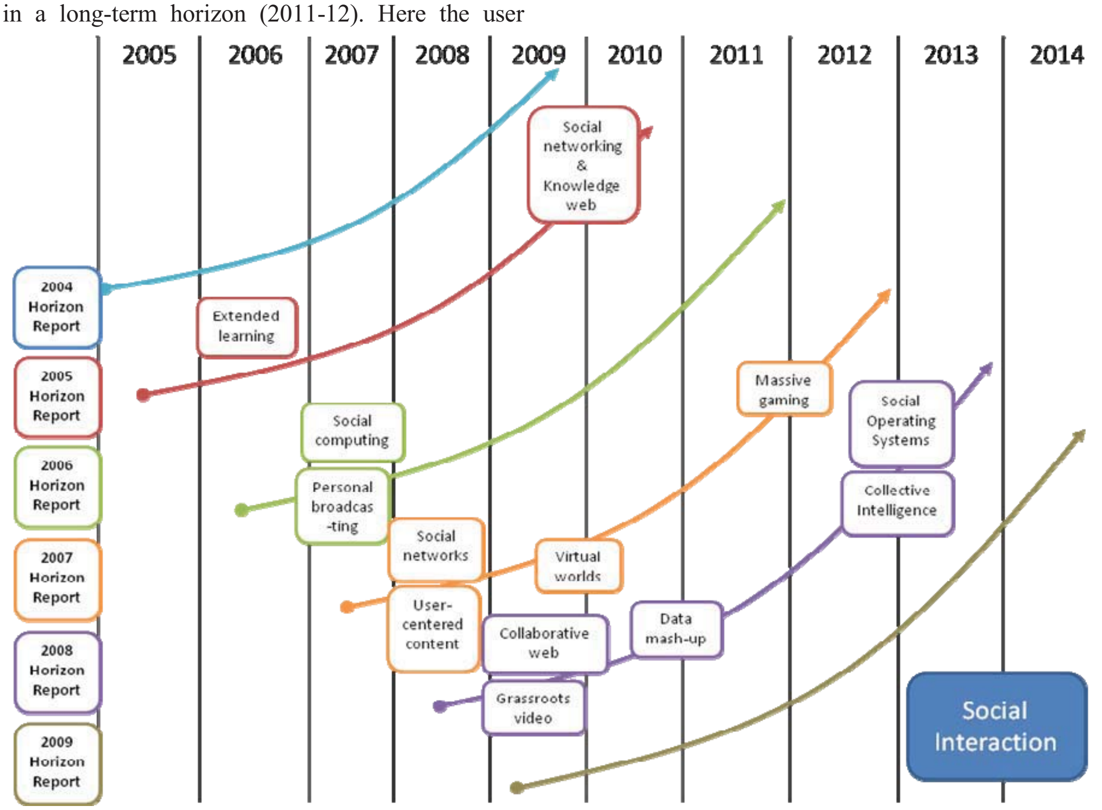

Figure 4. Most likely social technologies to have an impact on Education according with Horizon Reports from 2004 to 2009.

VIII. UBIQUITY

Ubiquitous computing is based on the concept of an invisible computing power embedded in the environment that can act and react according with user's needs. This paradigm involves the most natural possible interaction between user and computer with the final aim that the user will not even realize that is interacting with a system [5].

Ubiquitous computing is not a technology itself, but a group of technologies that will support the arrival of this new paradigm such as: context-aware computing, ubiquitous wireless networks, smart objects, location-based systems and more recently mobile-based technologies. For many years many of these technologies have been considered by experts as some of the most promising technologies to have an impact on all levels of our society (Figure 5). But the truth is that its arrival has been delayed.

In the 2004 HR, context-aware computing was foreseen as a key technology in a long term horizon (2008-09). In the 2005 report, an important technology for this paradigm appeared as implanted or in process of implantation in a short term: Ubiquitous wireless networks. In fact, it is one of the key requirements to support the arrival of ubiquitous computing, but experts again foreseen its implantation in a long term (2009-10). In the 2006 report, the phenomenon of mobile devices in education seemed to be a reality in a mid-term (2008-09). Context-awareness arrival is again delayed until 2010-11, although mobile devices could act as catalyst. Mobile devices were corroborated in the next report, but delaying its arrival one year (2009-10).

In the 2009 HR this paradigm returns as a promising technology. Here, mobile devices appear as a technology to be implanted in a year-term, as probably will happen. Obviously this implantation will not be worldwide, and cannot be seen in all the centres, but it will probably start becoming a reality.

Regarding with the other key-technologies in this report, it is interesting the impact in a mid-term (2011-12) of location-based technologies (geo-all). It is a fundamental piece of the puzzle, due to the fact it allow retrieving a very important part of the context (where the user is) to use it in a great variety of applications (e.g. just giving personalized services and information according with the location or integrating it with data mash-up systems). On the other hand, smart objects (Internet of Things, RFID systems, etc.) are forecasted for a long-term horizon (2013-14), which will allow to provide some intelligence to common objects.

The role of mobile devices in education started just as the basis of a very rudimentary mobile learning, but with the integration of ubiquitous computing and context-awareness paradigms, such as location-based technologies its functionalities are being extended to provide a real improvement on the learning experience [6]. The success of mobile devices in education in a short-term and its integration with ubiquitous technologies will probably foster the arrival of ubiquitous learning in a few years.

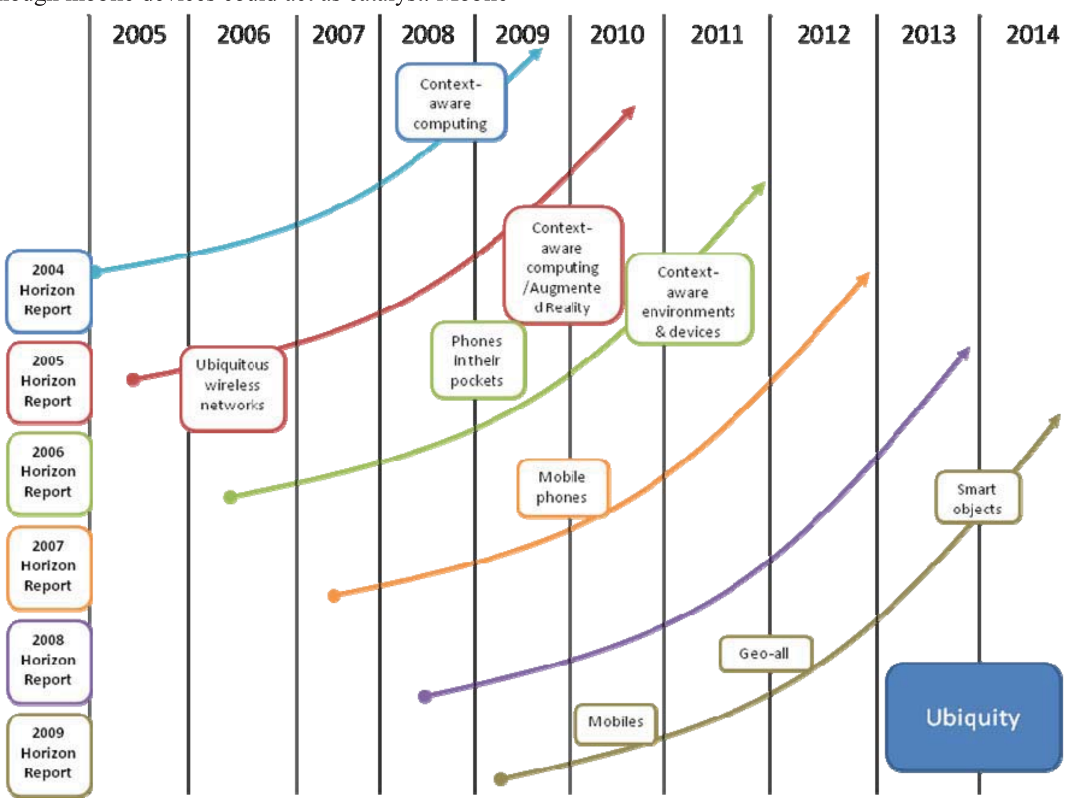

Figure 5. Most likely ubiquitous technologies to have an impact on Education according with Horizon Reports 2004-09.

IX. Mobile devices

Today's generation has grown with a new kind of technologies that the previous generation might not have imagined: cell phones, Smart-phones, portable video-consoles, GPS navigators, etc. Mobile devices have deeply impacted in our society changing the way we communicate and keep in touch with each others. Nevertheless today mobile devices are not just a communication method as the telephones are [7]. Today mobile devices are also changing the way we work, supporting any kind of applications (further of the typical office apps, Internet, and e-mail); spend our spare time with video games, Internet videos, podcasting, etc; get information, through GPS navigators, augmented reality or just surfing the Web; or even education. This field is where we are most interested in. Currently mobile learning is a promising technology that goes further than the traditional content-delivery by SMS or Web.

According with the studied HR's it is not until 2006 when for the first time experts think phones will have an impact on education. They foresee it in a midterm, it means in the 2008-09 period. This prediction has not been changed like the next report (2007 HR) only postpones it one or two years (until 2009 and 2010). Finally the 2009 HR place its implantation in a short-term horizon, it means for the 2010. Although there are only these references to this technology in the reports, its development has been accompanied by other related technologies such as location-based systems (context-awareness) (2004 and 2005 HR). Thanks to this technology it is possible to provide personalized services to a student according with his/her profile and location, therefore this involves a mobile device. As we have previously studied these ubiquitous technologies were foreseen to impact in education firstly in 2008 but its arrival has been constantly delayed.

Other important related technology is wireless networks. This is a key technology to support the success of mobile devices due to the fact anytime and anywhere connectivity makes the mobile device not being isolated but another part of the environment. Its arrival was foreseen for 2006 (according with the 2005 HR), and currently wireless networks are a reality anywhere (Figure 6).

The only related technology foreseen in the 2006 HR is data-mash-up. It supports merging useful educational information into maps to provide an added value. Its implantation was foreseen for 2010-11 but is today fully implanted (2009). This concept also appears as Geo-everything in the 2009 HR for 2010-11 (mid-term horizon) but with the particularity of the use of data mash-up in mobile devices using the location-based features (context-awareness).

Finally the last related technology is personal web. It is based on the concept of reorganizing the Web instead of just viewing it. It started mainly for desktop computer but thanks to the proliferation of mobile devices it is very likely to have impact in education with both devices at the same time. It was also foreseen in the 2009 HR to impact on a mid-term horizon so its implantation should be around 2011 and 2012.

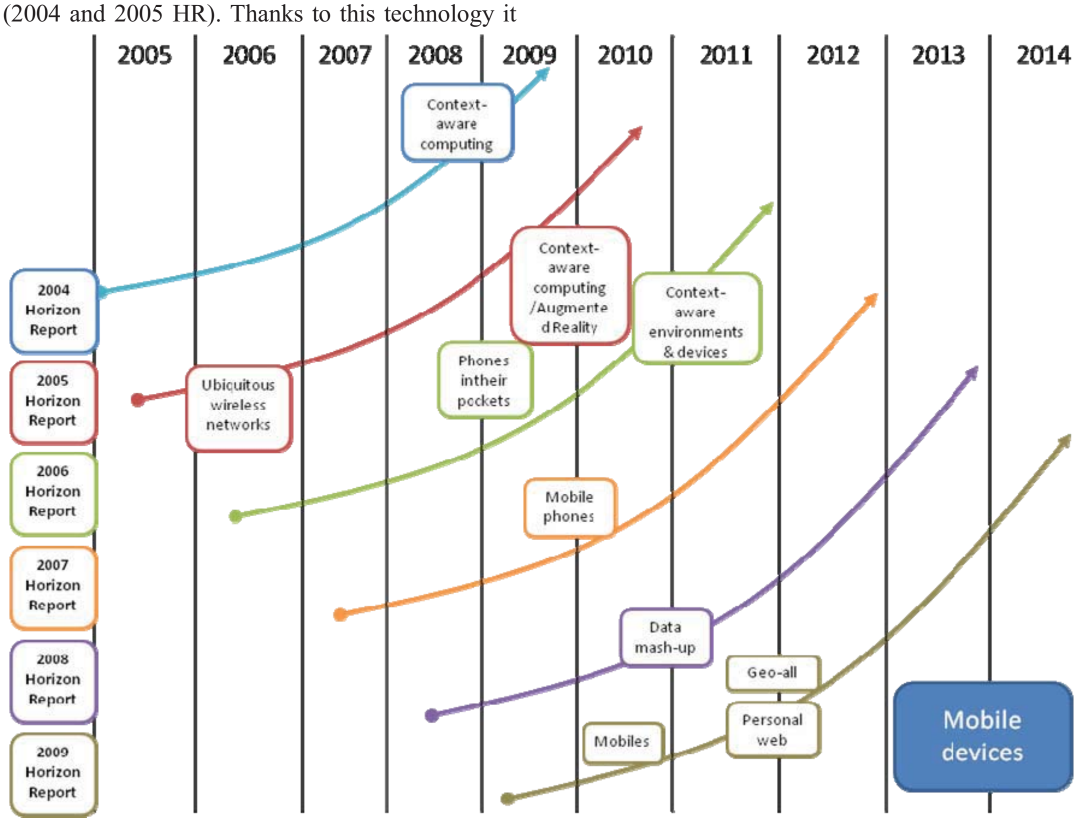

Figure 6. Most likely mobile technologies to have an impact on Education according with Horizon Reports from 2004 to 2009.

X. Games

As we discussed in the previous chapter, today's generation are used to other kind of interaction. New generations demand more interactive and engaging materials for learning. Since this is the way they have acquired many of their cultural knowledge. Many students spend many hours watching attractive contents on TV, surfing personalized contents in the Internet or playing engaging games using their desktop computer or their mobile phone.

This fact makes necessary a change in the way of teaching or even better in the way of learning. New generations are not usually engaged with lectures in a classroom. Therefore many research efforts have been accomplished in order to create engaging games to support learning and not just for fun.

Along these lines the 2005 HR (Figure 7) forecasted the implantation of educative gaming in a mid-term horizon, i.e. between 2007 and 2008. Probably, the next report (2006 HR) again forecasted its implantation in a mid-term (2008-09), i.e. one year later, as this learning methodology had still many detractors.

The 2007 HR focused on two related technologies: Virtual worlds (forecasted for 2009-10) and Massive gaming (foresaw for 2011-2012). The reason is that both environments had successfully reached an important part of the society by 2007, so it was very likely also to impact education in a few years. In many aspects of our society Virtual Worlds have deeply impacted, giving rise to a parallel world, where people work, communicate, earn money, spend it and even receive education. Maybe the difference with reality, and the basis of its success, is merely the opportunity to do it without the fear to failure. When all is said and done, virtual worlds are just games and you always can start again. On the other side, massive multiplayer games also own the same engaging component, as they are also basically virtual worlds, but with a clearer objective: to defeat the enemies, to save the princess or to get the best scores.

These both predictions could make to suppose the idea of continuity; therefore this methodology should also appear in the following HR. But in fact, none 2008 and 2009 HR mentioned anything about it again. Maybe the reason is the mentioned doubt of a great part of academics who do not believe it can really contribute to education. Some of the allegations against educative gaming are the high-cost of game development (both economic and timing), its difficulty for non specialist (which is currently being improved through open source engines) and finally the required creativity for its creation. The reason is that it can be difficult to teach in a different way to this you have used to learn.

Nevertheless, some attempts are being done to move the power of games and virtual worlds towards companies [8] but not for training but for serious work due to its engaging power in repetitive jobs (e.g. a call centre). If games finally get to enter into serious companies, it is very likely to assume its final arrival to education.

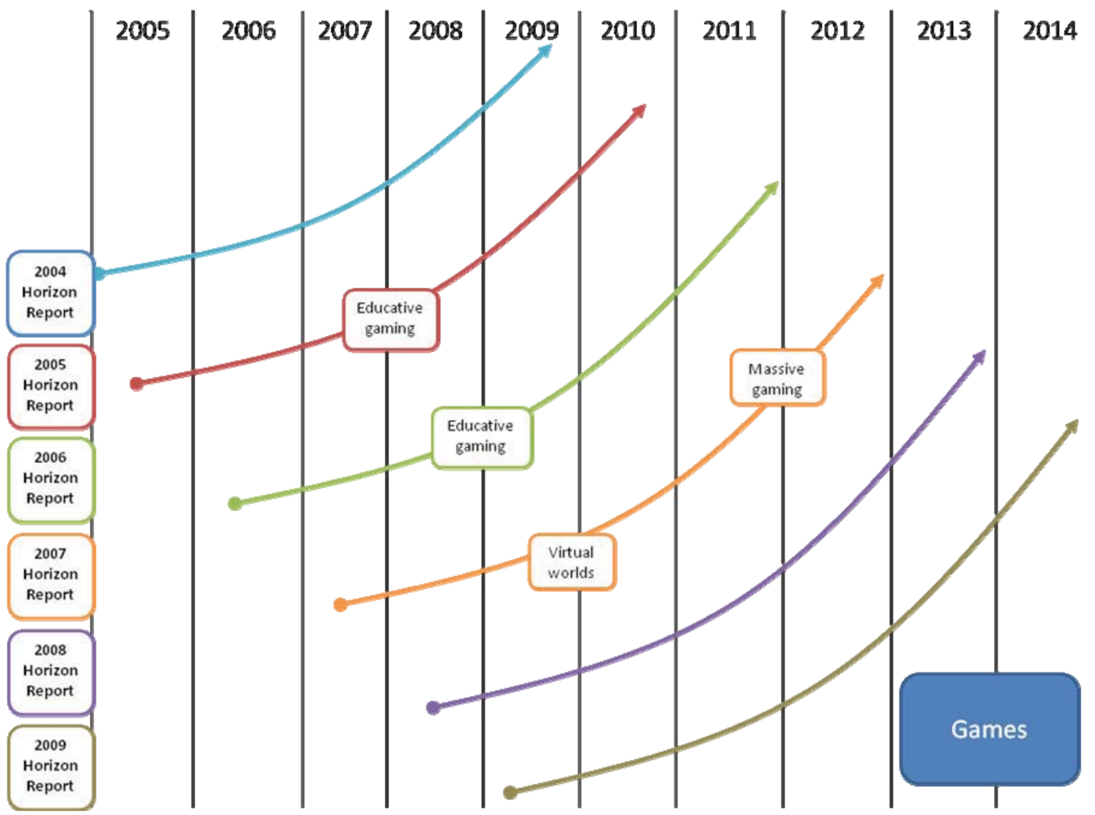

Figure 7. Most likely gaming technologies to have an impact on Education according with Horizon Reports from 2004 to 2009.

XI. Other promising technologies: Services

In addition to those already studied and grouped, there is other technology that will likely have an important impact on education, or better yet, on the way education is going to be built in the coming years. Some authors call this trend 'service-oriented learning', 'service-based learning' or 's-learning' [9].

This technology is related to the concept of learning object already forecasted in the 2004 HR to have impact on 2005, and also to the concept of Cloud Computing, forecasted in the 2009 HR for its impact on 2010. Likewise it is based on the idea of having different services available on the Internet (on the Cloud) that can be used and integrated regardless its physical location.

This service-based trend is based on the concept of modelling the educative services with the objective of providing better interoperability capabilities in different levels: service-services, platform-platform and service-platform. Equally it is based on the encapsulation of services, as the learning objects are, to develop autonomous and self-contained services that can be easily integrated in different environments such as Learning Management Systems, mobile learning environments, remote laboratories or assessing tools. Within this concept, there are many subjacent technologies that are its foundations, such as Web Services and Cloud Computing. Also there is another surrounding concept such as the Digital Ecosystems [10], which is based on the idea of creating environments made of different systems integrated in a plug-and-play way. It is achieved through the use of technologies such as SOA (Service-oriented architecture), ESB (Enterprise Service Bus) or ontologies.

Although emerging, this concept is getting more importance on education, and is becoming one of the key technologies as developers are realizing the necessity of reusing services not only inside the same platform or programming language but also among different platforms and architectures.

XII. Trends and flows: Technologies that seem not to impact and convergence

During the previous categorization and analysis we have detected some promising technologies that finally have never impacted on education.

As an example we find Ubiquitous Computing. Although this concept was firstly forecasted by the 2004 HR to have impact on education by 2008 it has not even had the expected impact on any of the other aspects of our society. But although slowly is getting a place in the industry; it is still too small to propagate its effects to education. For that reason it seems obvious we will have to wait until it finally takes the important place that seems to belong to see its effects on education.

On the other hand, mobile devices should be observed from a different prism. This technology has deeply affected our society, especially with the new wave of Smartphones, such as the iPhone or those based on the Android or Windows Mobile operating systems. The incorporation of new features such as location or motion sensors are giving rise to a revolution in the way people use these devices.

In fact, partly motivated by this revolution there is a technological trend that is making converge many of the technologies studied here into one. For example, thanks to the appearance of new multimodal interfaces, wireless networks and context-aware technologies (such as those related with location and motion sensors) mobile devices are getting more important. At the same time other promising technologies such as social networks are starting to arrive also to the mobile environment that seems to power even more these devices with never-seen communication capabilities.

Other key-technology for the near future is Augmented Reality, which is becoming also to be implanted in mobile devices providing more flexibility and variety of applications. The new range of environments that can be affected by the combination of both technologies is enormous. For example, in education, this technology in books and magazines could revolutionize the way people study or spend their spear time just providing additional multimedia information over the books through the mobile device. Other relevant example could be for out-of-the-class activities such as those related to agronomy, archaeology, history, natural science, and in general any subject which an in-the-field or challenge-based work that could provide an improvement on the learning experience. At the same time, this is closely related to games because they are based on the concept of challenge. In addition, mobile devices strengthen even more its engaging capabilities because are themselves attractive devices especially with the incorporation of more natural ways of interacting, such as multi-touch screens, motion and light sensors and location capabilities.

Finally, the last key group of technologies studied is also converging with mobile devices as their new operating systems are developed with the idea of simplifying the access to the information and the personalization of services. As an example we find the Google personalized searches depending on the user's location (from cell-tower triangulation or GPS) or the quick access to relevant information of the user through the utilization of Widgets and RSS.

In conclusion, mobile devices are called to be one of the most important technologies on every layer of the society in a near future including of course education. It will be the technology base for the successful arrival of many other promising technologies like:

- Ubiquitous computing
- Social networks
- Augmented reality
- Games
- Personal Web

XIII. Conclusions

This research is aimed to clarify which of the main technologies are called to have an impact on education according with the history provided by HR. This analysis tries to provide a perspective on the evolution of some technologies towards others. Having the aim to support a better understanding of the technology flows in the past and to predict what could be the future.

The result is that there are six groups of technologies that are converging into one: mobility. However, it does not mean they are going to disappear and mobile devices are going to be the most important technology. In contrast, these groups of technologies will go on getting more importance, through different branches; and being enforced thanks to the flexibility and synergy power that mobility provides. And at the same time, mobile devices will probably be enforced thanks to the growth of the other convergent technologies, because it will be a tool able to support all of them.

As a conclusion and using the results of this analysis, authors consider important the development of strategies and architectures able to support the forecasted convergence and integration of different technologies into mobile devices. The objective is to provide suitable communication methods and interoperability among these technologies, in order to support their better development.

XIV. Acknowledgements

Authors would like to acknowledge to the Spanish Science and Innovation Ministry for the support in the project TIN2008-06083-C03/TSI "s-Labs – Integración de Servicios Abiertos para Laboratorios Remotos y Virtuales Distribuidos" and to the CYTED-508AC0341 "SOLITE- SOFTWARE LIBRE EN TELEFORMACIÓN" project support. Authors also want to acknowledge the support provided by e-Madrid Project, S2009/TIC-1650, "Investigación y Desarrollo de tecnologías para el e-learning en la Comunidad de Madrid".

Secondly, authors would like to give a special acknowledgement to The New Media Consortium and the EDUCAUSE Learning Initiative (ELI) for the public accessibility that the Horizon Reports have, which have been the key-stone of our research and the inspiration and guidance of many researchers during the last years.

And finally, authors also want to acknowledge the time dedicated by Dr. Byron Reeves from Stanford University to explain us how the engaging power of games can be part of serious work. And also, to DEBI (Digital Ecosystems and Business Intelligence) Institute from Curtin University of Technology (Australia) for its support in the study of the Digital Ecosystems concept.

Abstract— **Collaboration is supposed to be easily implemented in Learning management systems (LMS). Usually the basic functionalities in that respect support grouping students and providing communication features so that they are able to communicate with each other. However, related collaborative learning and CSCL studies and developments, which have been investigating how to manage, promote, analyze and evaluate collaborative features for decades conclude that there is no easy way, and much less standards-based approaches to support effective collaboration. The mere use of a typical set of communication services (such as forums, chat, etc.) does not guarantee collaborative learning. Further, managing collaborative settings in those LMS approaches is usually a time consuming task, especially considering that a frequent and regular analysis of the group's collaboration process is advisable when following and managing the collaborative processes. To improve collaborative learning in those situations we provide tutors and learners with timely information on learners' collaboration in a domain independent way so that the model can be transferred to other domains and educational environments. After setting a collaborative experience in an open and standards-based LMS, we have analyzed, through various data mining techniques, the learners' interaction in forums during three consecutive academic years. From that analysis we have built a metric with statistical indicators to rank learners' according to their collaboration. We have shown that this rank helps learners and tutors to evaluate the collaborative work and identify possible problems as they arise.**

Keywords- Collaboration, Data Mining, Distance Education Learners

I. Introduction

The current web-based Information and Communication technologies (ICT) bring people closer together. In particular, Learning Management Systems (LMSs) use the ICT's so that learners can interact with educational contents and other learners. Collaborative strategy can be implemented in those LMSs to improve the learning and mitigates the typical conditioning factors (loss of communication quality with fellow students and teachers) of the distance education [2]. Even AI techniques have been applied to model mainly learners and their knowledge [7]. However, collaboration so widely used and useful in educational environments has not been deeply researched and a standard method to analyze collaboration has not been established [24]. Although some research works have focused on collaboration [25], the proposed methods are difficult to transfer to other educational environments [21].

Moreover some researches claim that collaboration analysis is necessary to verify that collaborative learning takes place [14] and the metacognitive information on collaboration, which is obtained from the analysis, helps learners to improve the control on the learning and collaborative process [10].

In this paper we propose an approach to rank learners' collaboration according to their interactions. The objective is to help learners to improve the collaboration process through a method that both provides information on learners' collaboration, and can be used in others LMSs. Accordingly we focus our approach on a quantitative analysis of interaction data in an open-collaboration learning environment.

The educational context of our research is suitable for collaborative learning, because our learners at UNED (The National University for Distance Education in Spain) are used to the distance learning model. UNED's students are mainly adults with responsibilities other than learning. For this reason UNED's students cannot be forced to collaborate in a typical CSCL where they are requested to meet demanding time restrictions and fixed collaboration patterns [12]. We have solved this problem by providing learners with an open collaborative learning experience supported by an LMS, where students could manage their own collaborative learning process. We designed a long-term collaborative learning experience with 4th-year Artificial Intelligence and Knowledge-based Engineering (AI-KE) students. This experience consisted of 2 main phases within a step-wise approach: the first phase covered 3 consecutive weeks and the second phase covered 10 weeks. It was enough time for students to complete the collaborative work and be able to manage their collaborative process. We offered the collaborative learning experience during the academic years 2006-07, 2007-08 and 2008-09, and more than 100 learners every year participated in the experiences.

To cover the objectives, we proposed an approach based on quantitative analysis of the learner interactions in forums. Forums are a very common service in a collaborative environment and the statistics from forums can be obtained just after the interaction has occurred. We propose building a metric with statistical indicators, which are related to learner's collaboration. First we suggest some statistical indicators, which describe the initiative, activity, learner constancy and activity caused by learners. As the relation between statistical indicators and collaboration is unknown, we have used machine learning algorithms to reveal the relation. After the machine learning analysis, we found that the most collaborative learners are learners with high and constant initiative, high and constant activity, and they caused more activity than others. After the machine learning algorithms had selected the statistical indicators, we built a metric to rank learners according to their collaboration. We conclude that the ranking is an approximation of learner collaboration.

A short overview of methods already used in evaluating the collaboration process is given below. We describe the collaborative learning experience and the inferring method. Next we show the results obtained afterwards by applying the inferring method and we explain in depth how the inferring information has been shown to learners. Finally, we conclude with the discussion and future works.

II. Related Works

There have been various experiments to measure or identify the collaboration that is taking place between users of a system, although the methodology and standards are scant to analyze collaborative educational environments [24]. We mention two main points of research works, which focus on collaboration: data acquisition and inferring methods.

We can identify three data acquisition methods: 1) Qualitative [18, 15]: where participants are asked directly or experts evaluate the activities of the participants. 2) Quantitative [25, 21, 13, 5], which collects statistical information on the activities of the participants. 3) Mixed [8, 9, 17, 19]: the use of both methods simultaneously.

After the data had been collected, they were then analyzed using several techniques. These systems can be characterized by the inferring methods used. The methods may include: 1) Analysis by an expert [18, 15]. 2) Comparison with a pre-existing model using machine learning methods [21]. 3) Different statistical techniques [13, 9, 17, 5], or machine learning, such as clustering [25, 19], fuzzy logic [21], sequential pattern mining [19]; 4) Systems can even be characterized by not using any inference method [8, 9, 17].

Some research works focused on the experts' analysis to obtain evaluations of the collaboration [18, 15], others monitored learner interaction to improve collaboration knowledge but they did not obtain any evaluation of the collaboration [8, 13, 9, 17, 5] and some others used machine learning algorithms to analyze collaboration, although the expert's analysis is necessary [25, 21]. For this reason the regular and frequent evaluation of the learners' collaboration are delayed or the approach cannot be transferred to other learning environments.

We propose an approach to obtain evaluation of the learners' collaboration in a frequent and regular way, and reusable in other collaboration environments. This evaluation rank learners according to their collaboration. The approach uses both statistical indicators of learner interaction without semantic information and also the expert's analysis of collaboration as a data source, and machine learning algorithms to relate the statistical indicators to the expert's analysis of collaboration. With the statistical indicators most related to the expert's analysis we propose building the metric to rank learners.

III. Collaborative Learning Experience

The loss of communication quality that usually affects the distance education environment can be solved, if collaborative learning strategy is used [2]. However, the collaborative learning strategy must be focused on the learner to use all advantage of collaboration [11]. The distance education learners can be characterized by their diversity (different ages, residence, background, objectives, experience, etc) [4]. These learners are used to managing their own learning process, because they have responsibilities other than learning. Thus, a collaborative learning experience must allow the learners to manage their own collaboration process.

We offered learners a long-term collaborative learning experience during three consecutive academic years; 2006-07, 2007-08 and 2008-09. The collaborative learning experience provided learners with enough time to perform the tasks without the typical time restrictions of CSCL systems.

The learning experience consisted of practical collaborative tasks, which covered 3 months of an annual subject on AI at the Computer Science School. The activity structure was divided into 2 main phases within a step-wise approach. The collaborative learning experience was offered to all students enrolled in the subject. The Figure 1 shows the learning experience schema.

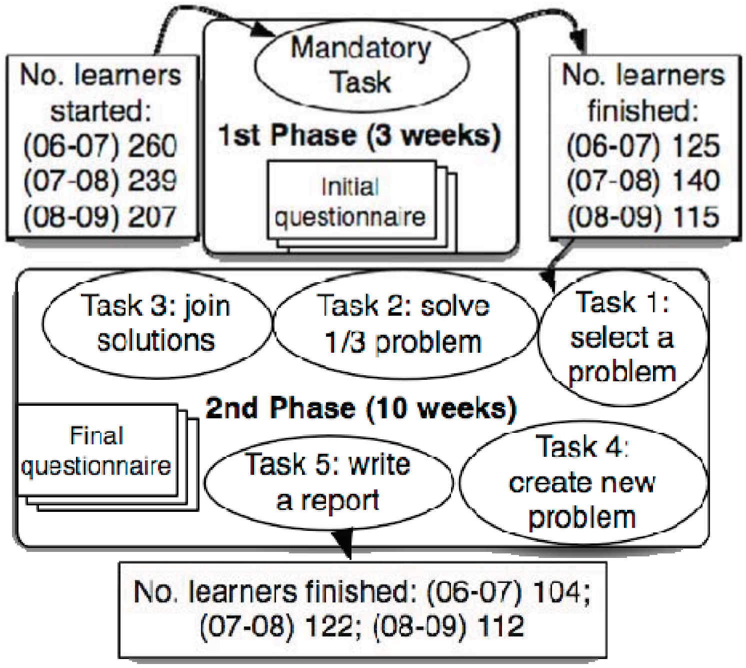

Figure 1. Learning experience schema

The first phase went on for 3 consecutive weeks where the main learner tasks were answering an initial questionnaire and solving an individual task. The questionnaire asked personal data and information about their willingness and availability to collaborate with one another. The individual task was mandatory and its results had to be integrated with the collaborative work to be performed during the second phase.

The second phase covered 10 weeks and the learners were grouped in 3-member teams. The team members had to follow 5 consecutive tasks throughout the collaborative experience. (1) In the forums teams discuss which problem they are going to address from the ones that are given to them. (2) This task is mainly individual work and consists of each team member solving one of the three different subproblems. (3) The team members have to integrate their previously generated individual solutions. (4) The experimental task takes place in this phase and here the team has to create other related planning problems that are based on the original one. (5) Finally, the team has to provide a report that covers all the activities and their corresponding results. At the end, the learners were asked to fill in a final questionnaire, which includes several topics with valuable information associated with the collaboration results. The team-work increases the difficulties depending of the done tasks, from the easiest (Task 1) to the most difficult (Task 4). Thus, the learners can be developed and improved the collaboration skills [16].

The whole range of activities included in the collaborative learning experience was supported by the open and standards-based learning platform dotLRN [23]. This learning platform stores all the interactions, which take place on the platform, in a relation database. During the first phase a general virtual environment was open for all students. The general virtual space included several services to support their collaboration needs, such as the file storage area, FAQs, news, surveys, calendar and forums. During the second phase a virtual spaces were opened for each 3-member team, where they could perform the tasks. The specific virtual spaces included documents, surveys, news, task manager and forums.

IV. METHOD

To know the collaboration learning happens, a frequent and regular analysis of the collaboration is needed [14]. In the aforementioned collaborative learning experience the learners have the control of the collaboration process. The tutor has difficulties to analyze the collaboration of all learners and teams in these circumstances. However, machine learning techniques can be used to analyze the learners' interactions to infer evaluations of the learners' collaboration.

The research objectives were twofold. Firstly, to build a domain independent method, which was capable of identifying the interaction features that were more relevant to support learner collaboration. Secondly, providing collaboration managers with timely results so that they could provide corrective actions wherever appropriate. We argue that quantitative data can support the overlapping required between user interactions and corrective actions. Besides, quantitative data without domain information (for instance, quantitative data without semantic analysis of forum messages) make it easier to transfer the method to other environments, because the data are domain independent. Our hypothesis was that the statistical indicators derived from learner interactions in forums could support both requirements, i.e. domain independency and simultaneousness.

We proposed a set of statistical indicators to characterize the forum interactions. We built datasets with these indicators and the dataset was labeled with information on learner collaboration. An expert, who was the tutor throughout the whole collaboration experience, supplied this information. We used machine learning algorithms [3], decision trees, to infer the relation between the statistical indicators and learner collaboration. The decision tree algorithms classify the given dataset instances according to the students' collaboration label, which corresponds to their level of collaboration. These algorithms provide a logic tree, which shows the dataset attributes used in the classification process (i.e., those that were more discriminatory). As we know the logic and theoretical difficulties (what the collaboration is, how to collaborate, what indicates the best way of collaboration [14]) of finding a model describing learner collaboration, we did not look for a model, which indicated how people collaborate. We looked for an estimate of indicators, which describe the collaboration in some way. This estimation is provided by decision tree algorithms, which link a model with the dataset attributes. Other methods like Bagging [6], whose approach is similar to the method being described here, improve the learnt model. As we did not look for the best model learned, we did not use those approaches. The decision tree algorithms are very sensitive to small changes in the instances. Accordingly, all dataset attributes should be used in the logic tree of some decision tree algorithm. However, the attributes that were most related to the collaboration should appear more than others and thus the machine learning algorithm bias is removed or alleviated.

The statistical indicators considered in datasets were as follows. We selected the statistical indicators to describe learner initiative, activity, constancy and regularity, and their acknowledgement by their fellow students, which are suitable for collaboration according to [22]). The statistical indicators considered in datasets were: number of threads or conversations that the learner started (num_thrd), and their average, square variance and the number of threads divided by their variance; the number of messages sent (num_msg), and their average, square variance and the number of messages divided by their variance; the number of replies in the thread started by the user (num_reply_thrd), and divided by the number of user threads; the number of replies to messages sent by the user (num_reply_msg), and divided by the number of user messages. The indicator number of threads started and its associated indicators are related to learner initiative. The square variance of the indicator number of threads is related to the constancy of the initiative. The indicator number of messages sent and its associated indicators are related to learner activity and constancy of activity. The indicator number of replies to messages sent and its associated indicators are related to the activity caused by the learner.

The statistical indicators are grouped into datasets expressed in tables where each row refers to the twelve statistical indicators of a student's interactions. Datasets were constructed with the indicator values for each academic year.

The doubt arose as to whether it was necessary to filter the datasets as some teams participated little in the forums because of coordination problems or they used other means of communication. Thus other datasets were created with the same data but without the students in the teams with little interaction. In other words, the students in teams with little activity were eliminated from the original dataset. The criterion for filtering was: eliminating students from a team, whose interaction was below half the average interaction of all the teams. During all the collaboration period these team members sent an average of 65 messages in the academic year 2006/2007, 73 in the academic year 2007/2008 and 87 in 2008/2009. In the academic year 2006-07 12 teams were filtered, 11 in the academic year 2007-08, and 8 in the academic year 2008-09.

The machine learning algorithms were trained to provide the validity of the different indicators. Then the datasets were labeled with a list of learner collaboration levels. An expert, who read the forums messages of each team and gave one value for the collaboration level to each learner in comparison with the other team members, supplied this list. The expert used a scale of 9 values (1 very collaborative, 9 not very collaborative, although the label "9" was used only to label students who did not send any messages).

Finally 2 dataset were built with the students' statistical indicators of every academic year. Thus, the non-filtered datasets were D-I-06-07 (104 labeled instances), D-I-07-08 (124 labeled instances) and D-I-08-09 (107 labeled instances), and the filtered datasets were D-II-06-07 (79 labeled instances), D-II-07-08 (97 labeled instances) and D-II-08-09 (88 labeled instances).

We needed machine learning algorithms that could classify learners according to their collaboration level. We used decision tree algorithms, because they return a logical tree, where each tree node is an attribute of the dataset. The logical tree informed us of the statistical indicator in relation to the labeled learners' collaboration. Instead of choosing the best learning algorithm for a given dataset, we experimented with several. There was no criterion to say which algorithm was the most appropriate taking into account that some decision tree algorithms classify all instances correctly but the tree is very complex, and others return a simple logic tree, although the logic tree does not classify all instances correctly [21]. For this reason there was no suitable criterion to choose only one decision tree algorithm. We used the data mining software WEKA [25], which includes several decision tree algorithms. We proposed the following working method: 1) Train all possible decision tree algorithms, which return a logical tree. 2) Identify the statistical indicators used from each logical tree. 3) Counting up how many decision tree algorithms use the identified indicator in every dataset. 4) Construct a metric with the most used statistical indicators. 5) Relate the metric to the collaboration level provided by the expert.

V. Results

We trained the decision tree algorithms with the labeled datasets and counted the number of decision tree algorithms that used some statistical indicator in the logical tree. The decision tree algorithms used were: Best first decision tree, DecisionStump, Functional trees, J48, Logistic model trees, Naïve Bayes tree, Random tree, REPTree, Simple Cart. Table I shows these results.

TABLE I. NUMBER OF DECISION TREE ALGORITHMS THAT USED SOME STATISTICAL INDICATORS IN EVERY DATASET.

	D-I-06-07	**D-II-06-07**	**D-I-07-08**	**D-II-07-08**	**D-I-08-09**	**D-II-08-09**
Num_thrd	4	3	3	2	**7**	**8**
Med_thrd	2	2	3	2	3	4
Var_thrd	4	3	4	3	4	5
Level_thrd	**5**	4	4	4	5	4
Num_msg	**5**	4	**5**	4	2	5
Med_msg	2	2	2	1	3	4
Var_msg	4	4	4	3	5	5
Level_msg	4	**5**	4	**5**	4	**8**
Num_reply_thrd	3	3	3	2	4	4
Med_reply_thrd	2	3	4	4	2	5
Num_reply_msg	4	3	**5**	**5**	3	**8**
Med_reply_msg	3	3	**5**	**5**	5	5
No. algorithms used	6	6	7	7	7	9

Each column represents the number of decision tree algorithms that used the statistical indicator (first column) in their logical tree with each dataset (first row), and therefore the importance of a given statistical indicator in relation to collaboration. For example, four (see column 2 and row 2 in Table I) decision tree algorithms (J48, Logistic model trees, Random tree, REPTree), which were trained with the dataset D-I-06-07 (2006-07 dataset without filtering non-active teams), used the statistical indicator "num_thrd" in their logical trees. However seven decision tree algorithms, which were trained with dataset D-I-08-09 (2008-09 dataset without filtering non-active teams), used the statistical indicator "num_thrd". We note that some decision tree algorithms did not return any logical tree in some cases, but in other cases they returned the logical tree. This is the reason for the last row in the table above. Slight differences can be observed between the unfiltered datasets of teams with little activity (D-I-XX-YY) and the filtered datasets of teams with little activity (D-II-XX-YY). The differences are due to the sensitivity of these algorithms to small changes in the data provided [20]. Adding the filtered datasets, in this instance, the number of trials is increased, so each decision tree algorithm's bias can be reduced.

To better identify the relationship between the indicators and collaboration, we added up the number of uses for each statistical indicator. As the number of decision tree algorithms were different depending on the datasets (see the last row of the Table I), we weighted the addition with two criteria: I) Each value in the table above is divided by the maximum value in the column and then the values are added up in each row. II) Each value in the table above is divided by the number of algorithms used (the value of the last row) and then the values in each row are added up. The results are shown in Table II.

TABLE II. WEIGHTED ADDITIONS ACCORDING TO CRITERIA TO IDENTIFY THE MOST RELATED INDICATORS TO COLLABORATION.

	Addition I	**Addition II**
Num_thrd	4.40	3.77
Med_thrd	2.73	2.25
Var_thrd	4.00	3.29
Level_thrd	4.61	3.80
Num_msg	4.51	3.63
Med_msg	2.33	1.97
Var_msg	4.34	3.60
Level_msg	5.17	4.25
Num_reply_thrd	3.27	2.73
Med_reply_thrd	3.51	2.82
Num_reply_msg	4.83	3.91
Med_reply_msg	4.54	3.70

From the table above we conclude that the statistical indicators most related to the collaboration level are: **level_msg**, **num_reply_msg** and **level_thrd**. With these statistical indicators we have created this metric:

$$\text{Metric I} = \alpha(\text{level\_msg}/\max(\text{level\_msg})) + \beta(\text{num\_reply\_msg}/\max(\text{num\_reply\_msg})) + \gamma(\text{level\_thrd}/\max(\text{level\_thrd}))$$

We note that the statistical indicators are normalized. The possible values of the statistical indicators are between 1 and 0. We normalize because the "level_msg" is always higher than "num_reply_msg" and "level_thrd" values and the effect of the "level_msg" on the metric would be too high. We introduced the constants α, β and γ to weight the metric. In this experiment we did not weight the metric, thus $\alpha, \beta, \gamma = 1$.

Finally, we related the metric to the collaboration level list. We calculated the value of the metric in each dataset. Then we grouped the instances according to their collaboration level, which was provided by the expert, and we measured the average metric of each group. The results are shown in Table III.

TABLE III. METRIC I AVERAGES FOR EACH COLLABORATION LEVEL IN EACH DATASET.

Level	D-I-06-07	D-II-06-07	D-I-07-08	D-II-07-08	D-I-08-09	D-II-08-09
1			1.03			
2	1.89	2.10	1.89	1.64	1.83	1.83
3	1.61	1.68	1.53	1.58	1.50	1.50
4	1.37	1.54	1.50	1.49	1.27	1.33
5	1.08	1.30	1.34	1.43	0.98	1.02
6	0.78	1.21	0.95	0.97	0.93	1.12
7	0.69	1.07	0.86	0.86	0.54	
8	0.60		1.22	1.27	0.95	0.95

We note that each level has a different metric value and this value increases when collaboration increases. Only the metric predictive value is wrong in the extreme levels (1, 7 or 8), where the number of instances was small. There are cells without value, because there was no instance with this collaboration level. In other words, higher values in the student's metric mean that s/he is more collaborative than others, and lower values (but not the lowest) in the student's metric mean that s/he is less collaborative. As this metric behavior is repeated in all the datasets, it can be suggested that the metrics are related to student collaboration, so the approach was validated.

VI. CONCLUSION AND FUTURE WORK

In this paper we have proposed a data mining approach to rank learners according to their collaboration. We think that the data mining method covers the objectives needed to improve the collaboration process. The objectives are: to obtain information on learner collaboration just after the collaboration interactions have finished and to be domain independent. These objectives are needed to apply the data mining method to other open collaboration learning environments and help learners in collaboration process management.

This research focused on obtaining information on the collaboration process using the statistical indicators of learner interaction in forums. As the statistics from the forums do not give any semantic information, the statistical indicators are domain independent. We propose that the statistical indicators are related to the initiative, activity and constancy of learners and the activity caused by learners. Our first objective was to build a metric, which represented learner collaboration mathematically. This metric had to collect some proposed statistical indicators. We needed to know the relation between the statistical indicators and collaboration. We used decision tree algorithms to establish this relation. An expert's analysis labeled the statistical indicator instances of learner interaction according to learner collaboration. Thus, the decision tree algorithms relate the statistical indicator to collaboration.

To validate the approach the experimentation of his research took place over three consecutive academic years 2006-07, 2007-08 and 2008-09, and over 100 students took part in the collaborative learning experience each year (125 in 2006-07, 140 in 2007-08 and, 115 in 2008-09). We built datasets with the statistical indicators of learner interactions in forums. At the same time, an expert labeled each learner according to his/her collaboration level. The labeled datasets obtained were used to train decision tree algorithms. The logical tree algorithm offered those statistical indicators that are used to learn the classification according to collaboration. We used the statistical indicators, which were most related to collaboration, to build a metric. Finally, we checked that the metric was associated with collaboration.

We have shown that the metric proposed establishes a mathematical relation with collaboration. Therefore, learners can be ranked automatically according to their collaboration while they are in the collaboration process. This metric can be used during the collaboration process in all LMSs or collaborative environments that use forums as the main communication mean. We have observed (see Table 3) the metric represents approximately the learners' collaboration. High values in the metric mean very collaborative learners. We have checked that this behavior is equal in all datasets of the research. Thus we argue the metric I can represents the learners' collaboration in future collaborative learning experiences, and the metric can be built easily, because the metric is a mathematical relation along some statistical indicators of interactions in forums. In addition, thanks to the flexible and general nature of the approach it can be transferred to other LMSs or collaborative environments.

Moreover in terms of the metric the method informs regularity and frequently about the learners' collaboration, which is needed to ensure that the collaborative learning happens [14] and gives information on metacognitive characteristics related to their collaboration, which helps learners to improve the collaboration process [10], and from that it is expected to affect positively their learning process.

After this research, to measure the effect of using the ranking method in an educational environment we need to check the improvement of the collaboration learning in comparison to other learning experiences without the ranking method. We have considered this issue and we researched other inferring methods [1]. We obtained positive results and deduced that an inferring method on collaboration improved the collaboration process management. We have to research this issue with the ranking method in future collaborative learning experiences. Other open issue is if the current inferring method can be improved. We have researched other machine learning methods to obtain the same objectives. In [1] we described our research when we used clustering algorithms to classify learners in spite of decision tree algorithms to rank learners. Both approaches have advantages and disadvantages. We must compare both inferring methods with the same data. However since the goal of the approach is to support learners' collaboration rather than applying the more precise machine learning approach we do not expect significance variations on the method. Another related open issue is the metric itself. In this paper the results were obtained when the metric constants α, ß, γ = 1, without weighting the metric. We are currently researching with weighted metrics where the constants (α, ß, γ) have different values and from that we will be able to compare the results between weighted metrics and non-weighted metrics in order to identify which one obtains better results.

Abstract — **The Technical University of Madrid (UPM) is pioneering the introduction in Spain of a new Degree in Materials Engineering, with a four-year duration, accessed directly from the baccalaureate-level studies. The materials engineers from the UPM will be prepared to meet the challenges not only in the field of structural materials, but also in functional materials and biomaterials. With the objective of enhancing student exchange programmes, the third year of studies will be taught entirely in English.**

Keywords: Materials Engineering, Degree Programmes

I. Introduction

The ability to manipulate, understand and use innovatively materials is an important measure of the sophistication of a civilisation. Our lives are enhanced and restricted by our relationship and ability to use materials effectively.

Materials engineering is an interdisciplinary field that studies the relationship among the structure of materials at atomic or molecular scales, their macroscopic properties, their processing and their applications. Materials scientists and engineers help to develop the materials required for new products, find better lower-cost manufacturing routes, and enhance the performance of existing materials. They consider the environmental impact and sustainability of their products. They discover how to optimise the selection of materials and create sophisticated databases from which properties and service behaviour can be predicted.

The study of materials engineering has for many decades been established across the economically-developed world. The academic study of materials encompasses aspects of the physical sciences and of engineering, with two central themes: the link between structure and chemical, physical and mechanical properties; and how control of microstructure through processing can be used to optimise engineering performance. The range of programmes to which this benchmark statement applies is diverse and extends from science-based to engineering-based programmes.

In this paper, the new Degree in Materials Engineering that the Technical University of Madrid (UPM) has started in 2009 is described. First, the scientific and engineering related knowledge and skills of Materials Engineering discipline are analysed. After that, characteristics of the Materials Engineering programmes at present in Spain and the rest of the world are revised, and finally the main features of the new Degree at the UPM are exposed.

II. The Materials Engineering Discipline

Historians have categorised the early ages of humankind in accordance with the materials utilised, with the emergence of the terms Stone, Bronze and Iron Age. In more contemporary times both concrete and steel have arrived, with the latter material being at the base of the industrial revolution.

The field of materials engineering began to be considered as a discipline in itself around the mid-1960s. At first, many materials science departments were named metallurgy departments and focussed their research and teaching on metals.

Yet if there were a material that could be said to have characterised the second half of the twentieth century, such a material would be silicon. Silicon is the *steel* of the semiconductor industry [1]. As steel allowed the industrial revolution to transform the more advanced countries of the time, silicon has provided the support that has enabled information technology to transform the contemporary world.

Developments in silicon have shown that materials engineering was not merely the legacy of metallurgy or even that of structural materials. There is no doubt that the field of structural materials engineering has a significant part to play in the aerospace, automotive and energy sectors. But, in addition, the area functional materials, those without a resistance function, cannot be overlooked, in particular those linked with the area of electronics (the next revolution in information technology will use light to transport and amplify information through photonic materials), as well as in the production of *clean* energy (materials for solar cells and fuel cells will be essential for the development of such *clean* energies) [1].

However, equally important is the development of biomaterials in the assessment, cure and replacement of organs and tissue. The dawn of a new age has been reached, one which has been termed the age of biomimetic materials. Materials will be developed that are able to “mimic” the properties and processing of biological materials. Previously little known nouns such as hierarchical microstructure and self-assembly will serve as basic terminology for the materials of the future. Furthermore, nanotechnology – applied to the field of biomaterials – is providing new approaches in the design of materials that will permit diagnostic and therapy techniques which will revolutionise healthcare.

In the 21st century, the field of materials engineering has been broadened to include every type of materials, including ceramics, polymers, semiconductors, magnetic materials, medical implant and biological materials.

III. Materials Engineering Programmes at Present

With significant media attention focussed on biotechnology and nanotechnology, in recent years materials engineering has been propelled to the forefront at many universities.

The study of materials engineering has for many decades been established across the economically-developed world, in particular in the member states of the European Union, in the United States and Japan [2]. In these countries, the degree in materials engineering – undertaken by students who have completed baccalaureate studies – provides graduates with a high level of professional competence throughout its four-year duration.

The preparation of the syllabus of the new Degree in Materials Engineering at the UPM has involved consultation with more that 70 European institutions and more that 40 private and state universities in the United States [3]. In the latter, a country which boasts more than 20,000 qualified materials engineers, these professionals occupy a leading place in the annual salary ranking that spans the different fields of engineering [4].

In comparison with other developed countries, in Spain the materials engineering degree course is a relatively recent programme. The UPM was the first institution to introduce an upper-level degree in the field in 1995 [3]. To be accepted to the course a prerequisite of three years of studies in another area of engineering was set. The orientation of the course was to structural materials, evolving from metallurgical engineering. At present, this upper-level degree is taught in another 14 universities across Spain. Since the first students of engineering materials graduated in 1998, more than 10 years of running the course have allowed alumni to access excellent career opportunities in all fields of engineering.

IV. The New Degree at the UPM

With the arrival of the Bologna Process and reform and adaptation of higher education in Europe, in Spain the UPM is once again a pioneer institution in the introduction of a new post-baccalaureate, four-year degree course in materials engineering [5].

The degree programme is measured in accordance with the credits awarded by the new European Credit Transfer and Accumulation System (ECTS). Considering one ECTS credit to involve 25-30 hours of study, the new Degree in Materials Engineering will entail 240 such credits, structured over four academic years (eight semesters) of 60 credits each one (30 credits per semester). Under such a structure a final-year dissertation or end-of-degree project (equivalent to 12 credits) will be undertaken.

The objective of the new programme is to provide engineering graduates with an interdisciplinary technical preparation, seeing them equipped to work with any type of material (biological, ceramic, metallic and polymer), and primed with a high capacity to adapt, both in terms of research and in development and innovation. In a rapidly-evolving world, the materials engineer will have to know how to model (to extract the characteristic parameters of a given situation), design (both new material and structural elements) and possess multidisciplinary knowledge.

The course involves a forward-looking curriculum in which students acquire knowledge of the three main branches of the field of materials: traditional structural materials, but also functional materials (semi, dielectric, optical conducting and magnetic materials used to create integrated circuits, storage media, sensors and other devices) and biomaterials (materials that interact with biological systems; materials of biological origin; and biomimetics) [5].

Basic skills

On account of its content and orientation, the Degree in Materials Engineering will be attached to the area of knowledge of Engineering and Architecture, including a total of 60 ECTS credits of basic subjects of such an area (see, Table I). The primary topics include acquisition of knowledge and skills in mathematics, chemistry and physics, as well as biology in order to support aspects of biomaterials programmes. Economy and Industrial Process Management has also been included. These subjects will be studied in the first two years of the programme.

TABLE I. Basic Subjects

Subject	ECTS
MATHEMATIC	12
ELECTRICITY AND MAGNETISM	6
ESSENTIAL CHEMISTRY	6
MECHANICS	6
THERMODYNAMICS	6
BIOLOGY	6
QUANTUM PHYSICS	6
SURFACE CHEMISTRY	6
ECONOMICS AND INDUSTRIAL PROCESS MANAGEMENT	6

Clearly, skills in maths and physics are a requirement for filling the pipeline of future engineers. It may seem logical to teach the foundational concepts for an engineering problem first, and only then introduce the engineering task. In many ways, the traditional engineering curriculum follows this model. However, the “basic first” approach is a poor instructional strategy at present [6].

Several studies have shown that it is expected the number of students who enter engineering programmes in college is projected to drop. To address this problem, new motivators are urgently needed, and engineering design activities is one of them. Introducing engineering problems from the first courses could help to create a powerful motivation for learning relevant science, and improve the interest in engineering careers.

In the new degree programme efforts have been made – from the very first semester – to involve students in working with the nucleus of materials discipline: that is to say, in knowing how to associate the structure of materials with their properties (Table II). Property and structural synthesis is carried out as early as possible in the programme, which is something that has a bearing both on the design of the material and on that of the structural element.

TABLE II. SUBJECTS INTRODUCING PROPERTIES-STRUCTURE DESIGN ACTIVITIES

Subject	Semester Schedule
STRUCTURE OF MATERIALS I	1st
STRUCTURE OF MATERIALS II	2nd
METALLIC MATERIALS	2nd
CERAMIC MATERIALS	3rd
POLYMER MATERIALS	3rd
SOFT MATERIALS	3rd

General and transversal skills

General (or transversal) skills identify shared attributes (in any degree course) which are considered to be of importance, whether by graduates or employers. Such general skills are distributed among three large groups:

- IT skills (use of information and communication technology)
- Communication and interpersonal skills (oral and written communication, organisational capacity, ability to work in a team, leadership skills, capacity to work in an interdisciplinary manner, ability to take on responsibility, and professional ethics).
- English language skills

All such skill sets, including the English language, will be taught and graded (as there will not be a specific module to cover them) in a horizontal manner, shared between all the subjects. Specifically, teaching in the English language will be deemed a priority, given its lingua franca position not only in science and technology but also in business and economic development. Consequently, the third year of teaching will take place entirely in English.

Itinerary: Specialties

Training in materials engineering requires a multidisciplinary and polyvalent approach, in the sense that the graduate will learn the foundations and applications of materials in three extensive fields: material structures, functional materials and life-science materials. Consequently, the subjects of the syllabus have been structured in a way that these three areas appear in obligatory study, both in their most fundamental aspects and in their applications, covering the necessary study needs of all graduates.

However, in order to address the complexity and specialisation of the three above mentioned areas, the syllabus will involve a specific approach, through three blocks of optional subjects taken mainly in the fourth year. Each such block marks a well-defined itinerary under which students will have to choose five subjects of a total of 24 ECTS credits. The three blocks are described in Tables III, IV and V:

TABLE III. ITINERARY: STRUCTURAL MATERIALS

Subject	ECTS
OBTAINING MATERIALS	6
SAPHE PROCESSING	5
MATERIALS ANALYSIS AND TESTING	5
JOINING TECHNIQUES	4
METALLIC MATERIALS III	4
BUILDING MATERIALS	4

TABLE IV. ITINERARY: FUNCTIONAL MATERIALS

Subject	ECTS
WORKSHOP ON FUNCTIONAL MATERIALS: STRUCTURAL	6
ADVANCED MATERIALS FOR OPTOELECTRONICS	5
ADVANCED MATERIALS FOR MICROELECTRONICS	5
WORKSHOP ON FUNCTIONAL MATERIALS: ELECTRONICS	4
WORKSHOP ON FUNCTIONAL MATERIALS: OPTICS	4

TABLE V. ITINERARY: MATERIALS FOR LIFE SCIENCES

Subject	ECTS
BIOMIMETICS	6
BIOMECHANICS	5
BIOSENSORS	5
ENGINEERING OF CELL MATERIAL	4
TISSUE ENGINEERING	4
WORKSHOP ON BIOLOGICAL MATERIALS AND BIOMATERIALS	4

Exchange programmes with other institutions

One of the primary objectives of the European Higher Education Area (EHEA) is to open education systems to free movement of students. In this sense, a primary objective considered for the new degree has been that of enhancing student exchange programmes with other European higher education institutions.

The third and fourth years of the new Degree have been open to exchange programmes, and specially important is that the third year will be taught entirely in English (Tables VI and VII).

TABLE VI. SUBJECTS TAUGHT IN ENGLISH IN THE FIRST SEMESTER (SEPTEMBER-JANUARY)

Subject	ECTS
MECHANICAL BEHAVIOUR OF MATERIALS III	6
PROPERTIES OF MATERIALS	6
COMPOSITE MATERIALS	6
NUMERICAL SIMULATION	6
OBTAINING MATERIALS	6
WORKSHOP ON FUNCTIONAL MATERIALS: STRUCTURE	6
BIOMIMETICS	6

TABLE VII. SUBJECTS TAUGHT IN ENGLISH IN THE SECOND SEMESTER (FEBRUARY-JUNE)

Subject	ECTS
QUALITY AND QUALITY MANAGEMENT	6
MECHANICAL BEHAVIOUR OF MATERIALS	6
NANOTECHNOLOGY	6
SURFACE ENGINERRING	6
RECYCLING OF MATERIALS	6

V. CONCLUSIONS

New materials have played an essential part in providing technology needed for scientific development, which has in turn brought great benefits to society. For this reason, empowering students in materials science and engineering is one of the paramount long-term investments that can be made in the technological future of a nation.

The first lectures of the new Degree in Materials Engineering at the UPM commenced in September of the academic year 2009-10, with the course being 100% subscribed.

ACKNOWLEDGMENT

The authors gratefully acknowledge the continuous support and effort of all the members of the Department of Materials Science of the UPM, whose work is and will be essential for the success of this project. Help and useful comments from the Vicerrectorado de Ordenación Académica of the UPM, and specially its Área de Planificación y Evaluación, are also acknowledged.

***Abstract*-- In RF and Microwave Engineering course, usually students struggle to build connections between the theory they have learned and practical applications in the laboratory. The laboratory applications are usually very limited for hands on experience since the high cost and maintenance requirements of the equipment. Additionally, new engineers need to know how to use at least one engineering design tool in order to practice designing RF components, circuits, or antennas. In this study, a curriculum model including recent developments and technologies in the RF and Microwave Engineering field by addressing above problems of the course is proposed. This study covers the description of the content of theoretical and hands on applications, the integration model of the technological tools into the proposed curriculum, and the instructional approaches used in the new course design which covers the use of a remote laboratory environment, Concept Maps and an engineering design tool. The course is structured with a balance between theory and laboratory, including remote and in lab measurement experiments as well as modeling and designing microwave components by means of computer tools and design fabrication. The newly designed course is implemented at the Atilim University. The first semester implementation shows promising results.**

Index Terms—RF and Microwave engineering course, curriculum design, remote laboratory, simulation tools

I. INTRODUCTION

Advances in the telecommunications industry and the widespread deployment of wireless network services have affected the career programs related to high frequency technology. These developments have also forced practicing engineers, computer specialists, and managers to re-educate themselves in the area of telecom/radio-communications technology [1], [2]. Parallel to these developments, a report by an industry/education partnership (Global Wireless Education Consortium-GWEC) involving more than 30 universities and 9 large companies in the wireless sector in the USA has identified new requirements for such professionals as well as noted a lack of Radio Frequency (RF) specialists [3]. Accordingly, several related educational programs have begun offering courses covering electromagnetic, RF, antenna, and microwave concepts, which are important components of any Electrical and Electronics Engineering (EE) and computer-related educational curriculum [4] and technical colleges, which are usually supported by hands-on experimental environments. For example, a remote laboratory on frequency modulation experiment principles [5], a face-to-face laboratory implementation in the field of antennas [6] and RF-microwaves [7], an RF hardware design laboratory with project oriented approaches [8], and wireless information networks [9] have been integrated in the curriculum of these courses. As Cassara [9] summarizes, some of these implementations exist that generally focus on wireless networks, radio frequency-microwaves, antennas, radar or optical communications. These implementations and studies show the recognition of the importance of these topics in the educational arena.

Parallel to these developments simulation (and CAD) applications are also started to be used as a critical and efficient tool on these courses. Additionally, Web-based and Web-assisted education alternatives are a new paradigm that is started to play an increasingly significant role in the instructional design efforts in these fields [4]. Accordingly, in order to prepare engineers satisfying the requirements of the industry, new approaches need to be reflected and emphasized in the curriculum of these courses.

In this study, the current situation and problems of electromagnetic, RF, and microwave courses offered at Atilim University are discussed first. In order to address the identified problems, this study proposes a curriculum model that reflects recent developments and technologies such as remote laboratory environments, simulation tools, and mind map graphical representations. This study covers a description of the content of theoretical and hands-on applications, an integration model of the technological tools into the proposed curriculum, and the instructional approaches that are used in the new course design. The newly designed course has been applied during one semester in the EE education program at Atilim University. This study also describes how the newly designed course is offered, as well as the problems faced and gains achieved during this course.

II. COURSE DESCRIPTION

As juniors, students with an EE major at Atilim University take one semester-long required RF and Microwave Engineering course. The aim of the course is to prepare the students for their future professional careers in RF and Microwave Engineering and for the sequence of senior courses, such as Antennas and Propagation, RF Microelectronics and Optical Communication Systems and Design Projects. These courses are offered as technical elective courses in the curriculum of the EE program of the university. The course is structured with a balance between theory and laboratory, including remote and in lab measurement and evaluation, modeling and designing microwave components by means of computer–aided design (CAD), and fabricating.

A. Course Content

The course is designed as an introduction to RF and Microwave (MW) systems. The following concepts are covered in this course: analysis of transmission lines and waveguides, the Smith chart, scattering parameters and matching networks, LC networks, single and double stub tuning using the Smith chart, RF and microwave passive components and system parameters, high frequency configurations of filters and amplifiers, PCB realization of RF and Microwave circuits, microstrip lines, and RF, Microwave, and Antenna design tools and measurement techniques.

B. Course Objectives

In this course, students should acquire the following skills and be able to:

- state the applications of electromagnetic spectrum above 300MHz frequency band;
- identify wave propagation on transmission lines and expand it to include microstrip structures;
- identify the fundamentals of transmission line systems, radio frequency (RF) and microwave components, sub-systems, and technology;
- operate tools and equipment used in the design and analysis of RF and Microwave components and sub-systems,
- design microwave components such as a microstrip line, microwave filters and single-stage microwave transistor amplifiers.

C. Laboratory Activities

Laboratory experience is an important part of an electrical engineering (EE) education. As shown in recent Internet-based remote and virtual laboratory studies, effective learning in EE education can only be achieved by approaches that combine theoretical courses with laboratory work where the learner can practice as necessary [1]. Laboratory experiments are usually performed as demonstrations on the following subjects: scattering parameters measurement, VSWR measurements and transmission line impedance, power measurements, and antennas measurement.

D. Problems with the Course

The course instructors face with several problems in this course. We can group these problems under three main headings: Laboratory hands-on experience problems, implementation of new technological tools in these courses and implementation of new instructional approaches used in these courses.

Problem 1: Since the only chance to provide the laboratory experiments by means of demonstrations in the laboratory, it is usually not clear for the students that what they have learned and how to relate it with the theory that they learn during the classroom instructions.

Problem 2: The instructor usually group students into 8-10 for each demonstration section. However this number is also still high for the demonstration sections and it is usually not possible to organize smaller student groups because of the high number of students enrolling this course.

Problem 3: The instructors also face with some maintenance problems in the laboratory since students accidentally broke some parts of the equipment. For example, once a student has broken while connecting 2.4mm to SMA adaptor of the Vector Network Analyzer (VNA). The instructor had to order this part from the company and it took three months to fix the problem. Accordingly, the instructor could not be able to use this port of the VNA in that year and only be able to show measuring S11 parameter.

Problem 4: There is a need for implementation of new technological tools in these courses. It is very important for the industrial organizations that the new engineers should know how to use at least one engineering design tool in order to practice on designing RF components, circuits or antennas. For example, our graduates are usually getting a job offer easily and becoming more competitive if they have experience on the design tools for RF, microwave or antenna. Additionally, the simulation tools such as CAD, help them to better figure out and experience the real-world industrial applications based on the theories that they have learned in the classroom. Introducing a simulation tool in such introduction courses also help students to better prepared for the advanced level courses such as RF and microwave circuit or antenna design and design project courses. In these courses they have a quick start without loosing time on learning and practicing on the simulation tools.

Problem 5: There is a need for implementation of new instructional approaches used in these courses. The instructors of these courses should provide some instructional approaches for building relationships between the theory and practical content of the course. Otherwise, students are having problems to build this relationship by themselves and they think that some of the theoretical content is not applied in theory. As a result, students usually forget the theoretical information because of the loss of connection with the theory and practice components of the course. During the laboratory hours, students always complain about finding related theory on a specific experiment that they are working on and performing and usually their intension is on thinking that the lecture instruction (theory of the course) is not related with the experiments that they are performing. On the other hand, students' learning expectation differ each other. Some students prefer to reach directly to the content that they are searching for, while others prefer to study the content from the beginning and then continue the experiments. Some of them prefer the graphical representations while the other prefer to read the text [10]. Accordingly, the instructors may have problems offering lectures that meet the needs and expectations of the students.

III. Background of the Study

In order to solve the above problems, we have researched the literature to investigate appropriate solutions. Some studies that address the problems faced in this course are summarized in this section. In traditional ways, the laboratory applications of these courses are offered by means of face-to-face training in particular laboratories. Usually, even for ideal cases, face-to-face laboratory applications in these courses have some limitations for both the instructor and the learner [11]. For example, offering such courses requires a large number of educators and supporting personnel as well as high setup and maintenance costs for some EE laboratories (such as those covering radio frequency and microwave techniques) [5]. If an open laboratory environment is not provided, students are restricted to a specific schedule and location for a particular course and are not be able to repeat the experiments as often as they wish or possibly need. Students also tend to have very limited opportunities to analyze the experimental data mathematically: usually the measurement device itself is unable to handle a large amount of data. In the absence of time constraints, students have the opportunity to process experimental data by using powerful software analysis tools, thus obtaining a clearer notion of the functionality of a certain device or setup.

Recent developments in Internet-based services also encourage training and educational organizations to attempt e-learning models. Nowadays, educational and training organizations, particularly universities, are frequently using Internet technologies to enhance and supplement traditional face-to-face education. For example remote laboratory platforms enable learners to access physical instruments at a distant location and perform experiments remotely on the Internet [12]–[15]. Hence, a remote laboratory application in the RF domain seems to be a very critical tool in order to improve and support current educational environments.

Additionally, computer simulations have been used in the curriculum of some EE courses such as electromagnetics, RF, microwave, and millimeter-wave areas [16], [17]. As Gupta et al. state, these simulators encourage building realistic design examples, verification of these designs, evaluation of the effects of real-life parameters on circuit characteristics before investing in the actual fabrication of the circuits, and building case studies that bridge the gap between classroom instruction of microwaves and the practice of microwaves in industry [4]. According to Gupta et al., for the first time in the history of microwave education, the aim of providing classroom instruction that is 100% relevant to the practice in industry is becoming possible [4].

On the other hand, concept maps are the tools used to build relationships among concepts. These tools have been used in educational environments to better connect the relationships among theory and practice as well as among other concepts covered in a course. These tools also help the learners build relationships between previous knowledge and newly introduced concepts, encouraging meaningful learning rather than rote learning (memorizing concepts, no relationship to previous learning) [18].

IV. Newly Designed Course

To improve the course, new approaches have been proposed for the laboratory and theoretical parts. This section summarizes the proposed curriculum for this course.

A. Laboratory

In new course design, laboratory session is supported by Remote RF laboratory [12]. In this environment for teaching how to use VNA, an electronic performance support system (EPSS) tool is used [19], [20]. Remote experiments provide fundamental knowledge in electromagnetic wave propagation, knowledge about the analytical and graphical methods used in deduction of formulas used in microwaves, the ability to make correlations between the physical phenomena (what is happening and which are the causes) and the ability to handle high complexity measurement devices (e.g. VNA). European Remote Radio Laboratory (ERRL) provides RF and microwave remote experiments (http://errlmoodle.atilim.edu.tr/).

Implementation of Computer Aided Design Program (CAD)- Additionally, the new course curriculum is enriched with the applications on Computer Aided Design Program (CAD) and The AWR® Design Environment (donated by AWR Corporation) experiments. Laboratory hours include design tools to be used in the design, fabrication and analysis of RF and Microwave components. The students, after learning how to use Microwave CAD program step by step asked to design RF microwave filter for a substrate and design requirements given by the course instructor. Selected filters whose have best properties (not all of them) are fabricated in our laboratory by using PCB prototyping system, LPKF Promat C100/HF. Fabricated RF filters are measured by using VNA and analyzed.

Laboratory Applications Design Of the New Course

First week, laboratory equipment' are introduced to the students in the Remote Lab environment. For this purpose, an electronic performance system (EPSS) tool is used which provides just in time training for the users by providing the instruction according to the user needs and expectations [19], [20].

Second week, the students learn how to use RF Remote Lab website in laboratory hours. Now, the students are ready to use laboratory at anytime and anywhere without guidance .

Students freely perform the following remote lab experiments any time and any where according to their preferences:

Remote Experiment 1: Measurement of Scattering Parameters of Open, Short and Match load. This experiment is developed in order to familiarize users with control panel of VNA, fundamental principles of VNA. Furthermore, they can do basic measurements with VNA and calibrate of VNA, and observe SWR and impedance measurements with VNA. Figure 1 shows the actual physical laboratory setup for the experiment.

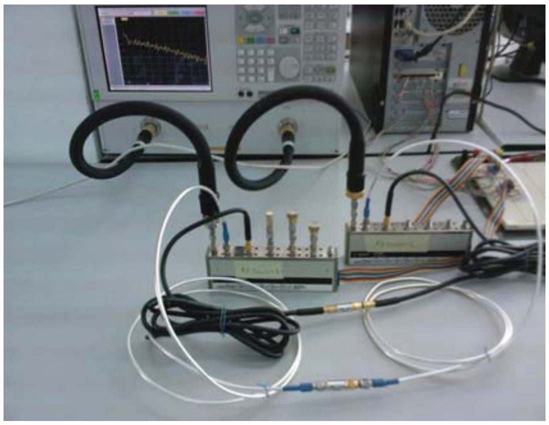

Figure 1. Setup for Measurement of scattering parameters of open, short and match load experiment

In this experiment, fundamental functions and controls of AGILENT's 8363B VNA is examined. Open load, short load and 50 ohm load are used as DUT (Device Under Test). Calibration procedures are defined, as well. VNA are used by the users to validate concepts like VSWR, reflection, and impedance matching by means of Smith Chart. Users can observe differences between theory and experiments since a remote laboratory works with real physical effects.

Following three weeks (3-5th weeks), the students learn how to use CAD program and to design simple microwave components :

AWR Experiment 1: Design a Simple RC Filter to be familiar AWR environment and to understand how to simulate, create graphs and analyze a circuit in AWR.

AWR Experiment 2: Transmission Line and Microstrip Line Analysis to study the behavior of an ideal transmission line (TL) at various lengths , to calculate width and length of microstrip line by using AWR and to gain an ability to use some AWR tools , to store the information of the substrate material used in the microstrip line, to solidify students understanding of transmission line theory and be able to design a microstrip line.

AWR Experiment 3: Design a 10-dB T-Attenuator by Using Lumped Elements in order to strengthen to simulate, create graphs and analyze a circuit in AWR, to design a passive RF component, to analyze the network behavior of multiport microwave systems.

AWR Experiment 4: Smith Chart and LC Matching Network to get familiar with the Smith Chart by plotting different impedance values and design a LC matching network, to use Smith Chart when solving transmission line problems, to analyze generator and load mismatched transmission line.

AWR Experiment 5: Single Stub Tuning to gain an ability to use some AWR tools, to improve the ability of simulate, create graphs and analyze a circuit in AWR to design a microstrip line, to use Smith Chart when solving transmission line problems, to analyze generator and load mismatched transmission line, to design single stub tuning networks in the design of microwave components and circuits

Remote Experiment 2: Measurement of Scattering Parameters of RF Filters. In this experiment, users are familiarized with the basic microwave passive elements and measurement techniques. The objective of the experiment is to observe the concepts of reflection and transmission (return loss, standing wave ratio, reflection coefficient), to measure the frequency responses and the behavior considering the direct and reflected wave of a microwave filter and insertion loss, bandwidth and out-of-band-rejection. For the experiment on measurement of scattering parameters the user must set VNA parameters such as the frequency range and number of points. One of the scattering parameters must be chosen. In this experiment, a user can view transmission characteristics of the filter and find the type of the filter (band pass, low-pass, high-pass, or not-sure), the frequency at which the minimum attenuation for the filter occurs, minimum loss and the 3dB cut-off frequency for the filter, defined as that frequency where the transmission coefficient is reduced by 3dB from the minimum attenuation.

Remote Experiment 3: Extraction of Physical Parameters of a Coaxial Medium with Vector Network Measurement is performed. When a typical calibration is processed, the measurement reference plane is moved to the very ends of the test cables. But what would happen if we had a transition (such as connector, cable, adaptor…) between the DUT and reference plane. In this experiment we perform two measurements, with transition and without transition (Fig. 2). After the measurements we decide the effect of transitions. The effect of a transition on phase and reflection coefficient (S11) is examined and phase constant (β) and relative permittivity (ε_r) are calculated by means of these measurements.

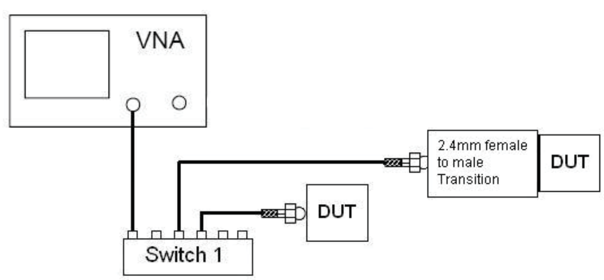

Figure 2. Remote experimental setup for extraction of physical parameters of a coaxial medium with vector network measurement experiment.

At certain frequency, phase constant (β) and relative permittivity (εr) are calculated by using the measurement results and $\lambda = \frac{2\pi}{\beta}$ $\varepsilon_r = \sqrt{\frac{\lambda_0}{\lambda}}$

During following two weeks (weeks 6 & 7), students perform the following experiments freely by using the distance laboratory environment [ERRL referans]. During this period, students are also free to use the physical laboratory environment to design any RF component.

Remote Experiment 4: RF Amplifier Measurements experiment. In this experiment basic measurement of power amplifier (Fig. 3) with VNA is performed for constant input power. Frequency characteristics are measured for different frequency values. This experiment allows the user to become familiar with the power amplifiers and their frequency band measurement with VNA. When completed, the user has an idea about characteristic such as gain, flatness, impedance, return loss etc . Vector network analyzer measurement capabilities are also improved.

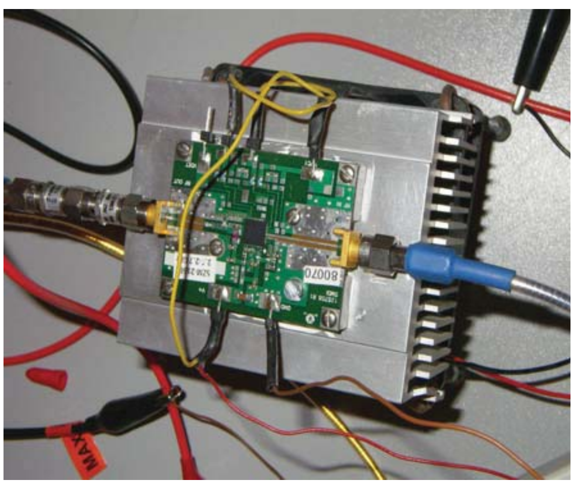

Figure 3. RF power amplifier.

Remote Experiment 5: Antenna Analysis. This experiment is focused on the measurement, of reflected-transmitted power, of input impedance vs. frequency and SWR of several antennas (Fig. 4). With this experiment various measurements on wire, horn and patch antennas are performed with the Vector network analyzer. Aims of the experiment are measurement of loss power, reflected power and transmitted power of the antennas and the SWR and the input impedance of the antenna at the certain frequency range.

Last three weeks (8-10th weeks) are reserved to the students for designing, implementation and measuring their own RF microwave filters. Students work in a team to design a filter with specifications that is provided.

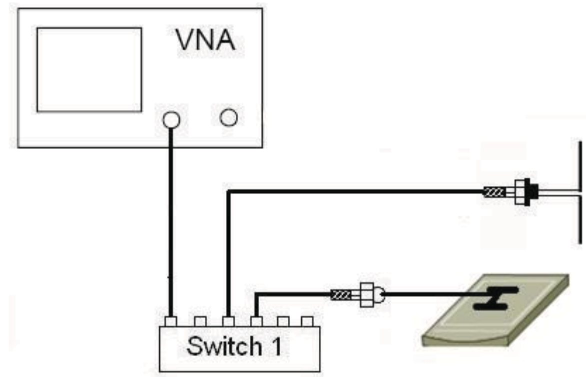

Figure 4. Remote experimental setup for antenna analysis experiment.

B. Theoretical Instruction

One of the problems of this course was building relationships between course content and laboratory applications. Accordingly, as shown in Figure 5, we have developed a concept map in order to help students develop these relationships. The map in Figure 5 shows how the relationships between the course content and laboratory experiments can be formed. The graphical represantation also helps to better visualize the possible relationships.

In this concept map experiments are connected by lines to the course content by using keywords. In this way it is expected that students will be able to build relationships between the experiments and theoretical content and analyze the experiment results accordingly. They are also able to find the theoretical details by using the search functionality of the remote laboratory environment[1].

We have applied this newly designed course for one semester at Atilim University. Students' feedback and course instructor's opinions were very positive after the implementation of the new course. They all declared that the problems that they had faced in previous years were all addressed with the new course design.

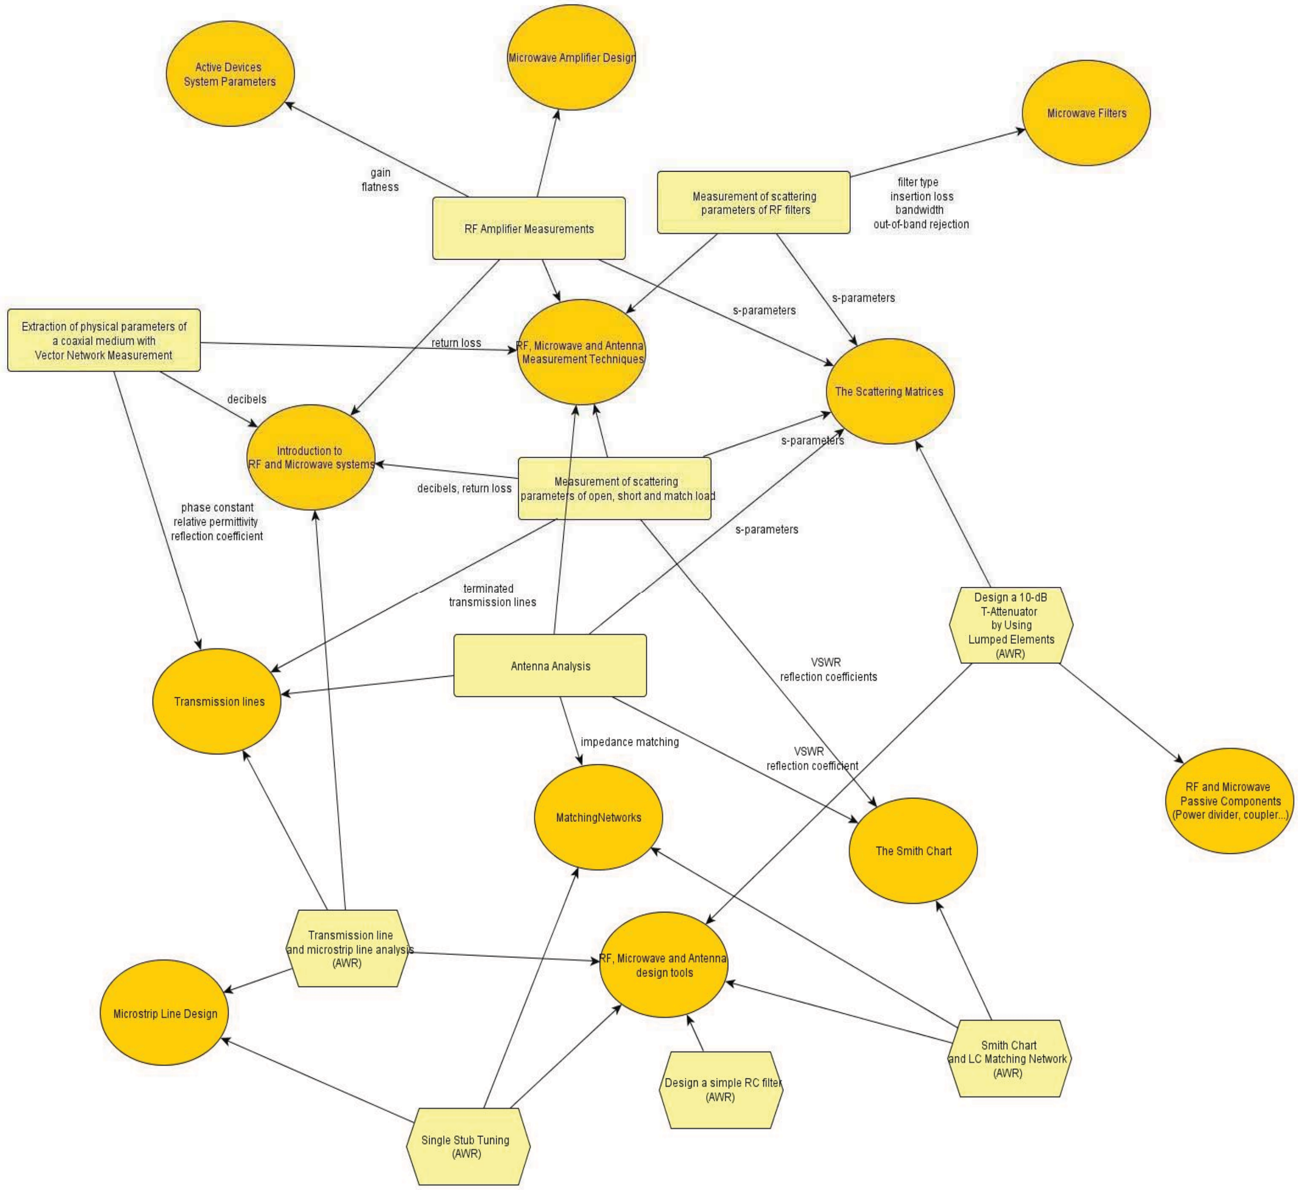

Figure 5. A Concept Map of Course Theory and Hands-on Application Activities

V. Discussions and Conclusions

In this study, we first listed the main problems of the introduction to RF and Microwave (MW) systems course. Then, in order to address these problems, we proposed a new curriculum model for both the laboratory and theoretical parts of the course. Finally, we applied the new curriculum of the laboratory activities for the course over one semester.

The course instructor believes that, because of the new approaches used in this course, instructors will have more time to extend course content and provide more experiments for the students. For example, in this semester the course instructor had time to demonstrate seven experiments that had not been studied in previous years.

The course instructor also reported that the remote laboratory environment significantly improved students' understanding of the experimental studies when compared to previous years. Additionally, since the students were better prepared to understand the background of the RF/Microwave components design, they were able to fabricate and measure the RF/Microwave component.

After taking the newly designed course, the students will not need to learn how to use the design and measurement tools featured in elective courses and design projects that follow in the sequence of the EE program at this University. These skills are expected to eliminate the need to provide repeated instructions on the usage of these tools throughout the curriculum, which allows for additional time for the instructors to perform other activities.

We believe that, in the long term, the students will receive greater numbers of job offers and their job performance will improve because they will be better prepared for industrial environments due to their exposure to the new technologies and more practical hands-on, trial-and-error type experiences.

***Abstract*— IPLECS is a virtual campus platform for the development of performance-centered reusable learning materials, and its application in mLearning for educational and training purposes. The combination of performance support systems and mobile devices present both opportunities and challenges for work-based learning design.**

Keywords-* *Internet-based learning; Performance-centered learning, curriculum development.; Engeenering Education.

I. INTRODUCTION

We present two Projects financed by Socrates Agency. The first in about the curriculum development of one ' Information and Communication Systems' Master; the second one is about its application and development in mobile leaning.

Internet-based Performance-centered Learning Environment for Curriculum Support (IPLEC S) is a virtual campus platform for performance-centered reusable learning materials development, their composition and organization in performance-centered settings and their usage to support university curriculum in physic-engineering education. IPSS_EE is an integrated electronic environment, which is available via Internet and is structured to provide individualized online access to the full range of information, guidance, advice, data, images, tools and software to permit the user to perform a task with a minimum of support and intervention by others. The system has elements of performance system, elements of traditional Web-based educational programs and automatic test system. The system uses a new technology for improving students' competency and performance by providing support for processing, analysis and reflection on information and learning experience.

The idea of educational performance support system had been implemented in different European universities and training institutions within a number of pilot projects such as IPSS_EE (Internet-based Performance Support System with Educational Elements) and DIPSEIL (Distributed Internet-based Performance Support Environment for Individualized Learning), with strong positive results in students' learning. [1].

The combination of performance support systems and mobile devices present both opportunities and challenges for work-based learning design. We describe four possible mobile performance support scenarios, namely: mobile performance support courseware; industry-based mobile performance support systems; mobile social support system; and context-based performance support.

The mobile performance support courseware repackages the existing courses in which the principles of performance support are implemented. In the second scenario, industry-used mobile performance support systems become part of higher education learning and instruction. Students learn how to use them when they perform particular work-related tasks. The social support scenario explores the opportunities created by Web 2.0 technologies (micro-blogging tools such as Twitter, social bookmarking and wikis) to connect people and facilitate their collaboration. In the fourth scenario, mobile performance support is part of a blended solution of knowledge distribution rather than a primary channel for content delivery. Mobile performance support is included in a broader constructivist instructional context and used only in particular times. Within the scenarios a set of pedagogical guidelines are formulated based on a number of theories: Four Components Instructional Design Model (4 C/ID) [2]; Cognitive Apprenticeship [3]; Cognitive Flexibility Theory [4]; Cognitive Load Theory [5]; Multimedia Learning [6] ; Minimalism [7]; Design Theory of Problem Solving [8]; and Anchored Learning [9].

Learning materials in IPLECS take the format of "learning objects" (LOs), specific for the performance-centered approach and presentation. We present the conceptual model and description of so called IPSS_EE LOs and extend the IEEE LOM. Model and description of IPSS_EE LOs are useful for understanding their features, for enabling their publishing in a Web context and for enabling their reuse across different learning sessions. A new curriculum in the field of science and technology - " Information physics and communications", will be developed. Learning materials to support a complete integrated program, developed and used in a virtual performance-based learning environment will be developed. In the whole process, various competences, innovative and consolidated information and communication technologies will be used.

The main reason for the application of Performance-centered Approach in Mobile Learning for educational and training purposes is to contribute to the continued development of mobile learning and to address the imbalance between mobile devices availability and the lack of education and training provision on the sophisticated communications devices which every student and workers carries and uses constantly – except in education. The advantages for trainees are derived from providing learners with a job aid in their own work context. Given the trend to lifelong learning, many "students" are workers adults with full- or part-time jobs. Mobility offers them an opportunity to maximize their learning time.

Mobile devices are always available and can be used for a variety of learning functionality - providing access to content (both informational and instructional) and for communication and collaboration purposes. They can be used with formal or informal learning purposes as well as performance support, i.e. for delivering information and support just-in-time and in context.

II. Objectives and target population

The IPLECS and mPSS Projects aim: Design, composition and reuse of IPSS_EE LOs and experiment the usage of the learning platform and of IPSS_EE LOs for the physic-engineering integrated curriculum support.

The main purposes of the IPLECS project are:

- Design a master on Information and Communication System (ICS), online, performance centered,
- Apply the ICS master, by means of an educational platform, in Bulgarian Universities involved in the project, Plovdiv University and Technical University of Sofia.
- Evaluate the 'ICS master' in its design, during the process and in their results.

Together with the main objective, others purposes of the project's are:

- Support the development of innovative ICT-based content, services, pedagogies and practice for lifelong learning to support university curriculum in physics-engineering education.
- Provision of open educational resources on-line and testing innovative performance-based e-learning.

The target groups to which the project is addressed are:

- Higher education teachers in physics-engineering and other fields, by transference.
- Students in the same field and, by transference of lessons learned, in other specialities.
- Universities and enterprises management, by transference of outputs and results.

The main purposes of the mPSS project are to contribute to the continued development of mobile learning and to address the imbalance between the availability of mobile devices and the lack of education and training provision on the sophisticated communications devices which every student and workers carries constantly.

The projects objectives are linked directly to support the realization of an European Higher Education Area as much as the development of innovative ICT-based content, and open educational resources on-line provisions, testing innovative performance-based e-learning and contributing to mobile learning development in education.

III. The Project Approach

The project approach responds to the '*Principles of Performance Centred Curriculum'*, which are derived from the first concept of Electronic Performance Support System, but evolved, to adapt it to the Higher Education System.

The Principles of Performance Centred Curriculum: The EPSS concept (Electronic Performance Support System) includes the idea of just-in-time, just-enough, and just-at-the-point-of. This needs computer support for an effective and efficient job performance. An EPSS is an integrated learning environment structured in a particular way to provide immediate access to the full range of information, advice, guidance and tools allowing effective and efficient job performance.

EPSS to PSS in Higher Education is characterized by its focus on active learning, acquisition and application of skills, technology power in addressing instructional issues, appropriate representation and filtering of learning resources and one integrative approach for operational performance support.

The integrative approach to PSS is based in the following learning theories: Cognitive Apprenticeship (Brown, Collins & Duguid, 1996[3]); Cognitive Flexibility theory (Spiro & Jehng, 1990) [4]; Four-Components Instructional Design Model (Van Merriënboer & Kirschner, 2007[2]); Design Theory of Problem Solving (Jonassen, 2004) [8]; Cognitive Load Theory (Sweller, 1994 [5]).

The Performance learning center concept operates by defining a set of authentic problems and constituting tasks related to a specific working environment; shifting the focus from the lower levels of the learning taxonomy such as knowledge and understanding, towards its higher levels such as solving real-world problems; applying adequate summative performance-oriented assessment methods.

The learning support is delivered by the following learning strategies:

- Designing a sequence of easy-to-complex tasks;
- Creating opportunities for deliberate practicing these tasks: giving formative performance feedback;
- Gradually diminishing the amount of support (scaffolding);
- Adapting instructions to students' knowledge level and learning style;
- Providing a variety of instructional stimuli (resources) and
- Allowing constant access to learning resources.

The system is characterized by using recent developments of information and communication technologies (ICT), presenting embedded performance support into the interface and functionality of the application. The system depends on how comprehensively performance and support are defined and how well they are operationalized in the architecture and in the interface of the system.

The Structure of the learning content, for all the courses in the ICS curriculum, lies in:

- Background information (facts, definitions, principles and theoretical frameworks)
- Examples (worked-out examples, modeling examples, demonstrations and simulations)
- Procedures, techniques and tools
- Presenting learning content
- Split-attention principle (People learn better when words, pictures and graphics are physically and temporarily integrated)
- Self-explanation principle (People learn better when they are encouraged to generate self-explanations during their learning)
- Guided discovery principle (People learn better when guidance is incorporated into a discovery-based multimedia environment)
- The main purposes of the IPLECS project are:

'The instructional design for Performance-centered E-learning of DIPSEIL, as a typical performance support system [11], [12], is an integrated electronic environment, which is available via Internet and it is structured to provide individualized online access to the full range of information, guidance, advice, data, images, tools and software to permit the user performing a task with a minimum of support and intervention by others.

IV. The Desing of the Iplecs and MPSS Projects

In the IPLECS Project, the ICS Curriculum Design has been developed having into account 'The Principles of Performance Centred Curriculum' and 'The Instructional Design for Performance-centered E-learning' of DIPSEIL, we have developed 'The Workflow Model for an Information and Communication Systems curriculum'. With these three elements teachers in charge from different courses have enough information for developing the ICS courses.

The Workflow Model also offers to the course developer complete guidelines, with explanations, and examples that give all the partners unified criteria for developing the courses and their activities supporting the ICT performance centered task design.

The IPLECS Workflow Model for curriculum development is based in:

1) State a reference situation in which the students will use what they are going to learn.

2) Formulate a few Learning goals and clear and specific objectives oriented to competences.

3) Create learning tasks with performance support, to provide the students:

  - Background information,
  - Examples,
  - Procedures and
  - Feedback,

  in order to help the students to perform the task easier and also to facilitate their learning.

4) Summative evaluation.

The 'Workflow Model', at the same time that serves as a guideline to courses developer, also works as a complete check-list for evaluation purposes of the ICS courses design, being used as a 'PSS Validity Scale'.

The ICS Master Program and its ***Implementation Plan in DIPSEIL Platform***

The ICS Master Program is integrated by 6 mandatory courses and 4 electives courses. The student should enroll 8 courses in total, divided into two semesters.

- Semester 1
  - Introduction to Information and Telecommunication systems (PU)
  - Realtime and Industrial Communications (UNED-DIEEC)
  - Internet Technology (DEIS)
  - Advanced electronics for information and communication technologies (TUS)
- Semester 2
  - Satellite and Mobile Communications (PU)

- Optical Fiber Communication Systems (CIME)

And two of electives from these four courses:

- Power Supply for TICs Equipment (UNED-DIEEC)
- Multi Media (DEIS)
- Digital Functions Design (CIME)
- Microelectronics and Nanolectronics (TUS)

The different subjects programs that integrate the ICS Master have been developed according to the 'Instructional Design for IPLECS project and the guidelines included in the Workflow Model for IPLECS.

The designers were facilitated to send their reviewed courses to the responsible of PSS Model, in order to check them according to the 'PSS validity scale'. In July - September 2009 the courses designers had sent to the experts in curricula design their courses.

The course started the 15th of October 2009 in two Bulgarian Universities (Plovdiv University and Technical University of Sofia).

The mPSS application is presented as a form of performance support system for educational and training purposes. This is the case of learners who are studding something in relation with their job, studding to improve and promote themselves at work what is really frequent, specially in Distance Universities. The majority of students in Distance Universities choose careers related with their actual job to gain in knowledge and improve their professional practices and to obtain benefices of the relationship with professional-teachers and other students-colleges, in collaborative relations.

The advantages for trainees are derived from providing learners with a job aid in the context of their work:

- Puts training and performance support where their actual work is taking place.
- Allows new skills or knowledge to be immediately applied
- Enables training when it is needed
- Allows use of rich media when appropriate

The advantages for students:

- They have more flexibility and choice in where and when they learn, outside of the wired (or un-wired) classroom.
- Students use the technology in their study that would enhance their readiness for tomorrow's workplace where employers want graduates who know how to use technology for learning and working, as one opportunity/chance for lifelong learning.

Given the trend to lifelong learning, many "students" are working adults with full- or part-time jobs. Mobility offers them an opportunity to maximize learning time [13].

V. Application of IPLECS to MPSS Project

Research by Stoyanov, Kommers, Bastiaens and Martinez-Mediano (2008) [1], shows that the concept of performance support system (PSS) should be implemented adapted to the specific goals and characteristics of higher education. Thus, it is important to keep in mind the specific goals of education when developing the support to improve learning. This means that students should not only be supported to perform the task at hand well, but also to understand underlying processes and concepts. They should learn from performing the task. Furthermore, it is important to keep in mind that when designing mobile PSS, this should be done from the perspective of the learning process and the learner and not from the perspective of mobile technology. [14].

Founding in results obtained in previous research in IPSS in higher education, we propose concrete instructional design steps for four scenarios for the implementation of PSS in mLearning. The scenarios are based on existing learning theories and take into account different learning processes and educational goals. The following scenarios are distinguished:

a) Mobile performance support courseware,

b) Industry-based mobile performance support systems,

c) Mobile social support systems and

d) Integrated mobile performance support learning.

Each scenario requires a different structure and presentation of the content and addresses different educational goals.

VI. The Evaluation Strategies of the IPLECS and the MPSS Projects

Our conception of evaluation is the following: 'Evaluation is the systematic application of scientific methods to assess the design of one program or project, responding to some needs, having into account its goals, action plan, implementation, results and impact, with the purpose of knowing how well works the program to meet goals and achieve valuable results, in order to contribute to its understanding and to guide its improvement, with the criteria of its worth and merit'.

The evaluation strategy of the IPLECS and mPSS projects aims to study the total purposes of the project. Our main objective is to validate the ICS curriculum by means of different strategies and instruments.

To content validity we will use the IPLECS Validity Scale, based in the PSS instructional design.

To check the mPSS-IPLECS characteristic of educational design and the functionality of the platform we will use specific one check-list and usability questionnaires addressed to collect users' evaluation: teachers and students that follow the courses. The evaluation of the 'usability and functionality of the platform' deals with how well the platform satisfies the user needs and requirements. This variable works as estrange variable that should be controlled, because in one online course the way that the platform or the 'system 'works could affect the entire learning process and also the final results.

The instrument to evaluate the platform is a 'usability questionnaire', which is showed in the Annex 1 .Instruments. 'Computer System Usability Questionnaire' based on Lewis, (1995). Beside the questionnaire the platform is evaluate by the peer review technique before starting the courses. The projects partners and teachers, which will collaborate in the Implementation of the ICS curriculum, are the sample to evaluate the platform.

Attitude is a factor that could be an important influence in learning. Only when there is a favourable attitude towards the TICs an e-learner can effectively face web-based learning tasks. Learning requires a positive attitude from the users to show their full potential. [15].

In according with Anastasi [16], attitude is defined in terms of the tendency to react favourably or unfavourably towards a certain class of stimuli, was determined by visible, both verbal and non-verbal, behaviour.

We will use a questionnaire on 'Attitude to learn by computer', based in a Likert scale, valuing every item from 1 to 5, minimal to maximal agreement with the statement contended in every item.

To value the entire learning process we will use specific 'reflective questionnaire' as satisfaction indicators on the learning process. We will collect information by personal interviews to students and teachers, in order to check satisfaction indicators with the functioning of the program, the IPLEC and mPSS models and the dipseil-iplecs platform during the process, taking measurements from teachers and students.

We want to measure the satisfaction with the ICS curriculum, in relation with the ICS curriculum goals, and with the implementation process and their results. These are indicators of impact, in relation with the ICS Master and IPLECS Model.

The research design is the proper of the evaluative research, focused on multiple sources and variables. The methodology is exploratory. We will use descriptive statistical analysis, and value analysis, using quantitative and qualitative data analysis as correspond to the evaluative studies.

The majority of curriculum evaluation models suggest evaluating the planned, enacted and experienced curriculum;

- The planned curriculum is the theoretical curriculum that one intends to implement, that is, the program
- The enacted curriculum is the curriculum that is actually implemented, the program in action
- The experienced curriculum represents the curriculum as it was experienced by its users, such as teachers and students.

Programs, processes and products should be evaluated. This means that we should evaluate not only the match between the objectives of the curriculum and performance outcomes, that means the effectiveness of the curriculum, but also how it is functioning during the execution of the curriculum and how is being used the resources, the IPLECS Model and the media trough the dipseil-iplecs platform.

To summarize, we need to centre the curriculum evaluation in the following:

- Planned, enacted, experienced curriculum
- Process & product
- Objective & subjective variables
- Quantitative and qualitative data
- Teachers' and students' experiences

The data analysis that we will do are:

- Quantitative, descriptive and correlation analysis, by mean of the Statistical SPSS program.
- Qualitative, Grounded theory, Content Analysis, with the 'Quantified Content Analysis, Lexim ancer' program.

The sample from which we are collecting information are the own courses authors, teachers responsible of applying the ICS curriculum, their students, and the partner as experts to validate the ICS curriculum.

VII. Conclussions

Our projects have time duration of two years and nowadays we are in the first years. The theoretical frame-mark and the strategies and resources for its application and evaluation have already fulfilled. In the current year we are applying the course in both project, and following the process to collect information to evaluate their application and results. The evaluation strategy, using quasi-experimental research methods besides qualitative one, give a good expectative to be able to contribute to the scientific community about some advance in both projects, center in PSS in computer and mobile learning device.

Abstract— **The goal of the GALILEA project is to design and implement innovative programs and curricula, providing solutions to the changed job specifications for engineers and natural scientists and are capable of attracting more female students to these programs. In this article we outline the design, implementation and the first evaluation results of our pilot program, the bachelor course of "Natural Sciences in the Information Society" that started in the winter term of 2007/08.**

Keywords- engineering education; natural sciences education, gender studies; e-education;

I. INTRODUCTION

For years experts have warned that the number of graduates in engineering and natural sciences fails to meet the growing demands in a high-tech society [1, 2] (c.f. Figure 1). Unresolved, this situation will have a strong negative impact on the future development of society and economy. Despite a growing presence of high-tech devices in everyday life, the portion of high-school graduates choosing to study engineering or natural science programs is declining. A negative image of technological studies has been identified as one of the major reasons behind this trend. They are perceived as focusing too much on theoretical issues, while ignoring experimental, hands-on aspects of technological disciplines. At the same time, potential students are alienated by the perceived lack of social relevance and the failure to teach important core skills in school education. In particular, the lack of young women in these fields has been the topic of an intense debate for some time.

When designing gender-balanced courses and curricula, it is necessary to emphasize that technological-oriented programs are not less attractive for women but that women's interests, educational preferences, and requirements differ from those of "standard" male students [3]. In addition, not only women would benefit from such an alteration of curricula also supporting non-technological skills and expertise (e.g. soft skills, analytical competencies, or information literacy). The demands of the economy of the 21st century such as lifelong learning and the effects globalization has on today's employees require engineers and natural scientists to be autonomous, and disciplined. Employees must have sophisticated communication skills such as speaking different languages and working in teams with different cultural backgrounds. In order to accept the challenges, universities have to reconsider their structural and educational concepts.

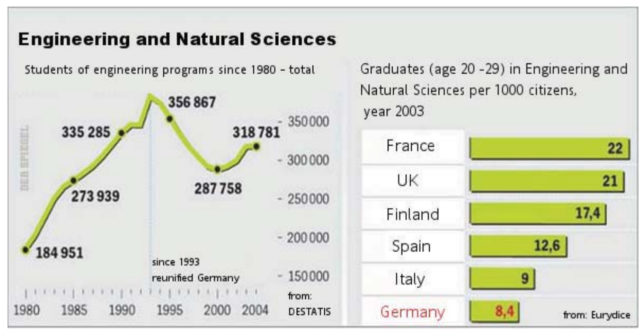

FIGURE 1. Left: Number of students in engineering and natural sciences programs from 1980-2004 in Germany (pre- and post unification), Right: Graduates in engineering and natural sciecnes per 1000 citizens in selected European countries as of 2003. Graph published in Spiegel Online [4], translation added by authors

Due to the Bologna process, European universities have the opportunity to reform their curricula. Within the GALILEA project [5] our goal is to design and implement such innovative curricula, which answer to the changed job specifications of engineers and are capable of attracting more female students. Our first new Bachelor of Science program "Natural Sciences in the Information Society" started in the winter term of 2007/08. If offers a *studium generale* of natural sciences at Technische Universität Berlin (TU Berlin) and can be continued either by a corresponding Master of Science course "Natural Sciences in the Information Society" or Physics, Mathematics, Computer Science or Chemistry.

This article reports on our first experiences, and evaluation results.

II. THE GALILEA PROJECT

Originally, GALILEA was established at the Department of Mathematics and Natural Sciences; however, it is operating as a supporter for many courses at the entire university. The aim of the GALILEA project is to design and implement new gender-sensitive courses within technical and scientific disciplines. Therefore new curricula have to be proposed, combined with modern educational styles overcoming the above described challenges. In this manner, practical aspects as freedom of scope, comprehensive projects, teamwork, and an internship play an important role. The program has been designed with educational preferences of women in mind. It allocates educational key qualifications and interdisciplinary skills as well as leadership and management qualities. Since language requirements have become important, especially in technical and scientific fields, we decided to offer at least some of the courses in English (Figure 2).

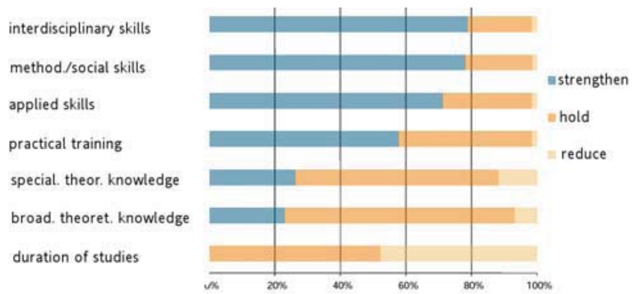

Figure 2. Wishes of the industry regarding programs. Source [6], translation added by the authors

One of the main deficiencies in academic education in Germany is the low attendance of young students in large universities. GALILEA has an integrated mentoring program, especially for freshmen but also for older students.

A. *Natural Sciences in the Information Society*

The “Natural Sciences in the Information Society” (NidI) program as the first GALILEA course started in the winter term of 2007/08 with 15 students (9 female and 6 male) and 37 students (17 female and 20 male) in the winter term of 2008/09. It offers a wide repertory of natural sciences, engineering and non-technological courses at TU Berlin. The core attributes of all natural sciences are the close correlation between theory and experiments and the high standards in mathematical and computer sciences education. These connections are the guidelines of the two-tier program:

1) *Bachelor program*

The NidI Bachelor program provides a great range of access to the basics of natural sciences. The curriculum of this three year program is built on a theoretical basis (59% of the credit points) and supported by a compulsory elective (21%) part, a freely chosen part (10%), an internship (3%) and a bachelor thesis (7%). In fact, students have about 110 compulsory elective subjects to enrich their individual study plan. The technological broadness of the curriculum accommodates the multidisciplinary interests of women. Therefore, emphasis is put on integrating natural and life science aspects. During the concentrated study, the mandatory internship (of at least 12 weeks in duration) has to be concluded. It ought to give an insight into professional life. The theoretical basis of the curriculum is formed by mathematical and physical courses supplemented by several courses in computer science. Additionally, in the first year there are two mandatory modules in scientific information management chosen selected by at least one the following criteria:

- Content-related course of study,
- Teamwork in co-ed teams,
- Teaching core skills,
- Project-oriented work.

Students are taught general scientific methods they will need for managing projects (i.e. experiments), regardless of the explicit fields they will specialize in. Therefore we provide two new project-oriented Bachelor program lectures “Scientific Information Management” and “New Media in Teaching and Research”. The students are taught basics of knowledge management, presentation techniques, multimedia education, and research. The first course is carried out by the staff of the university library, the second by the Center of Multimedia in Education and Research of TU Berlin.

2) *Master program*

After graduating with a bachelor of ‘‘Natural Sciences in the Information Society’’, students have the opportunity to join a master program that will result in the "Master in the Natural Sciences in Information Society". Since the bachelor program offers a wide basis in the natural sciences it is also possible to join other master programs from the natural sciences (i.e. astrophysics or nanotechnology).

3) *Mentoring program*

Students can participate in an internal mentoring program providing organizational, social, and technical aspects. This program aims at improving the educational and organizational atmosphere in large universities by a close mutual relationship between freshmen, older students and academic staff. Our goal is to increase the motivation and performance especially of freshmen and women. Beside individual meetings, we provide a wide offering of social events, and additional non-technological and technological advanced training (i.e. exam stress, programming, or mathematical workshops). The mentoring program also allows us to react quickly if structural or technical problems of the program become apparent.

B. *Aim of the program*

The industry and economy still have a high demand for interdisciplinarily educated graduates with great scientific knowledge (cf. fig. 2). Multi-disciplinary, application and research-oriented programs impart methods and fundamentals of computer science, mathematics and natural sciences. In the bachelor program students acquire the necessary knowledge and familiarize with general and specific methods for treatment and solution of problems in natural sciences. This enables them to transfer their knowledge to practice and create the basis for continuing their academic studies, e.g. in the master program.

The following cross-technical competencies and social skills are mediated beyond the purely technical aspects:

- responsible life-long learning,

- problem-analysis and development of problem solving concepts,
- social, scientific, gender-specific and ethic points of view in action and decision strategies,
- multi-disciplinary communication and ability to work in a team,
- presentation skills including the presentation of scientific results for different target audiences,
- modern methods of scientific information management.

After graduation the students are able to find jobs that require great scientific and methodological knowledge whereas the specific skills are acquired on the job. Some examples are: technology writers and other activities with scientific publishers, scientific librarians, advisory activities in politics/ministries/authorities, project-management in scientific-technical areas, science management at universities and research institutes, activities in financial and insurance companies.

Most of the structure of this multi-disciplinary program is tailored to suit women's preferences, yet the large amount of experimental modules might be a problem. Due to their socialization women frequently underestimate their abilities and do not possess the same degree of experience as men [7]. Experiments and theory are closely connected in natural sciences. Consequently it is neither possible nor desirable to design programs in these areas without experimental components. On the contrary: strict emphasis has to be put on the connection between theory and experiment and on offering additional possibilities for experimenting, e.g. virtual laboratories [8].

The bachelor and master programs "Natural Sciences in the Information Society" are the basis to modernize programs, e.g in physics where in general the ratio of female students is one of the lowest of all programs. The development of a program in astrophysics as the field of physics that is traditionally very attractive for female students could be an example. This is reflected in the numbers of students graduation in physics at TU Berlin: Only about 10% of all physics students are women, yet approximately 30% of all female graduates and scientific assistants choose astrophysics as their specialization.

For a detailed summary of the "Bachelor of Natural Sciences in the Information Society" programs please see [9].

III. Evaluation of the New Courses

Overview

So far students' feedback indicates that we are on the right track. We learned that the high relevance of practical courses and projects in these modules, the extensive access to laboratories and independent experimenting, the possibility of a wide choice and the internship are of special interest for our female students.

The mentoring program of the course also allows evaluating the success of the program itself. This feedback from students is crucial, especially in the first year, in order to make adjustments to the program. This hopefully leads to more support from graduates in the future, e.g. by becoming mentors or providing internships for students.

We evaluated both courses and found out that the concept was generally well accepted. Male students appreciated the courses focusing on gender aspects even more than female ones. The courses were offered a second time, but an evaluation has not been conducted so far To find out if and how the students' point of view changes during the term, each course was evaluated twice. There was a weekly poll for "Scientific Information Management" and a final questionnaire evaluation, whereas "New Media in Teaching and Research" has been assessed monthly and ended with a final questionnaire session. The results will be presented in brief.

A. Integrated Lecture: Scientific Information Management

22 students took part in the weekly evaluation over a total of nine weeks. Every time five male and five female randomly-sampled students were interviewed. The male students followed the lessons a bit more concentrated and took part more actively than female students did. They also expressed to have learned a lot for use in the future.

In the final evaluation, the students evaluated the course with average grades. They expressed that they had learned a lot and were able to transfer it into practice. The students were able to handle the level and scope of this course very well. Different kind of media used in the lessons motivated the students. They preferred to work in mixed teams. The students even appreciated the mandatory attendance of this course because they understood that it was adequate due to the teaching methods applied [9].

B. Integrated Lecture New Media in Teaching and Research

Each of the 20 students (12 male and 8 female) and the three lecturers were interviewed to compare their impressions of the students' participation during the lessons (monthly evaluation). While the assessment of their own contributions to the lessons was balanced around a good average, the lecturers were more pleased than the students thought they would be. However, this changed in the second half of the term.

For the final evaluation, only students were interviewed. They considered this course to be useful for their future and that they would use the learnt methods (e.g. presentation skills) in their everyday life. They really liked this course and graded it with an average of 1.75 on a scale from 1 (best) to 4 (worst). The level and scope of this course were adjusted to the students' previous knowledge. There was no mandatory course attendance, yet 45% of the students visited almost every lesson, 70% attended more than half of all lessons. Four of them would have even preferred a compulsory attendance. The students enjoyed the different kind of examinations ("prüfungsäquivalente Studienleistungen"): There were four different types of exams: an oral exam, several assignments, delivering a scientific paper and a presentation. The students appreciated the oral exam the most (average: 1.42 on a scale from 1 to 4) and the assignments the least (average: 1.95). Referring to these types they claimed to be able to present the topic and their knowledge more easily. Altogether, we found that the concept was well accepted both by male and female students.

Besides the acquired knowledge students developed useful soft skills and applied them immediately in other courses. Although there are some aspects that still need to be improved, the concept seems to be successful. During the present term similar evaluations are carried out to validate these results and to find out what has improved and what else needs to be done.

C. Mentoring

The evaluation of the mentoring program was included all participants – mentors and mentees. All mentors were evaluated through means of a short questionnaire, and all mentees completed four guided interviews with some additional questions included in a short questionnaire. Two female mentees and two male mentees filled out the questionnaires. Respectively, one of each mentees was actively participating in the mentoring program. At the time of the questioning, all mentees were at the end of the second term.

Generally, the acceptance of the mentoring program by active mentees was positive, whereas the temporal effort strongly varied (2 to 9 hours per term). But only one non-active mentee positively reviewed the program. According to the asked mentees the aim of the program is to assist students through a contact person during their studies and especially at the beginning. However, the interviewees seem to have no specific conception of the program. Therefore, the mentoring program was used mostly at the beginning of the studies, in order to clarify organizational questions. If no concrete questions arose, the mentees did not make use of the program. It was criticized that there were difficulties to make appointments and that clear guidelines were missing. Both mentors and mentees should have had a clear conception of the meaning of mentoring. However, if there was a personal relationship between the mentor and the mentee, the conceptions and expectations of the mentees were satisfied. This relationship was characterized as amicable. The general aspects of the mentoring program were of interest to the mentees. This part of the program was also used in parts if the student did not have a mentor.

An obstacle of active participation in the mentoring program is represented by the first appointment with the mentor. If this took place, then generally a good relationship between the two formed. However, different challenges appeared due to the status group of the mentor (student, scientific staff, professor). Thus, appointments with the status group "professor" hardly took place. In contrast, friendly relationships arose out of the status group "students" in which the mentoring becomes less important.

IV. Summary And future Work

Especially the German industry needs more qualified engineers and natural scientists at this point in time. The number of students currently enrolled in the corresponding programs is too small to fill this gap. While more female students could stand in, the majority of these programs are rather unattractive to women. In particular, many students in these fields are not well prepared for their future professional life. Thus, important soft skills or communications skills are needed.

Numerous evaluations [3, 10, 11] prove that the quota of women in the programs mentioned is considerably increased by special adaption to their needs (e.g. multidisciplinary). However, this can only be achieved if the curricula are readjusted. Moreover this can also motivate numerous male students. The awareness in Germany to readjust courses of studies is developing very slowly, yet constantly growing. In addition, there are many efforts to encourage female students. Thus, female students will be supported from kindergarten onward all the way to studies at the university level through scholarship programs. However, the criticism grows that many male students are now facing disadvantages due to the changing gender stereotype settings and activities [12]. Therefore a lot of male school graduates would not continue to university any longer and would also not come into consideration for a qualified profession.

At TU Berlin the mentioned challenges are well-known, and different solutions are being sought out. TU Berlin strives to be a forerunner for new challenges in research, economics, and society, in order to achieve a new image of engineering and natural sciences. One of these approaches is the GALILEA project financed by the European Social Fund (ESF). GALILEA is designing programs in order to increase the quota of women in engineering and natural sciences by integrating specific female requirements and new educational paradigms. Through the Bologna declaration [13, 14] the incentives for completely new programs are provided since the two-tier bachelor and master system is a completely new structure in the academic education in Germany. Therefore, the GALILEA project designed the new program "Natural Sciences in the Information Society" aiming at a quota of about 50% female students. This new approach is integrated not only into the concept of the entire program but also through the individual lectures "Scientific Information Management" and "New Media in Teaching and Research".

These two lectures for the Bachelor program were evaluated. Generally, the lectures were positively assessed. During the first run of these lectures students identified some technical procedures such as high expenditure of work or too many examined topics to be disadvantageous. The multidisciplinary approach was assessed as good, and the students had the feeling that the lectures impart soft skills that can be useful in further studies or future jobs.

In addition to the changed curriculum a mentoring program is integrated into the GALILEA program, accompanying students throughout their studies. An evaluation of the mentoring program took place as well. Here, the biggest issue found was that the meaning of the notion "mentoring" is not universally understood, in spite of efforts of explanations in training courses. Students are already aware of the existence of a contact person, but this offer is accepted mainly in the first term. Nevertheless, the program was evaluated positively. A good approach was to enlist sophomore students as mentors for their freshmen fellow students. The developing relationships are considered amicable and lasting.

In further evaluations, we would like to examine specific problems within the lectures and the mentoring program to improve our courses.

Abstract— **Technological advances are improving the standard of living and working conditions. Curiously, the number of students that choose technological studies and careers continues to decline. This fall is particularly noteworthy in respect of females.**

One of the main reasons for this is that neither the model of professional profile promoted, nor the global approach of the mission is attractive or appealing.

Some studies indicate that problem-based and project-based learning methods are conducive not only to acquiring social and interpersonal skills that are valuable in a workplace, but also to increasing gender diversity in engineering degrees [9].

In this paper we present a pilot project, ICT4Girls. The main goal is to diffuse computer science as a real tool for service of society, with a principal aim of promoting ICT careers.

Based on a wireless sensor network (WSN) platform, several real projects by undergraduate students are presented. For our purposes here, two projects have been defined. Beginning from a basic-skill framework, each presents a different audience and goals.

Computer Science, technical skills, Profession, Real-world Project

I. Introduction

The lack of technological vocations is a reality in undergraduate studies as well as in professional careers [1]. This is particularly noteworthy in respect of females

One of the main reasons for this points to the lack of knowledge of the professional profile in the computer science field [2]. Teenagers and undergraduates do not have clear models in their lives (neither real people nor fictional characters). Consequently they do not know the kind of job an IT professional performs, and do not pursue the corresponding degrees (Computer Science and Computing Engineering) as an option relevant to their future career.

One possible solution to this problem may be to introduce a real project in the curriculum: describing a problem, devising a specific solution and making the implementation in a real platform.

Choosing a people-centric project to improve their own community (school, neighbourhood, shopping-mall) they will become familiar with the social aspects of their future job. This aspect is a fundamental part of making Computer Science appealing to new generations: to appreciate the tangible improvements that transpire from their own technical work for both the environment and the people.

These project-based classes also have the advantage of allowing the student to develop other professional skills such as leadership, teamwork and decision making analysis.

Similarly, they offer scope to learn and improve technical skills such as modular and parallel programming, event management or testing experiment design, as well as new areas of interest including open source software, low power analysis and mobility.

With this in mind we present a foundation to develop real projects based on a wireless sensor network (WSN) platform and two project proposals presented by undergraduate students [3].

The rest of the document is organised in the following way: in the next section, we describe the project goals and introduce our project-based proposal. In the third section, we introduce the basic platform to develop our framework. In section four we present our methodology and two current projects, each with different characteristics and requirements. Section five presents some related work in the project-based learning methodology field. Finally, section six deals with the conclusions and future work.

This work is supported by the HiPEAC European NoE, the Ministry of Science and Technology of Spain and the European Union (FEDER) under contract TIN2007-60625 and TIN2009-07333-E/TSI, and by the Generalitat de Catalunya (2009-SGR-980))

II. OUR PROJECT-BASED LEARNING APPROACH

There are well-known references and experiences [9][12] which show project-based learning to be a methodology that connects better with the skills required by employers and encourages the recruitment of more women engineering students [9]. The research in the area shows that learning is a rich context of experiences, not only based on abstract information, but on the exchange of this through hands-on experiments, social activities, community discussions, and real problem solving, among other forums.

The main concerns when designing these types of courses are 1) how to link them with other previous courses; 2) how to use the course to learn specific social and other transferable skills and 3) how to acquire the desired technical and science skills.

The choice of the platform and environment used to build the project is as important as determining the objectives and methodology to accomplish all of these three goals. This platform should allow for a variety of situations to promote creativity, acquire professional habits and attitudes, and to improve their comprehension in computing, among other goals.

Another important point for this choice was that secondary students already had familiarity with these devices (sensors, network issues, etc), so they were able to share experiences and even participate in the projects with undergraduate students.

In this project, we have chosen a wireless sensor network platform and the activities have been designed jointly with a technological enterprise DEXMA, http:www.dexmatech.com, which provides professional expertise and advice on the appropriate devices. They are also in charge of introductory seminars.

To initiate the activity, we engaged a reduced team of female students to participate in a program to introduce secondary female students to ICT careers. In this program there were two main activities:

- To present a set of solutions to current problems using well-known technology and devices;
- To introduce personal experiences of undergraduate life on Campus.

From these activities, we had the beginnings of the first project, in which both undergraduates and secondary students participated (see 4.1).

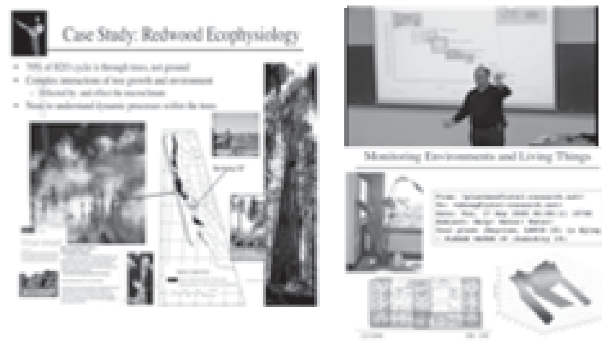

Fig. 1. Introducing technology and familiar devices to manage real current problems.

A. Link with previous courses

A main goal in project-based learning (PBL) is to improve usability, deeper element knowledge and a more mature relationship between different subjects, already done.

In our case, the sensors are programmed in a specific C-like language –nesC- based on events, the servers that receive data are programmed in C++ or Java, and user applications can be programmed in more user-friendly web or graphic-based languages. In addition, scripts that act as glue for the different parts of a complete application should be written in python.

Programming language requisites are covered in lower-level courses for students of Computer Science, as well as Computer Architecture and Network Systems introductory courses.

Some other courses such as graph theory, statistics and other mathematical topics are also interesting and can improve the project results.

Obviously, depending on students' background, the project definition and goals must be adapted.

B. Social habits and attitudes

The European Parliament and the Council of the European Union defines key competences as "…those which all individuals need for personal fulfillment and development, active citizenship, social inclusion and employment. By the end of initial education and training young people should have developed the key competences to a level that equips them for adult life, and they should be further developed, maintained and updated as part of lifelong learning" [8]. And it sets out 8 key competences:

- Communication in the mother tongue;
- Communication in a foreign language;
- Mathematical competence and basic competences in science and technology
- Digital competence;
- Learning to learn;
- Interpersonal, intercultural and social competences and civic competence;
- Entrepreneurship; and

- Cultural expression.

The last three competences are qualitative, personal and subjective skills more related with personal attitudes such as willingness to listen to, to look at, to discover the needs of the other. Being capable of interacting with the resources, using the technology to make a more comfortable, more sustainable world, and to facilitate and to improve the quality of life of people, offering specific services – these are all skills which will be addressed in different ways by the projects we propose.

Engineering education should promote "habits of mind" [1] aligned with what many believe are essential skills for citizens in the 21st century. These include systematic thinking, creativity, optimism, collaboration, communication and attention to ethical considerations [10]

In engineering areas employers seek "people persons"- people who not only have technical knowledge and technical skills, but those who also have interest in the human needs and environmental issues [9].

"The engineer of 2020: visions of engineering in the new century ", [11], takes these aspirations a step further in chapter 4 by setting forth the attributes that will be needed by the graduates of 2020. These include strong analytical skills, creativity, ingenuity, professionalism, and leadership.

The environment where the projects are carried out is the Campus of UPC with the university community acting as "the society". The applications chosen to work on come from the community's needs and research work on the community's style of life. In this way, students also have to learn to communicate with the user (listen to and understand the real needs, establish feedback channels to make progress, decide the best user-application interface, etc.).

Specific examples of the social and communication skills (potentially) included in each project will be considered in a separated paragraph when explaining the respective project. Again, depending on the skills targeted, the basic model of a project can be modified to suit.

C. Technical skills

PBL courses assume that main technical skills are already acquired [7] in the previous courses, as see in section 2.1. With their technical skills, students have to manage the different programming models and network connection programmability; decide the communication model to use (master-slave, pervasive, mesh connection); propose the data structures to keep information; design the user-interfaces to input/output information, etc.

However, some specific tools should be provided to help participants apply their (often rather generic) skills to a real situation with very specific demands. In our referenced projects, these tools include the following two examples. First, a weekly seminar to introduce students to how-to-do issues: system configuration and setup, application examples, etc. Two of these seminars were organized by DEXMA. Second, a twice-monthly team brainstorming session to share the experiences and work done by each team member and to propose new applications and services to develop.

[1] The committee has adopted the term "habits of mind", as used by the American Association for the Advancement of Science in Science for All Americans (1990) to refer to the values, attitudes, and thinking skills associated with engineering.

III. A WSN FRAMEWORK FOR USE IN PROJECTS

The technological basis for the project is a pervasive and ubiquitous platform with wireless sensor networks (WSN) to collect data. This data should allow for the development of different applications to improve the site and to make it more user-friendly.

Our first location is a University Campus (Campus Nord in UPC). The sensors capture temperature, luminity and presence to be processed in different ways by the various proposed applications. There will be some servers distributed throughout the Campus to collect and manage data. End users will connect via wireless to different applications depending on the information needed. Data connexion will be through the Campus wireless service, via intranet. In this way we can guarantee security and privacy in accessing the data.

Different sensor distribution in the area can restrict the different configurations to collect data. So, depending on whether there is a master reading all of the information or the information is based on a "multi-hop" style, some decisions have to be taken about network connections.

This general framework, with minor modifications, can be adapted to different contexts; for example a shopping mall, a school or a neighbourhood.

Once the infrastructure to work on is decided, we have to consider other aspects:

1. How to introduce students to programming WSN. A weekly seminar.
2. How to express the "social skills" as demanded by the European Parliament (last three on the list above).
3. Which applications are most suitable to develop. To do this students have their own meetings, brainstorming with other classmates, and sharing information from related projects and papers.

Starting from the basic platform, the applications will be proposed by the students, following one of two main models:

A. Energy-saving oriented: in this case, the information given is more general, related to resource use such as lighting or heating. It can be used to promote sustainability and power management in everyday personal and working activities.

B. Service oriented: the information provided is used to give specific services the users require on demand.

In the next section we explain the general methodology we follow in the projects and we present a representative example for each one of the application models: a monitoring application and a parking alarm.

IV. Project based learning methodology

PBL is based on contextualized content. Usually the teacher works with a case that would have been real originally but it has no real-world immediacy for the students, and they consequently fail to engage with it. Additionally, these relatively abstract problems may or may not eventually arise in the real world. This can also dampen students' enthusiasm for fully applying themselves to the task.

For us it is very important the student detects the problem and looks for a solution: the student's role is active and allows for the developing of two basic competences in the entrepreneurial world. The first is to translate the user needs into technical words; the second, to work with different disciplines if necessary.

A. Firs project: Maximizing energy efficiency

This is a real project lead by students in collaboration with a technological enterprise, DEXMA [4]. The goal of this project is to sensitize people to energy saving by improving their habits in lighting and heating.

With this project we want to acquire not only technical skills, but also skills like the concern for human needs and environmental issues.

From the initial WSN platform deployed throughout the Campus, we monitor the temperature at different points to be able to quantify the energy we waste. This data collected will be the basis for an application – called AmbientReader- that allows us to measure the energy wastage and then propose different solutions [5].

For example, we measure the temperature in a classroom. A temperature higher than 21ºC when the room is full means that the place is overheated, so energy is wasted.

Steps to follow:

1. Characterization of the place to study. The study is done in the classroom buildings (see Fig. 1). First, we need to determine the temperature characteristics to take into account, For example, whether or not there are variations depending on the floor level, the orientation (north, south, east, and west), the time of the day, or the amount of people inside the room. The goals in this step are:

- To choose the most suitable position to place the WSN (ends of Campus, ends of each building, different floors);
- To measure the temperature changes depending on the classroom being in use or not (full or empty rooms);
- To measure how the temperature changes based on the time of the day (morning, noon, evening).

2. Evaluation of the fine tuning. The turning-on and turning-off of the heating needs time and has an associated delay which we can estimate as a constant value, so we will determine if it makes sense to stop or reduce the heating and for how much time do so. The goals in this step are:

- To calculate the time and temperature at which to turn on heating;
- To combine the two influences on temperature, the ambient and the dedicated, to maintain the temperature within the range of comfort.

This project is a practical example of technology being socially relevant [6].

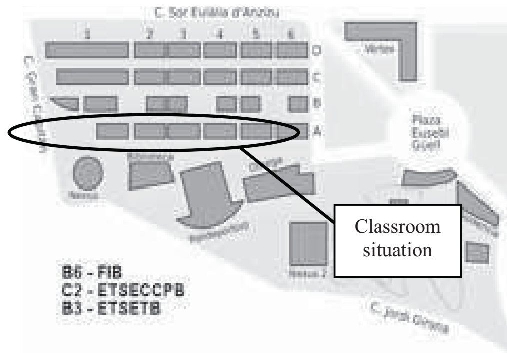

Fig. 2. Campus Nord map remarking the classroom situation, at South

B. Second project: Friendly parking

The second project also contributes to a friendly environment in that it helps to decrease CO2 emissions, but the main focus is more clearly customer-centred. The aim to facilitate parking is a real client need.

In this case, the proposal was born on the initiative of a participant to improve Campus services after having heard some user comments.

Campus Nord has a parking facility for the University community with 190 locations. The car park works as follows:

There is a single-direction traffic flow, so cars enter by one street (Sor Eulalia d'Anzizu) and exit by the opposite (Gran Capità).

If a car can't find a place, other cars might have their exit impeded; also there is a lot of waste in time and gas while looking for a parking.

Fig 3. Campus Nord map remarking the parking part, at North

The goal of this project is monitoring car parking to inform users when a place becomes free and where this free place is. When a space becomes free, the application will send a notification, via e-mail or sms. In addition it is possible to visualize the map with the exact places free in real time

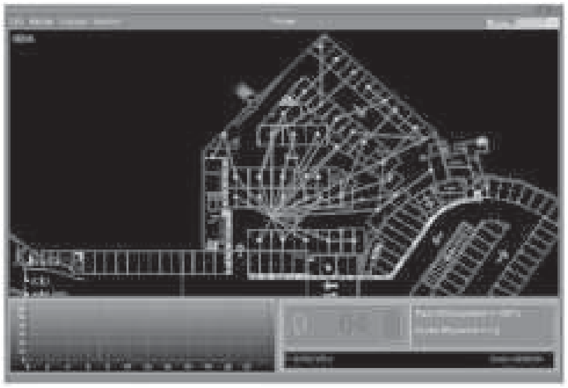

Fig. 4. An exemple of a mesh connection map

Again, the technical basis is a WSN with a sensor in each of the car spaces. The electronic device (mote) works with batteries, is able to detect the presence of a car and broadcast the information up to 70 m. to other devices. All devices form a mesh monitoring all the places in real time and communicate with the server, which manages information and offers a set of services to the users.

When a driver arrives to the Campus, if there is no parking he/her will notify the fact to the server (via mail, sms or web). The server has a specific policy to schedule demands, as it might be chaotic if all clients received a free-place notification at the same time.

A position map can be consulted from home or from the mobile phone, so it is possible to select different ways to reach the Campus. A warning system can be added.

This example has different levels of work, and students might be oriented just to one or combine several, in different teams, or courses, even course-level, depending on their background. For example, there is a very interesting study on the user-side: how to present the information, in which interface, how to warn (e-mail, sms, etc),... On the other hand, the technical concerns are also, very appealing and can be managed in different ways of expertise: how to detect a free place (automatically when the car goes or the car proprietary sends a message, etc), and so on.

V. RELATED WORK

There is a 2007 work from University of Waikato (New Zeland) [12]. In contrast to our proposal, the guidelines of the Waikato project are more rigid, the ends are more abstract, having no final application in the University community, and consequently this may appeal less to females.

Other PBL works are based on playing a role like the EnROLE project [13]. In this case, students and teachers play a role representing users, clients, businesspeople, etc. Again, in our proposal these roles are real and not imagined. The authenticity of the roles in our scheme makes the experience more "immediate" for the participant, and provides a more stimulating and rewarding learning environment.

Maybe the most comparable work is the Open Ended Project [7]. We differ from OEGP in the framework and how it will be established to set up the project, and also in the problem definition itself. Our priority is to produce a practical solution to a real-world problem, defining this solution through close communication with the "end-user".

Additionally, in this paper we present types of project that are suitable due to the skills they provide to students, while the OEGP approach looks for a specific course, with objectives, requirements, and so on.

VI. CONCLUSIONS AND FUTURE WORK

In this paper, we introduce two real projects to be used in PBL classes. This methodology "with more contextualised content resulted in an increased recruitment of women along with a substantial level of appreciation of learning" [9].

Reflecting on social contributions by their own profession improves students disposition toward technical careers. Additionally, the enthusiasm to contribute to their own community fuels the development of accomplished professionals.

On the side of the community, an increased awareness of the contribution of engineers and IT specialists leads to a more positive vision and higher valuation of these professions.

These two positive streams help create a virtuous circle.

Additionally, the technical platform for the projects (WSN) aims to introduce courses related with these subjects to allow students to acquire competence in these new future areas. Development solutions for the future involve the integration of mobiles with other IT as a usual scenario.

As explained above, our pilot projects have been developed as collaboration between undergraduates and high school students. The main goal was to engage females in ICT degrees, by becoming more familiar with the kind of work that is being developed in these areas. Although this is an ongoing experience, we have already received positive comments and reactions:

1. We have a positive influence on people's vision and behaviour regarding to technology, promoting personal and professional attitudes. For example:

- Fostering interdisciplinary dialog channels between people –students, teachers, and professionals-.
- Incentivize research into low-power high-tech (specialized processors, optimized code, power measurement tools, etc.).

2. We have collaborated with secondary school research projects:

- A team is implementing a similar project using a simpler, well-known technology in their own school;

- A student is using the same platform to monitor her home with its different climatization conditions (air conditioning, fan or blinds).

The approach we present will be also used as WSN hands-on material in laboratory courses, or along the degree in several courses.

Other future students' proposed applications are:

- To confirm whether or not a room is in use.
- To know in which of the bars on Campus there is a free table.
- To know if there is a free table in the Campus library.

In a more advanced phase, we plan to include also the participation of Electronic Engineering students to develop new hardware and sensors, as well as collaborate with other degrees to work in multidisciplinary teams.

ACKNOWLEDGMENT

We sincerely thank Nuria Carcelle, Georgina Punsoda, Marta Jimenez, Albert Franzi and Nacho Navarro, members of ICT4Girls project, and the anonymous reviewers for their comments and suggestions. We also acknowledge the support of the BSC (Barcelona Supercomputing Centre).

Abstract **Electrical Engineering (EE) is one of the largest engineering disciplines. Analysis of the student population specifically within EE provides insights into a large segment of the undergraduate engineering population. Using a dataset from universities in the United States of America that includes over 70,000 students who majored in engineering, this work considers the subset of that population matriculating in EE. The rates of EE matriculation and six-year graduation vary by race and gender. The relevant findings are that males out number females at all levels of undergraduate EE. EE is the most popular choice for Asian and Black males at matriculation and the second choice (after ME) for Hispanic and White males. EE is much more popular for Asian and Black females than Hispanic and White females at matriculation and graduation. In fact, more Black females graduate in EE than in any other engineering discipline. The six-year graduation rate of EE matriculants is higher than that of students of other engineering disciplines. These findings suggest the importance disaggregating by engineering sub-discipline and examining how such information is useful in improving recruitment and retention overall.**
Keywords-Electrical Engineering, retention, race, gender

I. Introduction

There have been numerous calls to diversify the engineering profession [1, 2]. Electrical Engineering (EE) is one of the oldest engineering disciplines dating back to the 1880s [3] and also one of the largest. Thus analysis of the student population within EE provides insights into a significant segment of the undergraduate engineering population. Despite having high enrollments of students, EE has one of the lowest percentages of women students around the world including in the U.S.A. [4], Canada [5], and Israel [6].

Many studies of undergraduate student persistence aggregate all engineering disciplines [7, 8, 9, 10, 11]. This may often be a practical limitation imposed by the available data that results in small datasets when disaggregated by engineering discipline. For example, York Young and Redlinger [12] analyzed the student flow for 23 EE matriculants at one institution over six years. They found that 14 (61%) of the EE matriculants graduated in six years. Six of these were in EE, three in Computer Science, and one each in five other majors. Humphreys and Freeland [13] found that 68% of 422 EECS matriculants at one institution were still in the major after four years. They note that women were a small fraction of the cohort and persisted in engineering at lower rates than men and switched out of the major at higher rates than males.

Given our extensive dataset, we are able to disaggregate not only by engineering discipline but also by race and gender. This permits an investigation of EE students at an unprecedented scale and detail. In this paper, we examine how the matriculation and six-year graduation patterns of EE matriculants in the U.S.A. vary by both race and gender.

Research on retention of women in science, technology, engineering, and mathematics (STEM) disciplines in general and engineering in particular contains "conflicting evidence" regarding gender differences in persistence [14, p. 23]. A variety of studies have reported that women matriculating in engineering majors persist at the same rates as men [8, 9, 14, 15, 16, 17, 18, 19]. Other studies found lower persistence for women in engineering [7, 10] although these contained unique metrics for success which are difficult to compare with others.

Despite the sparse evidence supporting the claim that there is a gender gap in engineering persistence, there is a pervasive popular belief that women persist at lower rates than men. One source of this assumption is the inclusion of studies that measure persistence from pre-college STEM intention rather than college matriculation. Starting at this earlier point reduces the overall persistence rate and conflates the gender gap in pre-college choices regarding college STEM enrollment with the persistence after matriculation. Another likely reason for the belief in a gender gap in persistence is the severe gender gap in the enrollment-presence of women, which may be confused with the persistence of women. Overall, a careful investigation reveals that amidst some conflicting evidence, most research finds no significant difference in men's and women's engineering persistence rates. The gender gap in engineering is not a problem of persistence; rather, it is the result of fewer women enrolling in engineering compared with other majors.

This work has been sponsored by a U. S. A. National Science Foundation Gender in Science and Engineering Research collaborative Grant (0734085 and 0734062). The opinions expressed in this article are those of the authors and do not necessarily reflect the views of the NSF.

In analyses of engineering persistence, it is important to adopt a critical race theory framework [20] and consider the intersectionality of race and gender. Intersectionality refers to how gender operates together with race, not independently, to produce multiple, overlapping forms of discrimination and social inequality [21]. Failing to disaggregate data on women by race produces results that are over-generalized rendering minority women “invisible”. Women in engineering do not necessarily share common experiences of marginality. For example, women of color may experience both sexism and racism, compounding their experiences of exclusion.

Reichert and Absher [22] reported data on minority retention rates from the National Action Council for Minorities in Engineering (NACME), but they neither tracked individual students nor disaggregated by race or gender. May and Chubin’s significant 2003 study for NACME [23] spoke clearly to the issue of representation of underrepresented minorities disaggregated by race and gender, but did not disaggregate by engineering major and did not track individual students to address the issue of persistence or graduation rate. Cook and Córdova [24] also disaggregated by race in their study of representation. Each of these studies provided valuable data relating the importance of examining race within engineering. Yet, understandably, each study was limited in scope because of the difficulty involved in examining all relevant variables: race, gender, cohort, major, matriculation status and persistence to graduation.

The vast majority of undergraduate engineering degrees in the U.S.A. are awarded to students who identify as “White”[1]. In 2004, Whites received 65% of the engineering bachelor’s degrees. Asians received about 12% of engineering bachelor degrees). Hispanics received about 7% of these degrees. Blacks received 5% of all engineering degrees while Native Americans account for less than 1% [25]. Except for Asians, each group received about the same proportion of non-engineering STEM degrees. In 2005 [26] about 1/3 of the bachelor’s degrees for Whites, Blacks, Hispanics, and Native Americans were in science and engineering fields. By contrast, almost half of the Asian graduates earned bachelor’s degrees in science and engineering. There is a wealth of literature on the experiences of people of color within science and engineering, yet much of this research aggregates science, math and engineering (SME) and/or underrepresented minorities: Blacks, Hispanics, and Native Americans and does not disaggregate race and gender.

A comprehensive study [27] found that Black and White students are as likely to select STEM fields of study and to persist for three years, but that differences accrued to graduation—62.5% of Blacks persisting for three years graduate within six years compared with 94.8% for Asian Americans and 86.7% for Whites. Yet these persistence issues may not be related to majoring in STEM disciplines alone. Rather, low minority persistence in STEM is a microcosm of low persistence in higher education. Research by Elliott et al. [28] found that ethnicity was not a predictor of persistence beyond what could be explained by ability as measured by scholastic aptitude tests (SAT) math (SATM) scores and achievement (high school grades). The SATM scores of Blacks and Hispanics are known to be substantially lower (1 and 0.75 standard deviations respectively) than those of Whites [29]. Large differences in persistence result when comparing high-performing Blacks’ (62% persistence per Hilton et al., 1989) to a broader cross-section of Black students (34% persistence per Ref 28).

Asian students are unique among students of color in engineering because they are not underrepresented, and they demonstrate the highest persistence [13, 30, 31]. They show the strongest predilection for engineering and the smallest proportionate losses in SME majors during their undergraduate years [7]. Smyth and McArdle [32] reported a 63% graduation rate for Asians matriculating in SME, as compared to 55% for Whites and 38% for underrepresented minorities including Black, American Indian, and Hispanic students (p.371). Similarly, research by Bonous-Hammarth [33] indicated that Whites and Asians had similar attritions rates from SME majors (25% and 26%, respectively) considerably less than the 44% for African American, Hispanics and Native Americans.

The Hispanic population is the U.S.A.’s fastest-growing minority group [34]. Demographic predictions suggest Hispanics may be poised to have the greatest effect on engineering education [35]. Yet the educational gap between Hispanics and other groups continues to widen, especially in engineering [36], possibly as a result of factors affecting Hispanics’ participation in education generally, such as health care, nutrition, adequacy and stability of housing, neighborhood environments, and a lack of engineering role models [37, 38]. Similar to women and Blacks, among Hispanics the proportion of bachelor degrees awarded in engineering has only marginally increased since 1991 [39]. Nonetheless, there is room for the numbers of Hispanics to increase in engineering because this major is the third most popular destination (after social sciences and psychology) among Hispanic bachelor degree recipients.

Native American women are much more likely to participate in higher education and to earn bachelor’s degrees than Native American men. Yet, like all women, they are less likely to choose science and engineering fields as college majors [40, 41]. In 2004, Native American women accounted for only 0.5% of engineering students in the U.S. A. [25]. From 1995 to 2005, Native Americans remained steady at approximately 0.65% of all undergraduate engineering students [42]. Of those Native American students receiving bachelor’s degrees, approximately 4% were in engineering [26]. Besides Lord et al. [16], no other references with details on the persistence of Native Americans in engineering could be found.

[1] In the U.S.A., the racial category “White” refers to people of European, Middle Eastern, and North African descent “Asian” refers to people with origins in any subcontinents of the Far East, Southeast Asian, or India. “Hispanic” refers to those who trace their origin or descent to Mexico, Puerto Rico, Cuba, Spanish speaking Central and South America countries, and other Spanish cultures. “Black” refers to Americans of African descent. “Native American” include American Indians and Alaska Natives. More details are available at http://www.census.gov/

II. METHODS

This study uses the Multiple-Institution Database for Investigating Engineering Longitudinal Development [11, 43], a dataset with more than 79,000 students matriculating in engineering at nine southeastern institutions that awarded 1/12 of all U.S. engineering bachelor's degrees from 1987 to 2004. The results should be generalizable to large public institutions. We focus on first-time-in-college U.S.A. citizens / permanent residents matriculating directly in an engineering discipline including Electrical (EE), Mechanical (ME), Chemical (ChE), Civil (CE), and Industrial (IE). Due to the small numbers, Computer, Materials, and other engineering fields including Bioengineering are not considered. In the population studied, the number of students in Bioengineering is two orders of magnitude smaller than the largest majors preventing disaggregation by race and gender. Students self-report gender and race choosing among Asian, Black, Hispanic, Native American, and White (as well as Non-Resident Alien and Other, each of which are not included in this study). Since we have whole population data, inference is unnecessary—all reported differences are valid. Note that students who matriculated into "first-year engineering" are not included here, since we are studying the disciplinary character of matriculation. Graduation is defined as having graduated by the sixth year following a standard of reporting by the Integrated Postsecondary Education Data System (IPEDS) [44]. Thus, in this paper, we consider students who matriculated from 1988-1998 and graduated six years later.

III. RESULTS

A. *Context and Rationale for Studying EE*

To contextualize our results for EE students, we begin by showing the numbers of students enrolled in various engineering disciplines at semesters 1 and 12. Women and men prefer different engineering disciplines at matriculation and graduation [45]. Table 1 shows the number of women and men at matriculation (Sem 1) and six-year graduation (Sem 12) for Asian, Black, Hispanic and White students. The top two choices of men at matriculation and graduation are Mechanical (ME) and Electrical (EE), yet the order varies by race. At matriculation and graduation, Asians and Blacks prefer EE to ME while Hispanics and Whites prefer ME to EE.

For women of all races, Chemical is the top choice at matriculation. EE is the second choice at matriculation for Asian and Black women while ME is the second choice for Hispanic and White women. Similar to the men, at matriculation and graduation, Asian and Black women prefer EE to ME while Hispanic and White women prefer ME to EE. By graduation, IE is the most popular major for Hispanic and White women, Asian women still prefer Chemical, and Black women prefer EE. The large number of students matriculating in EE results in a large number of students of all race-gender combinations in that population, making it suitable and interesting for detailed study. We next consider those EE matriculants in more detail disaggregating by race and gender.

TABLE 1
NUMBERS OF STUDENTS MATRICULATING IN (SEM 1) AND GRADUATING IN (SEM 12) ENGINEERING DISCIPLINES BY RACE AND SEX.

	Women at Matriculation (Sem 1)				Women at Sem 12			
Major	**Asian**	**Black**	**Hispanic**	**White**	**Asian**	**Black**	**Hispanic**	**White**
Chemical	147	711	48	1110	91	330	19	448

Materials	58	44	28	633	35	31	22	478
Mechanical	522	1220	329	7053	279	530	130	3275

B. Matriculation in EE

Table 2 shows the number of EE matriculants and their percentage among engineering matriculants disaggregated by race and gender. The top panel of Figure 1 emphasizes that men of each racial group are more likely than women to matriculate in EE. A similar gender gap is found for ME and Computer Engineering but not other engineering disciplines studied [45]. Overall, 12% of women and 19% of men choose EE at matriculation. Of all racial groups, Black students choose EE at matriculation at the highest percentages of all subpopulations. Of Black men who matriculate in engineering, 30% choose EE, the highest of any group. The second highest percentage is 24% for Asian males. EE attracts 21% of Black women in engineering, the highest of any group of women with the second highest percentage being 14% of Asian women. Notably, only 8% of White women matriculate in EE resulting in a smaller number of White women than Black women despite the greater presence of White women in Engineering.

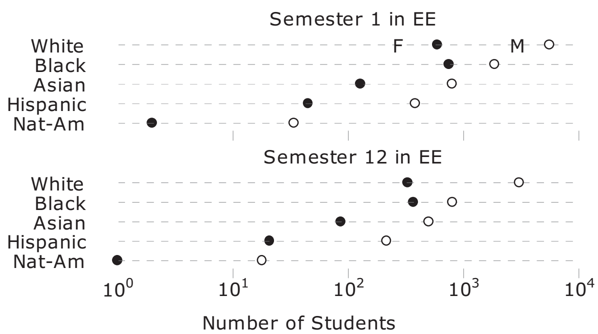

Figure 1. For all races, more men (open circles) than women (filled circles) matriculate and graduate in EE.

C. Six-year Graduation

The bottom panel of Figure 1 emphasizes that more men of each race also graduate within six years in EE than women [45]. Table 3 shows the number and percentage of EE matriculants who graduate in six-years in EE, percentage who switch from EE to another engineering major, and percentage who graduate in any engineering major. As shown in Figure 2 (for populations greater than 30 to avoid computing percentages of small numbers) the percentage of EE matriculants who graduate within six years in EE varies by race and gender from a low of 30% for Hispanic women to a high of 57% for Asian women. Asian students do particularly well in EE as evidenced by their high EE graduation rates. Asian and Black women EE matriculants graduate in six years in EE and engineering (ENGR) at a rate equal to or higher than men of the same ethnic group. Black women graduate at 43% compared to 38% for Black men. White men and women EE matriculants have very similar graduation rates: 41% of White men and 40% of White women EE matriculants graduate in EE. 56% of White women graduate in some engineering discipline compared to 55% of the White men. Except for Hispanic women, the graduation rates of female EE matriculants is consistent with other reports of performance of engineering matriculants disaggregated by race [16].

TABLE 2
NUMBERS OF STUDENTS MATRICULATING IN EE AND ENGINEERING BY RACE AND SEX. DATA ORDERED BY % CHOOSING EE.

Race & Sex	No. in EE	No. in ENGR	Percent EE
Black Male	1695	5707	**30%**
Asian Male	674	2799	**24%**
Black Female	701	3365	**21%**
Native-Am. Male	26	136	**19%**
Hispanic Male	248	1416	**18%**
White Male	4646	29286	**16%**
Asian Female	107	757	**14%**
Hispanic Female	33	332	**10%**
White Female	502	6673	**8%**
Native-Am. Female	2	39	**5%**
All Female	1345	11166	12%
All Male	7289	39344	19%
ALL	8634	50510	17%

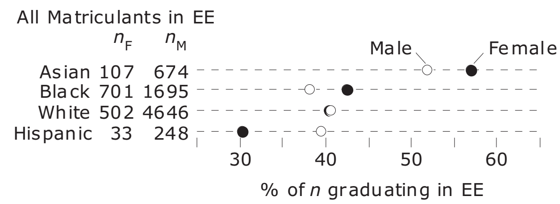

Figure 2. Except for Hispanics, more women (filled circles) matriculating in EE graduate in EE within six years compared to men (open circles).

If EE matriculants graduate in an engineering discipline, they are most likely to graduate in EE of any engineering major for all races and genders. By six years from matriculation, fewer than 16% of EE matriculants switch from EE to another engineering major. Within that 16%, women and men of each ethnic group are equally likely (within 2%) to switch from EE to another engineering major, except for Native Americans where our sample population is quite small. For those who switch, Computer Engineering is the most popular destination within Engineering for Asian, White, and Hispanic males. Industrial Engineering (IE) is the most popular second choice for White females, Black males, and Black females. Populations of other subgroups have less than 5 students switching to another engineering destination.

EE matriculants are a successful group among engineering matriculants. As shown in Table 4 for populations with sample sizes greater than 10, EE matriculants graduate in six years in engineering at higher rates than all engineering matriculants. Asian women show the greatest difference: 69% for EE matriculants and 62% for engineering matriculants. White women, Hispanic men, Black men and women are all have differences less than 2%. The only exception to this is White males who graduate at equal rates. This suggests that EE matriculants are similar to all engineering matriculants. Given that this is whole population data, the differences seen here are real. However, more study is needed to determine if they are meaningful for particular race-gender combinations. For example, what is different about Asian women who matriculate in EE versus those matriculating in engineering?

TABLE 3
NUMBERS OF EE MATRICULANTS GRADUATING IN SIX-YEARS IN EE AND ENGINEERING BY RACE AND SEX. ORDERED BY % RETAINED IN EE.

Race & Sex	Number in EE	Retained in EE	Switching from EE to another ENGR	Graduating in ENGR
Asian Female	61	**57%**	12%	69%
Asian Male	350	**52%**	12%	64%
Native-Am. Male	12	**46%**	8%	54%
Black Female	298	**43%**	7%	50%

All Male	1209	41%	12%	53%
ALL	3568	41%	12%	53%

TABLE 4
PERCENTAGE OF MATRICULANTS GRADUATING IN SIX-YEARS IN ENGINEERING BY RACE AND SEX. ORDERED BY DIFFERENCE BETWEEN EE AND ENGR.

Race & Sex	EE matriculants	ENGR matriculants	Difference %EE – %ENGR
Asian Female	69%	62%	**+7%**
Native-Am. Male	54%	47%	**+7%**
Asian Male	64%	61%	**+3%**
White Female	56%	54%	**+2%**
Black Male	43%	41%	**+2%**
Black Female	50%	49%	**+1%**
Hispanic Male	54%	53%	**+1%**
White Male	55%	55%	**0%**

IV. DISCUSSION

Researchers have begun to explore the reasons why women prefer some engineering disciplines over others. Early socialization, influence of parents and teachers, academic preparation and success, work experience and networks have been cited as important factors [46, 47]. Some research suggests that women prefer majors with a clear benefit to society; thus researchers advocate providing meaningful contexts for problem solving and applications to help attract women [48]. However, Hartman, Hartman, and Kadlowec [49] surveyed 83 first year female engineering students in mechanical and electrical engineering and compared them with those in chemical and civil/environmental engineering. They found that background differences, differences in general academic and math/science self-confidence, attributions of success, and expectations about the engineering degree did not account for the differences in proportions of women in the different engineering majors. No statistically significant differences were found between women and men in all majors regarding their expectation that their engineering degree would help them make an important contribution to society. The researchers did find differences in the reported engineering self-confidence of women entering the different majors. "Work needs to be done on raising the self-confidence of other qualified women, so that they too will consider the most non-traditional engineering disciplines." They also call for more research on the persistence of women in these majors. Our work addresses this quantitatively. Further qualitative analysis is necessary to understand the reasons why students matriculate and graduate in EE.

Interesting recommendations for promoting EE for women have been suggested by Hazzan, Levy and Tal [6]. They developed a one-day introduction to EE for female high school students and showed a dramatic change in the students' perception of the field and willingness to study it. They argue that it is important to show prospective students a realistic image of EE including the multidisciplinary nature and its connection to many aspects of society rather than dwelling on EE as an "exceedingly difficult" topic. Such workshops indicate the importance of diversifying images of engineering presented to potential students. For minority students and women students, exposure to similar role models and cultivating potential mentorships are also important. Many universities successfully host summer workshops designed to attract and immerse potential students into the field of undergraduate engineering.

EE is relatively successful at attracting students including women and minorities especially Blacks. This might be related to the large number of electrical engineers so that the chances of students having heard of EE or seen an EE role model are greater than for other engineering disciplines. Qualitative research examining differentiation by engineering major, race and gender is necessary.

V. SUMMARY/CONCLUSIONS

Based on the findings presented here, the trajectories of students matriculating in EE are gendered and racialized. This merits further study to better understand who EE students are and identify potential recruiting opportunities to draw more students into the field. Further qualitative research is needed to understand the reasons behind these enrollment and graduation numbers. This work raises questions for discussion among the EE education community where the input of many is vital to addressing the issues and enhancing the profession.

Abstract --- **Recruiting and retaining women in the STEM faculty ranks has been a national priority for many years. Recent research, sponsored by the NSF ADVANCE program, was performed mostly by doctoral institutions. However, for small undergraduate universities, the resulting challenges and decision frameworks are likely to be different. The prevalent recommendations need to be re-evaluated and re-interpreted for relevance and applicability.**

Multiple change agents have been identified, but it is believed that the departmental climate most strongly correlates with successful institutional transformation. The primary success factor is a set of formalized processes in: (1) teaching, scholarship and service, (2) mentoring, and (3) leadership. A secondary factor is a faculty support infrastructure capable of fostering collaborations and reducing isolation. A third factor is an introspective capability that broadens the understanding of the issues affecting women ultimately expressed in the form of better policies and procedures.

There is a strong connection between gender progress on the faculty side and improving the pipeline of female students. To effectively intervene on the supply side, it is important to have networking, mentoring and role modeling processes that match student demographics and global sociological conditions. In the case of our University, this requires recruiting, developing and retaining faculty whose principal focus is undergraduate education which is challenging in STEM fields where the traditional emphasis is on research.

Curricular evolution in doctoral institutions is typically driven by emerging trends and technological opportunities while the needs of regional industries and local programs are more influential among primarily undergraduate institutions. As advanced degrees become a professional requirement, baccalaureate graduates will be expected to pursue advanced studies early in their career. Hence, more undergraduate STEM programs will serve as feeders to doctoral institutions. The future supply of graduate students and ultimately faculty will become more dependent on these teaching universities.

This paper describes our specific efforts and successes in the context of an undergraduate teaching institution. We have demonstrated that even with limited resources and no external funding, it is possible to improve the community culture and climate. Tangible strategies and initiatives aimed at improving the climate are presented: (1) administrative leadership commitment, (2) grants and endowments, (3) faculty development resources, (4) workshops that mirror industry successes, (5) early and mid-career planning, and (6) recruiting and retention of female faculty.

Keywords- gender balance; female faculty; recruiting; student retention

I. INTRODUCTION

Recruiting and retaining women in the science, technology, engineering and mathematics (STEM) faculty ranks has been a US national priority for many years [1]-[9]. Recent research, sponsored by the NSF ADVANCE program, was performed mostly by doctoral institutions [10]. However, for small undergraduate universities, the resulting challenges and decision frameworks are likely to be different. The prevalent recommendations need to be re-evaluated and re-interpreted for relevance and applicability.

Our University is a small private undergraduate institution conveniently located among a vibrant array of high technology companies. A key strategic objective of the University is managed growth and improved retention by fostering unique and distinctive programs. The five-year academic strategic plan of the University is to sustain an academic community of scholars who embrace its mission. One element of this strategy is to increase STEM faculty diversity.

The STEM disciplines are primarily concentrated in Engineering and Arts & Sciences (A&S). Engineering supports ten while A&S has seven STEM-related programs with enrollments of about 500 and 170 students, respectively. These programs vary widely in size/demographics and gender diversity (student as well as faculty). The STEM matrix in Table I shows program enrollment and gender mix for the fall 2009 semester.

There is a strong connection between gender progress on the faculty side and improving the pipeline of female students. To effectively intervene on the supply side, it is important to have networking, mentoring and role modeling processes that match student demographics and global sociological conditions. In the case of our University, this requires the principal focus of faculty to be undergraduate education, a challenge in STEM fields where the traditional emphasis is on research.

TABLE I. STEM PROGRAM MATRIX

STEM Program Matrix AY 2009-10

Degree	Engineering Programs	Enrollment /Female/%
Bachelor of Science	Acoustical Engineering	34/06/17

	Physics	08/00/00

II. ADVANCE RESEARCH FINDINGS

The National Science Foundation's (NSF) Advancement of Women in Academic Science and Engineering Careers (ADVANCE) program is a national strategy designed to broaden participation in the STEM workforce [10]. The long-term goal is to advance the status of women in academic science and engineering, and NSF more specifically describes its objective as:

"…to increase the representation and advancement of women in academic science and engineering careers, thereby contributing to the development of a more diverse science and engineering workforce. ADVANCE encourages institutions of higher education and the broader science, STEM community, including professional societies and other STEM-related not-for-profit organizations, to address various aspects of STEM academic culture and institutional structure that may differentially affect women faculty and academic administrators. Since 2001, the NSF has invested over $130M to support ADVANCE projects at more than one-hundred institutions of higher education and STEM-related not-for-profit organizations…"

There are over 3,500 higher-education institutions in the United States, most of which offer one or more STEM programs. NSF contracts have historically been concentrated in the Top 100 research universities. Table II shows ADVANCE funding which mirrors this trend with the exception of 2003 where a majority of the awards were directed towards Tier 3 institutions. In three of the four cohort years, Top 100 universities were predominant.

TABLE II. NSF ADVANCE AWARDS

University or College	Ranking	UGs
Hunter College	Masters – North, 51	16 k
Univ. of Colorado	National, 79	26 k
Georgia Institute of Tech.	National, 35	12 k
Univ. of Michigan	National, 25	25 k

Purdue Univ.		
Rutgers Univ.	National, 1st , 64	27 k
Univ. of Nebraska Lincoln		
Washington State Univ.	National, 1st,116	20 k
Wright State Univ.	National, 4th tier	12k

The principal strategic activities undertaken by the ADVANCE institutions were to: (1) improve workplace climate, (2) attract and retain female faculty/students, (3) transform departments, (4) stimulate partnerships in scholarship and teaching, (5) measure and report progress and (6) promote advocacy and active research collaboration. A comparison of the projects reveals many similarities across the spectrum of awardees structured along the following lines:

- Comprehensive self-study
- Basic research on gender topics
- Visiting scholars
- Coaching constituencies
- Best practices training from industry
- Focused workshops and conferences
- Policy and procedure modification
- Collaborative research incentives
- Networking, mentoring and role modeling
- Department transformation
- Position funding (ADVANCE chairs)
- Leadership development
- In-house gender equity endowments
- Interventions for faculty
- Balance work-life issues
- Recruiting initiatives

While multiple change agents were identified, the departmental climate is believed to most strongly correlate with successful institutional transformation. The leading departmental success factor is a set of formalized processes in: (1) teaching, scholarship and service, (2) mentoring, and (3) leadership. A secondary factor is a faculty support infrastructure capable of fostering collaborations and reducing isolation. The third factor is an introspective capability that broadens the understanding of issues affecting women ultimately expressed in the form of better policies and procedures.

Now that the projects for Cohort 1 are completed, researchers are beginning to assess the degree of transformation that has been and will continue to be achieved. Transformations of this sort are likely to occur over a span greater than five years [11]. To be sustained, some level of institutionalized funding will be required. The issue of sustainability was addressed by Litzler *et al* [12]. where seven of the nine colleges and universities that received funding in 2001 were surveyed. The purpose of the work was to gauge the degree of institutionalization as measured by the presence of stable funding to continue one or more successful ADVANCE project elements. The three main findings were: (1) leadership change at the top decreased the likelihood of success, (2) there was no direct correlation to the level of state funding, and (3) transformation occurred in degrees based on support, duration, diffusion, and advocacy. From our perspective, the most interesting point was the success of state universities in the mid-range of financial assistance. Those in the lower and upper scales were unable to establish and maintain internal efforts. For small undergraduate teaching institutions, it appears that funding constraints may block progress even in the presence of perceived value and support at the top.

III. INTERNAL RECRUITING EFFORTS

On the engineering side of STEM programs at our University, there are currently 23 full-time faculty teaching core technical courses. In 2005, there were three female faculty members, one in each of three departments. One was tenured and had achieved the rank of full professor. Two others were assistant professors and on tenure-track. The total number of faculty has remained relatively constant since 2005 and is not projected to increase. In support of the University's mission, values and strategic plan, the focus in STEM faculty diversity is to recruit and retain women as new positions and vacancies arise.

Since 2005, six faculty searches have taken place to fill open engineering positions. In three cases, we were successful in recruiting a female. To date, all three have been retained as assistant professors and are progressing on tenure-track. Consequently, in the last five years, the number and percentage of female engineering faculty has doubled from 3 (13%) to 6 (26%). Meanwhile, of the two incumbent female faculty members, one has been tenured and promoted to the rank of associate professor. She was also appointed department chair, while the other is eligible for tenure and promotion this academic year. Table III summarizes our recent progress in improving gender balance within the engineering faculty ranks.

TABLE III. FACULTY RANK GENDER PROGRESS

Engineering Faculty		
23 total faculty in civil, electrical & mechanical engineering		
Female Faculty	**Academic Yr.**	
	2005-06	
	No.	**%**
Tenured/tenure-track	1/2	4/8
Rank: Assistant/Associate/Full	2/0/1	8/0/4
Chair: Civil/Electrical/Mechanical	0/0/0	0%
	2009-10	
Tenured/tenure-track	3/6	13/26
Rank: Assistant/Associate/Full	4/1/1	17/4/4
Chair: Civil/Electrical/Mechanical	0/0/1	33%

In recruiting six faculty from 2005-09, the Provost's Office assisted the departments by paying for additional ads to increase the number of women applicants. While the gender mix of the overall candidate pool is not known, women were finalists and granted campus interviews in five of six cases. It appears that the percentage of women who applied was higher than their representation in the national undergraduate ranks. The growth in doctoral graduates in recent years has been attributed to temporary visa holders, many of whom choose to remain in the US, including many women. This increases the female candidate pool and enables faster progress towards gender balance. Of the last six female hires dating back to 1992, five were international Ph.D. graduates who received their terminal degree domestically.

In the last six faculty searches since 2005, the committees chose one or more women as finalists five times. It is interesting to note that in none of the cases was a woman ranked first. However, as the leading candidates dropped out, the women rose to the top and some were ultimately hired. In one case, a promising female ended up second to another and would not have received an offer. The Provost's Office agreed to create an additional position to seize the opportunity.

Given this recent success in adding female faculty, our capacity to leverage their presence in student recruiting has been strengthened. We have experienced the impact of women as active role models in open house events, orientations and advising. Beginning in 2006, the number and percentage of women undergraduates entering the College has steadily increased with the most improvement in biomedical, civil and mechanical engineering. In prior years, female enrollment was flat.

IV. INTERNAL FUNDING OPTIONS

To create a successful track record of scholarship, new engineering faculty need to establish a technical research focus including journal publications and a supporting network of peers and collaborators. Start-up packages, customarily offered by research institutions, are not provided; consequently, new faculty must aggressively pursue funding from internal and external sources. In a primarily undergraduate institution with heavy teaching loads, the most effective research strategy is to integrate and leverage grants that include course releases. To assist with the research, it is also important to cultivate a cadre of undergraduate and graduate students in a non-Ph.D. environment.

The University offers a number of internal research and pedagogical grants, fellowships and prizes. This pool of funding is an effective way for all faculty to initiate work prior to receiving support from external sources. While awards are for the most part modest and the work must be accomplished within one academic year, they have been persistent and stable line items in the budget over time. The specific internal opportunities accompanied by a brief description are listed in Table IV. A high number of female engineering grantees have received awards over the last eight years. For example, the Greenberg grant has been in place since 2001 and engineering faculty have won four times; three of the recipients were female.

TABLE IV. INTERNAL GRANTS FOR FACULTY

Internal Grant Opportunities		
Name	**Female Awards**	**Description**
Vincent B. Coffin grant	3	Offsets the loss of income for summer teaching obligations in order to have release time to engage in substantive scholarly or creative work
Summer stipend	2	Offsets the loss of income for faculty from summer teaching obligations to engage in scholarly or creative work
Faculty Center for Learning & Dev. Grant (not active)	3	Supports course re-design to make it more appealing and effective
Greenberg Junior Faculty grant	3	Supports high-quality scholarship for faculty members just beginning their careers
Belle K. Ribicoff Junior Faculty prize	0	Awarded to one junior faculty each AY. A recipient of one of the above awards from the prior 3 years is chosen as the Belle K. Ribicoff Professor for 3 years, with a stipend to pursue course development, artistry, research or scholarship
Innovations in Teaching award	1	Recognizes innovative assignments and activities that positively impact student learning
Engaged Learning Fellow	1	Supports implementation of an engaged learning strategy including but are not limited to service learning, problem-based learning, and learning communities
International Center Faculty grant	1	Supports internationalization of course content, develop a study abroad course, partake in a faculty development seminar, present a paper, or conduct research
WELFund grant	6	Supports initiatives to enhance women's education and leadership both on and off-campus by awarding grants to innovative projects designed with women or girls as the primary beneficiaries

The funding sources shown in Table IV support the community as a whole with some emphasis on tenure-track faculty. An exception is the Women's Education and Leadership Fund (WELFund) which has evolved into the primary means for advancing gender-based initiatives irrespective of academic status. Established in 2006, the purpose of WELFund is to: (1) enhance the education of women, (2) advance women as scholars and as the subject of scholarship, (3) cultivate and sustain women's leadership skills, and (4) increase awareness about women as individuals and in communities. WELFund was established as a legacy to Hartford College for Women, a single gender institution affiliated with the University of Hartford in its final years, and the primary source of WELFund grants is the remaining endowment of this college. An eleven member board, composed of regional leaders, both women and men, establishes priorities, reviews application materials, and decides which proposals will be supported. In the nearly three years since its founding, the program has funded 62 different projects. Individual grants have ranged from $2,000 to $10,000, and any student, staff or faculty may apply, regardless of gender.

Faced with limited financial resources, the University community has come to rely on WELFund to enable projects in the following areas: (1) faculty research, (2) support for student research, (3) professional development, (4) STEM best practices, and (5) leadership initiatives. For example, three recent grants funded engineering research by female faculty in the areas of acoustics, transportation, and microprocessors, and each project included female undergraduate students. Thus, faculty have been able to secure a base level of support to initiate and grow research interests while simultaneously attracting female student collaborators. The obvious benefit for faculty members is to publish and present work beyond what would normally be possible (e.g., one conference per year). For most students, this is their first opportunity to participate in research, write peer-reviewed content and network with professionals in the field.

In addition to seeking support for research collaborations, engineering faculty and staff have been aggressively pursuing WELFund monies for recruiting and retaining female students. One of the projects created experiential modules of various engineering specialties targeting high school girls. Each of the modules emphasized the capacity of engineers to improve lives, an effective strategy to engage female students. Another grant supported a University-magnet high school collaboration; the outcome will be a two-week summer day camp to introduce incoming high school girls to STEM fields. Further, an after-school program was implemented to discover best practices in mixed gender situations using the comparison of a single gender afterschool program. Although it is hard to measure the quantitative impact of these efforts, our appeal to female students has been enhanced, and the faculty/staff continue to energetically pursue other promising avenues.

WELFund is one of the only organizations identified in the country to provide direct financial support to faculty, staff and students. Female students received funding to create and sustain SWEET Day (Society of Women Engineers Educating for Tomorrow). SWEET Day has become a highly successful event for prospective students and their parents that encourages young women to consider engineering as a career. Workshops, informative guest speakers, and a tour of College facilities help expand the image of the engineering profession as a positive force in improving quality of life. The attractiveness of our STEM programs has been improved and participants are now more likely to apply.

A female engineering student was awarded two successive grants to support a collaborative project, "Water for Abheypur," between the University, Engineers Without Borders (EWB), and the Indian village of Abheypur. In the first project, a multidisciplinary team with two female students installed a solar powered ground water pump and tanks. The second project funded the design and implementation of a rooftop rainwater harvesting system. The system provides a source of water during the monsoon season when the solar pump is not effective. Subsequent surveys among students revealed a high level of interest and support for these projects, and what was originally an engineering effort has expanded to include sociologists from the College of Arts and Sciences and design students in the Hartford Art School.

WELFund has supported a series of associations and activities that connect women students with staff, faculty, and alumnae, providing opportunities to discuss work/life balance, health, financial acumen, and more. In addition, an outside speaker series, open to both University and high school students, invites accomplished women scientists and engineers such as Jocelyn Bell Burnell**,** British astrophysicist, to present their experiences in preparing for a STEM career.

In 2008-09 WELFund began a pilot program, the Laura Johnson Initiative for Women Leaders,and brought together fifteen faculty and staff for monthly professional development workshops. Its aim was to provide the knowledge, skills, and networking necessary to facilitate both career enhancement and advancement. An outgrowth of this initiative is the Leading Forward leadership program, designed by the first faculty-staff cohort to provide a similar cohort experience to female graduate students. A series of sessions explore individuals' leadership styles, goal setting, and communication strategies. Each participant is provided a mentor who is a member of the University community. Both of these programs have been designated as on-going offerings of WELFund, and will have a substantial impact on the University’s culture for women.

V. DEPARTMENT CLIMATE

As mentioned previously regarding ADVANCE findings, the department climate most strongly correlates with successful institutional transformation. The leading success factors are formalized processes in: (1) teaching, scholarship and service, (2) mentoring, and (3) leadership. The faculty authors, both department chairs, received a WELFund grant to facilitate leadership mentoring and professional development for two junior female faculty and themselves. Junior faculty were provided an opportunity to address future research, educational, and academic challenges. The senior faculty focused on academic and positional leadership activities. The grant was designed to create a more systemic approach to mentoring and to foster a supportive climate in each department.

In our College, new tenure-track professors are assigned a senior faculty as a mentor. However, mentoring for leadership is not part of peer mentoring as we know it. The mentoring literature [13] has shown that faculty can benefit from multiple mentors; therefore, a good mentoring process should create an environment where 'giving and receiving guidance are embedded in the values and norms of the organization [14].'

New faculty members bring fresh perspectives to their respective programs, departments and colleges. They are typically well-suited to contribute in the following ways: currency in educational technology, developing new/improved courses, integrating topical threads across the curriculum and becoming a change agent. While the benefits of strong educational leadership are apparent, faculty who contribute in this area often do not receive appropriate recognition. Contrary to this practice, both junior faculty were successful in receiving internal grants to evaluate new classroom technology. The results were presented in the form of a workshop to our departments.

Both junior faculty have established a research focus including a track record of publications and a network of peers and collaborators. Their challenge in the area of technical leadership is to grow research funding and a local network of academic and industrial partners. Each was successful in obtaining research funds during their first academic year. One received an external grant, in part due to the mentoring by an assigned and motivated faculty member in the same program. Such proactive and quality mentoring is not common. Ownership of tenure-track success within any department is less than desired. The likely causes are heavy teaching and service loads, exacerbated by a mentor's need to sustain their own research area. Consequently, senior faculty exhibit insufficient professional interest in junior faculty development. This is somewhat buffered at the University level by a 'new faculty' first-year orientation. However, a mentoring gap continues to exist for junior faculty and associate professors.

Most engineering faculty do not seek opportunities in academic leadership. Our two departments have collectively five positional openings and often a single faculty member holds more than one because of insufficient interest or skills. Junior faculty have become active in open house events and first-year orientation sessions, and ultimately will have to decide what role(s) to accept. For example, supported by targeted funds within the author's WELFund grant, one went to leadership training while the other attended a first-year student retention workshop.

The positional leadership challenge addressed by the faculty authors was to improve the balance of their research efforts and administrative duties. The solution was to make greater use of delegation within the departments and to set personal goals that strengthen research efforts. Subsequently, the faculty authors received a total of 6 grants/awards within one AY. In addition, a number of technical and pedagogical papers were published and all grant participants attended multiple conferences over and above the norm, which is one per faculty member.

VI. PRIVATE UNIVERSITY-PUBLIC PURPOSE

Curricular evolution in doctoral institutions is typically driven by emerging trends and technological opportunities while the needs of regional industries and local programs are more influential among primarily undergraduate institutions. As advanced degrees become a professional requirement, baccalaureate graduates will be expected to pursue advanced studies early in their career. Hence, more undergraduate STEM programs will serve as feeders to doctoral institutions. The future supply of graduate students and ultimately faculty will become more dependent on these teaching universities.

To this end, the University has taken steps to strategically address our emerging role in the graduate pipeline by formalizing a shared values statement 'Committed to Community':

"At the University of Hartford, we are committed to community. We are an academic community that values integrity, curiosity, creativity, excellence, responsibility, and accomplishment. Enriched by our diversity and our engagement with one another, we take pride in our shared traditions and experiences. We are dedicated to building a culture that respects all of its members and celebrates their contributions as we work together to strengthen our community [15]."

In the spirit of the above values, a presidential commission on the status of women was recently formed to expand the opportunities for all women and men on the faculty and staff. Our College is well positioned to meet the challenge with recent female faculty hires as well as a healthy array of student-oriented activities including SWEET Day, EWB and K-12 engagements. We have demonstrated that even with limited resources and no external funding, it is possible to improve the community culture and climate. The recent spike in female engineering enrollment may very well be an early indicator of future success. In some respects, the positive changes we have made may be more sustainable since these were obtained at the expense of internal resources.

VII. CONCLUSIONS

Significant progress has been made within the engineering disciplines of our College in improving gender balance. The community has relied upon an ensemble of rather modest internal grants, awards and prizes. Given the relevance of its stated mission, the WELFund grant has become the primary vehicle for supporting many gender specific initiatives. Within the past five years, recruitment and retention of female faculty was successful. During this period, one female faculty was promoted and tenured, and the other is eligible soon. In addition, three new female faculty were successfully added, one in mechanical and two in electrical, both areas that typically have the lowest representation compared to other engineering fields.

Meanwhile, ADVANCE grants have funded five-year transformation efforts across four cohorts totaling 38 institutions. The majority of the funding was awarded to large research universities. The projects for the first and second cohort groups have been completed, and the challenge these institutions now face is how to continue the more successful activities, especially those that require stable financial support, well into the future. Research designed to measure the degree of positive transformation achieved, as well as the level of recurring internal funding after the grant ended, is beginning to be published. It will require several more cohort cycles and years for a clear picture to emerge and be disseminated.

The scope and breadth of effort afforded by ADVANCE goes far beyond what we have been able to accomplish. Many of the best practices that have or will stem from the broader impacts cannot be implemented at our University given the internal resource constraints. It is likely that some incremental improvement in gender balance will continue to be made. In some ways, this progress may be more sustainable because the value, ownership and investment stems from within. For a truly transformational change, external resources will be needed, and preliminary work along these lines has begun. In parallel to this activity, we will continue with efforts that leverage our internal capabilities and current momentum to build on recent successes.

Abstract— **In spite of social and political efforts to achieve equal opportunities, women remain a minority in natural sciences, technical and related fields. We hereby present the gender concept of the University of Stuttgart. First, the steps for promotion of female students within natural sciences and technical fields are developed.**

Keywords-gender concept, female academic education, diversity studies, women in natural sciences and engineering

I. INTRODUCTION

Despite comprehensive social changes and political efforts to achieve equal opportunities, women remain a minority in the natural sciences, technical study fields and the corresponding occupational fields. This paper presents the complete gender concept of the University of Stuttgart. First, the steps for promotion of female students and women within the natural science and technical fields have to be developed. Female underrepresentation in science and the demand for equality of the sexes have become a vital aspect of the ongoing reform discussions. A special look should be taken at the education-economic perspective, as well as the aspect of quality assurance and the capability to be innovative [1, 2]: –

- The underrepresentation of women in scientific and technological fields has implications on design, quality and diversity of products. In fact, creative innovations cannot be "all-inclusive" without the inspiration of women: products might be designed faulty because their usage options were only viewed under considerations based on requirements of special groups (e.g., airbags, artificial heart valves, voice recognition systems [3].
- The absence of women from certain technological fields poses a hard challenge for industry and economy: the demand of qualified specialists cannot be satisfied by men willing to pursue an academic education [4].. The existing loss of interest by men in technical and engineering subjects intensifies the challenge [5]. Moreover, demographic development in Germany and global competition only augment these challenges.
- Technical disciplines graduates are filling important jobs in our society, which are characterized by fields of responsibility and extensive influence. Technical authorities are a key factor for the shaping of our society [6]. The underrepresentation of women in these fields is a major drawback to equal participation efforts.

Indeed, there are numerous single initiatives aimed at "breaking down the gender-gap" in German universities, each engaged either by different single persons, offices for equal opportunity, as well as individual professors, centres, or initiatives in single institutes. Due to the lack of a comprehensive strategy, such efforts often lose consistency, continuity and transparency, which often leads to a "twofer" for some target groups, while other arrangements and initiatives are missing. Communication and information campaigns aimed at reaching a broad group, creating a common understanding of the challenges and requirements are an exception. Universities should coordinate existing and successful measures in order to achieve better results, aiming for a stronger gender master plan.,

- that comprises the full life-cycle from kindergarten to professorship with leadership function,
- with single steps that aim to make a seamless, coordinated transition between different measures possible,
- that incorporates all areas (education, research and organization)
- and that includes a concept of family-friendly policies for all members of the university.

The female professor program is a characteristic component of the gender master plan of the University of Stuttgart.

The underrepresentation of women in technological fields becomes particularly visible in predominantly scientifically and technologically aligned universities like the University of Stuttgart, where a large percentage of future scientists and engineers are trained. These universities are in charge to overcome the gender gap in the technological disciplines, justifying a broad and early commitment to gender management. Additionally, women are nominated as top position holders of technical disciplines in order to increase diversity in research and education presenting female role models to new generations.

II. SITUATION-(DEFICIT-) ANALYSIS

Girls and women are still underrepresented in technology-oriented programs. The University of Stuttgart is well aware of these challenges, being a long term driving force to raise the percentage of females. The structure and development plan SEPUS of the University of Stuttgart defines measures; each of them successfully proven. However, the University of Stuttgart neglects a master plan that connects all measures and sustainable networks that build on and support each other. The concept presented here pursues the goal of integration and sustainability of measures. The University of Stuttgart is a fully profiled university oriented towards technological and scientific programs, and the concept of equal opportunity is aligned with this profile. Therefore, the focus is on the recruitment of women into technical disciplines. They are initially acquired for scientific and technical degrees, then promoted, depending on their talents, and supported on their "job ladder" inside or outside the university. The objective is to boost the percentage of female students in scientific and technical disciplines from currently 20% to 30% (within the entire university from 34% to 40%) and the rate of young female scientists from 18% to 30% (within the entire university from 21% to 30%). The target in these disciplines is set for an increase of female professors from 6% to 10% (same within the entire university) within the next five years. Furthermore, 30% of the professorships have to be newly appointed until 2012. Therefore, a considerable increase is possible.

Baden-Württemberg is striving for a long term increase of the quota of female professors to 30% (defined by the head of the Office of Scientific and Technological Affairs, Frankenberg).

III. OBJECTIVES CONCERNING DIFFERENT TARGET GROUPS

Chapter IV.A describes the different measures to be implemented within the framework of the gender master plan of the University of Stuttgart in detail. This chapter summarizes the most important foci from the catalogue of measures concerning addressing the different target groups:

- Increase percentage of women in top scientific positions

The incompatibility of a scientific career and family is still a major reason for women to distance themselves from the former. To address this challenge, the University of Stuttgart is working towards improving the surrounding circumstance to unite a scientific career with family life. The intention of sufficient child care offers, a family friendly housing situation, the adjustment of study and examination regulations and development of alternative work schedules are supporting this goal. Another important point considering the encouragement of women in leading scientific positions is the inclusion of the career planning of their partners (Dual Career).

The University of Stuttgart is aiming to increase the ratio of female professors to 10% according to their structure and development plan. To create the long-term framework for this goal, the University of Stuttgart is developing a package of measures. Especially qualified female students and young female scientists are provided with individual sponsorship and a structural framework to improve the compatibility of scientific career and family. The financial support through scholarships is seen as of similar importance as the personal support through formal and casual networks and the acquisition of career-furthering qualifications. Versatile cooperation with regional companies put the University of Stuttgart in the unique position to offer attractive choices within the industry and economy to partners of female researchers.

- Career and personal development for young female scientists

The next important point is the phase between academic studies and the beginning of a scientific career: that is the point where future scientists should be made aware of the existing career options in order to begin to develop their career-strategies. They need to gain access to networks and acquire leadership and management qualifications. Community building between students and young scientists is fostered by employing comprehensive measures within the single institutes and creating positive role model, initiating a regular exchange of experience between successful young scientists and female entrepreneurs.

In order to raise female students and young scientists, it is important to create a supportive living environment and to present attractive employment opportunities to their partners, in short, offering Dual Career Options as early as the qualification phase. To achieve this goal the University of Stuttgart has set out to earn the certificate of "‘family friendly university"’ awarded by the Hertie-Trust.

- Acquisition of female students in the natural sciences and technological disciplines

A central condition is the awakening of enthusiasm for natural sciences and technology to foster the election of a scientific or technologically oriented field of study later in life. The University of Stuttgart has build a package of measures that incorporates the education of teaching staff, as well as considering research of gender sensitive deployment of toys and the creation of an academy for younger children. Furthermore, the University is compiling effective public programs - female students are given an age-based understanding of natural and technical questions. It is for such purposes, that existing programs like the Girl's Day have been expanded and new choices like the Technology-Camp were developed. Female students can use their vacation time to research exciting scientific and technological topics.

In order to help a girl on the decision of choosing a technological or scientific program of studies there is the offer of a trial course, as well as a program to support them from the last year of high school to the first semester at the university. In addition to the program "Try the University", girls in the last year of high school are being offered the full curriculum of available bachelor degrees and are enabled to collect credits towards their future studies.

IV. IMPLEMENTATION OF THE CONCEPT SPIRIT

The concept is following a life-cycle model. The target groups are girls and women which are accompanied from kindergarten to professorship by multifaceted package of programs: The single activities are weighted differently depending on the phase of life, build on each other and are interlocked. This ensures that measures exist for each state of the life cycle that aim towards a goal and support the progress towards the next phase. Special weight will be put on the systematic advancement of female migrants due to the fact that their requirements are defined by a different process of socialization compared to women without a migration background.

A. Measures for Each Scope of the Life-Cycle:

1. Gender Sensitivity Training Courses for Educators

Measures have to be taken already in kindergarten to ensure the best possible equal upbringing of girls and boys. |Sparking children's interest in natural and technical questions requires careful planning of all educational activities. To improve this concept the University of Stuttgart designs, prepares and implements gender- and diversity- sensitive scientific and technical professional training for educators. Evaluation and counseling is provided by the Institute for Social Sciences.

2. TechToy

Gender and diversity sensitive engineering toys that are accepted and appreciated by both sexes are necessary to awaken the enthusiasm for the natural sciences and engineering early and across both genders. The University of Stuttgart plans to apply a main research focus on the development of gender sensitive engineering toys. A co-operation of different chairs of engineering, the Institute of educational science and psychology, and the institutes for social sciences, technology and environmental sociology [7] will carry this research focus. This concept is built on the preparations for the initiative "Wissensfabrik" (knowledge factory). The University of Stuttgart will soon join this initiative - one of the first universities to do so. A pedagogic concept is being developed to allow for a meaningful use of the toys in pre-schools, schools and families. Such a concept could look similar to – the extremely successful – Roberta- teaching materials of the Fraunhofer IAIS for LEGO Mindstorms robot building (a Roberta Regional Centre is currently being build up and developed at the Institute for IT Service Technologies).

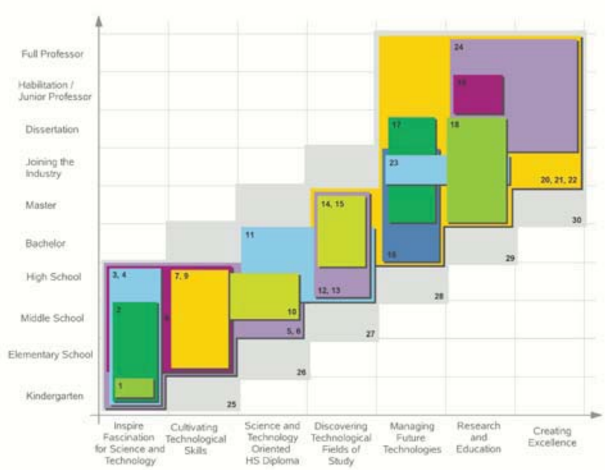

Figure 1. Life-cycles from kindergarten to professorship

3. Exhibition Team University of Stuttgart (ETUS)

The University of Stuttgart build a professional team that will focus on public relations with specific target groups. The field of responsibility for this team also includes the development of effective publicity programs for events at the University of Stuttgart including the Day of Science ("Children's-Campus – Program for young researchers"), as well as Technology exhibitions like the "Land of Ideas" or the "Cebit". During this process, programs will be prepared to fit the different target groups of preschool age, elementary school, junior high school, secondary school age, and for teachers. This project can build on the experience of the Student Counseling Centre and of the marketing office.

4. Rent-a-Scientist & SchoolgirlUni

This is a project in which pre-schools and schools are offered possibilities to "rent" (female) professors or (female) research staff of the University of Stuttgart. They visit the educational institution and answer questions from the fields of science and engineering with age group specific lectures and demonstrations. In reverse, the University of Stuttgart offers (female) students the possibility to come to the university to get to know it "from the inside" (student/schoolgirlUni). To ensure the success of such events a pedagogical concept is drawn up and staff members are trained (pedagogical mentoring by the Institute of educational sciences and psychology). The concept also addresses culture-based conflicts of interests – especially relevant for pre-schools and schools with a high ratio of children from migrant families. The measures 4–6 and 8–10 are part of the University of Stuttgart Young Academy which is currently being implemented.

5. Girls' Day

The University of Stuttgart has been participating in the mono educational Girls' Day for several years. Girls are invited to the university to have a look at the different scientific and technical areas. Specialized subjects from different departments are being prepared to spark the girls' interest. In this regard the girls have the possibility to try the experiments also on their own. The program will be further developed in the coming years and expanded inside of the university through the integration of more faculties and considering culture-specific differences in interests and approaches.

6. Partner Schools

Direct connections to partner high schools improve the cooperation between schools and universities. Common activities give female students a chance to gain some early insights into research and education at the universities. Such measures may help to facilitate the transition from high school to university, as well as the choice of a course. They should further benefit from the close cooperation with the successful "Mine-Mint"-Network. The continuing initiatives involving the Institute for Hydraulic Engineering, the Department of Physics, the Department of Chemistry, as well as the Department of Computer Science, Electrical Engineering and Information Technology and the freshly initiated cooperation with the "Landesgymnasium für Hochbegabte in Schwäbisch-Gmünd" shall be continued and further expanded.

7. Gender Sensitivity Training for Teachers

This training course is designed to enhance the skills of teachers in gender and diversity sensitive didactics for teaching technological or scientific courses. As the result of both formal and family education, girls are interested in different questions than boys. The course develops guidelines based on concrete examples to help teachers create a sense of fascination and adventure concerning science and technology in students. These courses are supported by the competency of the Institute for Social Sciences. The University of Stuttgart takes advantage of the unique situation created by the restructuring and modularization of the academic education of teachers in Baden-Württemberg to enhance the competencies of teachers in training for gender sensitivity. Current plans allot 6 credit points for this field.

8. Technology-Camps

Technically-oriented summer camps teach modern science in a hands-on approach. These "Technology Camps" present selected current topics from the fields of research and education at the University of Stuttgart in high school level lectures and experimental labs. High school and university students research interesting topics from the natural and engineering sciences in close cooperation with professors. These summer camps expand upon the already existing summer break programs offered by the University of Stuttgart (Stuttgarter Forschungsferien). The university can build on experiences gathered in the (Nanocamp, Faculty for Civil- and Environmental Engineering). Future summer camps will be offered as mono or co-educational. Mono-educational summer camps will make participation easier for female students from families with a migration background. The SPIRIT program plans to offer stipends for students from financially weaker families through the integrated foundation.

9. TechnoClub "Test your University"

The TechnoClub offers single workshops and one-semester courses for female high school students, held at the university. Lectures and labs held by members of the university are designed to familiarize high school students with the daily life at the university. These courses include a lab for Robo-Rescue and courses for electronics and soldering. Special attention will be given to culture-specific variations in interest and approaches in support of the main focuses 4, 5, and 8. The courses offered in the TechnoClubs are created by a representative cross section of all institutes within the university and are centrally coordinated. This mono-educational concept is based on a long running and successful program, "Try the University" ("Probiert die Uni aus").

10. Studium Experimentale

The "Studium Experimentale" presents several different approaches to familiarize students with the University of Stuttgart and the different programs offered. First of all, high school students are offered university level courses in a more compact form, including the final exam. This idea is based on the "SchülerStudium" at the FU Berlin. If a participating student should decide to pursue a compatible course of study at the University of Stuttgart, they will receive priority in the acceptance process and will be credited with the corresponding credit points. As a result, ties between students and the University of Stuttgart are created early and the transition from high school to university is eased. Secondly, since female students often find it hard to decide on one single technological or scientific course of study, the University of Stuttgart offers one-year courses with access to all available bachelor courses without forcing the student to enroll with any one particular program. The credit earned during this period is fully applicable to any future course of compatible studies. The University of Stuttgart is currently engaged in defining the necessary legal framework (crediting, BAFöG).

11. Mentoring "Transition from High School to University"

The Campus Mentoring Program matches selected university students with high school students to mentor them at the end of their high school and the beginning (first few semesters) of their university education. The mentors help the students adapt to the daily routine at university. The students will be gradually transferred to an advanced mentoring program supervised by professors as they enter university.

12. Gender Sensitivity in Technologically-Oriented Courses of Study

Technologically-oriented courses of studies and careers are not unattractive to women per se. However, motivation, specific interests, style and strategies of learning, goals and expectations can differ significantly from those of young men. The University of Stuttgart, under the leadership of the vice rector for academic affairs, will create concepts and guidelines for gender sensitivity in all courses of studies, taking advantage of the opportunity offered by the restructuring of all courses of studies, including their content, to the new, modular bachelor/master system.

13. New Technologically-Oriented Programs

Quite often female students fail to feel attracted towards the existing curriculum of engineering and natural science programs. The main reasons are that women do not see the social relevance and/or that they are worried whether their interests and talents qualify them to pursue studies in these fields. The Bologna-Process offers a unique opportunity to create new and reorganize existing programs. The University of Stuttgart is planning to implement a number of new programs addressing the specific interests of female students. These programs will build on the experience from the Galilea-Project at the TU-Berlin (www.galilea.tu-berlin.de, already existing cooperation [8–14]. The first two programs are already being designed (Renewable Energy and Medical Technology). The Galilea-Programs are characterized by a high degree of flexibility in the early choice of courses, as well as socially relevant, interdisciplinary foci.

14. Diversity Studies & Technology Management

It is necessary to understand the role of female engineers and scientists, including their special contributions and unique potential, to attract more women to studies and careers in the technological fields. To address these requirements, the University of Stuttgart is planning to create a program for diversity studies in the engineering sciences with a focus on technology management. The courses offered in the program will be credited as minors or mandatory elective courses in the engineering, economics, scientific and social studies programs, strengthening the impact of gender and diversity studies in the existing programs.

15. Program for Stipends: "Opportunity"

Stipends provide a means for direct promotion of talented students. As such, it is a tool well suited for supporting students from financially weaker families. In addition, they create social networks between the recipients and bring them into contact with prospective employers (often former recipients or even founders of the stipends). The University of Stuttgart plans to create specific stipends for female students of the natural sciences and engineering in close cooperation with successful regional companies and research institutions and with the European Social Fond, ESF. This increase in cooperation will further strengthen the regional economy. The "Opportunity" program complements the existing stipends (stipends for PhD students under the "Landesgraduiertenförderungsgesetz", Schlieben-Lange und Margret von Wrangell Programm).

16. Femtec Region Stuttgart

The low ratio of women in positions of leadership within the economy and the resulting perception of a lack of career opportunities has a direct, negative impact on the motivation of female students. The University of Stuttgart is planning to expand the existing cooperation with the successful Femtec program and its associated career building program. Femtec is a unique network of leading technical universities and successful international companies. The University of Stuttgart has been a member of the Femtec network since 2005. The aim of the program is to strengthen the cooperation with the regional economy. The associated career building program teaches leadership qualifications easing the transition to a successful, professional career. The University of Stuttgart is already represented on the advisory board of Femtec.

17. Entrepreneur Initiative SPIRIT

Based on the experience gathered in the joint project "Erfolgreich ist weiblich!" (in cooperation with the TTI GmbH, started in February 2007), the University of Stuttgart is creating an informational and consulting offer for students and post graduates, as well as the alumni of the University of Stuttgart who wish to found their own start-up. This network will provide gender specific support within and beyond the boundaries of the university itself.

18. Mentoring for Women in Science and Research

In addition to good qualifications and grades it is often the contact and support resulting from access to informal networks that is decisive in professional success. The University of Stuttgart is planning to expand existing and successful mentoring programs for women in science and research to support even more female students in implementing their career strategies. The mentoring program provides support for highly qualified graduates, post graduates and post docs. An additional focus of the program is on qualifying women for leadership positions.

19. Mentoring Program "ProFiL BW"

The University of Stuttgart is planning to create a program to support excellence in scientific careers, following the example of the successful elite mentoring program "ProFiL" (http://www.profil-programm.de/, existing cooperation) of the three universities in Berlin. Future expansions of the program will include cooperation with other universities in Baden-Württemberg. The (female) participants of this program will receive extensive support in planning and furthering their careers, including training leadership and management skills required of a full professor. Prerequisite for joining this program is an excellent PhD thesis, a one or two-year post doc phase and an interview with the applicants.

20. "Ladies' Community"

Female students often feel isolated during their studies due to their low ratio in most engineering programs. Support programs like girls-only exercise courses are faced with a low acceptance as they are perceived as further reaffirming this outsider role. The lack of social infrastructure on-campus will grow even worse in the near future as first semester students are getting younger due to the shortened high school education. This development necessitates a pervasive community building among female students beyond the boundaries of the single study programs. The University of Stuttgart has created a work group to design a concept for realizing such a community. Some measures already planned include regular seminars with successful female entrepreneurs and researchers, regular social gatherings and the creation of a special web portal for the female community. The community to be created should ideally include all female students and alumni of the university.

21. Colloquium "Women in Leadership Positions"

Female students are often missing role models, women who have mastered the obstacles and challenges of a program and have reached a leading position in research or business, which results in low motivation and an increase in the drop-out rate. To counter this effect, the University of Stuttgart is planning to hold regular seminars where successful women from research and business share their experience and advice with female students. Future synergies with the "ladies' community" and the alumni program will support this measure.

22. Family Friendly University

It is necessary to provide a family and children friendly environment for young families or single students with children to attract more women to study or pursue a career at the university. The University of Stuttgart has already implemented a number of measures to this end. Among these are: child care for the children of students (Kinderbetreuung für Kinder von Studierenden der Universität Stuttgart STUPS e.V., emergency child care, semester break child care) and the Stuttgarter Forschungsferien, an attractive child care program for school kids, organized by the Konzept-e GmbH and five different Fraunhofer institutes.

Going beyond these measures, the University of Stuttgart is aiming at the creation of on-campus dorms with integrated child care for students with children and on-campus housing for young families of employees with comfortable access to nearby child care centres. By getting the students themselves to donate their time to help support the child care centres, we hope to decrease the financial burden and to help with community building among female students.

Additional important measures should address the specific needs created by the burden of raising children (part time studies, postponed exams due to a child falling ill, virtual courses). Researchers with children will profit mainly from dual career models, family friendly work processes, flexible time, and specific support for researchers during the first years of parenthood and the possibility of working at home. The University of Stuttgart is aiming to be the first university in Baden-Württemberg to gain the certificate as a "family friendly university" awarded by the audit council of the Hertie-Stiftung.

23. Re-Entry Program "SPIRIT returns"

The knowledge and skills of many qualified female researchers and engineers is lost to the market due to the massive obstacles when returning to a job after a prolonged absence due to pregnancy and child birth. The University of Stuttgart is searching funding from the ESF based on the BMBF-Program "Wiedereinstieg für Ingenieurinnen leicht gemacht". Engineers are given additional scientific training to re-qualify them for their re-entry into the job market.

24. Dual Career Service Program "DuCaSUS"

As accepting the appointment for a professorship usually involves moving to another city, the career chances of the partner are often a decisive factor in decision making process. A similar situation exists during the post-grad and post-doc studies. Dual Career Services can advance the career chances of researcher couples. Currently, the University of Stuttgart is expanding the dual career supporting policies already common in appointment negotiations to include post-grads and post-docs in the dual career service program "DuCaSUS". This program will involve the creation of a support network including regional businesses and public and private research companies to offer a larger basis of possible career opportunities for the partners outside the University of Stuttgart itself.

B. Comprehensive Measures for the whole Life-Cycle:

25. Chair for "Diversity Studies & Technology Management"

The Institute of Construction, Production and Vehicle Technology will create a new chair focusing on gender and diversity, based on the example of the "Chair for Gender Studies and Information Technology" at the TU Munich. The main aim is the strengthening and localization of the gender concept of the University of Stuttgart. The academic focus of the chair will be on interdisciplinary courses in the field of gender studies, in particular for the new program "Diversity Studies and Technology Management", as well as interdisciplinary courses offered to students of other programs at the University of Stuttgart.

26. Gender Components in New Appointments

The University of Stuttgart is trying to appoint scientist as professors whose research focus integrates an explicit gender and diversity focus. Examples for such new appointments would be "Diversity in Usability Studies", "Diversity in Design and Construction" (for a chair in civil engineering), "Gender Aspects in Biomedical Technology" etc.

27. Media Offensive "Fascination Technology"

One of the central challenges for engineering and science is the public image. While being accepted as important for technological advances and therefore economic growth, they are also perceived as dry and boring subjects. Technologically oriented programs often paint an unattractive image of technology as they focus on scientific theory and implementation but neglect to demonstrate social relevance. The result is a negative image of "soulless technology" as a simple means to an end, not as a field with its own aesthetic and fascination. This might be less of a problem for young men whose studies of a given field are often the result of a love affair with technology. In contrast, young women are more interested in social relevance than technology per se. The planned media offensive focuses on presenting mathematics, science and engineering as a vital and fascinating part of our modern culture. The methodology could be based on the experiences gathered in the popularization of mathematics at the MATHEON centre of research.

28. Media *Offensive "SPIRIT"*

A program can only be as good as its general acceptance and public interest. This is one major challenge for most current gender programs and measures to overcome. Gender programs have to incorporate and implement a pervasive PR strategy. This includes extensive online presentations aimed at addressing students living in more rural areas outside of Stuttgart itself.

29. eCRM "SPIRIT"

One major factor in the success of all measures described above is the continuous contact to the participating high school and university students as well as researchers. Our gender concept can only be successful if we manage to address these "customers" directly and tie them to the University of Stuttgart. To this end, an eCRM (electronic customer relationship management) will register and record all transactions between the University of Stuttgart and the participating students and researchers. As a result, they can be addressed directly and the life cycle process can be specifically tailored to each participant using intelligent agent systems (under the strictest observance of applying data privacy laws).

30. Brain Storming "SPIRIT"

The University of Stuttgart performs an annual brain storming on gender topics and diversity to define, select and implement further measures, with the participation of all interested institutes. The aim is a higher degree of flexibility and a stronger bound to the rest of the university.

C. Measures to Ensure Structural Implementation and Sustainability:

To ensure the implementation and sustainability of gender concepts the following catalogue of measures is implemented:

1) Pervasive Implementation throughout the University:

The single measures are placed within the jurisdiction of existing institutions (e.g. the office for equal opportunity), organizational centres (e.g. career or academic counseling), and the chairs of the institutes. Concrete tasks, their implementation and adaptation are fixed in target agreements with the president of the university. Additional measures focusing on strengthening the gender competency are the object of future appointment negotiations and target agreements. Internal projects reinforce the acceptance and broad basis for the concept.

a) Collaboration with Existing Equal Opportunity Programs:

Plans of equal opportunity in the academic [15] and non-academic fields define a catalogue of measures aimed at achieving equal opportunity for women, based on detailed analysis of the current state. The structural and organizational preconditions for these measures already exist.

b) Collaboration with the Female Professors Program:

The program to increase the ratio of female professors becomes a vital part of the gender concept. Individual professors assume the operative responsibility for particular measures. These measures have already been made to increase the public visibility of the program.

c) Strengthening the Scientific Gender Competency:

The chair of "gender in the engineering sciences" is a component for the success of the gender concept. It strengthens the scientific background and provides the expertise required in the evaluation and long term quality control. The chair provides new input for additional projects and necessary adaptations. The competency of the chair is enhanced by the support of the office for equal opportunity and related chairs.

2) Financing:

Financing for the SPIRIT program is based on a three-pillar model:

a) Budget:

The present shift to success-oriented funding allows for funding further or extended measures. Target agreements with the institutes will initiate additional measures. Measures focusing on students directly can also be funded from tuition fees.

b) Third Party Funding:

Third party funding is an important component in the development and test of new measures and concepts. The EU, the ESF and the National Ministry of Science and Education as well as industrial partners have been increasingly supportive of gender and diversity projects.

c) Endowment:

It is planned to found a SPIRIT-Foundation to raise additional funds for the gender concept of the University of Stuttgart. This foundation will approach the industrial partners already engaged in the Femtec project, regional SMEs, alumni of the university, and private donors that recognize the need to support gender in the regional economy. The financial goal is an endowment providing a total annual funding of € 500.000.

3) Responsibility – A priority for the President!

The implementation of a pervasive and coherent gender concept is seen as a vital challenge for the future success of a technologically oriented university. The coordination, further development and quality control of the program will be the responsibility of the president of the university, who will managethe program. Further developments will be coordinated with the commissioner for equal opportunity under the leadership of the president.

V. SUMMARY

The University of Stuttgart takes the female professor program of the state of Baden-Württemberg as an inducement to re-evaluate the currently used measures and proceedings in the area of equal opportunity and equal treatment. Where necessary these measures should be amended, enhanced and optimized. The major need for action does not affect the – numerous and successful – measures of the last years but does affect the gender culture at the University of Stuttgart. The measures should not only be carried by the equal opportunity department and the commissioners for equal opportunity. It is essential to further anchor the measures in research and teaching at the University of Stuttgart. At the same time patency and continuity have to be raised by developing a complete gender concept that views women and girls along a life-cycles model. It should group the different target groups and measures with regard to content and organization.

Furthermore, a natural science and technology-oriented university has to take special responsibility for the participation of women and girls in the evolution of technology in our society: Women are still underrepresented in almost all natural science and technological areas. This under representation has serious consequences – for women and for society. The demand for adjustment for women is not just a demand for equality of opportunity – in a country like Germany with few resources, economic success is tightly connected to advancements in technology. The future requirement for skilled personnel and managers in this field cannot be met by the current number of male graduates and the number of female graduates is nowhere close to enough to build the necessary specialized "‘mixed teams"’ which are expected to provide an important part of economic success.

The University of Stuttgart sees the sustainable implementation of gender-justice as an important challenge. The realization of a profound gender concept based on the observation of the complete life cycle with measures for different target groups – schoolgirls, female students and female scientists – will become an attractor for the University of Stuttgart to survive the fight for the best minds – on national and international levels. Within the scope of the overall process the university administration coordinates the existing activities and combines and expands on them. Numerous additional innovative measures are currently being prepared and will be sustained by a financial package containing budgeting, third-party funds, and endowments. The professorships within the female professor program serve as seeds for new impulses and will develop institutional and thus sustainable responsibility for important building blocks of the master plan. The gender mission statement is being created under the leadership of the president including a road map with measures for quality control and operative realization – henceforth gender is given top priority!

Abstract—**The European Higher Education Area, an agreement by 29 countries to unite and harmonise qualifications and Universities' rapprochement to the real demands of the labour market, will make a significant change in the traditional model of teaching tools to carry out more personalised monitoring of the student's work, leading to the possibility of continuous evaluation. The suitable use of Information and Communication Technologies (ICT) can make a contribution to improving the quality of teaching and learning. In this context, a self-evaluation platform is developed using the technology of Intelligent Agents. This system can be adaptable as it adjusts the various self-evaluation tests to the student's level of knowledge. Each student has a profile and, depending on this, timing and interaction is set by the agents.**

Keywords-component: e-learning, user profile, self-evaluation

I. INTRODUCTION

In June 1999, the Education Ministers from 29 European countries met in the Italian city of Bologna to approve the declaration for the convergence process towards the European Higher Education Area (EHEA). 2010 was set as a final deadline to finalize this process which will allow the unification of fundamental questions related to Higher Education studies in the European Union.

The basic aims set by the EHEA are the following:

- Create a system of university qualifications which are compatible in all Europe, divided into two cycles (graduate and postgraduate).
- Use the same university credit system in all European countries, based on the student's efforts.
- Promote student and lecturer mobility in Higher Education establishment.
- Design a new teaching model focused on the student who becomes the protagonist of his own learning.
- Establish a high quality evaluation system based on the student's continuous work.

To achieve these aims, one of the most significant changes in the EHEA is the new vision of the concept of learning. The traditional University system focused on teaching (by the lecturer) will become a system which is focused on the student's learning, through the use of more active teaching methodologies, more personalised monitoring of the student's work by the lecturer, and more involvement and student autonomy in the process of teaching and learning.

Another significant change of the EHEA concerns the process of evaluation. Traditional teaching methods measure the student's learning by using objective processes – both written and oral – which cannot evaluate the student's continuous effort and have no clearly formative objective. In this new educational scenario, the student's continuous evaluation and the absence of a teacher are the main axes of the formative process. The lecturer will assist and guide, designing various activities focused on acquiring the desired level of competence. One technique which has formative characteristics is a self-evaluation test. However, this type of assessment is not very useful as it cannot adapt to different student's profiles. Most software tools built to date which incorporate this type of assessment are not adapted to the student's individual characteristics nor do they allow the extraction of information on student behaviour when sitting the assessment.

II. SOFTWARE IN EDUCATION: BACKGROUND

We are familiar with software used in education which is a combination of tools used didactically to facilitate and improve the process of teaching and learning [1]. Numerous systems have been developed but the results obtained were not those hoped for. The reason is that most do not have clearly formative characteristics and allow any kind of programmed activity to be carried out by the lecturer, despite the fact that the student has not acquired the necessary knowledge to do so in optimum conditions. Moreover, they consider that one particular student's level of knowledge will be the same as the others in the group, regardless of work developed and personal circumstances.

The main aim of these applications should enable the development of initiative and the student's autonomous learning through different tools which will allow him to check his own work, take advantage of his potential capacity for learning and let him choose the tasks to do, how to do them and the level of depth. Moreover, they should facilitate constructive learning by tutoring the student's actions providing an explanation of the mistakes committed and offering opportune help and support. Finally, they should give the learner the mechanisms to be able to plan, regulate and evaluate his learning [2].

A brief historical summary of the application of Information Technology to teaching is showed next, starting with the most basic systems up to Intelligent Tutor Systems (ITS) devised in the '80s. We will later show some proposals of the current perspective supported in instructive and constructive didactic approaches, noting the contribution of Intelligent Educational Systems.

The first teaching systems under the name of *Computer Aided Instruction* (CAI) appeared between the '50s and start of the '70s. They provide information to the student in the form of three categories: (a) Lineal Programs, whereby all students receive the same knowledge and in the same order. The student's particular aptitudes are not taken into account. (b) Ramified Programs, which offer all students the same knowledge, but the order depends on their answers. These do not take into account the student's aptitude and the system acts in the same way when given the same answers. (c) Adaptive Systems whereby all students receive the knowledge adapted to their needs, both the difficulty of the problem and the detail with which they must answer. The problem with these systems is that they are not valid for all subjects and only accept a single answer to a problem when in fact there may well be several.

In the '80s, these type of systems evolved towards *Intelligent Tutor Systems* (ITS), which combine techniques of *Artificial Intelligence (*AI*)*, psychological models of the student and the expert, and theories of education. An ITS is an expert system in a subject which adapts the information to the student's needs. As the student's learning process occurs step by step, continuous updating will be necessary of the information stored in the ITS.

In the '90s, the application of AI techniques to the development of these systems led to *Intelligent Educational Systems (*IES). Unlike previous models, IES do not claim to substitute a classic system of teaching and learning, but are an alternative complement to improve the quality of teaching. Depending on the student's own learning, different types of IES are distinguished: (a) Intelligent Training Systems, based on an instructional focus in which the lecturer provides continuous student feedback. Its main disadvantage is the student's passive role which can lead to the loss of motivation. (b) Adaptive Hypermedia Systems (AHS), based on a constructive focus, whereby the student chooses the route of his learning from those programmed by the lecturer. As a consequence of this amount of freedom, the student can lose direction and not achieve his aims. Despite being opposing, both options are valid and necessary and can be complementary.

Currently, given the expansion and familiarisation of the Web, under the name of e-learning systems, there are various software solutions designed mainly for supporting un-staffed teaching and learning, although they serve as a support resource for traditional teaching i.e. platforms and software systems which permit communication and interaction between lecturers and students, access and sharing of contents, materials and resources, the application of co-operative strategies of learning etc., which support (to a large extent) the student's formative process. The main inconvenience is the lack of adaptation to the type of student involved in this interaction. Any e-learning system should adapt the form, quantity and difficulty of content to the student's qualification to motivate both his progress and how he reacts when faced with obstacles. Thus one must program systems which can build a dynamic student's profile which summarises his abilities and aptitudes as regards a concrete topic.

III. Creating a Student's profile

A student's profile could be set up by uniting a piece of data which reflects the student's competencies as regards concepts, procedures and aptitudes for a subject. Such information can be obtained easily from evaluating various objective assessments, such as examinations or tests and from the lecturer's subjective evaluations such as the learner's participation in the classroom or in tutorials. This information, clearly symbolical, could be used to personalize any type of student evaluation assessment, adapting it to the level of acquired knowledge and aptitude. This applies in the same form as the design of self-evaluation assessments.

A computational model of a student's profile which is dynamically adaptable and up-to-date can be set up by evaluating various self-evaluation tests and analysing how this is confronted and how to solve the problem [3]. As a general rule, traditional teaching is divided into various sessions or seminars with a teacher, and these are accompanied by complementary activities which aim to strengthen, consolidate and amplify the fundamental concepts presented in each session. Taking this into consideration, a student's profile would be made up of two components: (a) a particular component, which is obtained from the student's knowledge and aptitude for a concrete topic; and (b) a general component, which is the calculation of all the particular components of the student's profile.

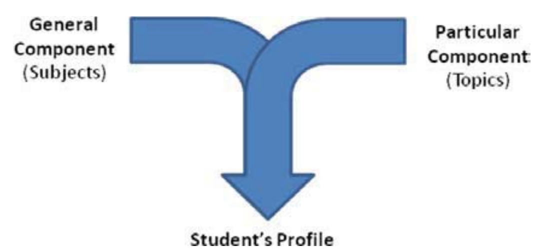

Figure 1. The components of the student's profile

The rationale behind considering this double component stems from the fact that the student may be very able in a concrete topic (as he has been successful in tests) whereas he lacks knowledge in other areas. Considering purely the general component of his profile, his knowledge would be low and consequently, further tests would not be difficult. Thus challenges would not increase and he could become demotivated. In the same way, if the successful result of a test raises the general component of his profile considerably, later tests would be more challenging even when the student has not shown a high level of competence. Thus, the general component of a student's profile measures his general competence in the subject and the particular component measures his level of knowledge and aptitude in each topic (Fig. 1). The former is updated when the student logout the system and its value is calculated as the average value of all profiles in each topic. The latter is updated after answering any test belonging to a given topic. The score of a test is a linguistic label representing the number of correct/incorrect questions answered and the student's behaviour whilst sitting the test. Table 1 shows how the student's current profile is updated by this score.

TABLE I. UPDATING STUDENT'S CURRENT PROFILE BY A TEST SCORE

Current profile	**Score of self-evaluation test**				
	Very high	**High**	**Medium**	**Low**	**Very Low**
High	High	High	High	Medium	Low
Medium	High	High	Medium	Low	Low
Low	High	Medium	Low	Low	Low

To obtain an initial student's profile, one can consider the mandatory realization of a number of non adapted tests. This initial profile would be constantly modified depending on results obtained in adapted test: correct/incorrect questions, consuming time to solve it, time to answer each question. This type of test would be set up automatically by selecting questions whose level of difficulty suits the actual student's profile: depending on his particular level of knowledge and errors committed when doing previous tests on the same topic. Once the test is corrected, the system shows the corresponding feedback and updates the student's profile (Fig. 2).

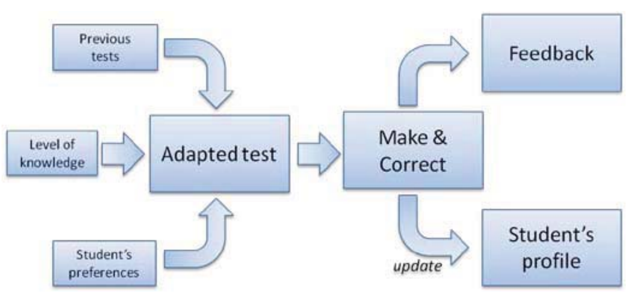

Figure 2. Three steps to personalize the construction of self-evaluation tests.

IV. COMPUTATIONAL MODEL OF THE SELF-EVALUATION PROCESS

As we have seen, in the new scenario created for the treaty of Bologna, evaluation is a process which continuously measures the student's effort. We have mentioned the use of self-evaluation assessments, adapted to the student's level qualification, as a means of evaluating acquired knowledge and help study. In this sense, we have developed a self-evaluation software tool, based on Intelligent Agents technology, which can automatically generate a test based on a personalised profile [3].

The multi-agent system developed uses a set of agents to manage the self-evaluation process, from the moment when the system is accessed, passing through the process of generating the test, to the moment when results are given. Fig. 3 shows the organisation of agents which carry out these tasks and which are described below:

- Interface Agents: interact directly with the User. These are classified as Student interface Agent and Generic Interface Agent.
- Intermediate Agents: carry out the tasks requested through the user interface. They are classified as Student Agent, Authentication Agent, Corrector Agent, Adaptor Agent, and Monitoring Agent.
- Information Agents: the Database Agent accesses the information stored in databases.

The main functionalities of the agents are detailed below:

- The *Interface Agent* allows the student's interaction with the tool. Two types can be distinguished: (a) *Generic Interface Agent,* for students who have not been authenticated, its aim is to negotiate access to the system for a User who is not authenticated, (b) Student *Interface Agent*, for authenticated users, its aim is to allow the student to do a self-evaluation test, inform him of the result, show the mistakes and give the feedback to improve his level.
- The *Student Agent* maintains the student's profile during the interaction with the system. Its aims are to inform and design the student's profile.
- The *Authentication Agent* controls a student's access to the tool and ensures he is identified until he has finished the interaction. It must check if the student is authenticated or not. When the *Authentication Agent* authorises access, a *Student Personal Agent* is created.
- The *Correction Agent* corrects self-evaluation tests. For this, it analyses and compares the information received from each of the student's answers, and the information stored in the database. It must correct and obtain the test result.
- The *Adaptor Agent* generates self-evaluation tests adapted to the student's profile. It endeavours to choose a host of questions and create the self-evaluation test.
- The *Monitoring Agent* supervises the student's activity when he does the self-evaluation test. One of its aims is to obtain the parameters of monitoring which depend on the difficulty and complexity of the topic of the test, i.e. the maximum time to do the test, the time for each question, etc. Another aim is to measure these parameters and give information on the student's behaviour whilst sitting the test.
- The *Database Agent* manages and centralises the access to information which is stored in the database. It must provide information on the User or on the test which will be created: questions available, configuration of the test and parameters to measure.

Each agent is assigned a set of sub-task and interacts with others agents to achieve his goals.

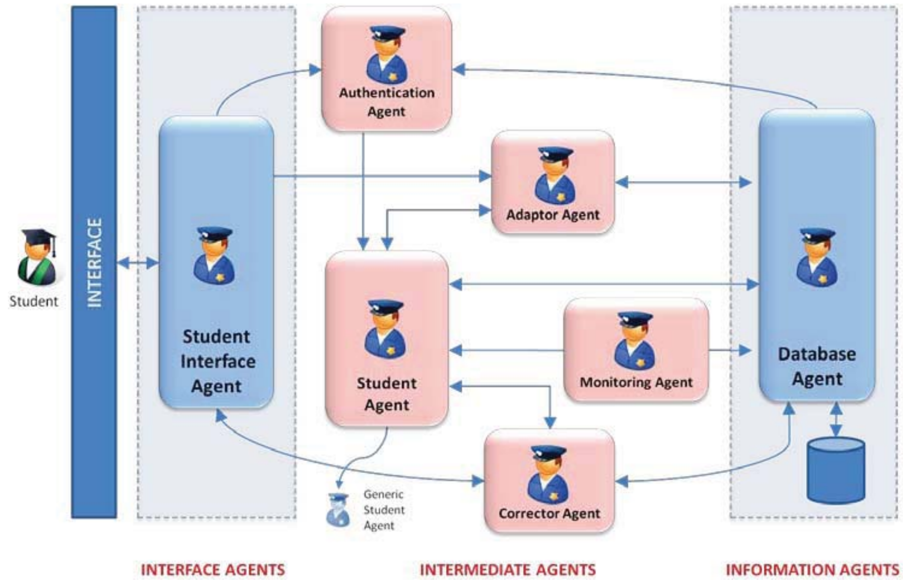

Figure 3. Organization of Multi-agent system.

V. IMPLEMENTATION OF THE SELF-EVALUATION TOOL

To implement the self-evaluation tool, a Web application has been developed whereby the agents' platform is situated. The global architecture of the system is composed of a Web client (a browser with which the student interacts), a Web server, and a database, as the multi-agent system is an extra component of this architecture as shown in Fig. 4. Through the Web interface, students interact transparently with the multi-agent system. The server collects information generated by interactions of the multi-agent system and database, from agents and from students. It processes and presents it in the form of dynamic Web pages.

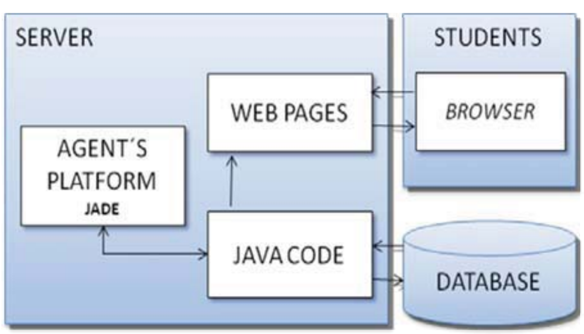

Figure 4. Global Architecture

Fig. 5 shows the interactions between agents to solve the request to obtain the result of a self-evaluation test, and how updating the particular component of student's profile:

- Ask for correction: the *Student Interface Agent* receives the request and sends it to the *Corrector Agent*.
- Ask for information on the questions: the *Corrector Agent* asks the *Database Agent* for the data necessary to correct the test, and when the test is corrected, the *Corrector Agent* sends the results to the *Database Agent* so that these are stored in the database.
- Carry out a correction: the *Corrector Agent* sends the test results to the *Student Agent,* charged with maintaining the particular component of student's profile belongs to a current topic. Also sends them to the *Interface Student Agent,* charged with showing the mistakes and giving the feedback to improve level of student.

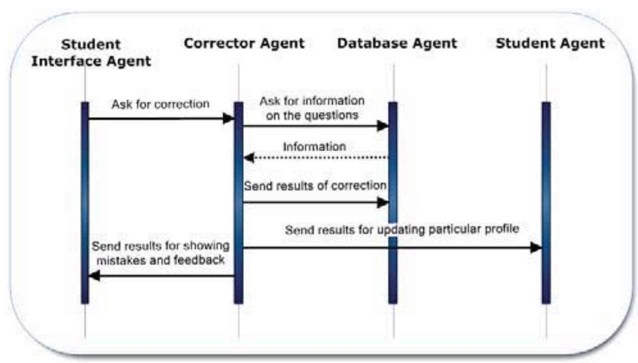

Figure 5. Interaction diagram to carry out a correction

Fig. 6 shows the interactions between agents when the student wishes to exit to the system and the general component of student's profile is updated:

- Request to exit: the *Student Interface Agent* receives the request to exit the tool and sends it to the *Student Agent*.
- Collect particular components of profile: the *Student Agent* ask the *Database Agent* for information about the particular profile in each topic.
- Update general profile: the *Student Agent* compute a new general profile from particular profiles and send it to the *Database Agent*.

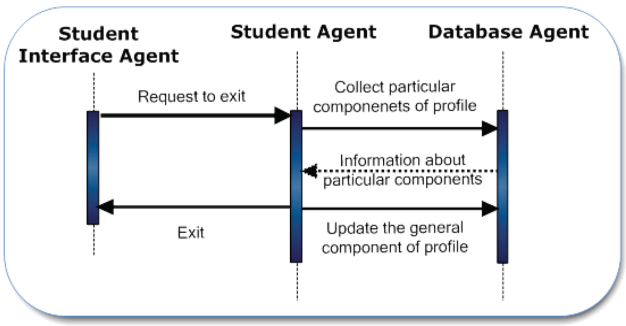

Figure 6. Interaction diagram to update the student's profile

The implementation of this architecture implies the integration of different technologies. Firstly, the multi-agent system is modelled by the IDK, tool of INGENIAS [4], an agent methodology which extends MESSAGE and establishes how a Multi-agent System has to be modelled and integrated with the "best practices" of engineering. The tool uses the Agents' platform JADE compliant with the FIPA standard.

Secondly, the Web application is developed in J2EE. For this, Apache technology known as STRUTS is used, following the Model-View-Controller pattern of architecture.

Finally, information on the students and the process of self-evaluation is stored and managed in a database implemented with MySQL.

VI. Conclusions

The EHEA proposes a teaching model which is student focused, as the evaluation will undergo a substantial change as will the student's level of knowledge, effort and continuous work. To carry out the changes considered by the EHEA, one must provide all the necessary help, not only to the students, but also to the lecturer.

Self-evaluation is a process which starts with an assessment in the form of a test and ends with information on errors committed. This type of assessment is beneficial both for the student and lecturer. For the student, a test result is an objective evaluation of the level of knowledge, understanding, mastery and progress reached in the subject, which allows him to direct his learning. In turn, the lecturer can gather significant information on the degree of satisfaction of the initially set aims, which will evidently depend on teaching strategies and resources.

To resolve some of these needs, a self-evaluation tool has been developed which allows the student to evaluate his learning process, helping him to check and consolidate his acquired knowledge and motivating him in his search for further knowledge. This tool can be adapted for each student, which satisfies a series of objectives. Firstly, it gives the student a flexible and dynamic way to evaluate his level of knowledge and know where he must improve. Secondly, it involves and motivates the student in his own process of learning. Thirdly, and lastly, it facilitates the continuous monitoring and evaluation of students by the lecturer, thus alerting him to competencies which will be more difficult to acquire.

The tool uses a Multi-agent System to build a student's profile based on the results of the self-evaluation test. Moreover, it records student interaction with the tool, generate adapted tests, and choose questions (and level of difficulty) which will be part of the test.

Therefore, by using this tool, the student will be able to control, verify and promote learning through the self-evaluation tests adapted to his profile and from the information of feedback generated by the agents once the test is corrected.

A Middleware for the Integration of Third-party Learning Tools in SOA-based Learning Management Systems

Supporting Instance Management and Data Transfer

Abstract— **The widespread adoption of broadband Internet connections and the need of institutions such as universities or enterprises to provide their staff with continuous education have led to a fast adoption of Learning Management Systems. These systems typically provide a centralized environment where students can communicate, carry out experiments, etc. However, the rapid growth of these platforms together with the unlimited need for learning tools, mainly in engineering education contexts (e.g. simulators, communication tools), are hindering their development. The natural alternative is to decouple these tools from the Learning Management Systems themselves, taking advantage of the *Software as a Service* distribution model. To perform such a decoupling a middleware is required to allow the integration and use of an external tool by the Learning Management System. In this paper a proposal for such middleware is described, with a special focus on the part devoted to manage instances and the transfer of data.**

Keywords- Data-transfer interface; Hard integration; Instance Interface; Learning Management Systems; Middleware; Software as a Service.

I. Introduction

Engineering education is experiencing great changes during the last years. Many of these changes have been promoted by the adoption of new technologies, broadly Web-based applications. Learning Management Systems (LMSs) are playing a key role in this scenario. Some of the best-known examples are Moodle [1], Blackboard [2] and .LRN [3]. These systems typically facilitate the control of educational activities, providing a centralized environment to organize and provide information, to support the communication between teachers and students, to enable the interchange of documents, to answer online questionnaires, etc. Nevertheless these LMSs are too generic. The "one size doesn't fit all" problem is very notorious here, since their functionalities are generally designed for the support of a general educational approach based on the delivery of contents. Nevertheless, many engineering subjects require not just the delivery of contents, but also the performance of experiments, practical developments and collaborative works among students. During the last years these activities have been supported in several ways by technology-based solutions developed outside of the LMSs: simulators, remote labs, agent-based environments, games, immersive environments, etc. As a result, a plethora of tools and services is currently required for the support of engineering education e-learning courses, but in general they are not available in LMSs.

The previous problems have been identified as LMSs' tailorability and extensibility deficiencies that need to solved. Up to date, some solutions have been proposed, but with limited success. For example, Moodle and Blackboard have capabilities to extend their own functionalities: the so-called "extensions" [4]. However, in these systems integration of external tools is considered only a supplement. As a result, it is possible to include a new tool in Moodle or Blackboard, but the integrated tools do not work in coordination with the core LMS. On the one hand, LMSs lack any means to monitor and control the way users work with tools. This is the case, for example, when we want to track students' activities. On the other hand, LMSs are not able to control the interaction of the users with the external tools.

The tailorability and extensibility deficiencies found in existing LMSs, together with the essential need of extensions, have led us to the conception of a middleware to enhance and facilitate the integration between LMSs and third-party tools. This middleware is based on a *Software as a Service* (SaaS) distribution model that allows the LMS to use third-party tools exposed as Web Services. In this paper we give an overview of the different communication protocols, components and software stacks involved. A comprehensible description is out of the scope of this article, and therefore we put the focus on two key parts of the middleware: the Instance Interface (those elements to create and manage the instances of a third-party tool), and the Data-Transfer Interface (those devoted to

–

transfer data elements between the LMS and the tool). Their development has been based on the study of existing solutions and the application of a rigorous analysis of requirements.

This paper is organized as follows. Section 2 analyzes different ways in which LMSs can be extended according to the level of functionality achieved, and puts the data-transfer middleware in this context. Section 3 poses a typical scenario where the need of creating and configuring instances and transferring data between a LMS and a tool is clear. Next, Section 4 gives a brief description on the middleware and the way it has been structured to accomplish integration of third-party tools, and Sections 5 and 6 focus specifically on the Instance Interface and the Data-Transfer Interface. Section 7 provides a proof of concept, and Section 8 ends up with some conclusions.

II. Integration of Third-Party Tools

The basic problem of this research has been how to develop an LMS whose functionality can be extended at a minimum cost. In addition, the new functionality has to be appropriately integrated with the previous one of the LMS. This problem can be considered in a broader context, as the general problem of extending a Web application.

At this point we have considered two different alternatives to integrate third-party tools in a Learning Management System, which are also considered in [5]:

- Soft integration of third-party tools. The LMS functionality can be extended through a hyperlink to an (external) third-party component. Once the user clicks on it, the graphical user interface of the tool is displayed. From this point, users are operating a system that the LMS cannot control by any means. Therefore, a new functionality is included but it does not work in coordination with the core LMS, resulting in a very “soft” integration.
- Hard integration of third-party tools. It includes the soft integration, but providing the LMS with comprehensible control over the integrated tools. We describe in the next paragraphs our proposal for such a comprehensible control.

In soft integration a third-party application can be “inserted” in the page of the LMS, providing its users with a unified environment to carry out their tasks. However, the only part of the application that can be controlled by the LMS is a link to the tool. The LMS does not have any means to supervise and alter the behaviour experienced by its users on the application. This functionality can be enough in some cases, but not always. Hard integration, on the other hand, allows the LMS not only to link the application, but also to supervise and alter the behaviour of the tool as required.

As discussed in [6], the control of the operation of the tool to achieve hard integration involves the following issues:

1. Creating a working account (i.e. an instance) for each user at the tool. For example, in a “Hydrodynamics” course an instance can be created for a student at a fluids simulator.
2. Transferring from the LMS to the tool all those data that the user may need in order to carry out his/her tasks. In the case of a fluids simulator, the LMS may send the boundary conditions required for the hydrodynamics problem.
3. Establishing some access permissions over these data and the tool functionality. In our example, the student may be assigned execution permissions over the part of the application responsible for launching the simulation.
4. Subscribing to events result of the manipulation of the tool. For example, the LMS may be interested in knowing when the student launches a simulation, and hence it has to subscribe to the corresponding event type.
5. Authorising the user to access the instance. In our example, the student may not have a working account at the fluids simulator, in whose case the LMS has to grant him/her access as guest user. Otherwise, if the student is not involved in the subject he/she should not be granted access.
6. Altering the behaviour of the tool according to the information provided by the events triggered. For example, if the result of the fluids simulation is correct the LMS may order the simulator to give a verbatim explanation of the physical laws involved in the problem.

Figure 1 summarizes the difference between hard and soft integration in terms of the six aspects mentioned above.

III. An API for the Integration of Tools

The highest level of integration can be provided by the architecture depicted in Figure 2. The picture corresponds to a refinement of the TCP/IP protocol stack. Unlike the typical TCP/IP stack, the Application layer is further decomposed into three additional layers:

- **High-level entities**. The LMS and the third-party tool. They provide the bulk of the learning functionalities, but employ the integration managers to interact and complement each other.
- **Integration managers**. A set of classes and interfaces used by both high-level entities that enable to control and supervise the behaviour of the third-party tool by the LMS. In other words, these integration managers carry out tasks that enable to achieve hard integration. Each integration manager deals with a different task.
- **Integration protocols**. A set of protocols that allow the integration managers at the LMS and the tool to communicate.

–

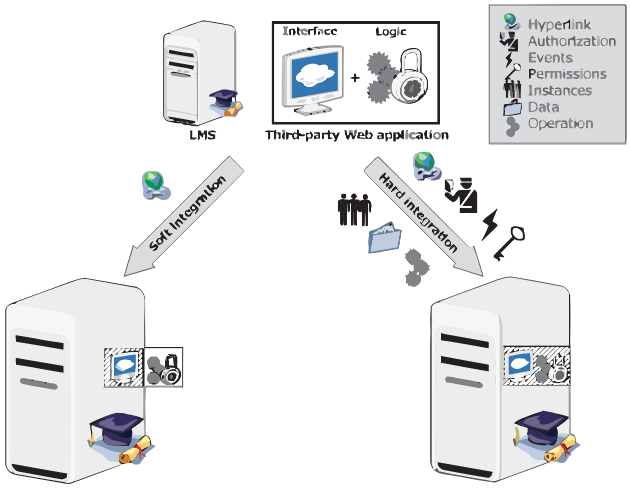

Figure 1. Difference between hard integration and soft integration.

As in the standard TCP/IP stack, each layer perceives a direct communication with an analogous layer at the remote host. Therefore, integration protocols communicate with analogous integration protocols, integration managers communicate with analogous integration managers, and high-level entities communicate with high-level entities, see Figure 2.

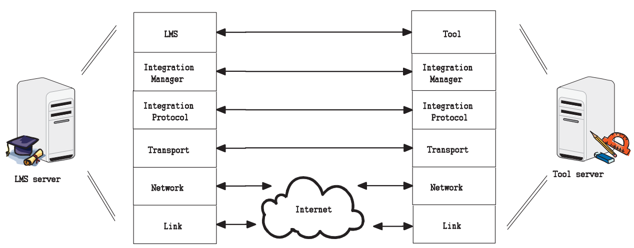

Figure 2. Hard integration architecture.

The conceptual layer diagram of Figure 2 is complemented by a class diagram representing the classes, components and interfaces that build up the layers of both the LMS and the Tool. Figure 3 provides such diagram just for the case of LMS. The diagram of the Tool is symmetrical due to the abovementioned property of the TCP/IP protocol stack of direct communication between layers.

In this diagram the high-level entity is represented as a UML component without any further class decomposition. The reason is that a high-level entity is a complex system, involving many classes and packages whose relationships are not relevant for our purposes.

Beginning with the diagram of Figure 3, the LMS invokes the methods of the integration managers to alter the behaviour of the tool (e.g. a method for granting write permissions over a file, for subscribing to a particular event). Each integration manager deals with a different aspect of hard integration, up to the six different aspects enumerated in Section 3.2. The LMS does not have to worry about the code structure of the integration managers but only about the methods they provide and the functionality of each of them. Therefore, each integration manager realizes an interface, which is exposed to the LMS.

The integration managers of the LMS use the integration protocols to communicate with the tool. The integration protocols, both those at the LMS or at the tool, carry out the effective exchange of messages, dealing with the logic of the messages sent between both entities (sequencing, detection of invalid messages, etc.).

When the message has been delivered to the integration protocol of the tool it is passed to the corresponding integration manager, which alters the behaviour of the tool.

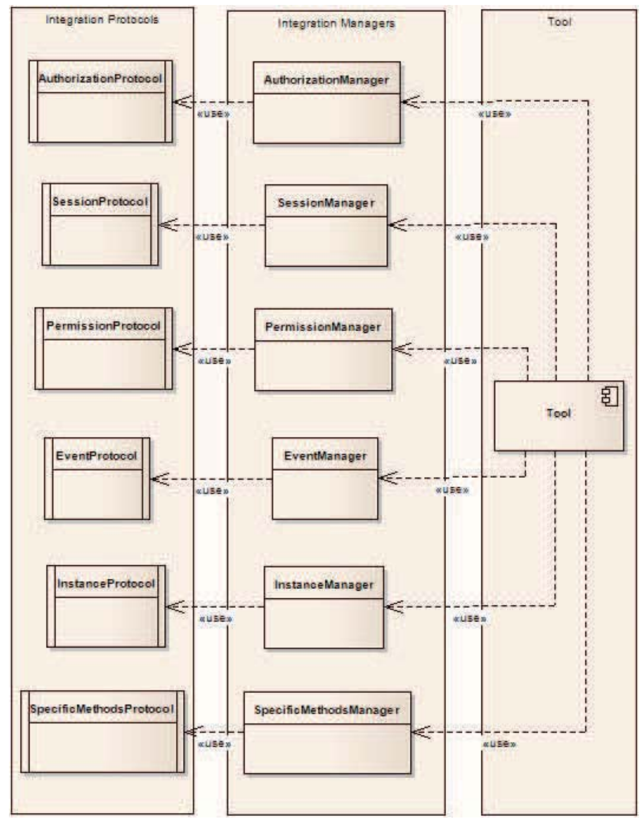

Figure 3. UML class diagram of the LMS.

In this article we will describe only the Instance Manager-Protocol and the Data-Transfer Manager-Protocol. Taking this framework as a starting point, the only missing points are the following:

- Firstly, an enumeration of the methods supported by the Instance Manager and the Data-Transfer Manager.
- Secondly, a description of the way the Instance Protocol and the Data-Transfer Protocol work.

In order to specify the functionalities of both pairs Manager-Protocols (or simply "Interfaces") we will firstly describe a typical use case in Section IV involving the creation and management of instances in a remote tool, and the transfer of data between a LMS and the tool. This use case will help us to develop the abovementioned logic in Sections V and VI. The descriptions carried out in Sections IV, V and VI follow a constructive approach, i.e. they represent the same creation process taken by the authors when developing the full middleware.

IV. A Typical Scenario

For our purposes (defining the Instance Interface and the Data-Transfer Interface) we will consider a LMS hosted and managed by the University A. This LMS offers its students the possibility to use a collaborative tool hosted and maintained by the University B.

Students of a certain course in a Telecommunications Engineering degree use the University A's LMS. At a certain part of the course, students are expected to work in groups to accomplish a task. The tool at University B provides the desired functionalities. Therefore, the LMS creates one instance of the tool per working group. The work of one group should not interfere with another group's (e.g. a group should not cheat trying to copy another group's work). In this way, when the members of the group get access to the tool they join their particular instance where they find a copy of the wording of their assignment along with appropriate documentation.

At a certain point of the schedule the teacher wants to qualify the pieces of work created by each group. At this time, the access to the instances needs to be blocked. When the teacher finishes the qualification instances are unlocked again to enable students continue working. This unlock may be followed by the transfer of the wordings of new assignments.

During all the process it is feasible that some students may have some tasks validated by previous activities. In this case they do not need to perform the assignments and therefore their membership to their respective groups should be revoked. Similarly, some new students may be assigned to some existing group by some reason.

Suddenly, some unexpected behaviour is experienced at the tool provided by the University B (e.g. server crashes). In view of this fact the LMS requests a full backup of all the data generated by the groups. If University C provides a tool with similar functionalities to University B's the LMS creates new instances in University C's tool for each group and restores the backup copies in them.

In sections V and VI we use this scenario to explain the requirements we have identified for the Instance and Data-Transfer Interfaces. We adhere to a strict software engineering approach, firstly identifying the requirements of a solution, then analyzing existing technologies against these requirements, and finally coming up with a proposal that overcomes the identified limitations.

V. The Instance Interface

The first of the interfaces that will be described is the Instance Interface. This Interface is devoted to the control and management of the instances of a tool. We understand by *instance of a tool* a working environment along with a graphical user interface, several files to manipulate, and a set of users allowed to access it.

A. Requirements

On the basis of the use cases included in the scenario described in Section IV we can enumerate the following requirements for a data-transfer solution:

- **Interoperability**: the LMS should interoperate with a Web tool even if they are in different network domains. This is necessary as in the general case the Web tool and the LMS are located at different network domains.
- **User-oriented instances**: as pointed in Section IV, it should be possible to add specific users to specific instances of the tool. Particularly, depending on the kind of tool one instance could be assigned one or many users.
- **Disjoint instances**: the membership of one instance should not affect either the membership or the state of other instances.
- **Dynamic reconfiguration**: it should be possible to remove participants from an instance or add new ones during runtime.
- **LMS-controlled membership**: it is the LMS which decides which user is assigned to each instance of the tool. In Section IV it is the LMS which creates the working groups.
- **LMS-controlled instances**: the LMS should be able to create, delete, suspend temporarily and resume instance depending on the requirements of the course. In Section IV the LMS suspends the instances during the teacher's evaluation.

B. Related Works

Previous to the development of an interface we perform a study of the state of the art. Unlike other interfaces such as the Data-Transfer Interface in Section VI or the Authorization Interface [7], the study of the state of the art in the field of instance management did not bring out significant results. There are not systematic approaches to control and manage instances, which in part is understandable due to the vast diversity of tools and requirements involved.

Given this heterogeneity we decided to concrete our research and investigate the state of the art of the most common learning tools [8]. This research has been fruitless in many cases, but in the fields of chats and conferences we came across several specifications to define how to create instances and manage them once created.

RFC2811 [9] addresses the creation and control of chat rooms or "channels" (i.e. concrete instances of the chat tool). In its simpler version, new channels are created whenever its first user joins it. This user is assigned the role of "channel founder" and has unlimited privileges over the channel. Since the channel is created other users are free to join it unless the founder explicitly puts them in a black list. Other parameters that can be set by the founder include silencing the room, setting a welcome message, or establishing a user limit for the

–

channel. When all users have left, the channel is finally deleted.

RFC4353 [10], on its turn, specifies how to use the SIP protocol in order to initialize, modify and terminate media sessions between multiple participants or “conferences”. The RFC regards a specific conference as an instance of a multi-party conversation. The document addresses common instance operations (creating and destroying an instance, and adding, removing and listing participants) and specific conferencing operations (adding and removing media, and recording a conversation).

Table I summarizes the behaviour of these two specifications against our requirements.

TABLE I. COMPARATIVE ANALYSIS OF RFC2811 AND RFC4353.

	RFC2811	RFC4353
Req. 1	YES	YES
Req. 2	YES	YES
Req. 3	YES	YES
Req. 4	YES	YES
Req. 5	NO	NO
Req. 6	NO	NO

We see that these RFCs have been written to describe services that, although they behave well against our requirements, they have not been thought to be operated by a third-party system but directly by (one of) its users. Therefore, our Instance Manager offers similar functionalities to these RFC, but providing the LMS with full control of the creation, deletion and state of the instances. Eventually, this control could be transferred by the LMS to the users.

C. *The Instance Manager*

As described in Section III, the approach we have followed is the decomposition into a Instance Manager providing a known interface, and a Instance Protocol responsible for the actual transfer of data (see Figures 2 and 3). Both the Manager and the Protocol have to be implemented at both the LMS and the tools. Table II summarizes the methods and input and output parameters of the Instance Manager.

TABLE II. METHODS OF THE INSTANCE MANAGER.

Method	Input parameter	Output parameter
createInstance	name	URI
suspendInstance	URI	result
resumeInstance	URI	result
addUser	URI, userID	result
removeUser	URI, userID	result
deleteInstance	URI	result

Instances are uniquely identified by its URI (Unified Resource Identifier). All operations receive the URI of the instance as an input parameter (except the method for creating an instance, which returns the URI of the new one). The field *result* contains a verbatim message containing the success or not of the operation (e.g. “OK”, “Error - Instance not found”). Finally, each LMS is responsible for assigning its users a unique *userID* to avoid colliding usernames at the tool.

D. *The Instance Protocol*

The specifications described in Section V-B describe complex and very specific protocols to manage instances from an external entity, which do not adapt to our scenario. Therefore, a light Instance Protocol has been specifically designed to work with the Instance Manager.

The Instance Protocol is based on the exchange of plaintext HTTP messages with specific headers. All the message exchanges take place exclusively between the LMS and the tool (i.e. the final user of the tool does not take part in them). HTTP is specially suited for the design of a client-server interface such as the Instance Interface, as it offers the capability to send parameters in the header of the messages.

The format of the headers follows a simple structure. Each parameter goes in a different extension header. For example, should the parameter URI be sent, the corresponding header would be something like *URI: www.mylearningtool.net/specificinstanceuri*. Additionally, there are two more headers. On the one hand, the *InstanceMethod* header specifies the method of the Instance Manager that is invoked by the LMS. On the other hand, the *RequestID* header identifies the request from any other request from this or any other LMS. This is useful for the LMS to match the incoming response with a previous request. Figure 4 depicts a sample message of the Instance Protocol.

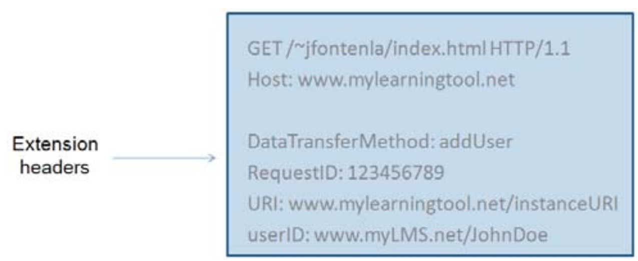

Figure 4. Sample message of the Instance Protocol.

VI. THE DATA-TRANSFER INTERFACE

In this section we describe the Data-Transfer Interface. As described in Section III, the approach we have followed is the decomposition into a Data-Transfer Manager providing a known interface, and a Data-Transfer Protocol responsible for the actual transfer of data (see Figures 2 and 3). Both the Manager and the Protocol have to be implemented at both the LMS and the tools, in order to allow the virtual direct communication among layers described in the TCP/IP protocol stack. It has been our intention to build a simple and lightweight solution that could work in any kind of learning environments where two entities need to transfer data.

The structure of this section is analogous to that of Section V. Starting with an analysis of the requirements, we list some related works and study their behaviour against our requirements. Next, we get into some detail of a Data-Transfer Manager and a Data-Transfer Protocol solving the previous limitations.

A. Requirements

As with the analysis of requirements carried out for the Instance Interface in Section V, On the basis of the use cases included in the scenario described in Section IV we can enumerate the following requirements for a data-transfer solution:

1. **Interoperability**: the LMS must be able to interoperate with a Web tool even if they are in different network domains.
2. **Bidirectionality**: the solution must enable to transfer data either from the LMS to the tool, or from the tool to the LMS. Moreover, the communication can be started by any of these entities. For instance, in the example of Section IV the tool could fetch from the LMS an avatar for each student.
3. **Granularity and bulkability**: the solution should accept the transfer of single data elements (Granularity) as well as the transfer of multiple data elements in a single message (Bulkability). In the use case of Section IV, for example, transfers involve both single data elements (the wordings of the assignments) and full backup copy.
4. **Scheduled and on-demand transfers**: the transfer of data can be made either on demand, or in a scheduled fashion. In the latter case, it should be possible to specify at least the time of the transfer, and which data elements are going to be sent. For instance, in the scenario of Section IV the LMS could request backup copies from the tool of University B every hour.
5. **Bandwidth efficiency**: the solution should not be bandwidth intensive (e.g. in the case of frequent bulk copies). This includes the sending of incremental backups, including just those elements that changed since the previous copy.
6. **Transparency**: the user should not be aware of the data-transfer process that is taking place while he/she is using the tool.
7. **Integrity**: in the general case, the data being transferred is not fault-tolerant. Hence, the solution should provide some mechanisms to check the consistency of the data.
8. **Confidentiality**: the solution should provide mechanisms to treat the data as confidential when necessary.

B. Related Works

During the course of our work we studied several standards and technological products devoted to the transfer of data between two entities. Some of these products have relationship with the e-learning field, while some others are for general purpose. Aware that this is a very wide category, we chose the following three representative technologies for study: SCORM RTE, IMS SSP and W3C's Storage interface.

ADL Shareable Content Object Reference Model [11] (henceforth SCORM) is an effort to provide a set of specifications, guidelines and standards to meet the requirements for the Web-based delivery of reusable learning contents. One of the results of this effort is the SCORM Runtime Environment [12] (henceforth SCORM RTE), which details the requirements for launching content objects (henceforth SCOs) and establishing communication between LMSs and SCOs. The RTE is a middleware that is downloaded to the learner's Web browser along with the SCO itself. Whenever a SCO wants to begin a data transfer with the LMS invokes the *getValue* or *setValue* methods of the RTE. All the transfers are initiated by the SCO.

There are two main deficiencies in SCORM RTE that avoided us from choosing it as our data-transfer solution. Firstly, it provides a very limited set of methods, as it only allows the transfer of single data elements and not full backups. Secondly, it has been designed with a very concrete and simplistic scenario in mind (namely, a SCO making requests to a LMS following a client-server approach) which is slightly different from ours. We are considering tools in general and not SCOs uniquely.

IMS Shareable State Persistence [13] (henceforth IMS SSP) has been posed as an extension of SCORM to support the storage and retrieval of information from shared dataspaces called "buckets". The main goal of IMS-SSP has been to provide SCORM's SCOs the ability to share information among them which, according to the IMS, would allow to make more reusable content objects.

On addition to the methods *getValue* and *setValue* of SCORM RTE, IMS SSP considers the methods *appendData*, *getData* and *setData* that work over buckets. Unlike the methods of SCORM, these three methods allow not only to transfer single data elements but also collections of them with a single call. Nonetheless the operation of IMS SSP is similar to SCORM RTE's: it has been designed for scenarios where SCOs makes requests to an LMS by means of a runtime, and the LMS consequently replies to the request. There is no kind of bidirectionality between the entities involved. Other requirements of Section VI-A such as Bandwidth efficiency, Integrity or Confidentiality are neither considered.

Finally, W3C Storage [14] is a mechanism designed for storing user's data in general-purpose Web applications due to the W3C Consortium, allowing persistent storage lasting the current browser session. Storage has been developed as an interface to access a standardised set of methods in the Web application. These methods include *getItem*, *setItem*, *removeItem* and *clear* to operate over data elements represented as key-value pairs (both keys and values are strings). The invocation of these methods is carried out by some JavaScript code running in the browser. Despite Storage is designed for a general-purpose scenario involving a Web application and a browser, its working principles remain the same with regards to SCORM RTE and SSP. The specification involves a client-server architecture where the browser makes requests to the Web application, and the latter performs some operations over the stored data and replies to the browser. On top of that, the set of methods work over specific data elements and do not allow any kind of planned transfers or incrementality. All these issues are a consequence of the fact that Storage is a quite simplistic solution for our needs, and therefore exhibits a poor behaviour against our requirements.

Table III summarizes the analysis of the three technologies considered in this section against our requirements.

TABLE III. COMPARATIVE ANALYSIS OF SCORM RTE, IMS-SSP AND W3C STORAGE.

	SCORM RTE	IMS SSP	W3C Storage
Req. 1	YES	YES	YES
Req. 2	NO	NO	NO
Req. 3	NO	NO	NO
Req. 4	NO	NO	NO
Req. 5	NO	YES	NO
Req. 6	YES	YES	YES
Req. 7	YES	YES	YES
Req. 8	NO	NO	NO

C. The Data-Transfer Manager

The underlying Data-Transfer Protocol is wrapped by the Data-Transfer Manager, which provides a standardised set of methods. Five methods, summarized in Table IV, have been considered to read the value of a data element (*getDataElement*), to overwrite it (*setDataElement*), to get an on-demand backup copy of the data of the instance (*getBackup*), to restore it (*restoreBackup*), and to schedule the transfer of future copies (*scheduleBackup*). These five methods can be divided into two groups: those that can be invoked by either the LMS or the tool (*getDataElement* and *setDataElement*), and those that can only be invoked by the LMS (*getBackup*, *restoreBackup*, *scheduleBackup*). An example of the first kind of methods takes place when the tool requests the name of the learner to the LMS using *getDataElement*, whilst an example of the latter could be an LMS requesting a backup copy of the data hosted at a tool by the use of *getBackup*, and transferring it to another tool using *restoreBackup*.

Table IV shows the methods along with their input and output parameters. All of them have an *id* input parameter, which refers to an identifier of the data involved (whether a single data element or a full backup). The parameter *data* contains the value of the data element or the backup being transferred, and has the same meaning whether considered as an input or output parameter. The parameter *result* contains a verbatim error code, if any (e.g. "The requested data element has not been initialized"). Finally the parameters *incremental*, *time* and *period* are specific for the request and scheduling of backup copies. The parameter *incremental* contains "false" or "true" if the backup is considered standalone or incremental. The former includes all the data at the tool, while the latter only contain those files that have changed since the last backup. This "incrementality" boosts the performance of a backup transfer, which is typically bandwidth-intensive. On its turn, the parameters *time* and *period* are devoted to schedule the periodical transfer of copies from a predefined point in time (e.g. the transfer of copies every 10 minutes from 9 pm).

TABLE IV. METHODS OF THE DATA-TRANSFER MANAGER.

Method	Input parameter	Output parameter
getDataElement	id	data
setDataElement	id, data	result
getBackup	id, incremental	data
restoreBackup	id, data	result
scheduleBackup	id, incremental, time, period	result

D. The Data-Transfer Protocol

A simple Data-Transfer Protocol has been specifically designed to work with the Data-Transfer Manager. The reason is that none of the technologies described in Section VI-B satisfies our needs to request, pack, transfer and restore data, and therefore a light ad-hoc Data-Transfer Protocol has been developed.

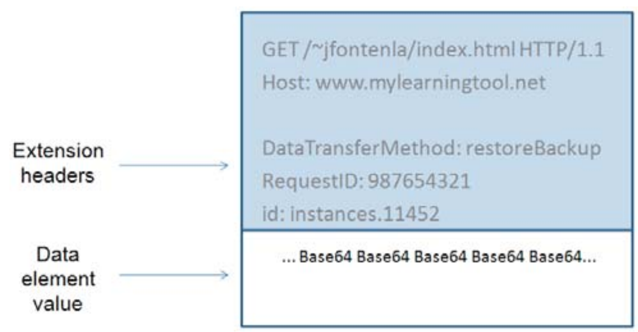

Figure 5. Sample message of the Data-Transfer Protocol.

As the Instance Protocol, the Data-Transfer Protocol has been designed as an extension of the HTTP protocol with special header extensions. Again, HTTP is specially suited for the design of a Data-Transfer Protocol, as it offers not only the capability to send parameters in the header of the messages (with the same format of the Instance Protocol), but also a payload to transfer binary data. On top of that, HTTP provides integrity as it works on top of TCP. In case that confidentiality

–

(e.g. when a learning tools wants to transfer the marks of a questionnaire to the LMS, at the transfer of a personal email account linked to an instant messaging application) or authenticity (e.g. to verify that the LMS managing the session data is the same that created the user account) were required, the Data-Transfer Protocol could use HTTPS instead.

Data are encoded using the BASE64 schema [15], and sent in the payload of the HTTP message. Full backup copies are packed as zip files prior to their transfer by means of the Data-Transfer Protocol. The use of this format is not as unusual as it may seem, as it is also the format used by Moodle to pack and transfer educational contents [16]. Should any problem occurred during the processing of the request, an error code would be returned for the Data-Transfer Manager, along with the habitual HTTP error code for the Data-Transfer Protocol. Figure 5 depicts a sample message of the Data-Transfer Protocol.

VII. Proof of Concept

In order to demonstrate the feasibility of the approach, a prototype consisting of a LMS and a learning Web tool has been designed. Acting as LMS we deployed an instance of Moodle (henceforth, "the LMS"). The choice of Moodle responds to its important presence in online universities, as well as to its opensource-ness. On the other hand, we deployed another instance of Moodle just to use one of its tools (a forum). The capabilities of the second instance of Moodle (henceforth, "the forum") to work as a full Learning Management System are not used, but only its forum. Whenever a user of the first instance of Moodle wants to use a forum, the one of the second instance is used instead. The forum of the first Moodle is "bypassed".

A full implementation of the six parts of the middleware described in Section III has not been made yet. Instead, we just implemented the Instance Interface, Data-Transfer Interface and Authorization Interface in both instances of Moodle.

A simple test, summarized in Figure 6, has been made. Firstly, the LMS used the Instance Manager to create a new instance of the forum (i.e. a new conversation thread) named "Waves". When the instance has been created, users must be added. In our case we added a student whose LMS user account had been previously created manually. This action does not grant instant access to the instance, but instead tells the forum that the instance will be visible to the user when he/she joins.

The next action carried out by the LMS was to post a welcome message giving some explanations about the wave equation. In terms of the middleware, this implied using the method *setDataElement* of the Data-Transfer Interface. During this proof of concept we tried to avoid the use of a complex agreed vocabulary in order to describe every data element hosted at the forum. Instead, we only used a data element called *newMessage*, but the Data-Transfer Interface is flexible enough to support any kind of vocabulary as long as it had been previously agreed by both parts.

Finally, when the user accessed the forum application (by means of the Authorization Interface, whose description can be found in [7]) found the post of the LMS as if it had been posted by any other user.

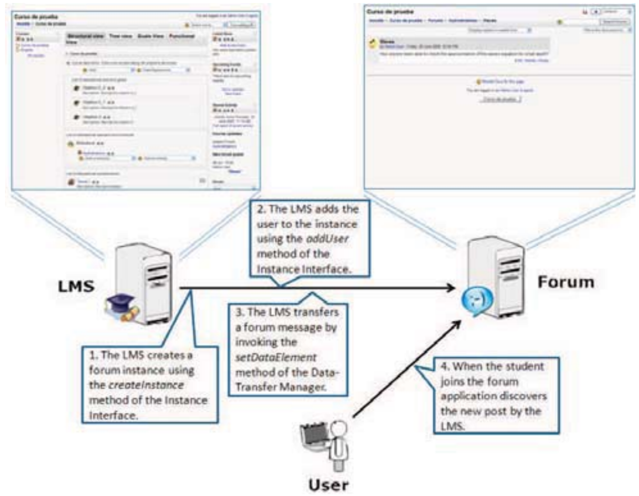

Figure 6. Proof of concept.

VIII. Conclusions

Current LMSs are playing an important role in providing engineering education. However, their possibilities are limited due a clear "one size doesn't fit all" problem. These limitations have been the starting point of our research. The work described in this paper tries to tackle these issues with tailorability and extensibility in mind by the use of the SaaS software distribution model.

The architecture described in this work is devoted to take advantage of the SaaS model while at the same supporting the concept of hard integration. At different with current solutions that only enable a soft integration of third-party tools, our architecture allows a harder level of integration. As a result, the LMS can extend its functionality, and can do it in a controlled way.

Our proposal not only implies the design of a new kind of e-learning system, but also an entirely new business model where the development of LMSs and educational tools follow separate (but complementary) ways. In the final term this business model implies more opportunities to bring students a better and more applied education.

One aspect of the Data-Transfer Interface we deliberately omitted is the use of some sort ontologies or agreed vocabularies in order to uniquely identify each resource hosted at the remote tool. Nonetheless, as pointed in Section VII the Data-Transfer Interface provides enough flexibility to support any kind of shared (semantic) knowledge. In fact, when we began to work on the interface we assumed as a starting point that there is already some kind of shared vocabulary, but no effective data-transfer mechanism between LMS and tools.

Currently we are working on the middleware to give full support to the other aspects of hard integration, apart from the

–

two interfaces described here and the Authorization Interface described in [7]. Nonetheless, the six parts we have considered are completely independent from each other, and they can be used in a standalone way if desired. The source code of the Data-Transfer Interface itself is available as open source and is freely available for anyone interested in its use.

Acknowledgment

Principles for the Design of a Remote Laboratory: A Case Study on ERRL

Nergiz E. CAGILTAY, Elif AYDIN** and Ali KARA**

* Department of Software Engineering, ** Department of Electrical and Electronics Engineering

Atilim University, Ankara, TURKEY

{nergiz, eaydin, akara}@atilim.edu.tr

Abstract-- **Remote laboratories are getting very popular in engineering education programs. However, there are not many studies addressing the requirements and design issues of such laboratories. This paper discusses the results of a study of the requirements for developing a remote Radio Frequency (RF) laboratory for university students. This study draws on the perspectives of the students at the university, department of electrical engineering. The results are based on a research study established by 111 engineering students from France, Germany, Romania and Turkey. It investigates how students would like to use the technical content of a state of the art RF laboratory. The result of this study is also compared with the previous outcomes showing perspectives of the other learner groups of such laboratories; engineers and technicians in the technical colleges on the Radio Frequency (RF) domain. Considering the outcomes developed so far, some principles that need to be considered while designing and developing such a laboratory have been proposed. As a case study the proposed principles are implemented in a remote laboratory project. In this paper, the details of user requirements of such laboratories, the proposed principles and the implementation examples are all provided and discussed. Primarily, the general aim of this study is to guide remote laboratory platform developers towards the most effective design of their platforms.**

Index Terms— higher education, engineering education, remote laboratory, distance education, Improving classroom teaching, lifelong learning.

I. INTRODUCTION

Nowadays, based on new technologies, educators and curriculum developers are able to provide a wide range of educational alternatives for learners. Remote and virtual laboratory environments are some of these alternatives which have shown that they are potential solutions for supporting current education and providing some alternative solutions for distance learning environments [2]. However, in literature, not many studies discussing the requirements of those laboratories and the instructional design issues that need to be considered in the design of such laboratories could be found. Furthermore, as Koohang and Durante reports, the web-based distance learning technologies rely on interface design elements such as usability, visualization, functionality and accessibility which play an important role in learning [3]. Accordingly, appropriate learning theories and principles as well as user interface elements need to be considered in the design of such laboratories [3]. In our previous studies, we have discussed the requirements for remote RF laboratory applications from the educators' [2], the technicians' and engineers' [1] perspectives. This paper aims to find out the requirements from the students' perspective which is organized for the European Remote Radio Frequency Laboratory (ERRL) project[1]. How do the students prefer to study in a remote laboratory environment is the basic question of this study. The study is established on potential students of such a laboratory environment: students in higher education institutions. The main scope of this study is limited to the instructional content design issues for such laboratories. The issues that need to be considered in the sense of user interface design of such laboratories are not included in this study.

II. COURSE DESCRIPTION

Instruction can be provided with several different forms in a remote laboratory environment such as text, animations, images, figures, interactive content, video and sound based instructions. In literature several studies have been established to find the effect of these different forms of instructions on different learner groups. Those studies show that, the preferences of the target learner groups and actual performance on these different forms of instruction also differ. For instance, reading a text requires linear information processing and significant skill and effort [4]. Differently from the test, pictures' symbol system is sensory and more efficient for representing nonlinear relationships among objects [4]. According to Mayer, visual presentation of learning material enhances learning [5]. From their study, Bele and Rugelj suggest including verbal and pictorial representations for each learning page and additional animations should also be provided for the choice of the learners [6]. Mayer also suggests using words and pictures in ways that promote meaningful learning: adding pictures to words, eliminating extraneous words and pictures, placing words near corresponding pictures, and using conversational style for words [5]. Research also shows that, combination of text plus line drawings shows clear advantage in learning process [7]. On the other hand, from their study, Bele and Rugelj suggest an interactive question for the design of each learning page for immediate knowledge evaluation [6].

[1] Guest access is available at http://errlmoodle.atilim.edu.tr/ with both user name and password being "visitor"

Additionally, studies also show that students' preferences on web-based instruction for linear or non-linear ordered instructional design is also different [8]: older students prefer direct instruction. Students who are more familiar with the windows-based computer applications tend to prefer non-linear instructions. These studies show that, organization of the content and design of the instructional material as well as the feedback system are quite important for improving the performance of the instructional systems. Accordingly, before an institution can offer the most effective remote training for learners, a requirement analysis must be conducted. This study was implemented in the ERRL project in order to identify the requirements from the learners' perspective.

II. DESIGN OF THE STUDY

This work initiates from the belief that the requirements should be clearly defined before technical and practical development of a remote laboratory. The remote laboratories have two main potential groups of users: the educators and the learners. This study mainly focuses on the requirements of the learners from such a system in order to answer the following research questions:

- How students prefer to use a remote laboratory environment?
- Do they need guidance and help while studying a subject?
- In which order do they prefer to study subjects (linear / non-linear)?
- How do they like the content to be displayed?
- What are the students' attitudes toward computer mediated communication?

To answer the questions above, a questionnaire was prepared for the students as potential users of a remote laboratory. This questionnaire[2] was presented to 111 potential students from different European countries: France, Germany, Romania and Turkey. The distribution of the subjects of this study among those countries is shown in Table 1. All of the subjects are under the age of 25.

Table 1. Distribution of the Subjects among Countries

	M %	F %	Σ %
France	11 (10%)	1 (1%)	12 (11%)
Germany	14 (13%)	1 (1%)	15 (14%)
Romania	37 (33%)	16 (14%)	53 (48%)
Turkey	24 (22%)	7 (6%)	31 (28%)
Total	86 (78%)	25 (22%)	111(100%)

M: Male, F: Female, Σ: Total

2 http://www.atilim.edu.tr/~nergiz/ERRL_Questionnaire_students.pdf

As seen from Table 1, most of the participants are male (78%), which is usual according to the general gender distribution in this field. After the analyses of the requirements of the potential learner groups, the ERRL content is developed to better address the learners' requirements.

This paper analyses the target learner groups' requirements from a remote laboratory environment as a case study, describes how the ERRL content is designed to better address these requirements.

III. RESULTS

The following section analyses the results of this study according to the research questions: the quantitative data is analyzed descriptively. Since the number of female participations was very limited the results do not have gender comparisons.

A. Need help and guidance

The participants' general preferences were asked while studying any subject. According the result of this question is shown in Table 2. Most students; 55% prefer studying with someone who knows the subject well. Their second preference is studying on their own and lastly they prefer to study in groups. In our earlier study [1], this preference order was found to be similar for engineers 50%, 29% and 21% respectively. However, the technicians' second preference found studying within a group (40%) and the third one was studying on their own (13%). In that sense, technicians' preferences found to be different from the students' and engineers'. This shows that the students and engineers in general are not comfortable while studying within a group.

Table 2. Study Preferences

Q4. When learning a new subject which one do you prefer? *(Please Select only one)*	Σ %
Studying with someone who knows the subject well	55
Studying on your own	29
Studying within a group	16

Σ: Total

This result shows that, technicians do not feel as comfortable as other groups of learners while studying on their own and they need more guidance according to the other groups of learners. Most of the students (59%) believe that they need guidance while studying a new subject (Table 3).

Table 3. Need for Guidance

Q6. Do you need to be guided when learning a new subject? (Please select only one)	Σ %
Yes, I need someone to teach me	59
No, I can handle it on my own	41

Σ: Total

On the other hand, 41% of all students feel comfortable while studying on their own.

B. Preferred order (linear / non-linear)?

As shown in Table 4, most of the students (60%) prefer to study the concepts in a linear order: starting from the beginning and going through the chapters in an order. The non-linear ways of learning approaches (keyword search, read the related chapters only, and do exercises only) are their less preferable alternatives. The situation was found to be similar for engineers and technicians in our previous study [1]. However, technicians never prefer keyword search or study only the end of chapter exercises alternatives. Additionally, the percentage of technicians that prefer linear way of studying (73%) is higher than that of engineers (63%) and students (60%).

Table 4. Perceived Learning Preference

Q5. Which of the followings best matches with your learning abilities? (Please select only one)	Σ %
Starting from the beginning of the subject and go through the chapters by order	60
Searching on the keywords (by using search engine of the site or the index part of the book) and then studying on the results	17
Read the chapter that you want to know and leave the rest	14
Trying to understand the end of chapter examples & questions never read the rest	9

Σ: Total

When the similar question is asked for the web environments, the ratio for the keyword search gets higher (Table 5). On the web, technicians, engineers [1] and students also behave differently from their traditional way of learning environments. For instance, most of the technicians and engineers prefer non-linear way of instructions on the web (reach information by means of keyword), where as in the case of traditional ways of studying they mostly prefer the non-linear ways Table 4 [1]. This finding may be a sign to show that when they have a chance to reach information directly they use this feature and their habits are changing through non-linear ways of studying by the introduction of the advanced technologies on the web.

Table 5. Perceived Learning Preference on Web

Q7. When you try to learn a new subject by using a web-site, how do you prefer to study? (Please order the items below according to your preference, 1 is the most preferred one)	Σ %
Go trough the chapters in a given order one by one	36
Reach the information by means of keywords and read only the chapter you need	39
By means of questions and answers between the system and you	25

Σ: Total

C. Display of Content

When the participants' preferences were asked on the ways of the display of the content, in the first place all students prefer interactive content. While engineers' preferences are similar to the students' preferences, it is observed that technicians' first preference is figures on the subject [1].

Table 6. Preferences for Computer Based Experiments

Q8. When performing experiments on a computer I prefer: (Please order the items below according to your preference, 1 is the most preferred one)	Σ %
1-Interactive	17
2-Batch jobs	9
3-Story based	11
5-Figures on the subjects	10
6-Several problems and exercises	12
7-Games related with the subject	10
8-Animations on the subject	12
9-Text-based instructions	11
10-Sound-based instructions	8

Σ: Total

D. Attitudes toward Computer Mediated Communication

In order to identify the participants' attitudes towards computer mediated communication, the advantages and disadvantages of such platforms were asked. Table 7 and Table 8 show their responses on this issue. As seen from Table 7, the students find the geographic independence as the most important advantage for computer mediated communication.

Table7. Advantages of Computer Mediated Communication

Q10. Please select the advantages you consider important for you in computer mediated communication	Σ %
1-Geographic independence	31
2-Temporal independence	20
3-You are not embarrassing for teacher's presence	7
4-Silent (nobody disturb you)	16
5-You can find quickly elements of all past communications	26

Σ: Total

The second one is listed as the finding quickly the elements of all past communication. Temporal independence follows this and silence comes next. According to students, the least important feature of the computer mediated communication is the embarrassment of the teacher's presence. Table 8 summarizes the disadvantages of the computer mediated communication according to the students.

Table 8. Disadvantages of Computer Mediated Communication

Q11. Please select the disadvantages you consider important for you in computer mediated Communication	Σ %
1-Absence of immediate feedback for asynchronous communication	32
2-Imperfect technology	17
3-Not yet sufficient experience with the web and the Internet	8
4-Reading online especially if the amount of information to be read online is significant	27
5-You may not be certain whether other participants have received your message	16

Σ: Total

As seen from Table 8, the most important disadvantage is the absence of immediate feedback for the asynchronous communication (32%). Reading online follows it. Imperfect technology and not being sure whether other participants have received your message come next. Students mostly feel that they already have sufficient experience with web and internet. However, according to the engineers and technicians, the most important disadvantage is found to be the difficulty in reading the online feature of the computer mediated communication (39%) [1], where as for the students this percentage is 27%. This shows that, the younger generation feels more comfortable reading online.

IV. A REMOTE LABORATORY IMPLEMENTATION

As a summary, depending on the first and previous studies, it is possible to conclude that, user requirements and preferences change among different learner groups. Because of the variations in different learner groups' preferences (the students and engineers are in general not comfortable while studying in a group), the technicians need more guidance according to the other groups of learners (while studying, technicians never prefer keyword search or studying only the end of chapter exercises), the percentage of technicians that prefer the linear way of studying (73%) is higher than that of engineers (63%) and students (60%).

General Characteristics of the Learner Groups

- The ratio for the keyword search is getting higher while studying on the web
- Sound based instructions are least preferred
- Interactive content, problems and exercises, animations and figures are preferred forms of content display
- Geographic independence and quickly finding elements of all past communication are listed advantages for the computer mediated communication
- Absence of immediate feedback and reading online are the most important problems of the computer mediated communication.
- The younger generation feels more comfortable as they read online
- The learners' habits are changing through non-linear ways of studying by the introduction of the advanced technologies on the web

E. ERRL Design Principles

As a remote laboratory implementation in the ERRL project, the following principles have been followed as the guidelines for the design of the ERRL system.

Instructions for different learner groups should be provided differently:

From the requirements study, it is understood that the different potential learner groups' requirements and expectations from the ERRL system also differ. In order to satisfy this requirement, the following design approaches were used: Reading texts in the study theory part and experiments are arranged according to these needs of different learner groups. Therefore, the content is divided into three levels as; basic, intermediate and advanced. That is, the content is simplified or enlarged according to the learner groups' requirements. Also, the ERRL platform is designed as flexible enough for offering the possibility to change the lectures from a semester to another and to add new experiments that correspond to these lectures. For this, the content is defined in the ERRL system as learning objects which defines smallest units of instruction that can be reused in different contexts [11], [12].

Support both linear and non-linear presentation of the content

From the study of requirements, it is understood that, in web-based environments, learners' intention on non-linear instructions become higher. However, they still prefer to use the linear way of studying materials. Accordingly, the ERRL system, providing both ways of instructions, has been designed. Learners do not necessarily have to follow each instruction in the system in a linear order. They shall be able to just reach the necessary information which is needed at the moment of the work. Accordingly, the system must be self-directed and also have to support non-linear instructions. For instance, if an engineer tries to get a little information about a feature of specific equipment and if the learner has to go through the whole content, it might also be boring or annoying. The system must provide the necessary information at the moment of need. On the other hand, the system should also support linear instructions and guidance whenever needed. In the ERRL system, the learning content in different studying orders has been designed to satisfy requirements of different learner groups. The instruction is provided in a highly guided manner. All the necessary instruction is given in a predefined order for beginners. Parallel to this, the same instructions are organized as an experiment manual that shows the instructors in order to quickly start the experiment for intermediate or advanced level users. Similarly, in the design of the teaching tool on how to use each piece of equipment, the search facility and the questioning and answering features are added. If the user needs some specific information about any piece of equipment, then learner can write the keyword or ask the question in the text field of "Search for:" part of the system. When the "Submit" button is clicked the results of the search will be shown in the right part of the system again. These results are listed as links in the form of text documents, videos, audios or other forms that are available in the Learning Management Systems' (LMS) database. On the other hand, experiments and study theory parts of the ERRL includes many hyperlinks providing direct access and guidance about equipment and content. In this way, the user doesn't have to linearly search all content in order to find the related material.

Forms of Instruction - Not many sound-based instructions

The ERRL content has been developed and distributed into different skill levels considering the target user groups' requirements. There is very limited movie or sound based instructions in the ERRL system as alternative for the other forms of the instructions. In this way, the users can select the proper content for themselves and the learners are free to study the concepts repetitively in different forms of training. Also, where possible, the lectures include suggestive animations and simulations that decompose and describe the physical phenomenon under study, in order to be clearly and appropriately understood by the students. Interactive animations used within the lectures can allow for a multitude of scenarios, creating unique situations in response to student inputs.

Providing interactive content such as exercises and experiments

As it is suggested by the literature, the experiments and exercises are very important for the engineering education [10]. Accordingly, the ERRL system is designed to provide as many exercises as the learners want to practice in a specific content. As seen from Figure 1, the learner can set the experiment parameters and repeat the experiment several times.

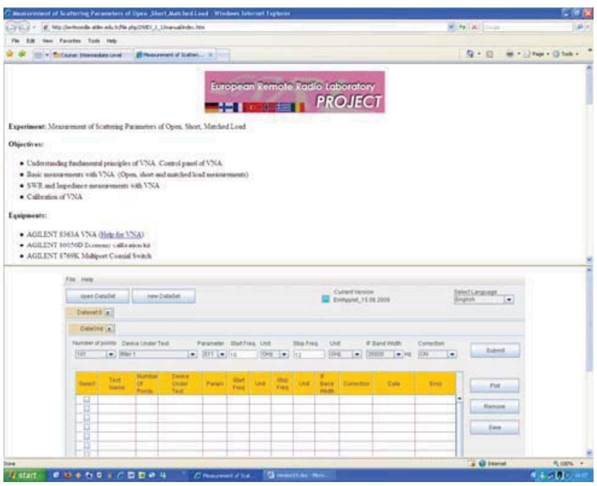

Figure 1. ERRL Experiments

This activity also provides trial-and-error type of learning approach for the ERRL learners.

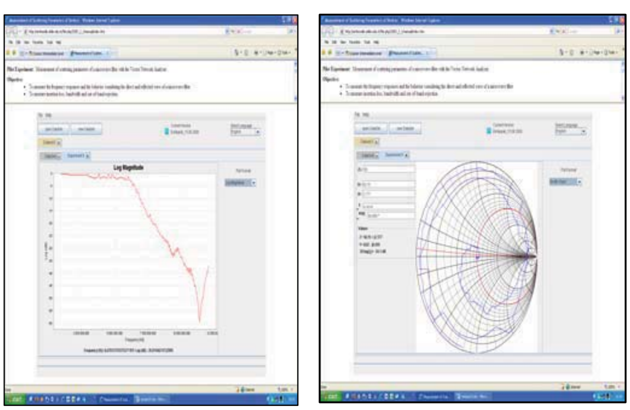

Figure 2: Analysing Experiment Results

As seen from Figure 2, they are also able to analyze the results by showing them in different graphical formats such as Smith Chart and Log Magnitude, to compare and choose the most suggestive one.

Providing a good feedback system

In the ERRL system, in order to provide feedback on the learning performance for both learners and instructors, the assessment system is organized as a skill level test, experiment and equipment test. A Skill level test is advised to be taken immediately after the registration of the system. It can be taken as many times as the learner requests. The main purpose of this test is to understand the beginning skill level and progress in the skill level of each learner. These pre-course assessments that identify areas where relevant background knowledge is missing or prone to misconceptions can serve to revise the curriculum, encouraging talk and curriculum development between instructors both within and across departments.

Experiment tests are applied immediately after the implementation of each experiment. Tests are generally short, and as they are multiple-choice, they are useful for immediate quantitative assessment of student understanding. The experiment user interface covers both theoretical backgrounds for the experiment as well as the experiment itself. The ERRL on-line tutorials with built-in assessments or interactive components combine instruction and assessment. Feedback from assessments, such as item analyses, can be used to inform instruction, enabling the instructor to target the specific components of the lessons that students find troublesome. Another assessment used method is: immediately after studying each experiment. The experiment test items cover both theoretical and experiment specific issues to be tested based on the objectives of the experiment. Each test item about the experiments is defined by describing the following details. Accordingly, each item in an experiment test is defined by its objective as well as if it serves for one of the knowledge, skill or competence purposes. There are at least 3 test items for each experiment objective. Also the number of knowledge, skill and competence type questions is evenly distributed throughout each test. In order to pass the experiment exam, learners are usually asked to be successful for at least 70% of each knowledge, skill and competence type of questions. Learner's current skill level is calculated by using the experiment test results. According to the request of the learner, a summative evaluation report is prepared to show the progress of the learner from the starting point to the current level. This report is based on the learner's progress on each skill level. More detailed reports on learners' progress in each test as well as each test item and an advisory report is also prepared for the learners to better facilitate their learning.

Another test that is implemented in the ERRL system is the equipment test. The main purpose of this test is to assess the learners' knowledge level on each piece of equipment. Learners are asked to pass this test before starting any experiment that requires specific equipment to be used. However, some skills such as the ability to handle the measurement devices may not be easily assessed. Accordingly, the questions are organized to focus on the equipment construction, how it works and the measurement possibilities. The equipment test content is prepared specific for each piece of equipment; however the testing system strategy is the same for the experiment tests.

V. DISCUSSIONS AND CONCLUSIONS

In this study, the learners' requirements specific to this case study have been collected and analyzed. The ERRL system has been developed based on these principles. The feedback from the sample groups from different countries demonstrated that the above principles are a good approach for the web-based learning and provided us the necessary certainty to continue the work in this direction. For future studies, this system is planned to be integrated into the curriculum and will evaluate the success of the system didactically by addressing these principles. Although these principles are developed according to this specific case study, it is believed that they can be improved and implemented into any web-based instructional system.

Currently we are adapting the ERRL system to curriculum of the related courses in the Electrical Engineering Program of the University by creating technology enhanced learning environments. In that context it is believed that this study will guide the instructional designers of such systems. Additionally, by establishing similar requirements analyzes, the educators may also adapt the ERRL system or other similar systems to their environments. Our preliminary results based on the created technology enhanced learning environments which is designed through the ERRL system according to the requirements of our learner groups, are promising.

Supporting Person-Centered Learning: Does the Choice of the Learning Management System Matter?

A case study with Moodle, Fronter and CEWebS

Abstract—**One challenge in the successful implementation of a blended learning scenario is the choice of the appropriate tools. The general question behind our practical approach is: "How well do different eLearning solutions provide functionality to realize a blended learning course, which is designed according to specific educational principles?" To approach a response to this question for our case, one typical person-centered blended learning course was implemented in three different eLearning solutions, namely Moodle, Fronter and CEWebS. The resulting realizations of the course and the necessary actions are documented and compared in this paper. The investigated eLearning platforms provided sufficient functionality to accomplish many of the basic tasks in the daily course routine more or less effectively. For tasks beyond the basic functionality of a solution, either the employment of extensions or customizations were necessary, resulting in an implementation that was in some aspects quite elaborated.**

Person-centered learning; blended learning; learning management systems

I. Introduction

In our understanding blended learning scenarios should be developed, in the first place, based upon specific learning paradigms and not on what a technological solution can offer. Since we aim to promote *person-centered, technology enhanced learning*, we see ourselves confronted with the question: Do current well known learning management systems sufficiently support person-centered learning designs?

PCTEL or Person-centered Technology Enhanced Learning [1], [2], [3] aims to facilitate a meaningful learning process by combining a humanistic, person-centered pedagogy with thoughtful use of eLearning technologies. In the PCTEL-approach learning is based on the values of humanistic-psychology developed by the renowned psychologist Carl Rogers [4] and on a deliberate use of eLearning-technology.

How does all this fit together? Can the person-centered approach be combined with technology enhanced learning in an enriching way? Learning is more likely *significant learning*, if it involves intellect and feelings [5]. The difficult issue with this concept is that the inclusion of feelings into a learning process does not happen automatically in a classroom environment. Inclusion of the whole person into the learning process is fostered by certain attitudes between teacher, professor or lecturer and his or her students. These basic attitudes are: *genuineness, acceptance* and *empathic understanding* [5]. Through living and communicating those attitudes so that learners can perceive them the teaching person becomes a facilitator who is providing a confident basis for significant learning.

In contrast, an eLearning situation lacks direct personal contact, but it can be employed to reduce administrative and organizational overhead and to make intellectual content easily accessible whenever learners request it [6]. Additionally online environments (e.g. communication boards) can provide space for exchanging ideas, opinions, feelings and meanings within the course community in a way that complements the socially rich but time-limited face-to-face meetings.

To sum up, person-centered scenarios benefit from the employment of eLearning elements by providing learning resources and by reducing administrative costs which allows for more person-centered communication in class, as well as supporting interaction between meetings. Consequently, in our case a central question arose: "*Which learning management systems meet the demands of person-centered technology enhanced learning scenarios best?"* An accompanying question would be: *"What are the major differences between various learning management systems in light of supporting person-centered blended learning?"*

The rest of the paper is organized as follows. Section 2 presents the methodology of this research. Section 3 details the case course structure whose three different implementations are discussed in detail in Section 4. Conclusions and final recommendations are given in Section 5.

II. Migrating an Online Course

Instead of analyzing the eLearning platforms with a fixed catalogue of criteria [7], [8] one typical course from the *Research Lab for Educational Technologies* was implemented in different eLearning environments. The underlying purpose of this approach was to focus on the implementation process, rather than on criteria analysis.

The example course was “Project Management”, which was conducted in the summer term of 2009 and initially delivered through CEWebS services. For the purpose of this research this course was migrated into a Moodle installation set up on a personal university Web space for testing Moodle, and into a testing course provided by the University’s computing centre for testing Fronter.

III. The Source Case Course – “Project Management”

The source case course for this migration, the course on project management, was conducted in the summer term 2009 at the Faculty of Computer Science of the University of Vienna as a combination of a lecture and lab course. The course was about learning the basic concepts in classical and agile management. Central topics were managing IT and interdisciplinary projects, controlling, cost estimation, risk analysis, organizational techniques and conflict management.

Students had to accomplish single and group assignments. The single assignments consisted of planning a small project, while the group assignments included planning of a bigger project according to predefined milestones and deliverables, and the development of a prototype.

The final student grade was composed of the results of the single assignment, the group project evaluation, several instructor evaluations of milestones, peer evaluations in the lab course and a final exam. A pattern-based blended learning scenario for project management modelled in UML is depicted in Fig. 1. Additional attributes of the patterns or so called stereotypes [6] are illustrated in Fig. 2.

A. Lectures

In the lecture (Fig. 3), lecturers and external guests from the field of project management held their lessons. Besides the presentations in class and publishing of lecture resources (e.g. PowerPoint slides) reaction sheets were employed.

Using the reaction sheets, reactions from students were collected online and taken into account in further proceeding of the course.

B. Lab Course

In addition to brief lab lectures and exercises (Fig. 4) a major task was the group assignment: Students were free to choose a project for being developed in groups of 2 - 5 persons.

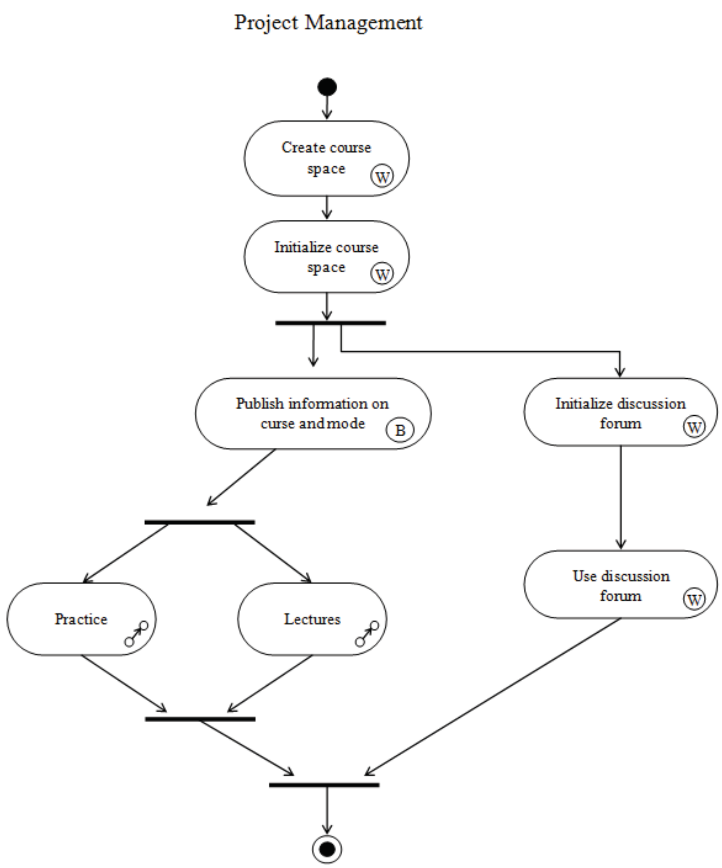

Figure 1. Activity sequence in Project management course

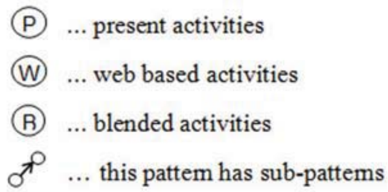

Figure 2. Stereotypes and their denotation

After a few weeks of development a peer evaluation was performed. The results of this evaluation were used to improve the reviewed projects. Additionally, each student worked on his or her own single project, which was reviewed by a tutor.

IV. Three Equivalent Solutions?

We briefly introduce the three eLearning solutions that are the subject of the case study. The course on project management had originally been developed for use with CEWebS and, vice versa, CEWebS had long before that been originally developed with PCTEL support in mind. Accordingly, we start with presenting the CEWebS implementation (Fig. 5) and proceed by discussing the transformations into Moodle and Fronter, respectively.

A. CEWebS

CEWebS stands for *Cooperative Environment Web Services* and was developed at Department of Knowledge and Business Engineering and the Research Lab for Educational Technologies at the University of Vienna [9].

The CEWebS-approach to provide an eLearning solution differs from the approach employed in the development of other learning management systems: *"Instead of relying on a central learning solution provider, we try to foster the exchange of tools and ideas on the organizational level"* [10].

CEWebS is a "homegrown" solution and it is built and adapted to the specific needs of the Department of Knowledge and Business Engineering and the Research Lab for supporting courses in a way to support person-centered, but also other interactive blended learning courses. Since the winter term of 2003 more than 100 courses (their eLearning components) have been delivered in CEWebS.

B. Migration to Moodle

Moodle is Open Source software and licensed under the GNU General Public License and therefore it might be altered, which makes it easy to be adopted or expanded for one's own purposes. The migration of the case course to Moodle was performed using version 1.9.5+.

While transferring the course on project management to Moodle we had to analyze the possibilities of this platform to support various aspects of person-centered learning and the development of specific activities needed for our case course.

- *User roles:* Standard user roles in Moodle match the following roles in CEWebS: the *Administrator* and *Course Conductor* are one role in CEWebS and correspond to the *Administrator* role in Moodle; other user roles in CEWebS are divided into two possibilities – either a user is assigned to a group, then the user-role is comparable with the *student role* in Moodle or if the user doesn't belong to a group, he or she is treated as guest. Additionally, Moodle allows the creation of a custom hierarchy of roles that can be assigned to users at the site, course or individual activity level.
- *Basic information providing - Wiki, Webpage, Lessons:* The basic idea of providing information in CEWebS is realized through a Wiki. In Moodle either a Wiki, linked Webpage or the Lesson module can be used for this purpose. The Lesson module seems to be the most appropriate one, because of its richest text-design possibilities.
- *Grouping of content:* Grouping of content in Moodle can be achieved by adding a Webpage resource, which offers links to the corresponding resources. To avoid that too much information is displayed, content can be placed in outlying sections (e.g. the course admin can create some reaction sheets in *section 7* and then limit the number of topics to two, so only *section 1* and *section 2* will be displayed – still the reactions sheets are available and can be referenced by a hyperlink). There are also some third-party plug-ins that can provide course structures which serve the similar purpose a bit more automatically.
- *Participants – Groups:* For sending mass-mails the most appropriate Moodle functionality is "add/send message" available in the overview of the participants.

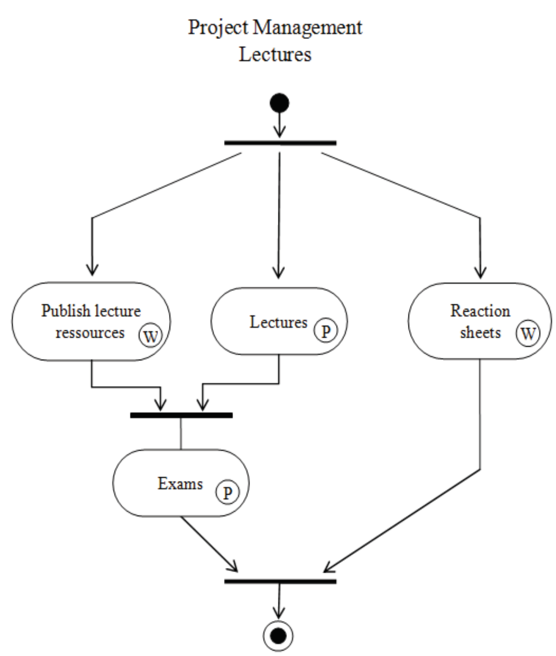

Figure 3. Activity sequence for reading lectures (VO) in Project Management course

Forums can also be used for distributing important bits of information to all subscribed students (students who opted for receiving copies of all the posts from particular forums via e-mail).

In Moodle there is a built-in tool to create groups. With the experimental feature called *"groupings"* groups within groups might be created. An even more differentiated group management, which is similar to the CEWebS group management, is achieved by using an additional Moodle plug-in [11]. With the help of this plug-in users are able to assign, move and remove themselves to/from groups. In order for students to assign or remove their colleagues to/from groups slightly stronger editing privileges concerning user accounts have to be assigned to them at the course level.

- *Assignments:* In our course on project management students have to upload their work, so that it can be reviewed by the lecturer, tutor or course conductor. Therefore a service is provided in CEWebS. In Moodle this task is achieved by using the *Advanced Assignments* activity module, where single user uploads are possible either as individual assignments or as uploads of a solution for whole groups. Group uploads might be carried out by all group members, but with an extra plug-in, with a possible limit to one upload per group [12].

  Although Moodle's Assignment tool seems to be the best match for any assignments at the first glance, this instrument cannot provide a feature that allows students to take a look into other students' solutions. This can be solved by using other built-in tools like *Workshop* or *Database*. Workshops are particularly convenient if peer assessment amongst students is to be conducted.

- *ePortfolios:* ePortfolios can be implemented in Moodle using a plug-in provided by Exabis Internet Solutions [13]. Unlike in CEWebS, when using this plug-in students can decide whether they want to share their portfolios with other course participants or not.

- *Reaction sheets:* CEWebS provides a comfortable way to collect the reactions of course participants. In Moodle reaction sheets are either realized by using *Online text* assignments or using the *Feedback* module. This is a third-party module that will be included in the standard package in version 2.0. It is quite suitable for creating different kinds of more or less complex questionnaires. It also enables the students to view the results of these questionnaires, not only the teachers. If reaction sheets are implemented as simple online text assignments they cannot be displayed to all students.

- *Discussions:* A discussion is simply realized by using a forum. If more forums are needed they might be grouped as described under *Grouping of content* as one initial menu item.

Once the user is accustomed to the amount of options and features, Moodle is easy to use and straightforward. However, special adoptions in the course design to meet communicative and person-centered-supporting requirements are sometimes a bit tricky. Nevertheless, additional modules or plug-ins can be installed easily. Further customization is possible by altering or extending the source code, though rather resource-consuming. Therefore, the preferable method of fulfilling this platform with all features needed to implement a course like Project management is the smart use of built-in features together with various extensions. Including useful plug-ins in the platform or integrating external applications can contribute to success, but it certainly leaves a lot of potential for further improvements on this platform [14].

C. Migration to Fronter

The migration of contents to Fronter was conducted with Vienna University's Fronter Installation provided by the ZID [15].

"Fronter is a virtual building, structured into rooms. Each room is equipped with the tools required to empower the collaboration and learning activity in that room. The room owner invites members and assigns rights according to each member's role in the room." [16]

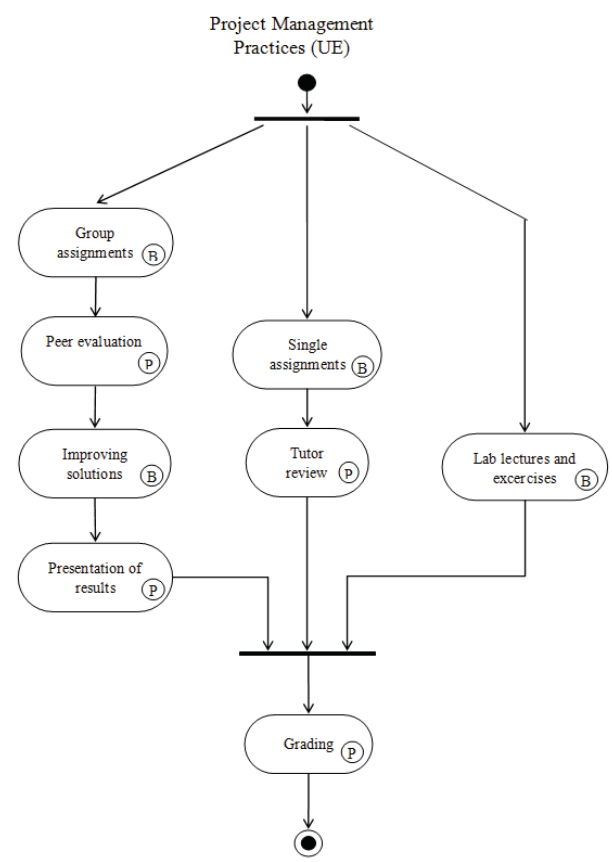

Figure 4. Activity sequence for practice (UE) in Project Management course

While transferring the course on project management to Fronter the possibilities of this platform to support various aspects of person-centered learning were analyzed in detail.

- *User roles:* The user roles in Fronter are, at least in the configuration from the ZID, divided into *lecturers, students* and *tutors.* Tutors have in the default case the same privileges as lecturers.
- *Basic information providing - Wiki, Documents:* Information can be provided as a page, article message or wiki. Sites might be designed and placed within the content-frame in different positions. It is also possible to add and remove site elements.
- *Grouping of content:* Fronter has the ability to use folders within many tools (e.g. discussion boards, resources) so grouping is done in a similar way as with CEWebS and more easily achieved than in Moodle.
- *Participants – Groups:* The participant information can be explicitly displayed in Fronter under the specified menu-item. Mass-mails can also be sent easily to all course participants.
- *Assignments:* User uploads are realized with the specialized tool. Users simply upload their solutions and lecturers are provided with the possibility to comment and rate the uploaded solutions.
- *ePortfolios:* Fronter's ePortfolio feature allows unrestricted visibility of the attainments of all course participants (not only teachers can see them or students who share their profiles with each other). The emphasis lies on a reporting functionality, but a satisfying handling of achievements is possible as well.
- *Reaction sheets:* Although Fronter has some features to upload text (for collecting reactions) or to conduct surveys these tools are not sufficient to manage those tasks in a straightforward way. Especially the survey tool cannot be used to implement questionnaires. So in this respect Fronter is not applicable.
- *Discussions:* A discussion is simply realized by using a forum. Different forums are easy to create and might also be organized in folders.

In general Fronter is easy to use and designed properly. However, Fronter is limited to its set of features and cannot be customized or extended as it is proprietary software, although it is presented as *Open Source* in the brochure published by the manufacturer [16]. Fronter, in our perception, lacks the ability to collect reactions from students in a *straightforward* way.

In Moodle even slighter shortcomings were solved with workarounds or extensions. In Fronter this is, thanks to the closed source policy not possible. However, if a learning scenario fits in with the technological possibilities offered by Fronter, the latter can be very productive. Still, we pose the question: Is it appropriate that the availability of a technological solution should guide the learning design?

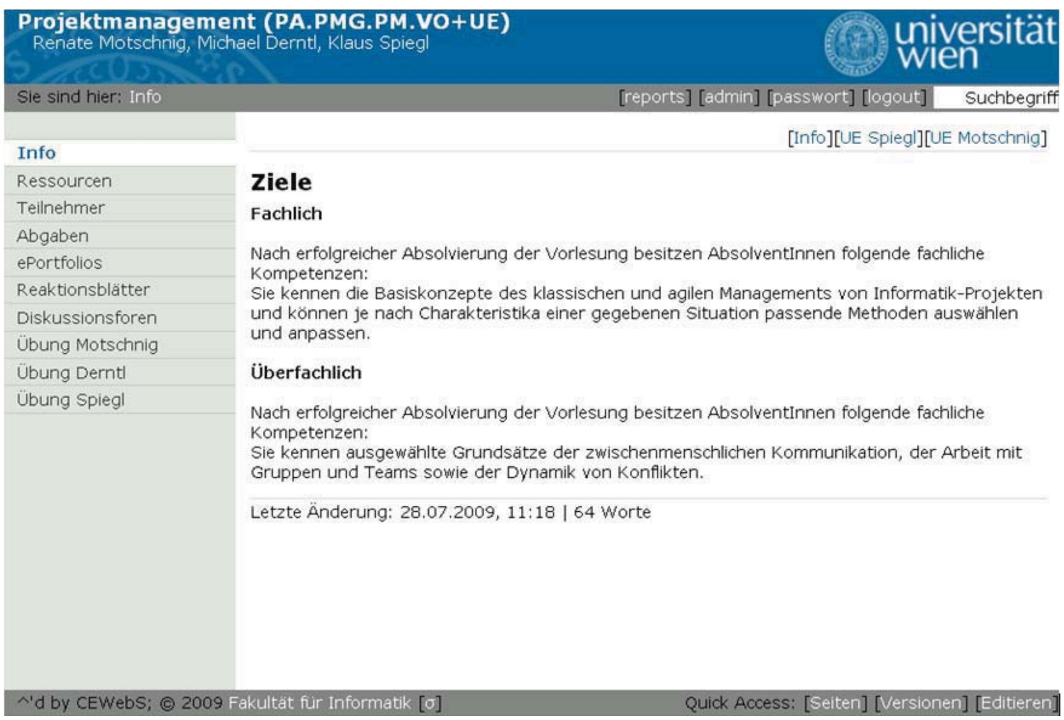

Figure 5. Screenshot of Project Management course in CEWebS

V. Conclusions

A successful implementation of a blended learning scenario according to the pedagogical and didactical principles of a person-centered approach was found to be - in an effective way - dependent on the choice of an appropriate eLearning solution.

Implementing an actual course in the field of project management was, from a technological point of view, in Moodle fully and in Fronter partly successful. Moodle provided several features and a good level of configuration for workarounds. Thanks to Moodle's Open Source license and numerous community contributions a course in Moodle was technically equal to a course in CEWebS. Fronter lacked some features, like the reaction sheets and was, because of its proprietary license, neither adaptable nor extensible. Fronter still might be a good choice for many standard blended learning scenarios.

From a practical point of view, however, the realization of the course on project management in Moodle and in Fronter did not completely satisfy the specific needs of a person-centered course design. Indeed Moodle provided enough features and usability, so that from a student's perspective, there would be – except from different interface design – no big difference. Nevertheless, an instructor would have to use some elaborated workarounds and customized extensions. All in all a lot of work had to be done to realize such a course. In Fronter not too much extra workload for the course designer arose, because a one-to-one implementation of the course was not fully possible.

Fronter provides well designed learning workflows and many specialized easy-to-use tools. As such it seems to be optimized for a defined learning purpose. Even if such a learning purpose is broadly and well defined, it cannot cover all learning approaches. In our case a person-centered approach was not completely implementable in this environment. In general it seems that for non-standard learning approaches the flexibility and openness of Open Source solutions remains indispensible.

The authors' personal conclusion regarding the migration to Moodle is that many elements of a course can be realized right away, but if you need more than a usual learning management system can offer, a more or less time consuming search for additional solutions becomes necessary. This fact was indeed an enriching experience. However, in certain stages the knowledge of experts turned out very helpful to accelerate the solution of problems and to point out new, even more elegant and practicable solutions. Moodle is without doubt a valid alternative to a specialized platform like CEWebS, but as long as the best fitting solution is supported and updated regularly, there is no need to "change the winning team". Trying to generalize our findings for a broader audience, differences in usability would even weigh more if students and instructors had less technical expertise.

Although eLearning technologies underwent a rapid development in the last years, the choice of an adequate solution is still an essential step in a successful and effective realization of a blended learning course. Especially in the field of eLearning technologies, the knowledge of experts proves once again as a time-saving and enriching enhancement to own efforts.

Abstract—**Since the beginning of men, knowledge distinguishes us as a species and has become the key to our own evolution. Humans have a complex psycho-pedagogic model, the result of millions of years of evolution. This model compromises very often the educational structures, because each of us – despite we can be inserted in specific groups, have a personal learning curve. Like nature, that develops special strategies for the evolution of the species, it is possible to find the correct individual learning path, using one of the oldest Mother Nature mechanisms – evolutive genetic. Using tools like JAVA, XML (eXtensible Markup Language), an open source LMS (Learning Management System), i.e. Moodle, a standard as SCORM (Sharable Content Reference Model), all controlled by a GA (Genetic Algorithm), it is possible to achieve a flexible platform to help all the educational process actors. The goal is to create a self universal monitoring and learning system,which follows the progression of individual learning – by using a mathematical function applied to a genetic algorithm, maximizing the results and achieve the subject "learning curve".**

Keywords: Java, XML, SCORM, Genetic Algorithm

I. Introduction

In current societies the growing need for a fast acquisition of knowledge, as well as the need to maintain the one already acquired, has led to the birth of various concepts of learning, such as the E-Learning.

However, the proliferation of various platforms and associated philosophies has not always achieved a full interaction between those who are learning and those who are transmitting the knowledge. The fast pace of modern life does not allow us the time to attend assisted classes and the aversion older people tend to feel towards new technologies are determinant factors for the global results not matching the expectations when it comes to the learning process.

In this article, the authors suggest a new transversal approach to the concept of E-Learning by using GA, Java and a LMS, SCORM compatible, thus fully innovating the applicability of the concept of E-Learning, taking it to a whole new level.

2nd Section – Presents the GA structure, and the statistic support function.

3rd Section – Presents the KB and the communication path structure between the LMS, the GA and the user.

4th Section – Presents the objectives and conclusions of the work done until now.

II. The Genetic Algorithm

The genetic algorithm has an important role in implementing this solution, since its performance will greatly affect the final results. It should be as dynamic as possible in order to achieve various goals, according to the predetermined guidelines. This should be achieved by giving weights to the cognitive profile or profiles, which are meant to be improved. The basic idea is to get the "fitness function" to be improved as much as possible in order to get a better approach to the most correct Knowledge Block, according to the previously achieved results.

The student results after an activities sequence build a set of binary values. The idea is to maximize the minimum obtained by the individual, i.e., find what difficulties are visible and redirect all the intellectual effort to overcome the problems, never forgetting the positive objectives already achieved.

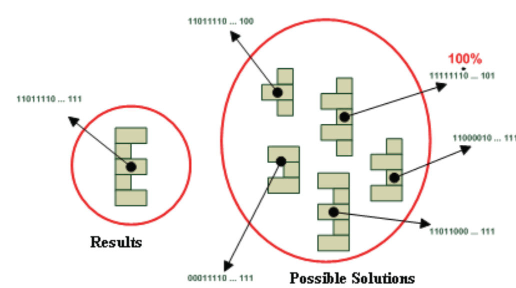

Fig. 1 – Binary correspondence of the population and possible solutions

The GA will select the KB that matches the student's difficulties. If the match is not 100% exact, 80% will be considered a fair value in the acquisition of the new block.

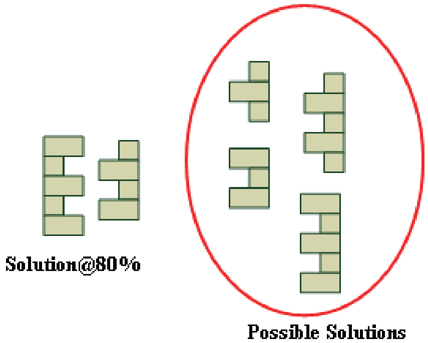

Fig. 2 - Solution @ 80%

The 100% match will be an ideal situation that the GA mechanisms will try to achieve.

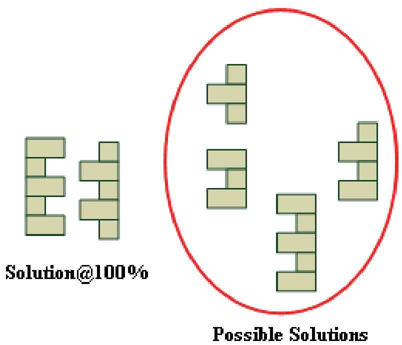

Fig. 3 – Solution @ 100%

This ideal situation will be only achieved after several cycles of study of the behavior of the individual. This ideal situation is also dependent on the availability of the block that has the desired binary value.

A. The Statistic Support Function

The chi-square is defined as a discrepancy measure between the observed frequencies and the expected ones (Fig. 4). [1]

$$Q = \sum_{i=1}^{k} X_i^2$$

Fig. 4 – Chi-square distribution

The GA uses this discrepancy measure, as its evaluation function. The obtained value will be used as a weight, to select the best candidate block.

$$x^2 = \frac{(o_1 - e_1)^2}{ej} + \frac{(o_2 - e_2)^2}{ej} + \ldots + \frac{(o_k - e_k)^2}{ej} = \sum_{j=1}^{k} \frac{(o_j - e_1)^2}{ej}$$

Fig. 5 – Chi-square distribution in extended form

The two observation tables (Fig. 6), represents a possible situation of what is sought as a final value - the expected, and that in "simulated reality" is obtained - obtained. The difference between what is expected and what we get is the deviation that must be compensated to achieve the objective - the expected value. In the simulation (Fig. 6), there are two blocks to simulate a process of classifying a given knowledge block. As it is observed in the (Fig. 6) illustration, χ^2 suffered a decrease from the 1st to 2nd KB, which can be understood as an improvement in the GA orientation, as the 2nd block to approach more of the individual's cognitive reality. It is still observed - and in spite of the illustration represents a random simulation of what is desired, that the orientation of GA is forced immediately when the discrepancies between expected values and obtained values are significant (between points 5 and 7 in the χ axis in the graph to the right, and between 5 and 8 in the graph to the left).

The theory is based mainly on the following two assumptions:

- H_0 is ignored until the learning curve of the individual is understood;

- H_0 is considered for future evolutionary terms after 1st premise has been achieved;

The use of the two hypotheses is due to the fact that the 1st objective is to understand the cognitive reality of the individual, and then improve it.

B. Algorithm for Individual Cognitive Sequence (10 samples example)

(1) Establish objective to be reached (0-100% or 0-20);

(2) Start ranking process (w/ sample = target);

(3) Get cognitive binary of the individual;

(4) Perform statistical operation on results;

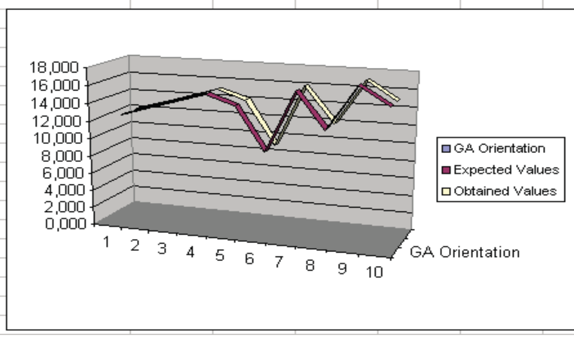
(9) Repeat (1) at least 9x (or as desired);

(10) Get Final Sum;

(11) Apply acquired weight (next module=objective to be achieved + obtained weight);

(12) Repeat (1) N times until obtain binary or objective;

Theoretical Cognitive Evolution Model - Memorization (Based in Chi-Square)												
	Observations										Average	
Obtained Values	12	13	14	15	14	13	10	12	17	15	13,5	
Expected Values	14	13	14	15	16	15	14	14	15	16	15	
	0,29	0,00	0,00	0,00	0,25	0,27	1,14	0,29	0,27	0,06	2,560	GA Orientation
Obtained Values	12	13	14	15	14	9	16	12	17	15	13,70	
Expected Values	12	13	14	15	14	9	16	12	17	15	13,70	
	0,00	0,00	0,00	0,00	0,00	0,00	0,00	0,00	0,00	0,00	0,000	GA Orientation



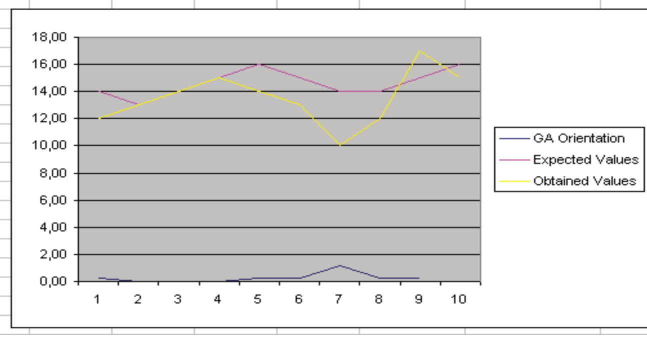


Fig. 6 – Theoretical Cognitive Evolution Model – Memorization

The algorithm begins by setting up a target, regardless of prior knowledge of the cognitive profile of the individual. The sequence (1 to 4) will be repeated at least 10 times and the value statistically treated to obtain a weight. The result will be used in obtaining the next module by the GA, with the aim to get closer to the maximum desired.

III. The knowledge block

The Knowledge Block (KB) is a simple structure that has SCORM compatibility and a binary codification, allowing the GA to be the most suitable choice to which specific case.

TABLE I. KB Coding

Reserved for Future Use	***Educational Level***	***Cognitive Profile ID***	***KB difficulty level***
00000000	00000	000	0000000000000000

Regardless of the used operator – crossover, mutation or both, 16 bits are up front considered enough for a KB selection to be uploaded in the LMS, without the risk of a premature convergence into a specific solution by the GA.

TABLE II. KB Difficulty Level

Binary Value	***Decimal Value***
0000000000000000	0
…	…
111010111000110	9,20 ≈
…	…
1100110000000110	15,94 ≈
…	…
1111111111111111	20

$$20_{10} - <65535_{10}><1111111111111111_{2}>$$
$$9{,}20_{10} - <X_{10}><Y_{2}>$$

$$X = <30150_{10}><111010111000110_{2}>$$

After being provided the results in decimal base, by the GA, those will be converted by an internal mechanism - a 3 simple rule in order to achieve the corresponding binary value of KB closer to the desired.

TABLE III. KB Cognitive Profile ID

Cognitive Profile	***Binary Representation***
Logical-Mathematical	000
Linguistic	001
Musical	010
Spatial	011
Naturalist	100

Considering that of the 10 (ten) cognitive profiles universally recognized [2], only 5 (five) will be subject to analysis, since the remaining four – Corporal, Intrapersonal, Interpersonal and Existential can not be considered in the context of this work, because they are virtually impossible to quantify due to their strong abstract nature, we therefore will need only a 3 bit code to represent them.

TABLE IV. KB EDUCATIONAL LEVEL

Educational Level	*Binary Representation*

Bachelor's	01000
…	…

In a similar way, the remaining 5 bits will identify the educational level best befitting the KB. The choice of such a wide identifier has to do with the possibility of reaching 32 possible levels of identification, in a specific educational system. In Portugal, these values can easily go up to 23 levels. The exchange of all the information between KB and GA will be made through XML files. The LMS, in turn, will provide the user with the KBs appointed by the GA, in a dynamic way, changing the links, according to the information received.

```
<language>
      <typename>
            <tysource sourcetype="imsdefault"/>
      <tyvalue>German</tyvalue>
      </typename>
      <contentype>
            <referential>

                  <indexid>language_01</indexid>
            </referential>
      </contentype>
      <proficiency profmode="OralSpeak">Excellent</proficiency>
      <proficiency profmode="OralComp">Excellent</proficiency>
      <proficiency profmode="Read">Good</proficiency>
      <proficiency profmode="Write">Poor</proficiency>
</language>
```

Fig. 7 – XML example of a record containing information of classifications

The exchange of all the information between KB and GA will be made through XML files (Fig. 7) [3]. The LMS, in turn, will provide the user with the KBs appointed by the GA, in a dynamic way, changing the links, according to the information received.

IV. OBJECTIVES

The authors aim at implementing a new paradigm, creating a system that, in most cases, will manage without the physical presence of a tutor. It will allow the student to have greater flexibility in learning, since there will be an exclusively – if it is so desired – man-machine interaction, with no third party involved, thus reducing certain constraints to progress, that might occur should it be done under the traditional methods.

V. CONCLUSION

The theoretic part of the work is ready. The authors have already designed all the interactions and mechanisms that will allow to proceed to the development phase. Field-testing will occur during this development. There is already a partner – a local kindergarten which has volunteered to test the GA results. In the future, it will be taken into account the possibility of this solution to include the capacity to make several choices of KBs, allowing the improvement of two or more cognitive profiles.

Abstract—**This paper presents investigations on formal and informal requirements for personal learning environments taking into account students' personal and social learning practices. The potential of global Web 2.0 educational service bundles and informal learning communities, as well as their recommendation by educators are addressed. A scenario showing how these new paradigms can be integrated in engineering education as a way to bring together personal and social learning practices is drawn.**

Web 2.0; Personal Learning Environments; Mash up; Social Learning; Personal Learning; Educational Widgets; Learning Communities

I. Introduction

A hidden revolution in higher engineering education is currently underway for multiple reasons. First, the students entering the university are digital natives often with higher technical skills than their educators, who are digital immigrants. Second, Web 2.0 technologies enable students to mash up the learning resources, the learning services and the learning communities of their choice. The same technologies also enable educators to move from blended learning approaches to blended contents (blogs, wiki, repositories) and blended learning environments called personal learning environments [1]. Such environments will progressively replace, or at least complement, learning management systems (LMS) in the coming years in a move towards personal and social learning environments. Third, students can access open learning repositories outside their institutions.

The opportunity for students to build their own learning environments or socio-academic contexts, as well as their own learning networks or communities has always existed at a local level (campus or hometown). People enrolled in the same study programs or courses are used to meeting in social settings to do homework or prepare exams. With the above-mentioned trends, higher engineering education institutions should have a closer look at these informal personal and social spaces and practices, which are expending at a global scale and are giving students access to an unlimited realm of potentially valuable resources and experts. In addition, educational scientists consider the construction of learning environments and the integration of learning communities as being an integral part of the learning process. Especially, it helps students to develop the high-level skills and competences required by their future employers. Hence, a challenge for academic institutions is to integrate in a proper way the students' practices and environments in the existing institutional ones in order to take advantage of them. Another challenge is to support the students in their informal learning practices and in the construction of their learning environments and networks as a next step in increasing digital literacy. Students nowadays need recommendation regarding trusty resources and networks that go beyond the traditional brick-and-mortar universities.

The ROLE European integrated research project (http://www.role-project.eu/) has been investigating since February 2009 the interplay between personal learning and personal learning environments. 16 partners with educational, technological and commercial background collaborate in a multidisciplinary and intercultural manner to sketch the next generation of personal learning environments that can contribute to changes in the education paradigm as described in Sections II and III. The rest of the paper concentrates on results regarding formal and informal requirements for personal learning environments (Sections IV, V and VI), taking into account the peculiarities of personal and social learning. The potential of Web 2.0 service bundles and their recommendation by educators are tackled [2]. A prototype of novel social software fulfilling part of the elicited requirements is described in Section VII. A scenario for integrating these new paradigms in engineering education is drawn in Section VIII before concluding in Section IX.

II. User-centered Perspective

The current practice in higher education for faculty members struggling to increase their h-index [3] (or any other fashionable academic metrics) is to concentrate on lectures and a few office hours. Lecturing is the most effective approach from an administrative (well recognized duty) and teaching (best return on effort ratio) point of view. However, its impact on students' learning (knowledge and competences acquisition and consolidation) is rather limited. As a consequence, most of students' learning activities occur through personal work; partially with the help of teaching assistants. In the last 2 decades, technologies were introduced mainly to extend the classroom reach. Nowadays, some lectures are podcasted as example in *iTunes U* and *PowerPoint*-like presentations are made available on institutional LMS. In the latter, the students can also post their homework assignments without heavy involvement of teachers or institutional staff. Additional interaction occurs between students and educators through email and course-related blogs. Recently, in a move to develop the acquisition of high-level skills and competences, more active learning opportunities like labwork or teamwork have been introduced and are supported by relevant technologies, which are also often integrated in LMS. Due to the lack of adequate institutional resources, the support for such activities – which are highly demanding in terms of coaching – is unfortunately not always sufficient.

To compensate for their increasing isolation [4] and the standardization of the resources, which result from the presence of LMS or just from the lack of sufficient face-to-face interaction with educators, the students are relying more and more on peers and technology of their choice to manage and complete their learning activities in a self-directed manner. As pointed out by Attwell [1], *Google* is the most used e-learning platform in such a context where students are struggling to find relevant and personalized resources [5] and support.

This trend is counterproductive for both the institutions and the learners. The institutions are undermining their reputation and their attractiveness by losing the control on the resources and their usage. The learners, especially the ones with little social network and limited digital literacy, waste their time in unproductive search rather than focusing on productive activities.

Fortunately and thanks to the spreading of social software platforms and open learning repositories, there is currently an opportunity for institutions and learners to establish a stimulating and constructive interaction to strengthen learning and increase effectiveness. The idea is not for the institutions to invade the social space of the learners, but rather to promote trusty resources and academic presence that can be integrated by the learners themselves in their own spaces and own communities [6].

There are several challenges associated with such a move. First, the social spaces of the students have to be better understood, especially their relations with informal or self-directed learning [7]. Second, one has to evaluate how engineering education resources can be integrated in such spaces without destroying their unique personal and social nature. In other words, could those personal environments be turned into personal learning environments [8]? Third, all the necessary features to turn personal environments into personal learning ones have to be elicited, taking into account the necessary bridges to link the digital Web 2.0 realm and the physical world that coexist when blending formal and informal education. Finally, the roles the educators and the institutions have to play with respect to this evolution have to be reconsidered carefully. This paper focuses on the third issue, which is discussed in the next sections.

III. PERSONAL LEARNING ENVIRONMENTS

Personal Learning Environments (PLE) are not monolithic systems. They can be simply a set of devices, tools, applications, and physical or virtual spaces associated by learners at a specific time, for a specific purpose, and in a given context. A student's desk covered by books and notes, combined with a computer holding a collection of slides and documents with the associated applications for reading and editing, integrating a browser to access the Web or just the institutional LMS, is already a PLE. Such PLE, even though effective, is yet to reap potential benefits of customization and collaboration offered by Web 2.0 technologies. In this paper, we focus especially on the exploration and exploitation of new Web 2.0 features that strengthen the role of the social repositories and communities in self-directed learning, enabling learners to assemble and customize even more effective PLEs. As a consequence, end-user Web 2.0 services, online social spaces and shared applications are especially investigated, with a special focus on platforms where they can be aggregated, integrated, or mashed up.

Approaches and standards for the aggregation and the integration of Web 2.0 components as PLE services bundles have been investigated with an emphasis on interoperability issues [9]. Mashup platforms like *iGoogle* (www.google.com) or *Netvibes* (www.netvibes.com) also show a high potential to be exploited as Web 2.0 PLEs. In such framework, Web 2.0 components or services bundled together are often widgets or similar Web artifacts.

As the integration of PLEs relies on tools, artifacts and people collected or invited by users from the whole Webosphere, trust in the quality of the resources, the security of the distributed information storage (especially for personal and competence-related information) and the reputation of the providers or the communities are instrumental in enabling the self-directed repurposing of Web 2.0 spaces and services for learning.

IV. REQUIREMENTS ANALYSIS APPROACHES AND HYPOTHESES

The design and deployment of Web 2.0 PLEs is a completely new design paradigm for three reasons. First, PLEs are not end products; they are rather contexts or spaces continuously crafted and personalized by individuals according to their goals, interests, activities and even mood. They are not controlled by designers, service providers, or Web masters, but by end users. The role of third parties is somehow limited to providing users with convenient integration and customization solutions. Second, the design and integration processes themselves as well as the appropriation of the PLEs are part of the underlying social or learning activities. In this perspective, design and integration cannot be decoupled from socializing, interaction or learning. Third, PLEs are not just collection of artifacts; they can also integrate individuals, groups and communities that impact their nature, features, and evolving structure. Finally, one should underline that PLEs are not unique, even for a given individual. People continuously move from one PLE to another when migrating to different learning contexts. The continuity of the activities, especially the learning activities, has to be ensured and sustained not only within a PLE, but also across PLEs if learners wish to do so. Conversely, learners may also want to keep a clear separation between some of their PLEs and the associated groups or communities. This vision of the exploitation of Web-based mashed-up PLEs in a personal learning framework constitutes the underlying hypotheses for requirements elicitation as presented in the next section.

In the ROLE European project mentioned in Section I, a multidimensional approach has been implemented to elicit the functional and non-functional requirements of personal learning environments. A range of conventional as well as emergent methods and tools for capturing and analyzing requirements have been deployed, including Web-based focus groups (testbed-oriented, longitudinal studies), workshops, questionnaires, interviews, and online communities of practice (CoP). Specifically, focus groups and CoP are consistent with the principles of participatory design, which is underpinned by the philosophy of user-centered design. Furthermore, CoP aligns with the emerging social requirements engineering approach [10][11]. Whilst the requirements engineering process in ROLE is ongoing, some interesting findings could already be derived from two workshops conducted and will be elaborated subsequently.

V. Requirements Analysis: Preliminary Findings

Instead of carrying out long ethnographical field studies with learners, a hybrid strategy employing both top-down (e.g., expert reviews) and bottom-up approaches (i.e., end-user focus groups) has been adopted. The intention is to actively involve all stakeholders during the entire design and development process. Scientific discourses among experienced researchers and practitioners in the field of technology enhanced learning (TEL) have been conducted through workshops and interviews. One of the workshops was held in May 2009 in which 26 ROLE project partners were involved to share their ideas and visions about responsive open learning environments. The academic backgrounds of the workshop participants were heterogeneous, including engineering, computer science, mathematics, education, psychology, management, etc. Most of them were experienced in interdisciplinary collaborations in the context of TEL. In the workshop, a series of short presentations outlining the main concepts of respective visions were followed by small group discussions where participants were asked to complete a template to describe pedagogical and technical approaches that were deemed essential for responsive open learning environments and to derive requirements from the descriptions.

The workshop materials were analyzed. Interestingly enough, during the presentations and discussions, the term personal learning environment was employed so frequently that it almost became synonymous with responsive open learning environment. However, strictly speaking, there are nuances between these two closely related notions. Here we do not delve into deeper discussion on this issue, but draw on the outcomes of the workshop that has incidentally set its focus on PLEs. The range of approaches and issues addressed during the workshop was diverse. Most commonly mentioned pedagogical and technical concepts for personal learning environments are depicted in Figure 1 and Figure 2 in the form of tag clouds, respectively. Considering the scope of the paper, we discuss only those that are highlighted in both figures.

The most important pedagogical aspect pointed out by the workshop participants is the integration of PLEs in a self-directed or self-regulated (the subtle differences between these two terms are out of the scope of this paper) learning framework where the communities play a critical role, as illustrated by the terms 'community-based', 'collaborative' and 'social'. The term 'activity-based learning' covers both individual and collaborative aspects of learning activities. Closely associated with the key concern of self-regulated learning is motivation. The term 'adaptive' has instigated interesting discussions about user-driven vs. system-driven recommendation.

The most important technical aspect pointed out by the experts is the usability of PLE widgets in a free integration framework. Not surprisingly, 'Web 2.0' and the associated concept of 'collective intelligence' are among the frequently mentioned technical terms. Open standards such as OpenSocial and XMPP (Extensible Messaging and Presence Protocol) were addressed alongside with the discussion about semantic interoperability. The term "cockpit" is used metaphorically to refer to the typical graphical user interface template of mash up platforms.

Figure 1. Tag cloud of pedagogical approaches relevant to PLE deployment.

Figure 2. Tag cloud of technical approaches relevant to PLE deployment.

Some interesting discussions also occurred regarding the necessity and the way to integrate learning paths or sequences of activities (as considered in pedagogical design) in a self-directed learning and PLE framework. No consensus emerged on this issue. However, this discussion led to a clear implication that PLEs are not persistent environments. They should evolve according to the learner's objectives and achievements, as well as competence management requirements.

In a follow-up workshop held in July 2009, twelve PLE and technology enhanced learning experts from all around the world external to the ROLE project helped to better specify key PLE features by contributing to the requirements elicitation and refinement process. They, together with 21 ROLE project partners, discussed in detail the two key concepts: *responsiveness* and *openness*. Specifically, the notion of PLE responsiveness was defined as "the ability of the learner to successfully configure the learning environment based on recommendations, adaptations and personalization". As adaptive learning systems strongly rely on centralized user models and learning styles, it appears that system-driven adaptive features should not be a priority in PLEs. It could even be counter productive to their success by giving the impression to the learners that they lose control. As a conclusion, a stronger focus on user-driven recommendation and personalization (preferences) should be considered.

Results from analyzing the data collected in the aforementioned two workshops corroborate the assumption about the need to enrich or even replace monolithic learning environments with a highly flexible, responsive and customizable environment according to the needs of the learner. The data analysis has also led to the initial set of pedagogical and technological requirements for the ROLE project. Pedagogically, it is important to incorporate design decisions around the concepts of self-regulated learning [12] with the intention to foster communities of practices. However, the range of learning tools, content, communities and services on the Web are so huge that it could become an overwhelmingly challenging task for a learner to decide what to use when, how and why. Hence, ROLE aims to provide learners with support for building a personal learning environment and learning with it in a pedagogically meaningful way. One way currently considered by ROLE is to provide users with pre-built PLE templates accompanied with screencasts showing how and why the templates can be assembled. Traditionally, learners within formal educational environment are used to instructor-led, organisational monolithic learning environments. Over the years, this didactic approach has given way to a more constructive self-regulated learning approach to facilitate life long learning. Technologically, an architecture and interoperability framework enabling the composition and federation of different learning services is required. An approach to integrating services, tools, and data relevant for a learner is deemed necessary as well.

Of particular importance is the notion of *usability*, which was regarded by most of the workshop participants as a very significant quality attribute for the integrated learning services and other outcomes of ROLE. Specifically, a comment from one of the PLE experts highlights the concern*:"…. even if you can solve the deliverability problems it would be great but some people can't deal with a PLE, how do they construct it….".* However, a usability study performed by Silva and Dix [13] indicates that the popular social networking website *YouTube* has some major usability issues despite its popularity. Paradoxically, user satisfaction is nevertheless acceptably high; it thus raises a question on the necessity of rigorous usability. This claim is confronted with an counterargument put forward by Rigutti and Paoletti [14] who suggest that users might overlook the usability factor when a technology is new, satisfies their needs and there are no competing products. However, as the technology matures and more products are developed, products that are highly usable will sustain. Through ROLE we are attempting to deliver a novel approach wherein learners will be able to assemble their own PLEs. As this is a new approach to learning in a more de-centralized form, the uptake of such an approach at an early stage is critical.

Through the different requirements capturing activities mentioned above, a set of testbed-specific and some general use cases have been documented. Consequently, about 50 functional and 15 non-functional requirements (e.g. usability, privacy, trust, security) have been identified. The functional requirements are sub-divided into three groups in terms of service types: learning domain/planning (e.g. assessment, tracking), core (e.g. authentication, authorization), and communication/collaboration (e.g. chat, calendaring). It is imperative to prioritize these requirements, thereby enabling the development teams to manage their tasks efficiently and effectively. We have adapted the Kano analysis approach [15]. Accordingly, requirements should be prioritized with regard to user satisfaction – a quality dimension that is upheld in the ROLE project. With the simplified analysis scheme, we have categorized each requirement with one of two values – "must have" and "recommended". As requirements capture, analysis and validation will be a continuous process throughout the project's lifetime, the preliminary findings reported above will be subject to further refinement.

VI. PARTICIPATORY DESIGN

Concurrently with the conversations between experts, five testbeds of complementary nature have been selected to elicit requirements at transitions between various learning settings. In these testbeds, a participatory design approach [16] is implemented under the collaboration of testbed coordinators, learner representatives, educational experts, and potential services providers to offer prototypes of PLE service bundles that could fulfill learners' expectations and strengthen their current practices. It has been demonstrated in previous similar initiatives that a proper selection of the stakeholders for the participatory design implementation is essential [17]. Especially, user and service mediators with similar decision power have to be selected to enable balanced negotiation of meaning [18] and construction of usefulness [19] regarding the requested services by the users or proposed services by the development teams. This process is also instrumental for the appropriation and the organic spreading of the solutions on the Webosphere.

Three testbeds related to higher education are discussed below. The two other testbeds are related to professional learning and are consequently outside the scope of this paper. One should however mention that a clear requirement of one of the two omitted testbeds is the necessity to make the LMS interoperable with the upcoming PLEs to enable a smooth transition between proprietary and open environments or contexts.

The first testbed deals with the use of a Web 2.0 *Knowledge Map* in a course on programming techniques at the RWTH Aachen University. The main objective is to couple the *Knowledge Map* service with a message board within a PLE in order to enable contextual discussions and map auditing between students and alumni working in software companies. This approach should bring added value to the course in terms of motivation, content and interaction. It should also ease the transition of students between the academic and the professional world.

The second testbed deals with second-language learning in a multicultural framework and in a continuing education context at the Shanghai Jiao Tong University (SJTU). The main objective is to enable live discussions with native speakers and personal practice at transition between jobs, thanks to the integration in the PLE of tools that can exchange data, such as online dictionaries, pronunciation, micro-blogging, videoconferencing, and multimedia discussion tools. In a political context where social sites are often blocked, a PLE in which services can easily be replaced by equivalent non-blocked ones is essential. The integration with mobile phones is also important as part of the activities is carried out at distance. The current PLE instantiation shown in Figure 3 is implemented using *Liferay* Portal Community Edition, (www.liferay.com).

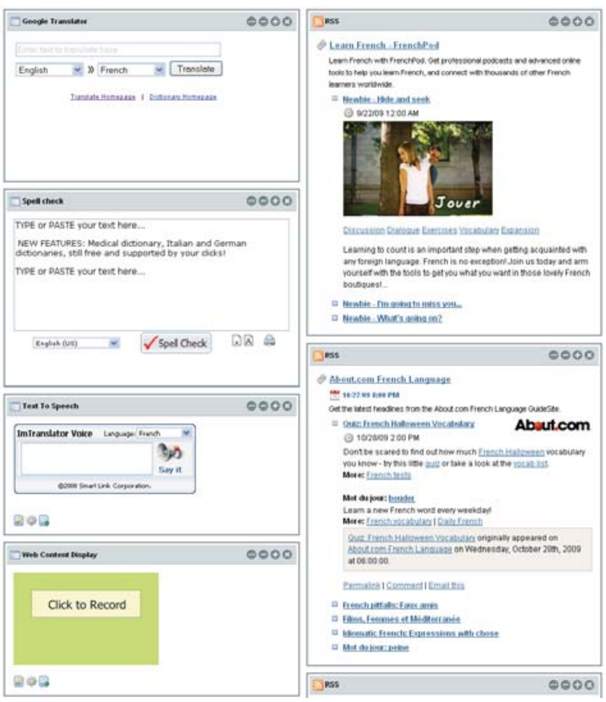

Figure 3. Screenshot of the PLE used in a French as a second language class at the Shanghai Jiao Tong University (courtesy of C. Ullrich, SJTU).

The third testbed deals with the exploitation of the OpenLearn learning space offered by the UK Open University for users in transition between informal and formal learning. Its objective is to progressively switch from a course-centric to a student-centric structure to better fulfill the users' repurposing needs, and to boost open content delivery technologies. It also aims at enabling any online learner to get support from a community of learners with similar backgrounds and goals. As it already targets educators and institutions, it is an interesting testbed to investigate the similarities between the educators' and the learners' integration approaches to combining resources in PLEs for sharing purposes or for personal usage.

Due to the heterogeneity of the testbed end users and the fact that they are geographically widely distributed; it is deemed cost-effective to facilitate the focus group discussions using a Web-based environment. The open source *elgg* (http://elgg.org) based social networking environment was selected as it offers all the basic Web 2.0 tools (blogs, wikis, discussion forums, social bookmarking, micro-blogging, etc) in a widget-based environment (Figure 4).

This widget-based environment enables the users to visualize what ROLE aims to achieve beyond the feature sets of similar systems currently available. It is expected that with each personal learning services bundle release, the focus groups will provide feedback on various aspects of the respective prototypes, thereby enabling us to collect evaluation data and identify potential issues that may result in refined requirements. Currently, the active focus groups are all end-user-oriented. These end-users (students, life-long learners) participating in the focus groups actively use the current learning environment provided by the test-bed institutions. The test-bed leaders have recruited the participants with the aim to provide a fairly representative sample. However, we plan to convene an expert-oriented focus group at a later stage when required. The rationale for putting together an expert-oriented focus group (internal as well as external) is to negotiate unresolved issues identified through other methods and to validate outcomes and findings from a top-down point of view.

Interestingly, the most requested features in the three described testbeds are a collaborative recommendation system proposing knowledgeable and trustful peers to interact with, and an integrated service for live interaction with them (such as *Skype* or *FlashMeeting*: http://flashmeeting.open.ac.uk). Knowledge mapping solution is also mentioned twice, maybe as an emerging Swiss knife of the knowledge worker dealing with information, ideas and competences (gap) management challenges. This low number of requested tools confirms previous finding [20] showing that typically a couple of services are used simultaneously and should be able to communicate synchronously for actual learning activities. This is coherent with the physical dimensional constraints of computer displays or Web browser windows when switching too often between contexts has to be avoided for minimizing cognitive overload. Communication with other services used at other stages in the learning process can rely on asynchronous data exchange. The XMPP protocol (http://xmpp.org) seems a promising solution for enabling communication and interoperability in the PLE framework. Various recommendation models and techniques are currently investigated in the ROLE project, including contextual collaborative solutions relying on users' weighted trust network. They will be reported in further publications.

To summarize, designing PLEs nowadays does not consist in developing one additional learning management system or

Web 2.0 social software applications, but it rather concentrates on providing the underlying infrastructure and recommendation solutions that rely on proper trust and reputation models mapped to the continuously evolving social and institutional contexts. Such solutions should enable users to aggregate in their own environments empowering technologies, communities, learning resources, activities and Web tools. The contextualization and repurposing of the aggregated environments for learning should be enabled according to implicit or explicit learning strategies or goals. The recommendation should be self-directed by unobtrusively involving the learner in the process, and by taking into account his/her learning contexts and interests, as well as his/her network of trusties.

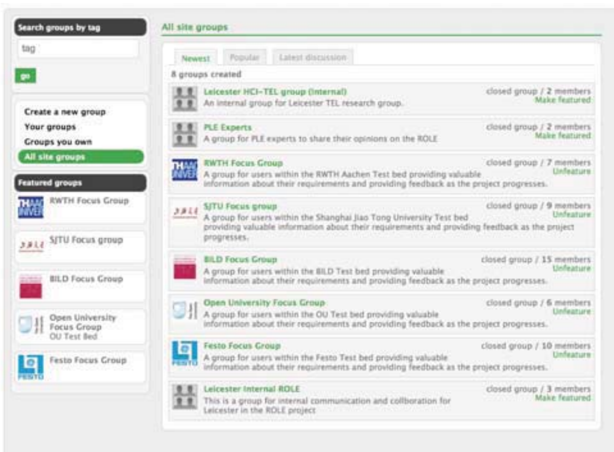

Figure 4. Web 2.0 based Focus Group facilitation.

VII. GRAAASP SOCIAL SOFTWARE PROTOTYPE

Successful Web 2.0 solutions result from a deconstruction-reconstruction process of the traditional collaborative learning practices and artifacts in order to extract essential features; followed by the implementation of a proper participatory design approach.

A previous attempt to develop and exploit a social software platform called *eLogbook* as a knowledge management platform in communities of practice and as a collaborative learning environment for engineering education gave good results in terms of integration of services (such as simulation and remote experimentation applets), but did not spread as expected outside the Swiss Federal Institute of Technology in Lausanne (EPFL) where it was developed due to usability reasons [21]. Specifically, it did not meet the requirements elicited in the previous section in terms of recommendation and relation with people. Only internal resources and registered members were accessible through a search feature. Invitation of external people was possible but required too much configuration and acceptation steps to be completed quickly. Also, most users did not understand its innovative graphical user interface (GUI) metaphor. As a matter of fact, this partial failure shows a pitfall associated with the participatory design approach that was implemented to design *eLogbook* in the framework of the Palette European Project (http://palette.ercim.org). The negotiation between the user and the developer mediators ended up with too many features that were integrated detrimentally to the GUI tuning. This problem can be avoided by pushing further the Web 2.0 philosophy of developing only wrappers to integrate as much as possible existing services or widgets in PLEs.

The *Graaasp* social software introduced in this section is an evolution of *eLogbook* hopefully correcting the flaws of the latter and that can be described as a Web 2.0 contextual aggregator. *Graaasp* is built on the 3A interaction model [22] that is particularly focused on describing and designing social and collaborative environments. The presence of three “a”s in *Graaasp* name is a reminder of this underlying model.

The 3A model accounts for three main constructs or entities: **Actors** are entities capable of initiating an event in a collaborative environment. They can be humans as well as virtual agents. Actors create collaboration spaces where they conduct **Group Activities** to reach specific objectives. In each of these activities, actors can take different roles, each of which consisting of a label and an associated set of rights. Furthermore, actors produce, edit, share and annotate **Assets** in order to meet activities objectives. Assets can consist of simple text files, RSS feeds, wikis, videos or audio files. The model accounts for Web 2.0 features: entities can be tagged, shared, commented, linked together and rated. As an aggregator of 3A entities, *Graaasp* can serve not only as a networking platform, a repository of assets and an activity management system, but also as a mounting space bringing together content and services from other Web 2.0 applications and social platforms.

While keeping the 3A model internally, *Graaasp* displays separately in its GUI physical and virtual actors, which are labeled as People and Tools, respectively. The main characteristic of the *Graaasp* GUI is its ability to enforce contextual aggregation of its four categories of entity, i.e. **People**, **Spaces** (group activities), **Assets** and **Tools** (widgets, applets). Any entity dragged and dropped in the main area (❶) becomes the current context of aggregation and interaction (Figure 5). The content of the associated columns (❷, ❸, ❹ and ❺) is automatically updated to only display entities with direct links to the chosen context. Direct links are relations explicitly made by users. New links with the current context can be created simply by dragging and dropping new entities on top of its dedicated grey banner area (Drop here to link). The new entities can be preselected favorites (❼) or entities kept in the clipboard (❽). They can also result from a search or be recommended by the systems according to user preferences (❻ or ❾). The recommendation takes into account all the direct and indirect links existing between *Graaasp* entities the user has access to and the current context. Indirect links can be common tags or links going through other entities (like two actors using the same tool or having collected the same asset in a space they belong to).

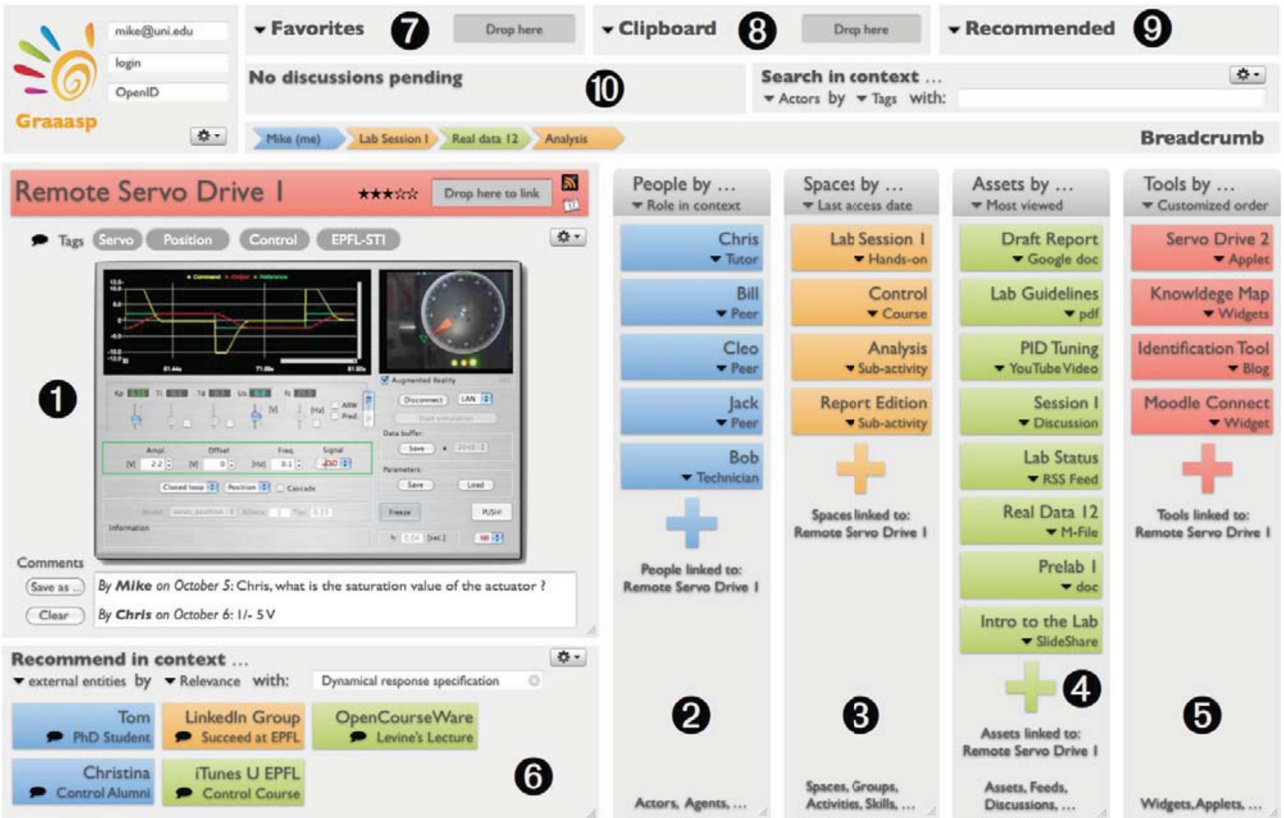

Figure 5. Recent Mock-up of the *Graaasp* social software (the current prototype is accessible at http://graaasp.epfl.ch).

The breadcrumb area displays the recent entities successively selected as context. The content of the columns can be displayed in predefined order (creation or last access dates, names, roles, so on and so forth) or in a customized order that can reflect the relative importance of the entities in the given context. Each category of entity supports different types that have different properties. For example, an asset can display the postings corresponding to a RSS feed, while another asset can just contain a static document.

Grabbing the nature and the implication of the various existing types of links may be challenging for users. However, the graphical representation should help in visualizing the existing relationships and in exploiting the contextual navigation. Hence, *Graaasp* uses pre-defined settings to translate drag-and-drop actions into meaningful relations. As an example, if a blue rectangle representing a person is dropped onto a space selected as current context, this person is invited to join this space as member with the relevant rights (this member role can later be modified). If a green rectangle representing an asset is dropped onto a person selected as current context, this asset is shared between the user and that person. The implications of the different drag-and-drop actions are currently adjusted and validated with volunteers.

The *Graaasp* internal recommendation engine will show its full potential in 2010 when resources for other social platforms will be mounted as external 3A entities. Currently, specific external resources can already be imported into *Graaasp*. As example, a *YouTube* video or a *SlideShare* presentation can be imported into *Graaasp* as an asset just by clicking on the Graaasp it! bookmarklet. A bookmarklet is an applet stored as the URL of a bookmark in a Web browser that can be executed at anytime when visiting supported websites to import interesting resources in *Graaasp*. Plug-ins to support additional websites can easily be implemented on the *Graaasp* server side, broadening in such a way the scope of the bookmarklet without the need to reinstall it every time improvements are made.

It is not clear yet whether users will indeed adopt *Graaasp* as a PLE. Further validation with educators and learners should be conducted. However, its design clearly supports the contextual aggregation of resources, including widgets in the tool category, and communities for general knowledge management or learning purposes. In that sense, it can be seen as a PLE generator that could be used by educators to prepare and propose potentially useful learning service bundles to their students. These bundles can be exploited directly in *Graaasp* or possibly exported in the future to other platforms. In such a way, the experience and the educators' accredited resources and networks can be embedded in shared PLE configurations that can include a predefined set of tools to be possibly exploited by the students. Hence, the burden for the students to build from scratch their PLEs may be reduced. These configurations can also integrate recommended experts using *OpenSocial* [23] technology.

VIII. Exploitation Scenario in Engineering Education

As a tentative exploitation scenario of the *Graaasp* social software as PLE in engineering education, one can consider the example of a student carrying out collaborative laboratory activities in control (a mandatory course offered at EPFL to students in mechanical, electrical, and micro engineering).

The students have three hands-on laboratory modules to complete during the last semester of their bachelor program. They can access the laboratory experiments directly on campus once a week, or remotely, 24 hours a day, 7 days a week. The typical laboratory setup introduced to practice position and speed control is a servo drive. An applet is available for local or remote data acquisition and control of this system [24].

Mike, a student in electrical engineering was already using *Graaasp* to manage the EPFL Jazz band. He decided to use the same social software to manage the control laboratory modules with peers. As EPFL strongly support the development of autonomy and teamwork skills, he knew that he could freely choose the other students he wished to work with. After a discussion at the cafeteria, Cleo, Bill and him decided to carry out the lab together. They had complementary competences and had already collaborated effectively in other contexts.

Mike connected first to *Graaasp* to create a new space called Lab Session 1 in order to support the lab activities associated with the first module to complete. He then invited Cleo and Bill to join this activity as peers. He also searched for available servo drives and linked the applet corresponding to the Remote Servo Drive 1 as tool in his Lab Session 1 space. He later picked Chris as tutor as he had got good feedback on his competences from Jack, a member of the Jazz band and master student in mechanical engineering who took the same lab session the previous year. Mike decided to invite Jack in the space, just in case further interaction with him would be required. Chris accepted the invitation to coach Mike's team, as he had not yet reached his quota of students. As a tutor, Chris is not in charge of the team evaluation in order not to refrain them from discussing the subject matter openly. Mike also added tools and assets useful for the lab in the space, including his favorite Knowledge Map widget, a nice *YouTube* video showing how to tune the PID controller they have to work with, and the RSS feed which is updated with the current status of the actual lab experiments, just to be notified in case their selected servo drive will be unplugged for maintenance. He also created a *Google* doc for the collaborative editing of the report and shared it within the main space (Lab Session 1) and its corresponding sub-activity space.

When Mike started his first real experiment by dropping the Remote Servo Drive 1 applet as context, Bob, the technician in charge of the maintenance appears automatically as linked person. Also, three additional tools linked directly and publically to the applet by Bob became visible. An additional servo drive that can be used as backup, an Identification Tool for the processing of the measurements acquired on the servo drive and the Moodle Connect tool enabling the storage of the data for the users that are still using the old LMS of the university.

Mike got a list of additional relevant entities related to his context and with the additional keywords he gave, including the podcasts of the EPFL control course on *iTunes U* and the slides of a related MIT course available on *OpenCourseWare*, which gave him an additional perspective on the subject matter.

As Cleo was so happy to get all the material necessary to complete the lab assignments at a single but open place, and to be able to keep it even after the end of the course, she decided to continue to use and populate *Graaasp* for most of her other social and academic activities. Lately, she exported one of her space dedicated to Philosophy just by one click to *iGoogle*, a platform some of her friends preferred to use.

IX. Concluding Remarks

This paper discussed the motivations and the challenges associated with the introduction of personal learning environments in higher engineering education.

In addition to highlighting the need for a fundamental change necessary in the educational paradigm to better account and support personal learning, essential pedagogical and technological requirements pertaining to PLEs are pointed out. Some of the issues identified and highlighted in Figure 1 and 2 are still being discussed within ROLE's TEL community. These issues (mostly pertaining to self-regulated learning, community based learning, recommendation, inter-operability standards, PLE usability) are contentious in nature and will require diligent negotiation among stakeholders to reach an acceptable resolution. Especially, usability is elicited as one of the most challenging features of personal learning environments, together with the need of powerful recommendation capability to help learners find relevant resources and people in the Web 2.0 realm. Hence, the reader must bear in mind that ROLE is an ongoing project and this paper reports some of the issues that we have identified so far and presents a preliminary PLE prototype with potential resolutions for some of the open issues like recommendation or community cohesiveness.

An example of a novel Web 2.0 social software that can be exploited in engineering education is presented, together with an implementation scenario for laboratory activities associated with a control course. This example shows how both the pedagogical and the learning environment design can be adjusted for a better integration of formal and informal learning practices.

As an emerging topic in field of technology enhanced learning, the design and development of open and responsive PLEs is deemed challenging. A number of controversies entail further scientific discourses and more empirical validations. Amongst others, we name several examples: striving the balance between system-driven and user-driven personalization mechanisms (cf. the privacy issue pertinent to user profiling), deepening the understanding of trust-building enablers and integrating them into recommendation protocols, and identifying viable means to sustain the development of ever-augmenting widget-landscape. We aim to tackle these challenges in our future research work.

ACKNOWLEDGMENT

Dr. Christophe Salzmann, Dr. Stéphane Sire, Ms Sandy El Helou and Mr Evgeny Bogdanov have contributed to the recent research and prototypes presented in this paper. The research work described in this paper is partially funded through the ROLE Integrated Project; part of the Seventh Framework Programme for Research and Technological Development (FP7) of the European Union in Information and Communication Technologies.

***Abstract*—This paper describes different proposals made at UNED, for post-graduated students, at the area of IT Services Management and specially trying to fill the gap, of paramount importance, of the treatment due in ITIL® (Information Technology Infrastructure Library) to Information Security Management. We analyze the treatment given to Information Security Management in ITIL, both versions 2 and 3, and describe the different at distance post-graduated courses we offer that fill these methodologies and discuss the opinions and evaluations of our students.**

Keyword: Information security management, ITIL, ISO 27001, Professional education.

I. Introduction

Every kind of organization is increasingly dependent of IT services to satisfy their corporative objectives and to cover their business needs [1] [2] [3]. This tendency provokes that IT (Information Technologies) Service Management is becoming an important factor for the success or failure of business in many organizations. A cause of the increase costs of IT services and low quality services is due to inadequate IT Services Management or does not work of desirable form [1].

But first of all, what is Service Management? Service Management is a set of specialized organizational capabilities for providing value to customers in the form of services. And, what is a Service? Service is a means of delivering value to customers by facilitating outcomes customers want to achieve without the ownership of specific costs and risks.

There are a number of widely applied standards and methodologies used for the alignment of Information Technologies (IT) departments with the business, inside each organization. One of the most relevant is called ITIL® (Information Technology Infrastructure Library) [4]. ITIL is the most widely accepted approach to IT service management in the world. ITIL provides a cohesive set of best practices, drawn from the public and private sectors internationally.

After this introduction of the context where we have done our research, the rest of the paper is organized as follows.

First, we do a small introduction to ITIL (Information Technology Infrastructure Library) both versions (2 and 3) and ISO 20000. In the next section we present the Security Management basis needed and its relation with ITIL. After that, this paper describes different proposals made at Electrical and Computer Department from UNED (Spanish University for Distance Education) [5], for post-graduated students, at the area of IT Services Management. Specially we try to fill this knowledge gap, of paramount importance, of security treatment due in ITIL. We explain the characteristics of these topics at distance courses, and how we try to stimulate the acquisition of practical knowledge by the students, promoting the practical work as a significant part of their works for the course.

Finally, we show the students evaluation of the last three years for these two courses that really encourages us to refine the courses and follow in the same direction.

II. ITIL® Version 2

ITIL (Information Technology Infrastructure Library), nowadays the most widely accepted IT service management framework in the world. ITIL arose in the '80s developed by the Office of Commerce of the British Government (Office of Government Commerce - OGC UK), [2] [3]. It provides a set of best practices detailed description, grouped in books, offering an extensive list of roles, threats, procedures and responsibilities that can be adapted to almost any kind of IT organization. The enormous amount of topics that those publications cover makes ITIL a reference, more essential day by day, to establish new improvement goals inside an IT organization.

ITIL Version 2 (which appeared at the end of the '90s) has two big modules as you can see in Fig. 1: Service Support and Service Delivery.

The other four ITIL version 2 core books (Planning to Implement Service Management, The Business Perspective, ICT Infrastructure Management and Application Management) are out of our research, because they do not have processes so they have not the same importance than Service Support and Service Delivery have.

Fig.1. ITIL version 2 core books (OGC source).

Inside Service Support book we can find the following six parts (which are five processes and a function): Incident Management, Problem Management, Configuration Management, Change Management, Release Management and a very important function: Service Desk.

Inside Service Delivery we can find also six parts (which are processes too): Service Level Management, IT Financial Management for IT Service, Capability Management, Availability Management, IT Service Continuity Management and Security Management.

ITIL processes all together are shown in Fig. 2, on the right you can see Service Support processes and on the left you can see Service Delivery ones:

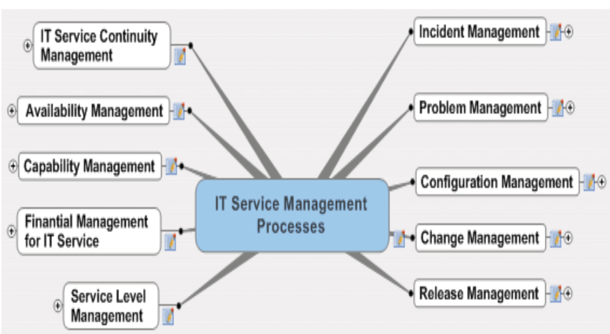

Fig.2. IT Service Management Processes (own source)

Service Support area describes how customers can access the appropriate services in order to assist to their business. Service Delivery area describes the services offered to the customer and what is required to provide those services.

III. ITIL® VERSION 3

Many public and private organizations worldwide implement these best practices following the version 2 of ITIL but since two years ago there is a new version that it is being implemented also, but in a much slower pace.

ITIL Version 3 [6] (also known as ITIL Refresh) took off two years ago and it has some big changes related to previous version. This new version is focused on the service lifecycle.

ITIL version 2 has undergone a major refresh which is version 3. Version 3 represents an important evolutionary step in its life. The refresh has transformed the guidance from providing a great service to being the most innovative and best in class. At the same time, the interface between old and new approaches is seamless so that users do not have to reinvent the wheel when adopting it. Version 3 allows users to build on the successes of version 2 but take IT service management even further.

Now there are only five core publications which describe the key principles of IT service management and provide a high-level overview (Service Design, Service Operation, Service Strategy, Service Transition and Continual Service Improvement).

Fig.3. ITIL version 3 core books (OGC source).

IV. ISO 20000

On the other hand, on 15th December 2005 ISO (International Standard Organization) [7] adapted BS 15000 British norm (based on ITIL and developed to officially define effective service delivery requirements for the business and their clients) into a new international standard: ISO/IEC 20000.

Although ISO 20000 does not formally include ITIL exposition, it does describe a set of management processes aligned and complementary to what ITIL defines.

ITIL provides guidance on what should be done in order to offer users adequate IT Services to support their business processes. ITIL certifications are available for individuals but until recently there was no way for an IT organization to prove that it is working along the ITIL recommendations. The ISO 20000 standard was conceived to fill this gap. Initiated by the two organizations itSMF (IT Service

Management Forum) [8] and BSI (British Standard Institute), it is modeled upon the principles of ITIL and for the first time offers IT organizations the possibility to have their IT Service Management certified.

Actually it is considered that each ITIL book offers deeper information and a best practices guide about subjects located in the scope of ISO 20000 norm. In contrast to the ITIL books, ISO 20000 does not offer specific advice on how to design your processes. It is rather a set of requirements which must be met in order to qualify for ISO 20000 certification.

The great implantation on private and public sector companies and the need of organizations to demonstrate their work this way by means of ISO 20000 certification, is causing a great demand of professionals on this field.

V. SECURITY MANAGEMENT

Information Security describes activities that relate to the protection of information and information infrastructure assets against the risks of loss, misuse, disclosure or damage. Information Security Management (ISM) describes controls that an organization needs to implement to ensure that it is sensibly managing these risks.

The risks to these assets can be calculated by analysis of the following issues:

- Threats to your assets. These are unwanted events that could cause the deliberate or accidental loss, damage or misuse of the assets.

- Vulnerabilities. How susceptible your assets are to attack.

- Impact. Is the magnitude of the potential loss or the seriousness of an event.

Standards that are available to assist organizations implement the appropriate programmes and controls to mitigate these risks are for example ISO 27001, ITIL and COBIT.

We consider that ISM has crucial importance because almost every company (even smallest ones) does their job using networks into their organization to exchange internal information, and uses Internet too. Each day is more necessary to deal with possible security problems on a global way, considering external threats from Internet but also internal treats. Information Security aspects are really important for company success and business stability.

VI. ITIL AND SECURITY MANAGEMENT

It is a proven fact that ITIL version 2 has a great weakness on Security matters. Between the existing set of Service Delivery books, there is a small one, called Security Management, that shows on a very light way what to do with security, and there is no later reference about this point in any other book of this version. Because of this weakness, organizations that implemented ITIL version 2 since years ago have had to fill this gap by their one, using other kind of approaches. That is the reason why Security Management process does not even appear in Fig. 1.

Nevertheless, on ITIL version 3, concretely in Service Design book, we can find much more information about what to do with Security Management. Although this new version touches Security on a deeper way, there are lots of links in the mentioned book to ISO 27001, which is the world wide extended standard followed on security subject.

Therefore, ITIL version 3 gives a much adequate treatment [9] to security that ITIL version 2 does, identifying the details of the structure and implementation of the Information Security Management process with the good practices for implementing an ISM System (ISMS) included in the ISO 2700x family of standards.

ISM needs to be considered within the overall corporate governance framework. Corporate governance is the set of responsibilities and practices exercised by the board and executive management with the goal of providing strategic direction, ensuring that the objectives are achieved, ascertaining that the risks are being managed appropriately, and verifying that the enterprise resources are used effectively.

The purpose of the ISM process is to align IT security with business security and ensure that information security is effectively managed in all service and Service Management activities.

An information security management system (ISMS) is, as the name implies, a set of policies concerned with information security management. The idiom arises primarily out of ISO/IEC 27001.

The key concept of ISMS is for an organization to design, implement and maintain a coherent suite of processes and systems for effectively managing information accessibility, thus ensuring the confidentiality, integrity and availability of information assets and minimizing information security risks.

As with all management processes, an ISMS must remain effective and efficient in the long term, adapting to changes in the internal organization and external environment. ISO/IEC 27001 therefore this incorporates the typical "Plan-Do-Check-Act" (PDCA) Deming approach to continuous improvement:

- The Plan phase is about designing the ISMS, assessing information security risks and selecting appropriate controls.

- The Do phase involves implementing and operating the controls.

- The Check phase objective is to review and evaluate the performance (efficiency and effectiveness) of the ISMS.

- In the Act phase, changes are made where necessary to bring the ISMS back to peak performance.

The best known ISMS is described in ISO/IEC 27001 and ISO/IEC 27002 and related standards published jointly by ISO and IEC.

Another competing ISMS is Information Security Forum Standard of Good Practice (SOGP) [10]. It is more best practice-based as it comes from ISF's industry experiences.

VII. The Computing Engineering Students Problem

On the other hand, Spanish students on Computing Engineering, when they finish their degrees, have little or no idea on Security Management and surely no idea at all about ITIL. If we are talking about the huge importance of ITIL all over the world, as the most accepted approach to IT service management, how is this possible?

We face a situation in which students that finish the Computing Engineering careers, at least in Spain, don't know all these kind of standards and methodologies and don't have a practical, day to day, approach to implement and maintain a good information security policy within an organization.

It is well known that the alignment of Information Technologies (IT) departments with the business is essential, and ITIL best practices are probably the best solution. That is the reason why from UNED we are trying to fill this gap in students knowledge, because at the moment we really believe this is a weakness. So, we are teaching post-graduated students to be experts on these topics, both Security Management and ITIL, just to be ready for the real world.

VIII. The UNED Solution

As everybody knows, UNED has distance students almost all over the world, so the way we teach is a little peculiar. We normally never met our students, therefore, teacher-student communication has everything to do with new technologies platforms, Internet and so on.

Our guidance and attention to students is made using computing and telecommunications, utilizing email on Internet or Learning Management Systems and, when this kind of communication is not possible, we attend them by telephone, post mail or fax.

Our attention is personalized, proper of a high quality education, which is a feature common in all UNED actions. Most part of material is given to students at the beginning of the course, so they can plan their study rhythm. Sometimes, when necessary, we make presence sessions using videoconference.

In addition to all this, during the courses we propose students to do a end of course personal work, that we correct, inform and send back to them, so they are able to evaluate themselves and improve their knowledge.

Due to all the reasons explained before, and trying to take advantage of the professional practice of some of the authors, from Electrical and Computer Department, four years ago we began to offer post-graduate at distance courses for helping students to understand all these matters.

At the moment we offer [11] two related courses:

1- Professional Expert in IT Services Management based on ITIL® and ISO/IEC 20000.

2- Professional Expert in Information Security for Computer Networks.

Professional Expert in IT Services Management based on ITIL® and ISO/IEC 20000 main goal is giving enough knowledge to students, so they can use a common language in service management based on ITIL. Also they get a very high level to face up ITIL foundations examination certification (1 hour multiple choice exam: basic understanding of the ten ITIL Service Delivery and Service Support processes and the Service Desk function).

Besides this, we try students understand tight relationship between ITIL and ISO 20000 and also students know different approach for new ITIL version 3. Each course is divided in four parts: introduction, 2 didactic units and the student's final work. The didactic units of this course (with three chapters in each unit) are the following:

1- IT Service Management and its implementation using ITIL best practices.
   a. Introduction to IT Service Management.
   b. Service Support Processes.
   c. Service Delivery Processes.

2- UNE/ISO 20000 standard and ITIL new version.
   a. ISO 20000 analysis and description.
   b. Life cycle new approach on ITIL version 3.
   c. Implementing ITIL version 3 practices.

Professional Expert in Information Security for Computer Networks main goal is giving to student completely updated technical knowledge on systems security and communications networks of computers. This course has two units (with three chapters in each unit):

1- Infrastructure security, systems security, organization security and biometrical systems.

a. Information Security at networks computer. Protocols at client/server communications.

b. Security Policy for company networks. Security attacks at network company classification.

c. Use of biometric techniques in security.

2- Cryptography and defense to attacks of security networks.

a. Introduction to Cryptography.

b. Modern Cryptography. Public and private keys Cryptosystems.

c. Non cryptographic defenses and cryptographic defenses at communication networks.

In our Information Security course first unit we also describe the goal and scope of Spanish laws which determine how to face the security problem of personal data files protection (LOPD, Spanish Law for Data Protection) [12] and also we describe security conditions on web servers (LSSICE, Spanish Law for Service Information Society and Electronic Commerce) [13]. More than 90% of our computer network traffic are TCP/IP [14] messages, so our students also study the comparison between stack IP and standard architecture OSI (Open Systems Interconnect) [15].

IX. Data and Tests Results

To keep in touch with the students real needs, we always make some exhaustive tests to our post-graduated students, to analyze if we are going in the right direction. And the results make us stand by.

As an example, these are some few questions and answers obtained during the last years:

1. To the question: Did you receive additional information about contents of your interest related with the course? Students respond yes: 91%.
2. To the question: Were your expectations about the course satisfied? Students respond yes: 86%.
3. To the question: Could you access to experts demonstration about application questions of the course? Students respond yes: 83%.
4. To the question: How do you value the course? Students respond yes: 86%.
5. To the question: Will you register in any other similar course? Students respond yes: 94%.
6. And finally, to the question: Will you recommend this course to anyone? Students respond yes: 92%.

In general, students' opinions should be very important at any university, but especially for us (teachers from UNED). We must know their opinions, checking that kind of feedback information, to be continually improving our methods and techniques to teach.

As we have explained above, we evaluate students with two kinds of tests. Firstly we evaluate them with at distance assessments for each unit that we correct and then we send the results and comments necessary to make students improve. And finally we evaluate students with a personal final work, which requirements are published at our web server. We are very proud of most of them. Examples of those final works are the following tittles:

- "Assessment of commercial and open source solutions for implementing Configuration Management Data Bases (CMDB): HP, Symantec, OneCMDB and ControlTier solutions"
- "Implementation of ITIL-based good practices to audio and video services"
- "ITIL and Prince2: Services Management and Projects Management"

This new academic year we are going also to give a new step in the ITIL course, trying to help the students to prepare the ITIL Foundations Certificate exam by having mobile evaluation tests on the main ITIL concepts. It will be as part of a European project, called mPSS (mobile Performance Support System for Vocational Education and Training).The students will have a number of simple tests, based on the ideas of well proven [15] DIPSEIL project for individualized high performance e-learning system, accessible from Internet via mobile devices, specifically mobile phones. The main idea is that the students can assess their knowledge of the main concepts related to ITIL and ISO 20000 at every moment and from anywhere and it will be part of several pilots related with the same high performance and individualized methodology, used also for another European Project, IPLECS (Internet-based Performance-centered Learning Environment for Curricula Support) that tries to build a complete European Engineering Master, completely accessible via mobile devices and for every European student.

X. Conclusions

In this paper we begin discussing what we think is a need to explain the differences in the approaches, of both versions of ITIL, to Information Security and the need for the graduate students to know, at least at a foundation level, these best practices approaches and standards.

With those two proposals from UNED, concretely from Electrical and Computer Department, we are trying to fill the gap we have just presented in this paper. We consider it is absolutely necessary students know all this methodologies, standards, laws ands concepts before they start working at any company in Spain or anywhere in the world.

Analyzing the results of the students' tests done at the end of each of our post-graduated courses, we conclude this is the path we have to follow to align students' knowledge and real world needs.

ACKNOWLEDGEMENTS

Abstract— **Technologies and especially information and communication technologies (ICT) are barrier breaking in the current social scenario. Their use is becoming essential for any professional, and their scope of use is becoming particularly widespread in education due to the existence of communication outside the classroom through e-learning tools. Universities, which play an innovative role in education, are using ICT-based approaches to adapt their learning methodology. In this paper, we present a model where students from first-world universities prepare and adapt course contents for use in educational institutions in developing countries. The objectives of this initiative of students' participating in e-learning projects with developing countries are to improve their motivation, develop a set of cross-curricular competencies, and transfer technologies within the scope of university development cooperation.**

Motivation; e-learning; development cooperation; cross-curricular competencies

I. INTRODUCTION

Over the past few years new and increasing concerns have emerged in Europe regarding education-related topics that were not taken into account until now [1]. Higher education, as a source of development, culture and science, is responsible for achieving an additional objective: human development. Educational institutions, and especially universities, are the cradle of the citizens who will determine the direction of progress in our global society in the near future.

Educational priorities have changed, and an academic education —and this applies to any field, including new technologies and technical studies— is no longer considered complete if it does not consider student instruction in topics related to human development and social awareness. An overview of the different problems affecting society means that the involvement of higher education students has to go beyond the scope of projects exclusively related to their field of work.

This change should be made simultaneously by all players in the higher education system. However, it is very common for teaching staff to be reluctant to introduce new methods, partly for obvious reasons, such as the increased workload, and partly due to under-motivation to finally achieve definite educational improvements. On the other hand, students tend to simplify their study methodology to optimize the time they spend on courses. Due to this lack of interest, most participatory methodologies are difficult to implement. This reality is clearly reflected in courses offering the option of assessment either by a final exam or through continuous coursework and group work, where many students opt for the traditional method and reject the educational improvement. Both students and the professors perceive that the workload is heavier, whereas attainment is similar. But, is attainment really the same? Of course, not. So, how can we motivate the two groups? Development cooperation naturally promotes both student motivation and some of the key competencies in higher education. Group work, communication, learning of other languages, awareness through development, and respect for the environment, are but a few of these skills [2]. We propose a methodology using e-learning applied to university development cooperation in Third World educational institutions applying a project-based learning strategy [3], as an effective instrument for motivating professors and students at a First World university, i.e. a highly motivating methodology for students and professors in a developed country. Project-based learning, or rather social project-based learning in this case, should be understood as a model for classroom work and homework that expands student learning with practical and real-world issues. This work with real-world projects is probably the key element of our learning approach that makes it so motivating for professors and students.

Distance education is no longer an experimental method. Educational tradition has, however, stalled the development of this method, which has been regarded as the main source of innovation in education during the past decade. e-Learning is an essential tool for cooperation and can also be used by professors to increase student motivation and training. Western students participating in these projects are involved in the development of society and receive training from the human standpoint. We get an improvement in the quality of available teaching material in developing countries and a wider dissemination of its contents. Additionally, acquired knowledge is consolidated at the same time as it is transferred to third parties. And all this with the added motivation

Work partially funded by the Universidad Politécnica de Madrid, Directorate for Cooperation and Development, http://www.upm.es/.

provided by the use of their output for both educational and human development.

This proposal has already being successfully tested by the TEDECO (Technology for Development and Cooperation) cooperation group [4] at the Universidad Politécnica de Madrid (UPM) in partnership with the University of Ngozi (UNG) in Burundi. In this context, the cooperation group has exploited its expertise in information and communication technologies to work on a proposal for using ICT tools (adapted e-learning tools) to improve education in developing countries [5].

II. Motivation

Internationalization in higher education, as in scientific research and other educational settings, is bringing together students, professors and researchers from more than one country, some coming from different cultures and social backgrounds [6], at the same university. Partnerships among European member states and their universities or other higher education institutions channelled through the Bologna process is a key component of this process of internationalization [7]. Another priority of higher education focuses on solving problems and responding to the needs and demands of society today, a global society that extends far beyond the European area [8]. Developed countries are now morally indebted to the developing countries; the developing countries' problems should be studied not only by non-governmental organizations but also by research centres and universities from developed countries. All these points are an initial justification for a more global education, aimed at developing not only language skills but also environmental education and intercultural awareness.

Below we justify from different points of view —divided into different sections— the reasons that brought us to develop this proposal linking education and development cooperation to improve the performance in both areas through collaborative work.

A. The European Higher Education Area

Changes in our global society have motivated the promotion of profound changes in education through the European Higher Education Area (EHEA) [9]. Cross-curricular competencies and student motivation have become central issues in the new scenario. The development and assessment of cross-curricular competencies not directly related to core technical knowledge is, however, one of the main problems facing professors during the transition period. A global solution requires adapting educational models and methodologies to achieve these new priorities.

One of the most important cross-curricular competencies is independent work, and Internet is playing a crucial role here. Plenty of free and open source material is available through the web, and students must use this information to complete and adapt their own technical material [10]. When students work on a topic they are only developing the core technical competencies of their specialty. But when students add to their material they are developing some of the cross-curricular competencies that are so difficult to improve through traditional education, such as capacity for analysis and synthesis, ability to work independently, team work, etc. [11].

B. Problems of Universities in Developing Countries

Education is the basis of a country's development process. In developing countries, it is very often impossible to wait until all basic needs have been covered to start up higher education programmes. Also, tackling higher education in a society with serious economic problems and no technical institutions to educate professionals in the area is a massive feat. Cooperation takes care of education. Traditionally, though, it has been more concerned about solving basic necessities than about higher education, which appears to be far removed from the possibilities of some developing countries. However, it is well known that higher education is a key field in the development of these countries, where local professionals will drive future changes. This is the main motivation for university cooperation with developing countries requiring assistance to develop their own adapted curricula and course contents. This is a key activity referred to as university development cooperation (UDC).

The traditional role of Western universities in UDC has often been limited to donations (donors of money, professors, and teaching material among other things). Over the last few years, however, a new concept of UDC has arisen, where universities from developed countries have become active participants working with developing universities. First World universities also gain benefits from this cooperation. This paper aims to conduct a methodological study of these benefits.

C. University Development Cooperation

Over recent years Western universities have become aware of their importance in the evolution of an increasingly global society. In this way, the activity of these universities —mainly (and sometimes exclusively) related to higher education and research— has traditionally focused on the needs of Western societies. However, 20% of the world population is clearly not a representation of global society, and therefore it is quite irresponsible for them to focus on solving the problems of just a small part of the world population and leave the problems of 80% of the population living in developing countries completely unattended.

Development cooperation aims to be the response to new concerns for solutions adapted to developing countries, and it has been included in higher education frameworks. There are codes of conduct signed *en masse* by a considerable number of universities —e.g. major Spanish higher education institutions [12, 13]. Universities are considered active agents of cooperation in the fields of education and research, as they are described in master plans designed by regional [14] and national development cooperation agencies [15].

Closely related to the research and innovation groups working on education currently operating at the UPM, there is a new label to identify groups working on development cooperation at the UPM and other universities. They are called **cooperation groups** and have become important technically highly qualified agents with sound expertise in both higher education and research on development.

D. Relevance of Information and Communication Technologies

Information and communication technologies (ICT) are fundamental in the developed countries where *"Information and communication technologies are transforming the way that individuals, institutions and societies learn, work and live. These technologies offer enormous potential benefits for the conduct of teaching, learning, research…"* [16].

Also ICT are fundamental for developing countries where access to information and communications is the key to development in the 21st century. Fig. 1 illustrates the cross-impact of ICT [17]. ICT is playing an important role in education, especially higher education. E-learning is the most common field relating ICT and education. However, traditional e-learning solutions and contents are designed for education in developed countries. Tools must be redesigned and contents must be adapted for application at developing countries' universities.

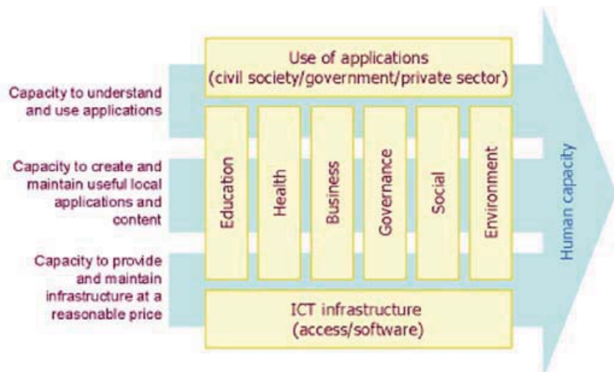

Figure 1. ICT cross-impact [17].

III. E-LEARNING APPLIED TO COOPERATION

Traditionally e-learning in the higher education model, i.e. at university, has been employed to: (1) increase university visibility, (2) extend the educational offer, and (3) as learning "virtualization" [18]. As shown in the last section, however, e-learning is especially interesting within ICT in developing countries, since it can overcome some of the physical and economic obstacles to education. Some of these obstacles that can be overcome by e-learning are the shortage of teachers or the lack of adequate training (especially in technical topics) of the available faculty. Hence technologies that enable distance learning are highly valuable in such environments, and e-learning could be the tool for transferring teaching activities to developing countries.

There are currently several projects using e-learning in developing countries as a support tool for education. Some of these projects are part of a broad educational program, divided into three noteworthy programs:

- The Latin American *Programa de Actualización de Maestros en Educación*[1] (AME) [19], a program specifically focusing on basic education teachers in Latin America using television and distance learning.
- The African Virtual University (AVU) [20].
- The Virtual University of Pakistan (VU), Pakistan's first university based completely on modern information and communication technologies [21].

Although our approach focuses directly on a university in a developing country, these projects are also good candidates for receiving the information that the method proposed here can provide. However, none of these projects has carried out a joint study of benefits for participants at First World universities: motivation, cross-curricular development, etc., encouraging and training students to prepare the necessary topics.

Within the TEDECO cooperation group [4], we published a novel approach (methodology, architecture and implementation) addressing this challenge. This approach included a new term, that is, c&d-learning [5], i.e. learning for cooperation and development. The c&d-learning model is based on the use of the Moodle[2] platform [22], adapted to the needs and infrastructures of developing countries. Not only does the c&d-learning model lead to an adaptation of the educational platform used, but it also proposes the requirements that must be taken into account when preparing the educational content of each course. In this paper we also propose an educational approach focusing on the fact that student participation in a c&d-learning project aims to achieve three objectives: (1) student motivation, (2) cross-curricular development, and (3) technology transfer.

In the remainder of this section we detail our approach. We justify this approach in Section 4, presenting a case study and its results, the experience of c&d-learning developed by UPM students with the UNG. In Section 5, we present the conclusions drawn from the implementation of the proposed method.

A. Scope

There has been much debate and many classifications of what is and what is not e-learning, but this is not the objective of this paper. It is important, though, to clarify some properties and uses of e-learning that must be taken into account when implementing this proposal. For example, depending on the communication and interaction between teacher and students, e-learning can be used as a synchronous or asynchronous (occasionally alternative terms, such as on-line or off-line education, respectively, could be used) teaching aid. Note importantly that e-learning extends the properties of the communication channel between teacher and students, thus providing new educational situations that did not occur in the traditional method. This is the case of an asynchronous communication where a message communicated by the teacher may not be immediately received by students.

In our case, c&d-learning should be classified as an asynchronous- and distance-learning model. First, the model

[1] Primary school teacher refresher course.

[2] Moodle is a course management system (CMS) commonly used in e-learning, also known as a learning management system (LMS) or a virtual learning environment (VLE) [20].

involves distance learning because courses developed as part of this approach are not applied *in situ* since there is a shortage of instructors. Second, the model is asynchronous because cooperation with developing countries does not require a constant or continuous communication. This last characteristic is the main constraint that the c&d-learning must overcome, since it requires the adaptation of course contents and e-learning platforms (designed for First World academic models) [5]. Some causes preventing a continuous communication can be: time difference among countries (which applies, for example, in partnerships between countries from Europe and Latin America, quite a common cooperation partnership), problems with Internet connections, different work schedules, or even cultural differences.

B. Role Description

Before detailing the planning strategy for our approach, this section gives a description of the different roles involved in the proposed methodology. Before we start to describe roles, let us clarify one point: from now on, when we use the term "local" in reference to professors, students or even resources, it should be considered as an indication of locality at the final destination of this educational proposal, i.e. at **universities in developing countries**. On the other hand, if used **without** the term "local", we will be referring to staff, professors, students or resources of **universities in developed countries**.

a) ***Professor*** *(at a First World university)* is responsible for starting this initiative (at a developed country's university), managing its evolution and performing the final evaluation. He or she supervises the process to assure the quality of the result. Furthermore, he or she could also be the beneficiary of the creation of repositories for learning resources [23].

b) ***Students*** *(at a First World university)* are the drive behind this approach, working together with the *Professor* to develop course contents at the same time as they assimilate the key concepts. Although they may not have all the training required to run a course, this approach is applicable thanks to supervision by the *Professor* and the lower academic level at developing countries' universities. In any case, first-year courses that are continued in following years (e.g. Programming I, Programming II) are the best candidates for running this proposal.

c) ***Local Professor*** *(at a Third World university):* Sometimes called *facilitator*[3], he or she is responsible for managing course contents at the target university, i.e. at a local university. He or she may need to perform some or all of the following tasks: present the contents *in situ*, answer questions or extend content, forward queries about user-level technical issues related to the e-learning platform to the *Professor* as necessary.

d) ***Local Students*** *(at a Third World university)* are the students located at the university in a developing country, i.e. the final beneficiaries of this approach.

[3] In the absence of local professors at the local university (i.e. in a developing country), a temporary entity, the facilitator, could possibly assume the role of teacher.

Henceforth the terms professor and student (whether or not they are preceded by the term "local") will be shown in uppercase and italics when referring to a specific role of this proposal, fulfilling the functions described above.

The roles defined above within a full c&d-learning scenario are shown in Fig. 2. All roles are linked by a common e-learning platform. The dotted lines represent all the paths between entities with the potential for content transfer (e.g. content preparation, supervision, evaluation, query resolution, etc.). An asynchronous channel determines communication between *Students* and the *Local Professor* from universities in developed and developing countries, respectively. Although interaction processes are flexible, delegating responsibilities to *Students* regarding course content transfer encourages a valuable communication with the *Local Professor*. In any case, it is essential for the *Professor* and the *Local Professor* to supervise topics, methodologies, assessments and content developed by *Students,* and communication.

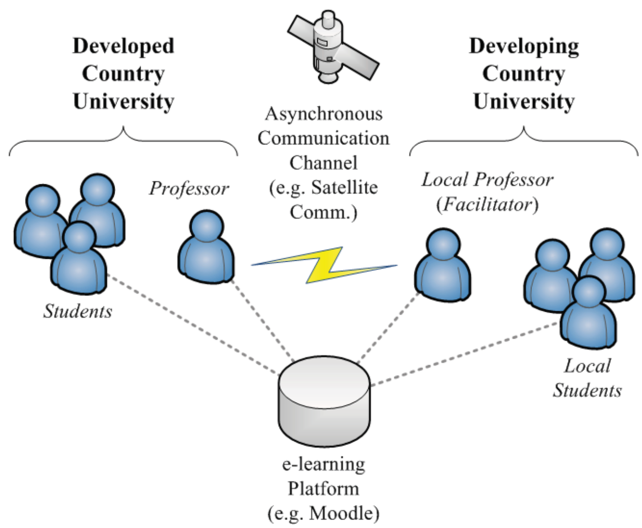

Figure 2. The c&d-learning scenario, including participant roles (*Professor*, *Student*, *Local Professor* or facilitator, and *Local Student*), communication channels and an e-learning platform.

C. Work Planning

The ultimate aim for participants in this initiative is to feed an e-learning platform with adapted course contents. This model delegates course scheduling and execution using the provided material, as well as supervision of course development, to the *Local Professor*. With the proposed delegation of responsibilities, we try to minimize interactions between *Local Students* and the external (non-local) *Professor*. This should bolster the figure of the *Local Professor*. In fact, after a training period teaching one or more courses, the *Local Professor* should be able to reproduce this ability, and dependence on the First World *Professor* should gradually decrease. The proposed educational method can be set up in three phases:

1) Student recruitment: the *Professor* in charge of *Student* recruitment should take into account a number of issues to launch this initiative.

a) Motivation: Development cooperation is a motivation in itself. As shown in the results section, the *Students* involved are volunteers. Since technology transfer is carried out where it is most necessary, development cooperation should be emphasized within the recruitment process.

b) Repetition: One of the main advantages of the proposed method is that the call —message used to engage *Students*— can be repeated periodically during each course. We recommend that the call be repeated and monitored during the development of the proposed approach to encourage student motivation throughout.

Note importantly that *Student* recruitment is a critical element for the success of the proposed approach, but educational methods should not be developed only to deal with the most appealing issues for students. In fact, the *Professor* in charge of these initiatives should use this proposal to complement their course planning to develop further cross-curricular competencies.

2) Initialization and Development: Once a group of *Students* has enrolled in this initiative, the required adaptation of the e-learning concept must be clarified. At First World universities, e-learning may facilitate two well-known models [18]: (1) uploading resources to supplement on-campus education, or (2) tele- or on-line education. Both models have a requirement that is only satisfied in developed countries: student Internet access from home or work. The situation in developing countries is the opposite: students usually only have on-campus access to ICT-based education. Bearing this in mind, content adaptation for *Students* must cover two important issues:

a) Resources self-sufficiency: If possible, the content developed by *Students* should provide methods to cover the complete educational process of each course. Otherwise, further resources must be available for off-line use, i.e. taking into account the limitations of the communication infrastructure in developing countries.

b) Self-assessment: Inclusion of self-assessment mechanisms to help *Local Students* to find out what they have learned.

c) Completeness: Local Students probably will not have access to additional content with which to increase their knowledge and training, and the information necessary to complete or understand an explanation.

Comparing the workload of traditional e-learning professors to the c&d-learning *Professor*, whereas working as an e-learning professor is a full-time engagement, the *Professor* in the proposed approach should transfer almost all responsibilities to *Local Professors*. In fact, their participation focuses mainly on the early phases of generating the course content and the final phases of evaluation. In the meantime, occasional and asynchronous interaction is required to answer advanced questions. This is potentially another argument in favour of motivation, since c&d-learning can be combined with the daily workload of the *Professor* and *Students* involved.

3) Evaluation: Although the main objective of e-learning technologies is to facilitate the move from “blackboard to on-line” education, they can also be used for [18]: (1) self-assessment and organization of the educational methodology, (2) content quality control and analysis, and (3) didactic refresher activities. In developed countries’ universities, student assessment must cover more than just specific knowledge acquired in the respective course. Besides the cross-curricular competencies mentioned in section II [11], the Organization for Economic Cooperation and Development (OECD) suggests three main groups of cross-curricular competencies in higher education [2]. With a project-based learning model [3] as proposed here, the following competencies can be developed and hence evaluated.

a) Use tools interactively (e.g. language, technology). ICT skills are developed through e-learning usage, not only at the user level, but, in this case, at the editor level as well. Regarding languages, when *Students* cooperate with a different country, they must use a foreign language to prepare the course content and communicate with the local university staff.

b) Interact in heterogeneous groups: Compared to First World university environments, personnel working at universities in a developing country are one of the most heterogeneous groups that *Students* are likely to work with in their academic and professional life. Contact with a really different culture is a valuable experience for *Students*, and how they cope with these differences is also an issue to be evaluated.

c) Work independently: In this environment, *Students* become leaders and are responsible for the development of a particular course. Although supervised by a *Professor*, they must make important decisions that may have a significant impact on things such as content extension, assessment implementation or available resources. Key decisions, such as methodological approaches or assessment procedures, are outlined by the supervisor.

Finally, technology transfer can also be evaluated through the final beneficiaries of this initiative, *Local Students* and *Professors*. Traditional mechanisms, such as surveys, academic attainment comparison or course content quality, are suitable methods for such an evaluation and are provided by the actual e-learning platform for use.

IV. CASE STUDY AND RESULTS

In this section we present the case of study and its results. This case of study was carried out as a result of cooperation between Spain’s Universidad Politécnica de Madrid (UPM) and Burundi’s University of Ngozi (UNG). In mid-November 2005, the UPM received a request for cooperation involving teaching staff from UPM teaching computer science courses at the UNG. They replied to the original request by sending two professors from the UPM’s School of Computing. These instructors gave their first classes during the months of April and May 2006. This initial cooperation was followed up by the design of an action plan to promote the self-sufficiency of the UNG based on ICT training and development.

After its initial contact with the UNG, the UPM's university development cooperation group, TEDECO, focused on designing a comprehensive action plan for UNG. It is here where the work of TEDECO really began. This project is divided into three phases, which have been carried out over the past two years. In chronological order, the planned tasks were: (1) the modernization of the computer equipment, (2) the installation of a shared Internet connection, and (3) the adaptation of a platform for planning educational material.

Currently TEDECO is working on the third and final phase described above, where we have started to simultaneously prepare the educational material necessary for the remote provision of courses at the UNG. We have also started to implement the educational methodology proposed here. To do this, we have used the previously developed c&d-learning model and delegated the preparation of the contents of the original materials delivered using e-learning since the 2006/07 academic year.

After the application of the proposed approach, the results can be viewed from two different perspectives. Firstly, we present UPM participation data: number of *Professors*, *Students* and other staff involved in this initiative. Secondly, we also discuss the impact of material provided by *Students* and *Professors* at the local university (UNG). From the analysis of these data we can: (1) evaluate the development of *Students* cross-curricular competencies ―although *Professor* supervision is the main source of evaluation, local course outcomes should be also considered―; and (2) motivation feedback through technology transfer evaluation.

A. Participation

Table I and Fig. 3 summarize the participation data of *Professors*, *Students* and others participants[4] involved in e-learning approaches implemented by the TEDECO cooperation group.

TABLE I. PROFESSORS, STUDENTS AND OTHER STAFF INVOLVED IN THE PROJECT.

Actors	Year			
	2006	*2007*	*2008*	*2009* [a]
Professors	2	4	4	5
Students	2	12	14	17
Others	1	3	0	4
Total	5	19	18	22
Project-based learning [b]	1 (50.0%)	3 (25.0%)	8 (57.1%)	10 (58.8%)

a. On-going year. Data may be incomplete.

b. *Students* involved in project-based learning.

[4] They are mainly former students.

The last row in Table I shows the number and percentage of *Students* over the total number of staff involved in project-based learning (listed in the second row).

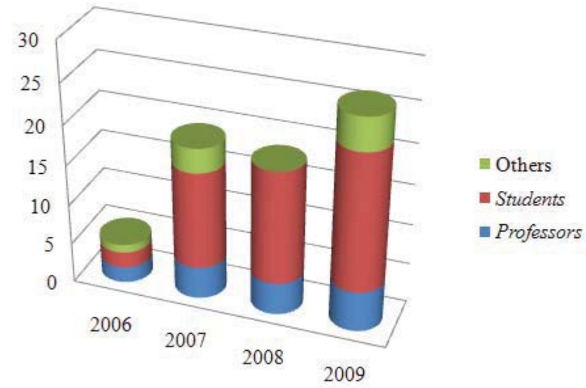

Figure 3. Number of *Professors*, *Students* and other staff involved in e-learning projects within TEDECO since 2006.

As shown in Fig. 3, the final number of participants has increased slowly but fairly constantly since the project kicked off and was consolidated. As the application of the approach has not been extrapolated to other institutions yet, further participation increments are not feasible.

B. Impact at the local university

Table II shows the evolution of the number of *Local Students* of computer science at the UNG. The number of *Local Students* is broken down by course and year. For the first two years, the UNG organized the computer science degree as a three-year course, which was expanded by a further fourth year from 2007 onwards. Row 5 shows the total number of *Local Students*, and rows 6 and 7 list the number of *Local Students* that have graduated in computer science vs. the number of *Local Students* that dropped out of the degree course. The last row in the table shows the evolution of the number of on-line subjects available at UNG [24]: Operating Systems, Programming Methodology, HTML and Web Development, Communications Networks, "*Java et bases de données*" (only French version available), and Linux Network Administration[5].

TABLE II. LOCAL STUDENT EVOLUTION IN COMPUTER SCIENCE AT UNIVERSITY OF NGOZI.

Number of Local Students	Year			
	2005/06	*2006/07*	*2007/08*	*2008/09* [b]
First year	35	55	58	62
Second year	17	19	24	18
Third year	12	14	18	19
Fourth year [a]			40	29

[5] Corresponding authors: F. Escudero Tello, A. Jiménez Castellanos, M. Cortés Cornax, F. J. Jiménez Martínez, M. A. González Gisbert, and D. López.

Number of Local Students	Year			
	2005/06	*2006/07*	*2007/08*	*2008/09* [b]
Total	64	88	140	128
CS Graduates	12	14	40	?
CS Dropouts	11	10	12	?
On-line Subjects		0	3	6

a. For the first two years, 2005/06 and 2006/07, the computer science degree did not include a fourth year.

b. Course units taught during 2008/09 are missing (illustrated by a question mark) because some data are not available or incomplete.

After UPM-UNG cooperation was consolidated, there was a notable increase in the efficiency rate and a drop in the dropout rate. Beyond a positive evaluation of the *Professors* involved in this initiative, these results suggest that the objectives of this approach (cross-curricular competency development, motivation and technology transfer) have been achieved.

V. Conclusions

In this paper we have presented a new method for applying a blended learning model (b-learning) to cooperation and development (c&d-learning). This proposal is based on the experiences of the TEDECO cooperation group at the UPM's School of Computing (Madrid, Spain) in partnership with the UNG School of Computer Science (Ngozi, Burundi). Following a study of e-learning differences applied to a university in a developing country and the implementation of a new methodology, we have conducted an analysis of benefits for participants, *Students*.

In traditional education, students receive the technical material required to acquire some specific competencies from their professors. Generally, students are not involved in the process of preparing, improving or updating course contents. However, we have proven that they are able to deal with such issues after taking the respective course. Independent work, interpersonal skills and teamwork, or foreign language communication are just some examples of the cross-curricular competencies developed by *Students* involved in this initiative. Also, this proposal is also interesting for improving the development of some of the least valued competencies in an engineering or information technologies degree —especially competencies related to ethical or social skills—, such as environmental awareness or ethical commitment to others [25].

In addition, development cooperation has proven to act like a catalyst of motivation, since *Students* got involved in the case study despite limited academic recognition: final-year projects or free choice credits in few cases. If this approach were also incorporated into new academic programmes through cross-curricular competency development, participation would be dramatically improved. However, this is also the main limitation of this approach, the double-edged sword of the participants' status as volunteers. Motivation is enhanced but effectiveness cannot be completely assured in these situations. Results suggest that this problem would be solved if this approach were adopted officially, where *Students,* coordinated by the *Professor* of the respective subject, would work with a *Local Professor* at the target university. They would coordinate and adapt the contents of the subject to the requirements of a developing country. This would increase *Student* motivation in the subject, cross-curricular competency development and, finally, technology transfer from the First World to developing countries.

Acknowledgment

We would like to thank the Universidad Politécnica de Madrid (particularly the Directorate of Development Cooperation and the International Relations Office) for its financial and logistic support: the UPM funded the TICAMEN 2006 (Information and Communications Technologies applied to Education Enhancement in Ngozi) and TESON 2008 (Technology for the Sustainability of the University of Ngozi) are projects related to this proposal. We would also like to thank the Bishopric of Ngozi and the University of Ngozi in Burundi for their contribution to developing the method proposed here.

***Abstract*— The purpose of this paper is to propose a practical and simple framework of engineering employability skills that will allow the concept to be explained easily and that can be used as a framework for working with engineering graduates to develop their employability before entering workforce. The framework was developed from existing researches on engineering employability skills issues and the requirement of the accreditation of engineering programme. The various skills of employability skills related to engineering included in the framework are discussed and their criteria justified bases on literature review of existing studies. The framework sets out exactly what is meant by engineering employability, in clear and simple terms, and the framework suggests directions for interaction between the various skills. The relationships between the skills within the framework remain theoretical. Further research to test the framework is planned and will be reported in future paper. The framework can be used to explain the concept of employability to those new to the subject, and particularly to engineering students and their future employer. It will be a useful tool for lecturers, careers advisors, trainers, employers and any other practitioners involved in employability skills. It will also be used to develop a model and a measurement tool for engineering employability skills. This paper contributes insights into the linking of graduate attributes, using national accreditation criteria and the framework of engineering employability skills from locally and globally expectation. It will be of value to anybody with an interest in employability issues.**

Keywords- Engineering; framework; employability; graduates; employers

I. INTRODUCTION

Today's engineering professions are continuously experienced major changes in knowledge, equipments, tools, systems and managements. Consequently, engineering firm continuously needs an engineer with a strong theoretical background, and require engineer equipped with employability skills. In order to face new challenges, new opportunities and on-going different circumstances, new engineers have to continually adapt and upgrade necessary skills such as self-learning [13], problem solving [10] and others personal skills [11] that can be applied in different situations. To overcome these phenomena, Higher learning institutions and employers need to have common understanding of which skills should be owned by engineering graduates. Therefore, a number of studies had been conducted to find this set of employability skills, and a few numbers of new frameworks of employability skills have been proposed. However, the aim of this paper is to focus on an acceptable and practical framework of engineering employability for Malaysian engineering graduates that are firmly based on requirement by accrediting bodies and professional bodies and existing research findings in employability skills.

II. OVERSEAS ENGINEERING EMPLOYABILITY SKILLS

The popularity of the employability skills has increased around the world since the 1980s [2]. The concept of employability skills have common purpose which is to recognise an important set of skills that support the effectiveness of practising technical and nontechnical skills in the workplace [2; 5; 6]. DEST 2006 [5] asserts the important of employability skills as a tool to assist learners and candidates for assessment to demonstrate the technical competent and skills to achieve and maintain successful employment outcomes. Employability skills were accepted as being important in a competitive business environment, with greater emphasis now being placed on these skills [6]. The skills are also transferable [14] and applicable from one place to another [2].

The United State of America (USA), United Kingdom (UK), Australia (AUS), Japan and European Union (EU) define the criteria for the framework of engineering employability skills as identified by industry and employers [6]. Following are the criteria of engineering employability skills in these countries that becomes reference to Malaysia. These frameworks on engineering employability skills as shown in Table 1 are used as a guideline for their engineering employers and employee as well as for engineering graduates.

TABLE 1: INTERNATIONAL ENGINEERING SKILLS/ATTRIBUTES REQUIRED FOR ENGINEERING GRADUATES

USA	***UK***	*AUS*	***Japan***	***EU***
ABET ***Engineering Criteria 2000***	***OSC Eng Occupational Standards***	*Engineers Attributes*	***Employable personal qualities***	***Generic Employability Skills***
Ability to apply knowledge of mathematics, science and engineering	Develop engineering products	Ability to communicate effectively, with the engineering team and with the community at large	**Personal skills** 1. Communication skills 2. Personal presentation skills 3. IT and computer skills 4. Problem-solving skills 5. Leadership skills 6. Visioning skills 7. Goal-setting skills 8. Self-assessment skills	**Mastery of one's native language** Including the basics of spelling and sentence structure
Ability to communicate effectively	Develop own engineering competence	Ability to function effectively as an individual and in multidisciplinary and multicultural teams, as a team leader or manager as well as an effective team member	**Attitudes** 1. Responsibility 2. Optimism 3. Curiosity 4. Ambition 5. Desire for challenge 6. Cooperation 7. Vitality	**Critical thinking** Ability to think through a problem or situation, distinguishing between facts and prejudices
Ability to design a system, component, or process to meet desired needs	Improve the quality and safety of engineering products and processes	Ability to manage information and documentation		**Understanding of the basics of maths and science** Particularly to cope with new technology
Ability to design and conduct experiments, as well as to analyse and interpret data	Install engineering products	Capacity for creativity and innovation	**Traits** 1. Initiative 2. Sensitivity 3. Flexibility 4. Individuality 5. Sincerity 6. Creativity 7. A balanced personality 8. An entrepreneurial mind	**Learning techniques** Ability to pick up new skills and adapting to new situations
Ability to function on multidisciplinary teams	Maintain engineering products	Capacity for life-long learning and professional development		**Team spirit** Ability to work in a group
Ability to identify, formulate, and solve engineering problems	Plan and manage engineering projects	Professional attitudes		**Personal discipline** Sense of responsibility
Ability to use the techniques, skills, and modern engineering tools necessary for engineering practice	Produce engineering products	Understanding of professional and ethical responsibilities, and commitment to them		**Decision making** Sense of commitment and willingness to take risks;

USA	UK	AUS	Japan	EU
ABET Engineering Criteria 2000	***OSC Eng Occupational Standards***	*Engineers Attributes*	***Employable personal qualities***	***Generic Employability Skills***
Knowledge of contemporary issues				**Initiative** Sense of Curiosity and creativity
Recognition of the need for and an ability to engage in lifelong learning				**Professionalism** Sense of achieving excellence and gaining competitive edge
The broad education necessary to understand the impact of engineering solutions in a global/societal context				**Civic mindedness** Sense of service to the community
Understanding or professional and ethical responsibility				

The Accreditation Board for Engineering and Technology (ABET) of USA required graduates from an accredited programme to have and demonstrate the attributes (educational outcomes) as described in Criterion 3 Basic Level Accreditation Criteria, ABET Engineering Criteria 2000 [4], as listed in first column, Table 1. Meanwhile, UK's engineering graduates are required by engineering industry to accomplish the competencies in OSC Eng Occupational Standards as reported by Dodrige [2]. Second column, Table 1 lists the competencies in OSC Eng Occupational Standards. As an Australian professional body and an accrediting body, the Engineers Australia (EA) developed a suite of professional attributes in engineering competencies based on the findings of the review in the development of engineering employability skills for undergraduate students. The professional attributes included in the Engineers Australia competency standards are listed in third column, Table 1. In Japan, a practical industrialized curriculum in engineering had engaged to the Japan Accreditation Board for Engineering Education (JABEE) guideline to integrate employable personal qualities into the academic curriculum in order to generate skilled engineers [11]. Column 4, Table 1, presents the Employable personal qualities practiced in Japan. Lastly, in Column 5, Table 1, lists the generic employability skills proposed by The European Round Table of Industrialists (ERT) in European Union (EU).

Malaysian engineering education mainly guided by accrediting body, Engineering Accreditation Councils (EAC) of Malaysia and the Malaysian Quality Assurance (MQA) Department of the Ministry of Higher Education Malaysia. EAC is the body appointed by Board of Engineers Malaysia (BEM) for accreditation of engineering programme in Malaysia. Accreditation policy required engineering graduates to have the necessary attributes, skills and competencies reflected in the graduate outcomes specified in EAC Manual. According to study done by Basri [4] and Abdullah [1], Malaysian employers agreed that more than 70% of the attributes for engineers in EAC manual are important. Table 2 shows the attributes required by EAC.

TABLE 2: ENGINEERING ATTRIBUTES REQUIRED BY EAC (MALAYSIA)

Attributes
a) ability to acquire and apply knowledge of science and engineering fundamentals;
b) ability to communicate effectively, not only with engineers but also with the community at large;
c) in-depth technical competence in a specific engineering discipline;
d) ability to undertake problem identification, formulation and solution;
e) ability to utilise a systems approach to design and evaluate operational performance;
f) understanding of the principles of sustainable design and development;
g) understanding of professional and ethical responsibilities and commitment to them;
h) ability to function effectively as an individual and in a group with the capacity to be a leader or manager as well as an effective team member;
i) understanding of the social, cultural, global and environmental responsibilities of a professional engineer, and the need for sustainable development;
j) expectation of the need to undertake lifelong learning, and possessing/acquiring the capacity to do so.

Source: EAC Manual

Based on the EAC requirement and the employability frameworks discussed above, this paper try to propose the practical framework of employability skills for engineering graduate in Malaysia for this near future. However, innovations, developments and technologies keep on changing in the world which requires the frameworks to be revised and to be updated as needed by industries.

III. DEFINITION OF ENGINEERING EMPLOYABILITY SKILLS

Skill is an ability to perform a specific task [5] and employability is about having the capability to gain initial employment, maintain employment and obtain new employment if required [8]. Employability skills was defined as 'those basic skills necessary for getting, keeping, and doing well on a job' by Robinson [12] and as 'skills required not only to gain employment, but also to progress within an enterprise so as to achieve one's potential and contribute successfully to enterprise strategic directions' by DEST 2002 [5]. Based on above definitions and other researches result [1; 2; 4; 5; 6; 7], hence, *engineering employability skills* can be defined as:

> *'Ability to perform engineering related skills, knowledge and personal attributes to gain employment, maintain employment and succeed in the engineering field.'*

Engineering employability skills are highly related to technical and non-technical skills or abilities. This definition and the overseas frameworks have been used as a starting point to develop a new theoretical framework for Malaysian engineering employability skills. This proposed Malaysian Engineering Employability Skills Framework (MEES) can be used as a guideline in training package and qualification in Malaysia. Every qualification is suggested to have an Employability Skills Report to describe how each of the employability skills is addressed in that qualification and embedded in the outcomes of the individual units of competence.

IV. PROPOSED ENGINEERING EMPLOYABILITY SKILLS FRAMEWORK FOR MALAYSIA

Employers and leading engineers in Malaysia agreed that engineering graduates are lacking of oral and written communication skills [3], generic skills and nontechnical skills [9; 10; 3; 2]. They required new engineers to perform engineering related skills and knowledge effectively. The fact that an engineering labour market becoming more knowledge-based and global, the importance of developing recognised employability skills globally become more critical [6; 9; 3; 2]. Therefore, this study proposes a **Malaysian Engineering Employability Skills** (**MEES**), a framework of engineering employability skills that intended to provide a framework for engineering related programmes. It can be used as a guide to generate skilled engineers that ready for industry practice locally and internationally, and as a benchmark for engineering graduates to be skilled and competent engineer. This framework was derived from existing researches on engineering employability skills issues, developments in other national frameworks [2; 6], literature on the views of Malaysian employers [1; 2; 4; 5] and the requirement from accrediting bodies of engineering programme. MEES satisfies the criteria and inline with the requirements of the Accreditation Board for Engineering and Technology (ABET), the Engineering Accreditation Councils of Malaysia, the Board of Engineers Malaysia and the Malaysian Quality Assurance Department of the Ministry of Higher Education Malaysia, Washington Accord and also satisfies qualification criteria of other professional bodies. Yet, the proposed framework of MEES is still open for consultation, discussion and debate in Malaysia. Following (Figure 1) is the Framework of MEES and the components made up for the framework.

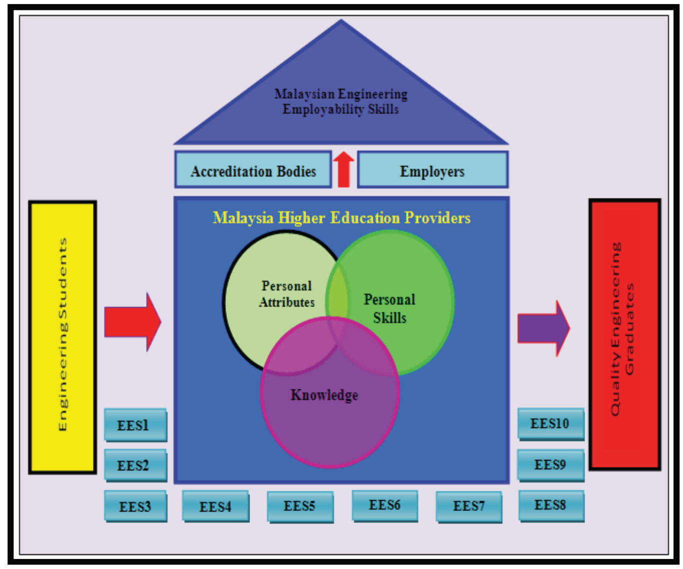

Figure 1: Framework of MEES

MEES comprises three main components: personal attributes, personal skills and knowledge. These three main components are integrated of communication skills (EES1), teamwork (EES2), lifelong learning (EES3), professionalism (EES4), problem solving and decision making skills (EES5), competent in application and practice (EES6), knowledge of science and engineering principles (EES7), knowledge of contemporary issues (EES8), engineering system approach (EES9) and competent in specific engineering discipline (EES10). Key components of the MEES framework is comprised of:

I. **Personal attributes: -** These attributes have been identified [2 − 11] as an ability needed to enable the engineer work well and effectively with others on a job and society.

EES1- Communication skills
EES2- Teamwork
EES3- Lifelong learning
EES4- Professionalism
EES5- Problem solving and decision making skills

II. **Personal Skills: -** These skills considered in an applied context which provide the foundations to gain employment maintain employment and succeed in the engineering field.

EES1- Communication skills
EES2- Teamwork
EES5- Problem solving and decision making skills
EES6- Competent in application and practice
EES10- Competent in specific engineering discipline

III. **Knowledge: -** knowledge which provides the necessary understanding of scientific and technologies principles to gain employment maintain employment and succeed in the engineering field.

EES3- Lifelong learning
EES5- Problem solving and decision making skills
ESS7- Knowledge of science and engineering principles
EES8- Knowledge of contemporary issues
EES9- Engineering system approach

The specific skills of MEES related to engineering included in the framework are justified based on literature review of existing studies, attributes required by accrediting bodies and graduate profile of professional bodies. The framework sets out exactly what is meant by engineering employability skills, in clear and simple terms as presented in Table 2, and the framework suggests directions for interaction between the various skills that being identified. It is obvious that in engineering students are recommended to develop their employability skills in conjunction with their subject knowledge while they are still in undergraduate studies. The higher education providers shall furnish their graduates with attributes that satisfy local requirement and global criteria. These skills are very important for new engineers as well as for engineers to succeed in their profession and being promoted [5; 6].

TABLE 2: MALAYSIAN ENGINEERING EMPLOYABILITY SKILLS (MEES) FRAMEWORK

Code	Skills
EES1	**Communication skills** Ability to present ideas with confident and effective through aural, oral and written modes, not only with engineers but also with the community at large. Engineering graduates should have the skills sufficient to: 1. *Speak in clear sentences,* 2. *Give clear direction ,* 3. *Listen and ask question,* 4. *Ideas presented with confident and effective,* 5. *Speak and understand more than one language.*
EES2	**Teamwork** Ability to function effectively as an individual and in a group with the capacity to be a leader or manager as well as an effective team member. Engineering graduates should have the skills sufficient to:
Code	Skills
	1. *The ability to function effectively as an individual,* 2. *Understand the role in a group,* 3. *Work in a group as an effective team member,* 4. *Accept and provide feedback in constructive and considerate manner,* 5. *Work in a group with the capacity to be a leader*
EES3	**Lifelong Learning** Ability to recognize the need to undertake lifelong learning, and possessing / acquiring the capacity to do so. Engineering graduates should have the skills sufficient to: 1. *Recognize the need to undertake lifelong learning,* 2. *Possessing and acquiring the capacity to undertake lifelong learning,* 3. *Able to engage in lifelong learning,* 4. *Set their personal learning targets,* 5. *Plan to achieve their learning goal(s)*
EES4	**Professionalism** Ability to understand the social, cultural, global and environmental responsibilities of a professional engineer, and commitment to professional and ethical responsibilities. Engineering graduates should have the skills sufficient to: 1. *Understand the social responsibilities,* 2. *Understand the cultural and global responsibilities,* 3. *Understand the environmental responsibilities,* 4. *Commitment to professional responsibilities,* 5. *Commitment to ethical responsibilities.*
EES5	**Problem solving and decision making skills** Ability to undertake problem identification, apply problem solving, formulation and solutions. Engineering graduates should have the skills sufficient to: 1. *Undertake problem identification,* 2. *Implement problem solving,* 3. *Apply formulation and solution ,* 4. *Be creative, innovative and see different points of view in solving problems,* 5. *Analyse and identify the root cause of the problems.*
EES6	**Competent in application and practice** Ability to use the techniques, skills, and modern engineering tools. Engineering graduates should have the skills sufficient to: 1. *Use the necessary techniques for engineering practice.* 2. *Use the necessary skills for engineering practice.* 3. *Use the modern engineering tools and software.* 4. *Work toward quality standards and specifications.* 5. *Assemble equipment following written directions.*
EES7	**Knowledge of science and engineering principles** Ability to acquire and apply knowledge of engineering fundamentals. Engineering graduates should have the skills sufficient to: 1. *Acquire knowledge of engineering fundamentals such as Mathematics and Science.* 2. *Apply the knowledge of engineering fundamentals,* 3. *Select and use proper tools and equipments for specific job / task,* 4. *Access, analyse and apply skills and knowledge of sciences and engineering,* 5. *Understand of principles of sustainable design and*

Code	Skills
	development.
EES8	**Knowledge of contemporary issues** Ability to continue learning independently in the acquisition of new knowledge, skills and technologies. Nowadays, the use of information, communication and computing technologies are very essential in the knowledge-based era. Engineering graduates should have the skills sufficient to: *1. Continue learning independently in the acquisition of new knowledge, skills and technologies.* *2. Use of information technologies,* *3. Use of communication technologies in the knowledge-based era,* *4. Use of computing technologies,* *5. Read news paper.*
EES9	**Engineering system approach** Ability to utilize a systems approach to design and evaluate operational performance. Engineering graduates should have the skills sufficient to: *1. Utilize a systems approach to design,* *2. Evaluate operational performance,* *3. Design systematically* 4. *Analyse engineering design* 5. *Demonstrate a knowledge and understanding of engineering system for management and business practices.*
EES10	**Competent in specific engineering discipline** Ability to acquire in-depth technical competence in a specific engineering discipline, competent in theoretical and research engineering and perform basic entrepreneurial skills. Engineering graduates should have the skills sufficient to: *1. Acquire in-depth technical competence in a specific engineering discipline.,* *2. Apply technical skills in a specific engineering discipline effectively,* *3. Design and conduct experiments,* *4. Analyse and interpret data,* *5. Knowledge in multidisciplinary engineering.*

Sources: ABET, EAC Manual, MQA, DEST 2006, Engineers Australia competency standards, OSC Eng Occupational Standards, JABEE, Washington Accord 1989 and The Future of Engineering Education in Malaysia, 2007.

National and international engineering accreditation criteria have a set of graduates' attributes that require the engineering graduates to be able to demonstrate these attributes after completing the study. The development of attributes and skills for engineering graduates will definitely link to the national and international engineering accreditation requirements. The local and global framework of engineering employability skills have to be parallel to local accreditation criteria. The local accreditation criteria satisfy the international accreditation criteria. Table 3 shows how the accreditation criteria and the framework of engineering employability skills from local and international can link graduates to a employable and marketable graduates, locally and globally.

TABLE 3: INTERNATIONAL, NATIONAL AND FRAMEWORK

International Accreditation Criteria	National Accreditation Requirement	Framework	Result
ABET Engineering Criteria 2000 (USA) ***OSC Eng Occupational Standards (UK)*** ***Engineers Attributes (AUS)*** ***Employable personal qualities (Japan)*** ***Generic Employability Skills (UE)***	MQA EAC	MEES	Employable And Marketable Engineering Graduates

V. CONCLUSION

The overview of overseas literature on framework for engineering related skills in this study has identified a renewed interest in engineering-related employability skills. In the study, this framework has been referred to as *Malaysian engineering employability skills* (MEES). The proposed framework inline with the work that has been undertaken overseas, particularly in Australia, the United Kingdom, the United States of America, Japan and European United. MEES comprises the personal attributes, personal skills, and knowledge that are required by stakeholders/employers [1; 2; 7] to enable engineering graduates to enter workforce, and progress in career path. The term e*mployability "*signals a connection to the world of work that is dynamic and long-term in nature" [6]. The identified technical and nontechnical skills included in the framework are accepted as commonly applicable in the all area of engineering. Adoption of this framework can create future opportunities for new engineer to become professional engineer. This framework can be a guideline to new engineers and "come-back" engineers to become employable and allowing them to remain as a valuable employee all time. The framework can also help engineers to develop their career and move up within the organisation.

The framework can be used to explain the concept of employability to those new to the subject, and particularly to engineering students and their future employer. It will be a useful tool for lecturers, careers advisors, trainers, employers and any other practitioners involved in employability skills. It would be useful for further research in developing a model and a measurement tool for engineering employability skills. This paper contributes insights into the linking of graduate attributes, using national accreditation criteria and the framework of engineering employability skills from local and international expectation.

Data collection and data analysis is still ongoing but it is expected that in-depth analyses of the framework will yield more insight to the implications of these findings for practice and policy making. Of interest would be comparisons of employer expectation ratings on the important of employability skills attributes should be own by graduates with employer perception ratings on the satisfactory of employability skills attributes own by graduates they hired. Some of these implications include a better understanding of how employers' expectations compare with that of employers' perceptions, and the implications such understanding might have on education and training.

However, as knowledge, technologies and workplace processes keep on changed and improved, there will be a need for ongoing skills development in employees for emerging new occupations and changing skills requirements [4; 6; 7; 13]. Continuously studies and researches need to be done to suit in the changes locally and globally.

ACKNOWLEDGMENT

The authors wish to thank to anonymous reviewers for their observations, comments and remarks that help to enhance the quality of this paper.

Abstract— **The authors propose a system for the assessment of Final Year Projects (FYPs) whose educational outputs have been defined previously in terms of competences. For building the proposal, eleven pre-defined competences were ranked and a different weight was assigned to each one. The ranking was made individually by all the authors following a blind two-step process. The first step consisted in ordering the competences by relevance and the second step in grading that relevance for each pair of competences having consecutive positions in the list. As a result, an overall weight was computed for each competence and the final proposal was produced by averaging the individual proposals. In addition, three moments are defined for the assessment of FYPs: the FYP process itself, the written report and the oral presentation. Bearing in mind this, the competences that can be evaluated in each moment are identified and a specific assessment form for each moment is also proposed.**

Keywords-component; engineering education, student assessment, competence-based learning, final year projects

I. Introduction

Project-based learning (PBL) has been recognized for long as a very valuable tool for engineering courses, since it helps students in developing skills that are closely linked to the execution of professional engineering tasks [1]. The recognition of this value of PBL has lead to the inclusion of project development activities in engineering courses [2], being the "Final Year Project" (FYP) the most remarkable of these.

In the currently ongoing process of creating the European Higher Education Area [3], the educational outcomes of university courses are being defined in terms of competences that are to be acquired by the students in order to get their degrees. Significantly, competences related to project management and development seem to be becoming relevant even for non-engineering courses [4]. In this context, both a definition of the pedagogical content of FYPs in terms of competences and a systematic assessment system linked to those competences are needed.

The issue of defining the educational outcomes of FYPs was approached by the authors in a previous work [5]. Within that work a set of eleven competences relevant for FYPs were identified, using the basis provided by [4] and [6]. Also in [5], competences were broken down into specific learning objectives and student tasks to be realized during the FYP were pointed out.

However, in authors' view, the question of defining a systematic approach to the evaluation of FYPs has not been satisfactorily solved so far. While it is true that the problem of assessing student projects is not new and that rubrics are becoming a standard for such assessment [7], the definition of rubrics for all the assessable aspects of FYPs is cumbersome. Moreover, filling such rubrics could be too time-consuming for the juries of the projects and an excessive level of detail could also mislead the attention of the juries towards too specific aspects of the work, thus making them lose the global view [8].

Another aspect of the evaluation of FYPs that is not defined yet, to authors' knowledge, is the ranking of competences, that is, the specification of which aspects should contribute the most to the final marks assigned to the students. Although a weighted average of different aspects was proposed in [9], such proposal did not consider competence-based learning; therefore it is not coherent with the current trends in the design of university courses in Europe.

Within this paper, the authors propose a system for the assessment of FYPs whose educational outputs have been defined accordingly to [5]. For making the proposal, the eleven selected competences were ranked and a different weight was assigned to each one. Also starting from the work in [5], but simplifying the therein described proposal, three moments are defined for the assessment of FYPs: the FYP development process itself (evaluated by the supervisor), the written report and the oral presentation (both evaluated by a jury). Bearing in mind this, the competences that can be evaluated in each moment have been identified and a specific assessment form for each moment is also proposed within the paper. In the design of the forms, both the simplicity and the prevalence of global aspects have been pursued.

II. Educational Outcomes

The definition of the educational objectives of FYPs in [5] was done by relating the experience of the authors in FYP supervision to a selected set of competences drawn from [4] and [6]. Within that approach, learning outcomes were

The work reported in this paper has been carried out in the framework of a Project for Educational Innovation funded by the Universidad Politécnica de Madrid

structured in four levels of abstraction: classes of competences, competences, learning objectives and project achievements. While this structure provided a comprehensive means to relate project activities to learning outcomes expressed in terms of competences, it was too detailed to be manageable both by students and lecturers as a guidance for the learning process associated to FYPs. Consequently, herein only the two levels with the highest degree of abstraction have been considered for the formal definition of learning outcomes: classes of competences and competences, as specified next.

A. *Classes of competences*

The educational purposes of the FYP can be classified, at the most general level, in four types or classes of competences:

1) **Intellectual competences**: related to the way reality is analyzed, reasoning on it is produced and proposals to change it are generated.

2) **Instrumental competences**: related to knowledge, techniques and working procedures that must have been acquired prior to the beginning of the FYP.

3) **Managerial competences**: related to the planning and implementation of activities, be them either individual or in group.

4) **Social contextualization competences**: related to analyzing and previewing the interaction between technology and the social context in which it takes place.

B. *Competences*

Individual competences that must be improved during the development of the FYP have been identified within each group.

1) Intellectual competences

C-I. **Competence for analyzing and synthesizing**: capacity for compiling, comprehending, interpreting and evaluating information and data relative to a technological problem in such a way that its main aspects can be easily identified.

C-II. **Competence for applying knowledge to practice**: capacity for solving specific problems making use of the specialized knowledge of the correspondent technology and for conceiving, if needed, new systems or devices that help in achieving the objectives and requirements of the undertaken problem.

C-III. **Competence for making research**: capacity for generating new knowledge from hypothesis and data, making use of the scientific method.

C-IV. **Competence for scientific and rational analysis**: attitude for systematically analyzing reality from a rational-scientific point of view, which is characterized by the appropriate use of theories and models, the production of coherent interpretations of facts, the critical analysis and the forming of personal opinions and judgments.

2) Instrumental competences

C-V. **Competence for dealing with the basic knowledge of the technological area**: familiarity with the basic concepts of the correspondent knowledge and technological area and capacity to increase the personal knowledge through autonomous study.

C-VI. **Competence for managing information**: capacity for finding information in bibliographies, distinguishing between primary and secondary bibliographic sources, making good use of libraries and locating information on the World Wide Web while assessing its reliability.

C-VII. **Competence for performing basic tasks with computers**: capacity for creating and storing information in several formats, for complying with norms relative to those formats, for communicating making use of computer networking, for using on-line resources, for registering experimental data in electronic format and for using software specific to the correspondent knowledge area.

C-VIII. **Competence for language communication**: capacity for elaborating written texts and oral dissertations following orthographic and grammatical rules, with a coherent ordering of ideas and arguments and with different levels of detail; having good fluency in a second language, at least in reading comprehension.

3) Managerial competences

C-IX. **Competence for inter-personal relations**: capacity for listening others' opinions and views, for using verbal and non-verbal codes, for working in a team and, if necessary, leading it, for presenting proposals and projects, for debating, for conducting interviews, for generating interactive environments, for interacting with people coming from diverse social and cultural contexts.

C-X. **Competence for task managing**: capacity for organizing time, for setting priorities, for working under pressure, for complying with compromises in results and time.

4) Social contextualization competence

C-XI. **Competence for analyzing the social context**: consciousness of the existence and the origin of social conditions, restrictions, beliefs and usages and capacity for assessing the social and ethical impact of technological projects.

As stated before, the educational purposes of the FYP could be further concretized. However, in the authors' view, this level is enough both to inform students on what they are expected to do and to design a competence-based FYP assessment system, as proposed in next section.

III. EVALUATION

A. *Assessment procedure*

As stated in section I, the student evaluation in a competence-based learning paradigm should be competence-based too [8]. Therefore, the herein proposed procedure for FYP assessment consists in directly evaluating up to which level the student has acquired each of the 11 competences involved in FYPs. In this way, the students' attention is not deviated towards specific aspects whose artificially increased relevance could bias the overall educational aim and, at the same time, the coherence between FYP educational objectives and assessment process is kept.

However, the diversity of competences to be evaluated results in a corresponding diversity of evaluation times and people involved. Considering both common practice and the FYP achievements listed in [5], at least three evaluation moments and agents can be identified:

- **Implementation process**: the work of each student can be assessed continuously by the FYP supervisor during group and individual meetings and also considering the project plan and the cooperation with other students.
- **Final report**: evaluated by a board formed by lecturers.
- **Oral presentation**: also evaluated by a board of lecturers with possible inclusion of colleague students.

Table I summarizes the authors' view on which competences can be evaluated in each of the three abovementioned moments. A detailed justification for this relation between competences and moments can be found in [5]. From this table, it becomes clear that the three evaluation moments are complementary in the sense that none of them can account for all the competences. Moreover, according to the same table, the evaluation board needs at least two of these views of the project to have a complete overview of it. Tables II, III and IV contain the questionnaires proposed for the evaluation at each of the three moments.

Regarding the issue of how to combine the marks given in all moments to produce a final mark for each competence, a variety of possible procedures exists, but the authors propose a consensus among the evaluators built in a private meeting after the oral presentation.

TABLE I. COMPETENCES AND EVALUATION MOMENTS

Competence	Impl.	Rep.	Pres.
C-I Analyzing and synthesizing	X	X	
C-II Applying knowledge to practice	X	X	
C-III Making research	X	X	
C-IV Scientific and rational analysis	X	X	X
C-V ... knowledge of the technological area	X	X	X
C-VI Managing information	X	X	
C-VII Performing basic tasks with computers	X	X	X
C-VIII Language Communications		X	X
C-IX Inter-personal relations	X		X
C-X Task managing	X		
C-XI Analyzing the social context	X	X	X

B. *Competence ranking and weighting*

A second question that arises in the design of the evaluation process when a final numeric mark has to be assigned to the FYP of a student is how to rank the competences and how to weight the marks given to each one in order to obtain a global mark. For solving this question, the authors have followed a two-stage procedure inspired by [10]:

- As a first step, each author has ordered the 11 competences by their relevance for FYPs.
- Secondly, a weight has been assigned to each competence relative to the following one in the ordered list. After that, a simple set of linear equations has allowed to convert these weights to a set summing 100%.

TABLE II. QUESTIONNAIRE FOR THE EVALUATION OF THE ORAL PRESENTATION

Competence	Mark
C-IV Scientific and rational analysis: The student has presented his or her work in a well structured way. He or she has adequately justified his or her decisions, proposals and answers.	
C-V ... knowledge of the technological area: The student has shown good knowledge of the subject in which the project is framed. He or she has used specific vocabulary properly and avoided superficial analyses.	
C-VII Performing basic tasks with computers: The student has adequately used supporting software for the presentation, shown well elaborated graphs and, if needed, performed software demonstrations.	
C-VIII Language communication: The structure of the presentation has been appropriate. Repetitions and ambiguities have been avoided. The language has been clear and concise and using appropriate vocabulary and register. The presentation length has been adapted to its contents.	
C-IX Inter-personal relations: The student has succeeded in maintaining the attention of the audience. He or she has answered all questions without avoiding any and recognized own mistakes. His or her position in the room and speech loudness and speed have also been appropriate. Reading has been avoided.	
C-XI Analyzing the social context: The student has spoken about the social context and relevance of the work. Topics and superficial approaches in analyzing ethical issues have been avoided. He or she has shown sensitivity towards the social impact of the project.	

TABLE III. QUESTIONNAIRE FOR THE EVALUATION OF THE IMPLEMENTATION PROCESS

Competence	Mark
C-I Analyzing and synthesizing: The student has understood the proposed problem and all its conditions and circumstances. He or she has been autonomous in critically searching, gathering and processing information. He or she has succeeded in relating the problem to others previously approached.	
C-II Applying knowledge to practice: The student has been autonomous in applying scientific knowledge and he or she has proposed well founded hypothesis and methods. Changes in methods and objectives have been well reasoned. Required time and equipment resources have been defined beforehand.	
C-III Making research: The student has shown ability to approach problems at different levels of abstraction, to design experiments, to process data using appropriate statistical and mathematical tools, to handle specific instrumentation and to interpret results.	
C-IV Scientific and rational analysis: The student has identified all the different parts of the problem. He or she has presented and defended arguments in discussions with the supervisor and with other students. He or she has decided based on objective criteria and has used multidisciplinary knowledge when needed.	
C-V ... knowledge of the technological area: The student has shown to be competent in dealing with procedures and concepts of his or her knowledge area and also in handling specific instrumentation. He or she has been autonomous in looking for information that helped in solving his or her doubts.	
C-VI Managing information: The student has been autonomous in gathering and selecting information. He or she has resorted to several sources of information and has been able to assess the reliability of each one. He or she has made use of on-line resources provided by the university.	
C-VII Performing basic tasks with computers: The student is skilled in managing diverse data and document formats, he or she has usually accessed to network resources and services and has appropriately used data processing software and also software specific to his or her knowledge area.	
C-IX Inter-personal relations: The student has regularly attended to meetings with the supervisor and has been able both to discuss and defend his or her approaches and to rectify them when needed. He or she has shared ideas with colleagues and, if required, he or she has participated in joint projects and coordinated part of the work.	
C-X Task managing: The student has written a project plan, kept a log book of the project activities, respected foreseen deadlines and activities and adjusted the plan when needed.	
C-XI Analyzing the social context: The student has evaluated results bearing in mind their applicability. He or she has included ethical and social issues in the context analysis.	

These two steps have been taken independently by each author, without knowing the proposals of the rest. Averaging the resulting weights results in the list of relative relevancies of competences included in table V.

Beyond the specific results shown in this list, which obviously are prone to variations depending on the specific group of people involved in its elaboration, the following aspects can be highlighted:

- All authors except for one agree that competences C-II and C-V are among the four most relevant.
- All authors except for one agree that competence C-VIII has a medium relevance.
- All authors except for one agree that competence C-III is among the four least relevant.
- • All authors agree that competence C-XI is among the three least relevant.

Regarding all this analysis, it should be recalled that the issue being studied here is the relevance of each competence in the educational contents and assessment process of FYPs in an engineering course, not the importance of each competence either in professional life or in other contexts. For instance, being competent in performing tasks with computers is undoubtedly very relevant for engineers, but such competence should be developed mainly before reaching the FYP. Therefore, C-VII plays a minor role in the marking of the FYP. Conversely, while certain research tasks can be developed during the FYP, the competence for making research is more closely related to higher educational levels (eg. doctorate). Again, this is the reason why C-III appears among the least relevant competences.

TABLE IV. QUESTIONNAIRE FOR THE EVALUATION OF THE FINAL REPORT

Competence	Mark
C-I Analyzing and synthesizing: Problem description and analysis are based on a sufficiently wide up-to-date specialized bibliography. The literature review has clearly synthesized contents, it is well structured and it includes a judicious analysis of the bibliography while avoiding plagiarism. The hypothesis and/or design criteria are clearly linked to the review of the state of the art. Data collected during the project have been adequately organized and analyzed and they provide a clear foundation for the conclusions.	
C-II Applying knowledge to practice: Project hypothesis and objectives are clearly stated, well founded on theoretical knowledge and realistic. Project objectives are original and result from a personal contribution of the student. The proposed methodology is coherent with the objectives, it is clearly explained and justified and it leads to the reported results.	
C-III Making research: Unsolved issues have been identified and corresponding hypothesis have been stated. Experiments and results have been adequately carried out and collected in order to confirm or reject such hypothesis. Data analysis has been unbiased and it clearly supports the conclusions. Findings and conclusions have been discussed and contrasted to previous results present in literature.	
C-IV Scientific and rational analysis: The contents of the final a report are well organized. The approach to the project is systematic. Statements and interpretations are correctly reasoned or founded in adequate bibliography.	
C-V ... knowledge of the technological area: Project implementation has involved knowledge related to the university course, and part of it has required autonomous study by the student. Conceptual errors have been avoided and, if needed, specific instrumentation has been correctly used and its specifications and using requirements have been reported.	
C-VI Managing information: The final report includes a list of references. All references have been cited in the text. Reference format is as specified. Sources of all copied material have been cited.	
C-VII Performing basic tasks with computers: The format specifications of the document have been respected. Usage of styles and formats is coherent throughout the whole document. Appropriate software has been used for generation of graphics and data processing.	
C-VIII Language communication: The structure of the report is correct. Headings and content are coherent. Both repetitions and ambiguities are avoided. The text is clear and concise. The length of the final report is adequate for its contents and it does not contain either syntactic, orthographic or semantic errors. The bibliography is multilingual.	
C-XI Analyzing the social context: The project context is mentioned and described. Both practical and ethical consequences of the project have been considered.	

TABLE V. RELATIVE RELEVANCE OF COMPETENCES

Rank	Competence	Weight
1st	C-V Dealing with the basic knowledge of the technological area	15%
2nd	C-II Applying knowledge to practice	14%
3rd	C-I Analyzing and synthesizing	13%
4th	C-VI Managing information	11%
5th	C-X Task managing	9%
6th	C-IV Scientific and rational analysis	9%
7th	C-VIII Language communication	8%
8th	C-IX Inter-personal relations	7%
9th	C-VII Performing basic tasks with computers	6%
10th	C-III Making research	4%
11th	C-XI Analyzing the social context	4%

IV. DISCUSSION

Within this paper, the authors have presented an overview of an evaluation proposal for FYPs in engineering university studies. While the details of the proposal may be somewhat biased by the professional background of the authors (6 engineers, 1 physicist and 1 linguist, all giving lectures in a telecommunications engineering faculty) and the specifics of their institution, the approach can be easily transferred to other contexts, as reasoned in the next paragraphs.

The assessment procedure is closely related to the educational objectives of the FYP by means of the so called project achievements enumerated in [5]. The proposed procedure follows the rule of directly assessing the relevant educational outcomes, namely the competences, as suggested in [8]. These two criteria, together with the search for simple questionnaires that can be contained within a single sheet of paper, have served as a basis for the proposal. As for the assignment of marks to each competence, although the proposal allows certain degree of subjectivity, it could be complemented with a rubric-type guide for evaluation. It should also be noted that, intentionally, no pre-defined scale for the marks has been given. In the authors' view, this is not a critical aspect of the proposal and it can be adapted to specific circumstances. Still, if an objective orientation were to be given, a scale consisting of four to five levels seems to be appropriate, according to [7] and [11].

Regarding the ranking and weighting of competences, the ordered list presented in section III-B is undoubtedly a result of the personal views of the authors. Yet, some aspects of the proposal can be generalized. In the first place, the two-stage approach (ranking in the first place, weighting in the second place) derived as a simplification of the proposal in [10] can be adopted within any group to identify the most and least relevant competences. In the second place, it is also significant that, after an independent ranking-and-weighting process, there was a remarkable degree of agreement in that:

- the knowledge of the technological area and the capacity of applying theory to practice are the most relevant competences to be developed and assessed during the FYP,
- making research and analyzing the social context are among the least relevant and
- the relevance of language communication should not be diminished.

Last, the whole approach could easily be extended to the final works in higher educational levels (e.g. MSc or PhD). As considered in [6], the set of competences to be developed at graduate and postgraduate levels is mainly the same, though the particularization of those competences for each educational level should result in different educational objectives. Thus, the evaluation process could remain basically unchanged but with different weights assigned to each competence, since the purpose of postgraduate studies is not the same as that of undergraduate courses.

Abstract—**Learning network protocols is not an easy task. We use them every day, but they have become transparent, as they are integrated in the Operating System. Its use also implies the interaction between different devices, including aspects like concurrency, noise and multi-threading. As a result, the student sees this subject as not necessary, and difficult, easily loosing his interest in the matter. This document is a summary of the work developed in an undergraduate course, where Wireless Sensor Networks (WSN) based on Sun SPOTs have been used to improve the comprehension and interest of the students. In the undergraduate course Network and Communications, a Game based lab has been developed. The results show the improvements from previous years.**

Network protocols; Wireless Sensor Networks; Game based learning

I. Introduction

Computer networks is an interdisciplinary subject that covers fields between electronic engineering and computer engineering. It is the base of our actual communication systems, going from the telephone, to the Internet, and, in a more subtle way, modern digital TV.

It is commonly assumed that network protocols are integrated in the Operating System (OS). They are seen as a commodity, as the OS itself[1]. The result is a student not too much interested in learning its implementation. Moreover, network protocols usually imply multithreading and concurrency, which are seen as complex by many students. Summing up, the students usually are not too motivated in the subject.

An experience has been made on the undergraduate subject "Networks and Communications" (NC). This subject includes a lab, whose objective has been implementing a small protocol with a basic stack, including:

- Frame definition
- Addressing
- Error control through an Automatic Repeat Request (ARQ)[2] mechanism

The definition of an ARQ implies the development of a sender and reception buffer, the control of the frame sequences, and the use of timers to detect possible timeouts.

Initially, the protocol was designed using an RS-232 null-modem physical layer. The introduction of noise and errors had to be made artificially by the professor. As a result, the students saw the protocols as an overreacting solution to an improbable problem. We wondered if our lab was a turn-off[3]. For this reason, since 2005, we have started to use Wireless Sensor Networks (WSN), with the objective to improve the students understanding and motivation regarding the subject.

The WSN alternative has been confirmed by an increasing number of experiences as an educational tool. Some use them as a tool for other purposes, like a system for kids to browse Internet[4] or for undergraduates to control the environment[5]. Others use them to teach network protocols [6]-[10], as is our case. In this work we present our experience in this field.

II. Networks and Communications

Networks and Communications is an introductory course to the network protocols. It is the first time in their curriculum that the students see the characteristics of a network and its protocols. The base of the subject is the OSI reference model, the main local and wide area network protocols, and the TCP/IP stack.

A. OSI Reference Model

There are different ways to approach to the networks (bottom-up[11], top-down [12]…), but the base is usually the Open Systems Interconnection (OSI) basic reference model [13] from the International Organization for Standardization (ISO). It defines seven different layers, which are stacked. Every layer provides services to the upper layers and is client of the lower one. The layers are:

- Application: Provides access to the OSI stack.
- Presentation: Gives the representation of the data transferred between the applications.
- Session: Its purpose is to provide means to organize and synchronize the dialog and manage the data exchange.
- Transport: Transfers data transparently, relieving the upper layers from any concern with the detailed way in which reliable and cost effective transfer of data is achieved.

- Network: Provides routing and relay solutions to the transport layer.
- Data Link: Provides means to transfer data over a specific physical layer.
- Physical: Defines the way the bits are transmitted through a medium. It usually implies the definition of connectors and cables, antennas… depending on the kind of transmission.

Taking into account the real implementations, sometimes the OSI stack is divided in three environments, considering the layers interaction [14]:

- The network environment: includes the lower three layers, and it is dependent on the characteristics of the network itself (medium, codification, format…). The interaction is between layers of adjacent nodes.
- The OSI environment: its services are more oriented to the applications. The four higher layers compose it. The communication in this case is between the layers at the end of the communication.
- The Real Systems environment: are the applications itself (browsers, word processors, terminals…).

A representation of both, the OSI reference model stack and the associated environments are shown in Figure 1.

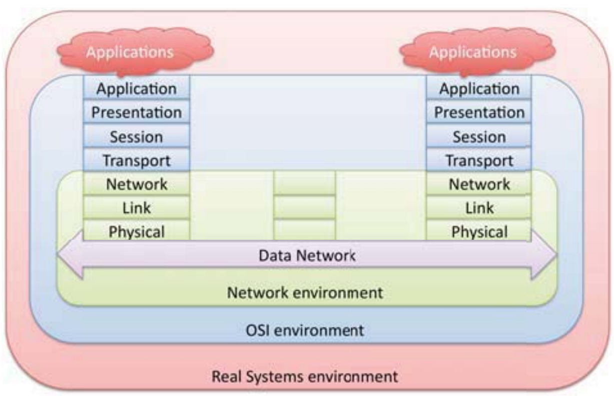

Figure 1. OSI reference model and associated environments.

The Networks and Communications subject (NC) is oriented to the network environment, with a brief vision of the OSI environment.

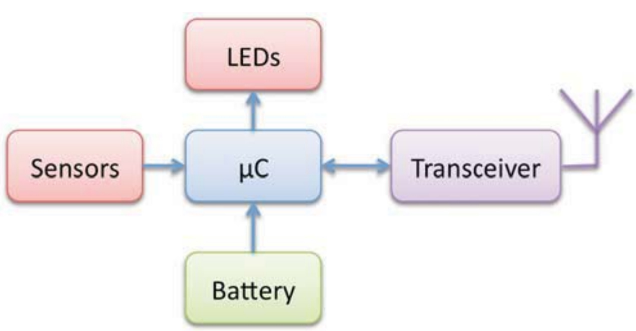

Figure 2. Block diagram of a basic WSN node.

B. *Wireless Sensor Networks*

WSN is a relatively new technology, which is based on the improvements of wireless communications, low power consumption and sensor size reduction. The results have been devices the size of 2 AA batteries, able to get information from their environment. Every device becomes a node of a network that allows transmitting data among them [15]. The block diagram of a basic device is shown in Figure 2.

The simplest WSN node includes a microcontroller, a transceiver and a battery. Usually it also includes some sensors and depending on the application, LEDs or other display to provide some information to the user. Initially the communication was using proprietary transceivers. Since 2003, the IEEE 802.15.4[16] protocol is available for this kind of networks.

IEEE 802.15.4 is a simple protocol, designed to work with little resources and power[17]. It uses three different bands, but the most common is the ISM 2.45 GHz band. This band is shared with Bluetooth and Wi-Fi, meaning that it has to include strategies to avoid interferences with these and other protocols. This is accomplished using an offset quadrature phase-shift keying (O-QPSK) modulation.

One of the first solutions for WSN was the TinyOS framework[18]. It provides a language (NesC), an Operating System (TinyOS) and the blueprints for different devices. One of the firsts commercially available was the tMote(Figure 3.). These motes were based on a Texas Instruments (TI) msp430 microcontroller. It also included an IEEE 802.15.4 transceiver from Chipcon (now TI), and some sensors and LEDs to get data and provide some feedback.

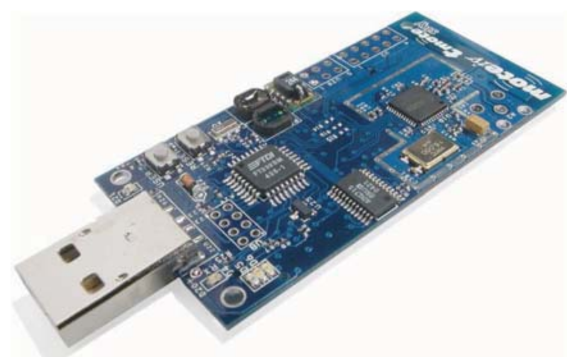

Figure 3. tMote photograph.

This alternative seemed interesting as more nodes could be included in the network, and no cable was necessary. For this reason, we started in 2004 to work with these devices. The organization of the labs was:

- Introduction to NesC programming.
- Introduction to the tMote sensors.
- Interchange of data between motes.
- Development a simple weather station based on the tMotes and using an ARQ protocol to transfer data between them.

The main difficulty was the change of point of view. When a student implements a program, usually thinks in solving a problem with an algorithm, easy and simple. He is the only user, and he knows how to work with it. As a result, the program works perfectly. In other words, if the algorithm is good, the results are warranted.

In computer networks, the situation is different. The algorithm can be perfect, but if errors are not taken into account, the system will work with bad performance, or simply it will not work. This implies that the student has to start to think about the inputs and outputs as something that can introduce errors. These errors have to be detected to take the necessary actions.

Using an RS-232 cable, this concepts where hidden as the communication was nearly ideal. With WSN the students started thinking for an ideal environment, more or less equivalent to an RS-232 cable. However, the situation was fully different. The networking concepts appeared naturally. Frames from one group were received by another (addressing), or some frames were lost when two motes transmitted data at the same time (collisions).

Another major issue was the difficulty of the students to learn the NesC language. Although it is similar to Java (the base language in Computer Engineering), it took between 10 to 14 hours to learn it, which was half the laboratory time. This time could not be easily reduced because there was not a simple simulator to continue the work at home, as TOSSIM[19] was not a good educational tool.

In any case, the difference between the use of an RS-232 cable and this tMotes was clear. Only the possibility to light a LED changed the face of the students. The lab results were better, but we continued to think about possible improvements.

Figure 4. Sun SPOT photograph.

C. *Sun SPOTs*

In 2004 Sun Microsystems started to work on a WSN device including an IEEE 802.15.4 transceiver and an embedded Java Virtual Machine. The devices were finally available in Europe in 2007. They created a grant for universities to use these devices in labs. This way we started to work with them.

A Sun SPOT (Figure 4.) is a device similar to a tMote, but more fancy. The first difference is its box, made of transparent plastic, which allows seeing the electronics. It includes sensors for acceleration, temperature, humidity and switches. It also includes eight tri-color LEDs, to provide information to the user. Last, but not least, it has a microcontroller with enough memory to run an embedded Java Virtual Machine.

From our point of view, the main improvements were:

- The platform is based on the Java programming language. This means that the students do not have to learn a new language, just a small API.
- There are more sensors and LEDs available, which allows more interaction with the device. The students see these devices like toys, and their interaction as a game.
- An Integrated Development Environment based on Netbeans, which simplifies the code development.
- A “console output” is available, which can display messages.
- Finally, a simpler simulator[21] has been developed, which allows the students to continue the work at home, without being necessary to have the device itself.

The result was an increase of the lab available time. For this reason, we started to think about new alternatives to improve the labs taking into account this increase of resources, and some requirements:

- The objective of the lab had to be an application, not a protocol
- The protocol had to become a tool to solve the applications requirements
- The target had to be adequate to the time available for the subject.

With these conditions in mind, we thought that the best objective was to develop a small game based on two Sun SPOTs.

D. *Laboratory modules*

The lab is organized in four modules and one presentation of results. The students are organized in groups of three people. We have chosen three to have at least two students of the group in the lab, as sometimes one has a “job emergency”. The exercises are solved as a group, but the documentation is presented individually. The modules are based on the tutorials and documentation from Sun Microsystems[22]. These modules are:

1) *First steps using a Sun SPOT (1 session)*

The purpose of this module is to introduce the student to the Sun SPOTs. Taking into account that we want the student to have the IDE and simulator installed at home, we explain them how to do it in the class.

After that, they learn how to update the Software Development Kit (SDK) and the Sun SPOTs. This task has to be done every year, as new stable tools are available.

Finally, they start to use the IDE to develop a simple demo application that blinks a led. The students usually end up feeling that the labs can be done.

2) Sun SPOTs anatomy (1.5 sessions)

The objective of this module is to introduce the different elements of the Sun SPOT to the students. They start to use the tri-color LEDs making counters and sliders to present the information.

The second step is to use the buttons to get information from the user. The students have to develop a program that changes the LEDs behavior depending on the buttons.

The third is to use the accelerometer, and then the fun is guarantied, as they see a quick feedback to their movements. They have to show the angle in the three axes on the LEDs. As a result, they see that it is not possible to get the horizontal angle using and accelerometer.

Finally, they start to work with the radio just measuring communication strength. They can see that if they separate the modules, the power is reduced. This experience also allows explaining the physics behind the transmission of data.

3) Sun SPOTs communication (1.5 sessions)

This module was the introduction to the way a Sun SPOT communicates. The difficulty of this lab is not the code itself, but the problems that the students have due to the concurrency of different devices sending information at the same time. As said before, in a few minutes the students perceive the need of addressing and error control.

4) Sun SPOTs game (8 sessions)

The last module is a small project. They have to design and develop the game that is the objective of the labs. For this purpose, they have to propose a game that can be developed using two Sun SPOTs that communicate. The action and results have to be shown with the LEDs. The students can use any sensor in the device. Examples of these games are:

- Bowling: The movements of the hand and arm are measured, when one button is pushed on a Sun SPOT. This is equivalent to throw the ball. Depending on the angle and acceleration, more pins are knocked down in the second Sun SPOT.
- Shake master: Two players have to shake as fast as possible two Sun SPOTs. The one that shakes the Sun SPOT quicker wins.
- Power master: Two players make the quickest movement that they can. The one that gets the highest acceleration wins.

From this small sample, it is easy to see that the preferred sensor is the acceleration one. The reason is the quick feedback that it provides. However, sometimes, the response is not as fast as desired.

All the games require interchange of data. This implies that they require developing some kind of network protocol, including an ARQ mechanism. Although the IEEE 802.15.4 provides an acknowledge mechanism, it is not used in the lab. This way, the students could define their own frames and its behavior.

The students also understand the frame control field and its contents. The required flags come from the functionality. They also, become conscious of the necessity of a sequence number to have a reliable link.

The main drawback was that some student relied on the simulator, which has an ideal behavior. This means that no noise is created. In this case, these students were unable to interchange data. A workaround was to include a node that sent random data. This created network noise, providing a more realistic scenario.

5) Presentation (1 session)

Finally, there is a session where students present their games, showing their behavior. Usually their focus is on the application itself, forgetting about the communication aspects of the project. For this reason, the evaluator has to ask questions regarding the protocol implemented and how they solve different problems.

The approaches presented by the students from the application point of view, can be classified as:

- Basic Client-Server: There are two different programs, one for every Sun SPOT. One behaves as client and a second as server. The start-up sequence has to be followed precisely, or the system is unable to run.
- Advance Client-Server: The Sun SPOT include both programs, the client and the server, and at the start-up sequence, the protocol defines which Sun SPOTs behaves as server.

At link level, the addressing implementation is necessary as explained before. Reliability is achieved through the implementation of an inactive ARQ mechanism. The main difference with standard protocols is the text-based codification of the fields. Only a minority of groups does the leap to binary codification.

Finally, all the students present the documentation of the project. It is also difficult for them to differentiate between the documentation of the project and the comments of the code. The difference between the application, and its elements, description and the way it has been implemented. In some cases because they have relied on their partners, in others, because they really do not know how to explain what they have done.

To minimize the problem, the outline of the documentation is explained in detail at the latest session. This solution has proven to be effective, improving the documentation quality.

E. Results

The marks of the students for the last five years have been analyzed. The graph shows on one hand the percentage of students that passed the lab; on the other, the rate of students that passed over the number of students that went to the first exam (Figure 5.).

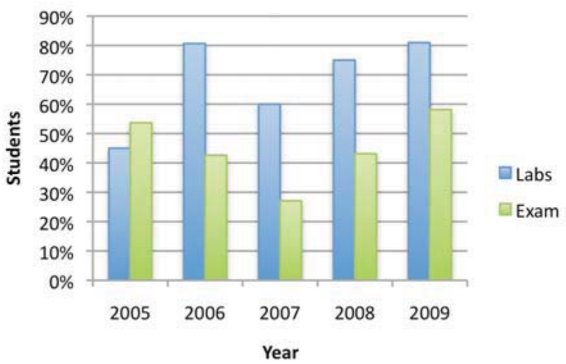

Figure 5. Percentage of succesful students in the lab and the first exam.

From the percentage of successful students, it is possible to see that there is an important change between 2005 and the rest of the years. The main reason is the change from an RS-232 based lab to a WSN one.

In January 2006 we started to use WSN in the lab. The number of students that pass the lab has its first maximum. The only drawback is a decrease of students that pass the exam. We thought this change came from the increase of difficulty of the labs, making the students change their priority from networks to learning NesC.

The number of successful students descended in the labs and the exam in January 2007. One reason was still the difficulty to learn and program NesC. Another reason was the motivation. There is a subject the same period that included the development of an application. The time required was high, and was seen as more interesting for them than WSN. At this moment, we started to think about a new change.

In January 2008 the results improved a little, although they were still worse than 2006 ones. This confirmed us that we had to rethink this laboratory.

In January 2009, with the introduction of the Sun SPOTs, both labs and the exams have had a maximum.

With the new labs, the students seem more motivated, asking more questions. A questionnaire has been done in December 2009 to confirm the last information (Figure 6.).

Questionnaire

1. How well did the introductory modules prepare you for the laboratory?
2. Did you find the SunSpots installation clear enough?
3. The SunSpot anatomy module provides enough information?
4. Did you find the SunSpots communication module appropriate?
5. Do you think a game is a good application?
6. The organization of the laboratory in a small project is a good option for this subject?
7. Do you think that the lab with SunSpots is interesting?
8. Did the laboratory help you to better understand the subject?
9. Do you think that this laboratory has to continue?
10. Summing up, do you think that this laboratory has been useful?
11. Comments

Figure 6. SunSpot laboratory questionnarie.

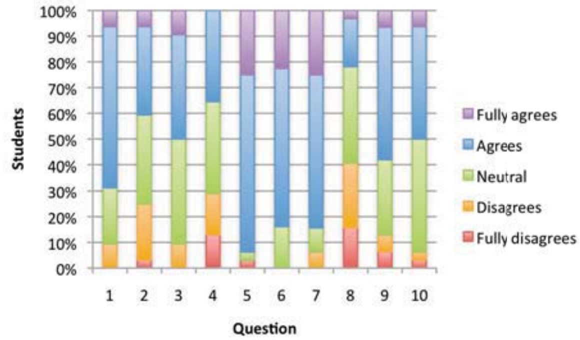

Figure 7. Questionaire results

The plot (Figure 7.) shows the results for the last cohort. In general, the students agree or fully agree on the actual organization of the laboratory. Only in questions 2, 4, 8 and 10 the agreement is below a 50%. Theses questions are analyzed deeply:

- Question 2: The installation of the SunSpots is difficult in shared environments like those that are used in a lab. Every year we have found problems with this. We are working to solve them.
- Question 4: This communications module presents how to program the SunSpots communication. To work with this module, it is necessary to understand communications and threads. From the comments, it seems that the problems come from the use of threads, so we are modifying the actual module with an extensive introduction on threads.
- Question 8: From the results of this question it seems that the laboratory is a failure, although it cannot be so bad if they think it has to continue (question 9). From our point of view, the problem is that the labs have been too centered on the game development. To solve this we will increase the stress on protocol aspects.
- Question 10: The sum is good; around a 50% see the laboratory useful, and less than a 5% disagrees. We think the alternatives presented will increase the quality of the subject, improving the number of agrees.

In summary, the use of SunSpots and WSN has proven to be a good tool to teach network protocols. However, the impact of related aspects, like the programming language or threads, has to be well calibrated.

III. Discussion

The results obtained with this lab can be qualified as good. The students have shown a deeper understanding of the subject. However, we have made a deeper analysis to evaluate pros and cons:

Pros:

- The students see the Sun SPOTs as a toy, which is easy to understand and use. This reduces the concerns for a new technology.

- The developing tools are free which is an important issue in an education environment[8].
- The use of Java has minimized the time required to learn. This has allowed focusing on the subject aspects.
- The use of a game as a target in NC has introduced network protocol as a tool, not as a requirement. This has improved the perception of the students.
- The students have shown, in general, creativity and motivation.

Cons:

- The students sometimes where more interested on the game image than its functionality, increasing unnecessarily the work, resulting in unsatisfactory outcomes[9].
- Sun SPOTs IDE does not include an easy debugging tool. This implies solving problems through console messages, which is not always easy.
- It is necessary to improve the interaction between theory, problems and labs in NC. A high percentage of students fail the course, although they have passed the labs.

Many of these results are shared by [7], which also uses Sun SPOTs to teach sensor networks.

IV. CONCLUSSIONS

The introduction of WSN on NC has introduced an improvement on the learning process of students. Now they see networks as a tool and not as commodity. It has also improved the number of students that have passed the lab. The students' learning curve is steeper, giving more time to focus on the subject aspects. They have also presented a stronger interest in the network related concepts, and better understanding. Finally, it is necessary to improve the integration between the theory, problems and labs to increase the number of successful students.

V. FUTURE WORK

These results have been used to redefine this subject in the new Computer Engineering Grade, based on the European Space for Higher Education (Bologna Declaration)[23]. Now, we are preparing the material for this new course, based on the results.

ACKNOWLEDGMENT

This work is supported by an equipment donation by Sun Microsystems.

***Abstract*—This article gives an overview of the organization and realization of an interdisciplinary practical course on grid computing. Both the lecturers and the attendees came from diverse backgrounds and disciplines including computer science, physics, medicine, and the humanities. We describe the management of the course, the assignments, the infrastructure developed and experienced in this interdisciplinary practical course at the University of Göttingen. The challenges and issues, the benefits, the expectations and their fulfillment are discussed. The experiences of the course show that diverse disciplines can be brought together to convey the benefits of grid technology by experiencing varied grid applications in production-like grid environments.**

***Keywords*-grid computing, interdisciplinary, practical course, D-Grid**

I. INTRODUCTION

The idea of an interdisciplinary practical course in grid computing emerged from an overlap of interests in the disciplines computer science, physics, medicine, and the humanities. Grid computing, an important research area in computer science, connects and advances research of disciplines with high computational demands, such as the participating ones.

A grid is a networked system “that coordinates resources that are not subject to centralized control using standard, open, general-purpose protocols and interfaces to deliver nontrivial qualities of service” [1]. It provides a service-oriented environment for collaborative and efficient sharing of computing and storage resources belonging to different organizations to fulfill the demand of distributed, high-performance applications, in our context grid applications. Today, grid applications are commonly used in research, as well as business domains such as financial, automotive, and pharmaceutical domains. However, the requirements of such applications grow steadily and need to be fulfilled by an appropriate infrastructure such as provided by a grid.

In this practical course, concepts and usage of grid computing in an interdisciplinary manner were taught. The expertise of the German grid initiative D-Grid [2] provided an excellent basis for studying and learning about grid technology. The students experienced and applied production-like grid environments. The D-Grid initiative is a research program initiated and funded by the *German Federal Ministry of Education and Research* (BMBF) to establish a national grid infrastructure for research and industry. The community projects of the D-Grid initiative involved in this course included MediGRID [3], *High Energy Physics* (HEP) Grid [4], and TextGrid [5]. These are all related to the disciplines mentioned above and located in Göttingen within the joint grid resource center GoeGrid [6].

The course took place in the summer term of 2008 at the University of Göttingen. The participants were assigned uniformly to groups according to their field of studies . Each discipline provided a tutor for supervising the students. For the establishment of a local grid environment, several computers located in a local computer network were allocated to each group.

The concepts of grid technologies were explained by practical applications of a grid environment using the grid software Instant-Grid [7]. Instant-Grid contains all necessary software to automatically set-up a pre-configured grid on computers in a local network by booting from CD. Within such an environment, the students were able to start, build, and use an experimental grid system for solving the assignments of the different disciplines.

This article is structured as follows: In Section II, the structure and content of the assignments of the three disciplines are explained. Afterwards in Section III, we describe the technical environment that the students used to solve the assignments. In Section IV, we present the evaluation of the described course. In Section V, we consider related work. Finally, we conclude with results and an outlook in Section VI.

II. Course Description

The goal of the course was to teach the concepts of grid computing by the application of grid computing independently of the field of study of each participant. In this section, the course and the posed assignments are described.

A. General Structure

The assignments addressed the HEP Grid of physics, the MediGRID of medicine, and the TextGrid of the humanities. All assignments involve inevitable concepts of computer science.

Each discipline developed a track of assignments, where each of the tracks referred to the corresponding D-Grid project. The students worked on the assignments on a rotational basis. The tracks of the assignments were structured in:

1) introduction and fundamentals,
2) exercises and practice, and
3) reflection and further discussions.

In part one of each track, the students prepared a report about the respective discipline that included the applications of grid computing in the fields of the discipline, their requirements, and the status of the related D-Grid project. During the preparation, the students looked into the specifics of the discipline and established connections between the discipline and grid technology. Furthermore, the students made suggestions and developed proposals for an optimization of the project with a focus on the grid perspective.

In part two, the students realized the ideas suggested in part one and solved practical assignments. This included the establishment of a production-like grid environment based on Instant-Grid and the technical realization of the assignments. Depending on the assignments, the students needed to discover, use, and start appropriate grid services and functionalities provided by *Globus Toolkit 4* (GT4) [8] or by the respective D-Grid project grid environment. With the help of these services, the students were able to develop efficient solutions for the assignments.

The assets of the solutions, as well as further optimization proposals were discussed and reflected in part three. At the end of each track, the developed grid software was presented and executed. The presentation included the design and challenges of the development, issues, and proposals regarding the existing solutions of the projects. These were then discussed and reconsidered. This also led to an improvement of the solutions presented by the students.

At the end of the course, the students compared the requirements and solutions between the three tracks. They reflected upon similarities and differences, but also expressed specific criticism and their opinions whether they would use grid technology for other areas.

B. Learning Objectives

The goals of the course can be divided into two areas – one related to technical knowledge about grid computing and, the other – to soft skills. The goals related to technical knowledge included understanding, explaining, and applying grid computing technology, in particular:

- concepts of grids,
- requirements of grids especially related to different disciplines,
- application and usage of grid technology on areas in different disciplines based on D-Grid projects,
- migration of legacy applications into a grid environment, and
- experiencing advantages of grid computing.

The goals related to soft skills on the other hand focused on the students' abilities to communicate clearly in the context of a wide range of topics, such as:

- collaboration across disciplines,
- establishment of effective and manageable team work in a heterogeneous environment,
- discussing results in a clear, structured, and concise manner,
- critical thinking,
- gathering and accessing relevant information from a library and other information resources,
- explaining the scientific method including the concepts of hypothesis and experimental controls, and why objectivity is essential, and
- writing effectively in an appropriate style and depth,
- integration and application of knowledge and experiences.

These learning objectives were promoted in several ways. These included team meetings with the instructors of the respective discipline, introductions to the disciplines, grid concepts, and available grid services. Furthermore, weekly assignments and tutorials of the grid used in the respective D-Grid projects were given. These activities were extended by regularly discussions, and final presentations.

C. D-Grid Projects Located in Göttingen

The D-Grid projects located in Göttingen supported by several faculties of the University of Göttingen built the basis for the assignments. The projects are described in the following.

1) MediGRID: The MediGRID project uses grid computing systems as an underlying infrastructure for providing services that access distributed applications supporting biomedical research, clinical research, and image processing.

These applications require high-performance computing and may access data from geographically distributed locations. The project represents institutions in the area of medicine, biomedical informatics, and life sciences. The objective was the development of a grid middleware integration platform enabling biomedical life science services. For this, four methodological modules (middleware, ontology, resource fusion, and e-Science) have been developed and served for the establishment of a grid infrastructure implementing the specific requirements of biomedical users [9]. Therefore, the grid middleware has been embedded in a user-friendly environment that allows intuitive access to e-Science services for biomedicine. Applications for image processing, ontology, and biomedical informatics are incorporated in a web based portal [10] that is easily accessible and usable. The services that access these application are based on an enhanced security model with different security levels. This is required because access to specific secured resources which host pseudonymized patient data is needed for the computation of medical data, e.g. for investigations on specific disease patterns [11].

A major requirement in up-to-date biomedical research is the creation, maintenance and usage of data located in shared resources. In MediGRID, this need is fulfilled by grid services provided in the e-Science platform that is continuously available. Within this platform, costs for the usage of resources for necessary tasks are pre-calculated and policies are established to allow a reliable deployment. Data can be stored and processed by using grid services independently of the geographical location. MediGRID demonstrates the feasibility and usefulness of grid services in medicine and life sciences by applying these services in biomedical research with multidimensional data and by correlating genotypic and phenotypic data.

2) HEP Grid: The D-Grid initiative supports the world wide *Large Hadron Collider* (LHC) [12] computing grid of the *High Energy Physics* (HEP) community. The LHC is a proton-proton collider at CERN in Geneva, Switzerland, where multi-purpose experiments – *A Toroidal LHC ApparatuS* (ATLAS) [13] and *Compact Muon Solenoid* (CMS) [14], – and two specialized experiments – LHCb [15] and Alice [16] – are performed. The computing challenges of these experiments are enormous. For example, the ATLAS experiment produces data in the order of 300 MB/s. This data needs to be reconstructed, i.e., the signals of the various detector components are combined to reconstruct the particles that are produced or scattered in the collision of protons. The demand on storage and computing resources can only be handled with modern grid systems.

Different kind of grid applications exists in the HEP community. Scientists all over the world access the experiment-data to perform a variety of physics analyses. This data is replicated to grid sites all over the world to avoid data loss. However, individual analysis jobs can also be very data or computing intensive. Thus they may need to be switched to another data location. In addition, detector components need to be calibrated regularly. The calibration jobs take detailed measured data as input and are performed on remote grid sites.

A large fraction of the grid jobs calculate simulated collision events, so-called Monte Carlo events. For a physics analysis, simulated and measured data of roughly the same size are required. Monte Carlo events are continuously produced to increase the available statistics. Similar to the measured data, the calculated Monte Carlo event-results are distributed on the grid for world wide access.

3) TextGrid: TextGrid is the humanities project in the D-Grid initiative. It establishes a trusted repository (TextGridRep) that ensures the long-term availability, interoperability and re-usability of research data in the humanities. Furthermore, TextGrid provides a platform for the co-development and sharing of dedicated services.

The humanities are a large and diverse discipline. TextGrid's first dedicated target group within the humanities are philologists, linguists, musicologists, and art historians. For these scholarly fields, TextGrid provides a virtual research environment (TextGridLab) that offers a single point of entry to specialized tools, content, and collaborative spaces.

The TextGrid infrastructure is based on the grid middleware GT4 with extensions along several lines to meet the requirements of research areas in arts and humanities. First of all, TextGrid developed a gateway between *Grid Security Infrastructure* (GSI)-based security – which is prevalent in grid environments – and Shibboleth [17] – prevalent in higher education. Another major effort was the integration of repository technologies for data and metadata management [18] solving problems of long term data preservation. On higher architectural layers, TextGrid creates an open service environment and provides a grid-based, interactive client based on the Eclipse Rich Client Platform [19].

D. Assignments of the Disciplines

In the following, the tracks according to the D-Grid project are described corresponding to the structure presented previously.

1) MediGRID track: Within this track taught by the biomedical informatics group, a brief and practical introduction to different biomedical applications in the MediGRID web portal was given. The participants used and experienced applications for medical image processing, bioinformatics, and clinical research in the MediGRID portal. Before using these applications, the students needed to be authenticated. For this purpose, they acquired X.509 certificates belonging to the *Virtual Organization* (VO) "Education" from the German D-Grid Initiative that was established especially for this course and for later teaching purposes. After applying this certificate to the MediGRID portal, the participants were authorized to use protected medical grid resources and to execute selected grid applications of the MediGRID portlets [11].

In part two of the MediGRID track, application programs from the production grid portal, such as image processing (3D ultra sound), bioinformatics (gene prediction) and clinical research (biosignal processing), as well as an identification portlet (as a Java deployment service) were gridified and added to the Instant-Grid environment. The distribution into the grid was carried out by command-line instructions. These commands were transferred into a shell script and started on available computing resources. The sequence of commands in this script corresponds to a grid workflow. A workflow is an abstraction of complex processes in the grid software stack. This script was exemplified by gridifying a gene prediction algorithm for the comparison of two species. The developed workflow was applied in the Instant-Grid environment and reflected the same operations that would have been stated on resources in the grid offered by MediGRID. The results of solutions and adjustments developed by the participants were taken into consideration in ongoing MediGRID developments.

In the third part, the discussions and reflections focused on issues about ensuring privacy of hardware and software resources. These included topic such as security requirements in application classes related to privacy levels compared to existing security measurements. Specific aspects as the need of certificates, and the procedure of applicable and operable security levels (security vs. usability) were considered. Finally, it was discussed which requirements future medical grid applications need to fulfill, and how ethical aspects and the acceptance of the end user need to be considered. The result was a report that has been presented for discussion in the MediGRID community at the university.

2) HEP Grid track: The goal of this track was to give insights on typical demands of computing required by modern particle physics experiments and to study the various challenges posed. The DØ experiment [20] at the Tevatron, a proton-antiproton collider at the Fermi National Accelerator Laboratory [21] in the USA was taken as an example. At the Tevatron, packets of protons and anti-protons collide at their highest possible energy at a rate of 2.5 MHz. After an online event pre-selection, the signals of the scattered and newly produced particles are recorded by the DØ detector at a rate of 50 Hz. The average size raw data of a single event is 250 KB. The experiment runs since 2001 so that already an enormous amount of data has been stored. From the raw data, physic objects are reconstructed and stored to further process them in various analyses.

In the first part of this track, the simulation of DØ events was performed step by step. The workflow of the simulation chain and the workflow scripting system were investigated in detail. From the duration of the simulation of single events and the file size of the different output data, the demand on computing and storage resources of the whole experiment was extrapolated. As an example, in 2005 the DØ experiment reprocessed 250 TB of raw data. Such enormous challenges for computing can only be handled with grid clusters distributed world-wide.

In the second part of the HEP Grid track, the interactive simulation of Monte Carlo data was adopted in such a grid environment. This has been accomplished by the use of Instant-Grid, similar to other tracks of the lab course. The students submitted simulation jobs to the Instant-Grid environment via commands provided by GT4. The use of a command line interface and scripts or macros is the typical way of applying grid computing in high energy physics. In addition, an supplementary introduction to gLite was given. GLite is the grid middleware of choice in the HEP Grid.

The third part included reflections and discussions of various grid applications addressed in HEP. Aspects like data archiving, data security and safety, data management, the structure of a grid system, demands on the middleware, and possible future developments were discussed. The students' conclusions were that grid computing has permanently been used for the production and storing of physic experiments and Monte Carlo data. For the calculation and analyses of the data, a stable, standardized, and tested grid environment is more important than the application of the latest features of grid technologies.

The computing challenges of experiments at the LHC at CERN in Switzerland increase the need of grid computing in high energy physics even more. As an outlook, the requirements of the Fermilab and the CERN experiments were compared.

3) TextGrid track: Building on the experiences of the D-Grid humanities project TextGrid, this track provided students with an overview of the opportunities of the e-Infrastructure used in the humanities. The first part of the track introduced exemplary research activities in the humanities including research on languages, literature, and art history, covering their diverse scholarly workflows [22]. Building on these information, the students derived requirements for grid technologies posed by the humanities. Amongst the scenarios mentioned by students were collaborative and interactive workflows, as well as data curation – the preservation, interoperability, and re-usability of digital objects. Particularly, the replication of data across multiple grid nodes potentially raises the stability and availability of data over long periods of time.

In the second part, students practiced how grid technologies support data curation. For an assignment, students replicated digitizations of ancient texts to distributed grid nodes using standard grid protocols. Further extending this exercise, the replicated data were processed at the distributed nodes with a typical function of data curation: the migration of digital objects between formats of varying quality or stability, e.g. proprietary formats versus standard formats with public format specifications. In particular, students were asked to take the digitize high-quality preservation formats (100 megabyte TIFF images without compression) and convert them into a scaled-down copy for presentation purposes (1 megabyte JPEG2000 format) making best use of distributed processing in the storage grid.

The discussions in the third part of the track reflected the opportunities of grid technologies for the arts and humanities. During the discussions, the perspective reverted, and students highlighted possible contributions of the humanities to current e-Infrastructure technologies. This includes existing mechanisms for data curation such as repository technologies that establish reference networks of data (cf. data-centric science [23]), as well as virtual research environments that foster collaboration through exchange of data and methodologies. Discussions about the integration of such systems into existing e-Infrastructure environments helped students to understand the opportunities and limitations in both worlds.

III. Technical Configuration

The practical realization of the course assignments required grid software. We chose Instant-Grid since it offers simplified possibilities for starting local computer grids and its software components are compatible with the ones utilized by D-Grid. Instant-Grid employs the open source grid middleware GT4 and is based on a Knoppix-Linux [24] environment. With the GT4, Instant-Grid provides a preconfigured security infrastructure and services for job management, data handling, and information delivery. With the Instant-Grid Live-CD, a computer grid can be started without a complex installation. This environment allowed the students to study and use a grid on their own computers without the restrictions that are associated with a remote production grid environment. However, starting many Instant-Grids on the same local computer network requires specific adjustments, as described in this section.

A. *Configuration in an Existing Local Network*

Instant-Grid was originally designed for closed *Local Area Network*s (LANs) in order to avoid conflicts with services, such as *Dynamic Host Configuration Protocol* (DHCP) services that run in the existing network. Thus, starting many Instant-Grids on the same local computer network is not possible without further adjustments. Therefore, the computers used for the course and required to boot Instant-Grid had to be separated from the lab network. For this purpose, we established layer three networks on a layer two switch to which the computers were connected. We grouped the computers of one Instant-Grid into different *Virtual Local Area Network*s (VLANs) on the switch-level and separated them from the local computer network (lab network).

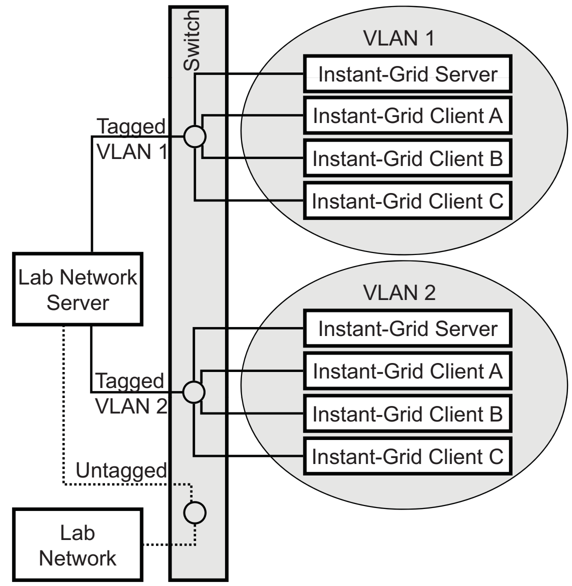

Figure 1: VLAN configuration

Figure 1 illustrates two project groups, VLAN 1 and VLAN 2, in which each starts an Instant-Grid server with up to three clients independently from the other project group. The packages sent out from the Instant-Grid networks were labeled (“tagged”) with the identifier of the VLAN, and filtered by a firewall to provide protection for the existing networks, and to route between the different virtual networks. The packages sent from the other networks, such as the lab network, did not have any labels (“untagged”), and thus were not filtered.

In our configuration, four computers from the lab network were configured and then assigned to each group. The students were able to start and configure their own grid on these computers. However, this was only possible at predetermined times, since the particular network configuration of VLANs had to be enabled by a course mentor. After the students finished their activities in their local grid, the network switch needed to be reset to the original configuration. This was necessary because of security reasons that require that only the standard operating system is started.

To access the Internet from the Instant-Grid network, *Network Address Translation* (NAT) had to be set up on the Instant-Grid server as well as on the router of lab network, i.e., on the lab network server. Figure 2 illustrates the NAT-gateways of our configuration.

B. *Technical Challenges of Instant-Grid*

Instant-Grid is based on Knoppix-Linux. Because of its Live-CD design, neither a component for the management of user accounts was provided, nor a configuration could be written permanently. Therefore, it was not feasible to create permanent grid user accounts. Grid user accounts have additional but very specific requirements according to

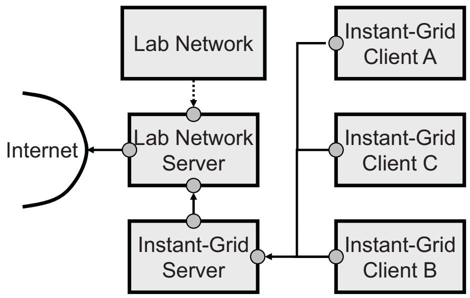

Figure 2: NAT configuration

TABLE I. FIELD OF STUDY OF THE PARTICIPANT

Computer Science	Physics	Medicine	Humanities
5	4	5	2

the grid environment compared with a usual Linux user account. The students were only able to work locally and, in addition, they needed to be supervised by a mentor, since misconfiguration of the network had to be avoided.

Instant-Grid requires a closed local network. Therefore, as described in the previous section, the integration of Instant-Grid into an existing network setup is a laborious task.

Students should not be able to make changes in the network configuration of a lab network server or set up the VLANs. In our setup, a script was started by a mentor, which then activated or deactivated the VLANs. If Instant-Grid had been started without configuring the VLAN, it could have caused serious conflicts within the lab network.

IV. EMPIRICAL COURSE EVALUATION

A. Course Workload

Due to organizational reasons, this practical course has been restricted to 16 participants. 16 students with heterogeneous backgrounds and training attended the course. The distribution of the fields of study of the participants is shown in Table I. The number of participants studying in the humanities was adequate. While the "digital humanities" are gaining speed in applying computer science technologies in their research, awareness about digital infrastructures such as grid technologies, as well as the adaptation of infrastructure technologies to the requirements of the humanities still remains to be increased.

B. Student Perceptions

Overall, the course has been evaluated as "good". The results of an anonymous feedback survey are summarized in Table II. They reflect the differences in the knowledge and the background of the participants. While students of technical studies missed details about programming, other students were overwhelmed by the technical detail. At the end of the survey, the students were able to make comments. One student mentioned that "it is preferable to work on the

TABLE II. PARTICIPANTS FEEDBACK SUMMARY

Assertion	Average	Median	Standard deviation
The course was excellent	3,43	4	0,73
The requirements of the course were too high	2,14	2	0,83
The dimension of the course was too big	2,57	2	1,29
At any time, I fulfilled the required premises of the course	3,71	4	0,77
Relevant content could be differentiated from irrellvant content	2,57	2	1,06
The contents of teaching were demonstrated by examples and viewings	3,57	4	0,72
Difficult terms have been clarified during the course	3,29	3	0,6
The used media (blackboard, beamer, etc) were appropriate for the course	4,14	4	0,61
The assignments were structured in an excellent manner	2,43	2	1,18
The speed of the course was too slow	2,57	3	0,73
The noise level during the course was very distracting	1,43	1	0,73
Questions were answered during the course.	4,86	5	0,33
Before the course, my interest of the topic was very high	4,14	5	0,92
After the course, my interest of the topic was very high	3,71	4	1,08
Cross-references to other lectures were recognizable	2,86	2	0,78
The benefit for a later employment is very high	2,57	2	1,06
The lecturers showed high professional competence	4,43	4	0,33
The lecturers presented the content of teaching in an excellent manner	3,29	3	0,7
I would recommend the lecturers to fellow students	3,57	4	0,72

assignments individually", and that "the assignments could include complex programming". Another student wrote that "it was interesting to know about financial and legal issues of grids". However, others mentioned the opposite. The foundations need to be taught at once and not repeatedly in the beginning of each track. Afterwards, the individual requirements of each discipline for grid and their differences can be imparted so that the student can learn to apply similar methods in different areas.

C. Tutor Perceptions

In this practical course, each of the three disciplines provided tutors for supervising the students. However, the interdisciplinary manner of the course required more collaboration between colleagues and students than in other usual courses of the disciplines. The preparation of the course took longer, because the different teaching methods and expectations of the different disciplines had to be evaluated, understood, and synchronized first. The tutors as well as the students had varying knowledge of the other disciplines and thus required proper introductions to the disciplines. Even technical terms for the same concepts of grid computing may vary. Also, it was necessary to get familiar with the technical environment chosen for the course so that the right tasks could be defined for the students.

Overall, the feedback given by the involved tutors showed that they had to dedicate more resources for preparing and supervising the course, but they also earned special competence for later teaching purposes.

V. Related Work

Several courses about grid computing have been taught at other universities. The courses focus mainly advanced computer science students. These include courses described in [25], or [26]. In contrast, Mache and Apon describe a course for undergraduate students only focusing on the computer science course of study [27]. They present five knowledge areas that should be covered by a grid computing course. This includes appropriate topics and exercises. Similar approaches of courses for undergraduate computer science students can be found in [28], or [29]. A top-down teaching approach is described in [30]. This means that the students begin with job submissions using a grid portal and, afterwards, they experience step-by-step the details of a grid computing infrastructure and its architecture.

The research projects and disciplines mentioned in this article offer in addition to the practical grid course an interdisciplinary seminary about grid computing in the winter term at the University of Göttingen. This lays the foundations for the students that attend the practical course about grid computing.

Our practical course aimed at students from diverse fields of study including physics, medicine and the humanities. They had to learn best practices from each field and its relation to grid computing. To our knowledge, this interdisciplinary approach of teaching grid computing is unique.

VI. Conclusion

The interdisciplinary practical course on the application of grid computing has been evaluated as "good" by the students and thus can be considers a success. Overall, the course provided students with diverse perspectives on grid computing from the various disciplines involved – physics, medicine, computer science, as well as the humanities. From scholarly requirements to hands-on experiences, as well as discussions about the current state and the possible future of e-Infrastructure research. The distinct perspectives contributed to the precipitous learning curve of the students during the practical course.

For solving the assignments, the students had to learn to apply their knowledge on other disciplines, but also to explain their field of study to students of other fields of study, for example, for the realization of inter-domain software. Grid computing builds a bridge between different backgrounds offering innovative opportunities and promising ideas in each discipline. The students had to solve the assignments by combining advantages of each discipline through developing, applying, and experiencing different solutions. The students learned to propagate their ideas and to communicate problems as it was best for the interdisciplinary solution and furthermore, to realize their ideas in a grid computing environment using available resources most efficiently.

In the final discussion and post-processing of this interdisciplinary course, the interactions and teamwork between the students of the different fields of study were considered. The goal of the course was not that the humanities students have to program or that the computer scientist learns the processes of the genetic prediction, but that they work in a complementary manner and solve the assignments together in a team. Ideally, the physicist, for example, would ask the correct questions, the humanities student would introduce methods for answering the questions, the physician would contribute with background knowledge, and the computer scientist would developed a technical solution. In each track, the adequate roles were taken by the students and, therefore, the tracks could be solved in an complementary manner.

From the technical side, Instant-Grid has been proven as an ideal tool for the realization of the course. Instant-Grid is an adjustable and scalable instrument for ad-hoc grid applications. For short-term development, extensions such as specific portals and even complete development environments can be included.

Following the character of this practical course, solutions have been elicited to solve the assignments of the disciplines. For imparting knowledge of grid programming expertise, especially for computer science students, Instant-Grid is the tool of choice. We experienced that there is a great demand for grid-developers in the IT sector, but also in other sectors. However, conveying techniques of grid programming to students in an interdisciplinary course is not feasible, because students who do not study computer science get lost in the technical details. The computer science students were responsible for technical requests of the fellow students and for the realization of their solutions. However, a practical course about programming in a grid has been offered in addition in rotation with the course on the application of grid computing.

At the University of Göttingen, the grid computing teaching track is well established. Good evaluation results and several successful applications for future grants underpin the stability of Göttingen's grid infrastructure and emphasize the need for substantial grid teaching to educate junior assistants.

For the interdisciplinary course described in this article, we plan to extend or exchange assignment tracks. For example, other fields of research that are active in Göttingen can be considered. This could include a track about quality assurance in grid computing [31], a track about numerical simulations in a grid environment, cf. OptiNum-Grid [32], or a track about legal issues [33]. Ideally, a training framework for the application of grid computing technology, as well as for programming grid services should be developed.

The skills that were taught in this course went far beyond the technical ones of applying grid computing. It was about collaboration with colleagues, who introduced different knowledge and who may solve tasks in a different way. It was about communication, in which requirements and proposals are not explained only with technical terms and concepts that are only understandable for people of the same discipline. The participants got deep insights in each discipline and learned to develop solutions in cooperation with students from other disciplines as it is often the case in the professional world, where the disciplines often melt. Acquiring such skills is a life-time experience for the students, as it can only be conveyed in an interdisciplinary course.

Abstract— **The aim of this work is to introduce scenarios into the first and second year of our undergraduate electronic and electrical engineering curriculum to improve the educational and learning experience of our students and in doing so improve the quality of our graduates. This paper introduces the curriculum development involved in the implementation of scenarios. We reflect upon and analyze the successful aspects of this trial and identify those areas that are in need of improvement.**

Keywords – Student centred learning, scenario-based-learning

I. Introduction

The UCL Electronic and Electrical Engineering (EEE) Department, in which this study is based, runs two undergraduate programmes: a three year BEng and a four year MEng. We aim to produce graduates who have a strong theoretical grounding in the fundamentals of the discipline, are capable of independent thought, able to approach new problems, can communicate results to others in a logical way and work in a collaborative environment.

Both students and academic staff have expressed a number of concerns with the undergraduate program which is largely delivered by lectures, tutorials and expository laboratory classes. Students find that the course is not as hands-on as they expect and don't appreciate the depth of theoretical background required to fully engage with the discipline. Academic staff are concerned that student motivation and performance has decreased by the time they get to the second year.

In an attempt to address some of these problems, we introduced a series of, week long, engineering design projects called scenarios, where students work in small groups in a realistic situation on a fairly open problem where the outcomes are undetermined. The scenarios are designed to draw on and consolidate the lecture material that the students will have received in the preceding weeks. As such, planning of the course and design of the scenario needs to be carried out in an integrated fashion with emphasis on horizontal integration across lecture courses and application of knowledge through engineering design projects (scenarios). The use of a series of short focused scenarios in the first and second year, rather than the more often used design project running over an entire academic term in parallel with lectures, was designed to: enable a greater range of areas within the curriculum to be covered, simplify time management for the students, and provide increased opportunity to provide formative feedback that the students can apply in upcoming scenarios.

Here we present the pedagogical rational for such an approach and describe the implementation of scenarios. The observations of the staff involved and the student evaluations for a selection of the scenarios obtained after the first year of this trial are presented and analyzed. The successful and unsuccessful aspects of the first year of this trial are identified and improvements are proposed.

II. Background and Pedagogical Context

This work was initiated by the pilot study of Mitchell et al. who used problem based learning (PBL) to teach an entire 3rd year electrical engineering module that was traditionally taught using conventional lectures [1]. The student feedback from this trial was overwhelming positive, however, one of the issues with this trial was getting the students to adapt and acclimatize to this new learning style, especially after two years of conventional lectures. As such this optional course now has a relatively low take-up rate. Here we wanted to build on the success of this trial and expose some of the benefits of the PBL methodology to our students at an earlier stage when they are more receptive to new approaches. In fact a number of them have already experienced such techniques in their secondary education.

Scenario based learning (SBL), Project based learning (PjBL), and Problem based learning are subsets of a larger class of learning techniques broadly know as enquiry based learning [2]. These learning techniques all emphasise a student centred approach where the students take ownership of their learning and are active participants in the process. They all require the students to develop the research skills and methodologies that are associated with the particular discipline. The role of the academic changes from that of the 'oracle' dispensing knowledge to that of a 'facilitator' whose role is to guide and support the students in their own learning.

At one end of the spectrum is problem based learning where 'the problem', which generally has a predetermined outcome, is used to direct the students to both acquire and assimilate the necessary knowledge in the process of solving it. In PBL the solution may be less important than the new knowledge gained during the process. At the other end of the spectrum is Project based learning, where 'the problem' is more open ended and the focus is on the application and assimilation of previously acquired knowledge, in the development of a solution. Project based learning is very focused on the production of an end product. Scenario based learning lies somewhere in the middle of this spectrum and different scenarios may be more 'problem' or 'project' like. The word scenario is used to denote several distinctive aspects of this learning mechanism.

Firstly, the scenario is seen as an integrated part of the entire course structure and not a mechanism for delivering an entire module as in PBL. Scenario based learning aims to get the students to draw on the experience, knowledge and skills that they have already acquired or been exposed to in lectures and laboratories across the entire course and apply this to a scenario that has not previously been encountered. This also means that the traditional lecture course element, albeit modified, remains. This eases the concerns of sceptical academics and is in line with research that suggests that PBL is no better at delivering knowledge than lectures [3].

Secondly, the scenario is designed to place the students in a realistic situation, where the problem is fairly open and as such the outcomes are undetermined. In this sense scenario based learning draws inspiration from the experiential model [4] and the situated cognition [5] theories of learning. The experiential model emphasizes the need for concrete experience in the learning cycle as Kolb conceived it, that is, the experience that comes with actively participating in and solving a problem. Situated learning stresses the importance of placing learning in realistic and authentic contexts. It draws particularly heavily on the apprenticeships model [6] where students learn on the job under the guidance of colleagues and a mentor. The social aspects of learning are also emphasised in situated learning. This is the learning that arises from interaction with and observation of other team members. This has a particular resonance with a discipline such as engineering, which until relatively recently, before becoming an academic discipline, was taught solely in this manner and where practitioners predominately work in teams.

Flora and Cooper found that students achieved the best results when they are taken on a journey starting initially with expository experiments where instructions are provided and the outcome known, followed by a more PBL type experiment, where the outcome is known but process is designed by the students, and then are finally given the opportunity to experience a PjBL design project [7]. The course structure, proposed here, with lectures, expository laboratories, and several scenarios, that employ elements from both PBL and PjBL, attempts to produce such a learning environment.

III. Scenario Design and Implementation

For the first trial of this program in the 2008-09 academic year we were able to run three scenarios in the first year and two scenarios in the second year, as summarised in Table 1. Unfortunately we were not able to restructure the lecture courses to deliver to the scenarios, however, in order to mitigate this we designed the scenarios to align to the current course structure as much as was practical.

TABLE I. Summary of trialed scenarios.

Title	Description
Scenario A: Electromagnetic lifting	Redesign an electromagnet to maximize the lifting force using only a single battery.
Scenario B: Java based image coding for airport security.	Develop a piece of software in java to scramble and descramble passenger images using a secret key.
Scenario C: The Transistor Radio Kit	Design and build a radio that could be assembled by hand in a third world country and powered off the grid.
Scenario X: Call Detection System	Design, build and test a system that is able to non-intrusively acquire the signal from a phone line and determine the number that has been dialled.
Scenario Y: Due Diligence Report on Broadband Access Solutions	Research, assess and compare the performance, practicality and economic implications of three potential next generation broadband access technologies.

The scenarios were run as group projects with 4-5 students in each group. Group projects allow the students to develop team working and management skills that employers value highly. They also provide an environment for collaborative learning where group members are able to learn off each other [3]. In addition group projects and reports makes running these

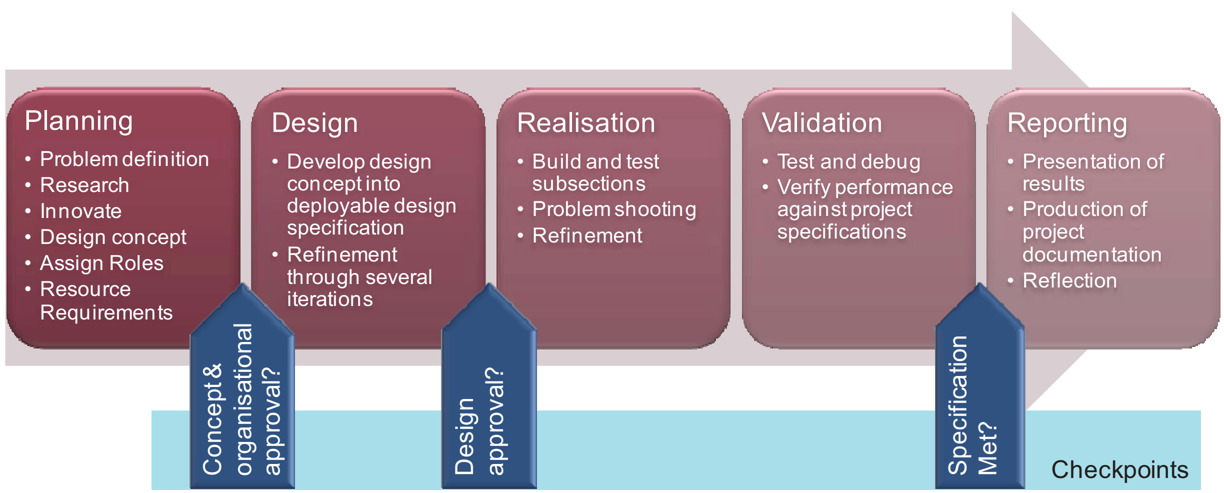

Figure 1. Generalised Scenario project model.

projects practical and reduces the marking load. The groups were changed for each scenario to ensure that individual students did not feel overly penalised by being in a group that they perceived as poor.

Each scenario was run over a week, during which there were no lectures and thus they could concentrate solely on the scenario. The students were presented with a problem on Monday morning and were given until the following Monday morning to submit the final deliverable. The scenario structure and timeline was based around the project model, shown in Fig. 1, which was adapted from Svensson et al. [8] to suit a week long project. In particular checkpoints (or milestones) were introduced to ensure that the students were making appropriate progress, to encourage particular types of activities such as brainstorming and to provide formative feedback.

IV. Assessment and feedback

One of the aims of introducing scenarios was to bring alternative forms of assessment and increased opportunities for feedback into the undergraduate program. Increasing the diversity in assessment helps to reduce the reliance on unseen examinations as the primary assessment mechanism and provides a more diverse range of situations in which the students can demonstrate their mastery of the subject [9]. The scenarios use both formative and summative forms of assessment that are intended to guide and enhance the students learning process and ensure that feedback is an integral part of the process.

Each scenario used a slightly different method of summative assessment ranging from individual or group based technical reports, oral or poster based presentations, through to critical review and comparison of another group's technical approach with that of their own. The type of assessment was chosen to be as authentic as possible and thus contribute to the realism of the scenario. For example, in Scenario Y, the summative assessment was based on a presentation of the group's findings and recommendations, and submission of a due diligence report to the board of the fictional company that had commissioned the research study. In addition for each scenario the students had to submit an individual reflective commentary.

For each of the reports the students were given a report template (MS word) that contained the suggested report structure and a marking grid. The marking grid was closely aligned with the published assessment criteria. Further guidance was also given in terms of the purpose of each section, the elements it should contain and the aspects that should be explained or described. Again, these are clearly linked to the assessment criteria given to the students. The group/individual reports and the reflective commentaries were submitted online as MS word documents using "Moodle". The submitted reports were downloaded, marked and then uploaded back into Moodle, completely electronically, to minimize the turnaround time and thus provide timely feedback. Feedback was provided using the comment function in MS word inserted where relevant in the report. The embedded marking grid was used to provide additional comments specific to the assessment criteria and to give an overall assessment of the report.

In addition to the summative assessment, formative assessment was also used throughout the week by introducing checkpoints into the scenario week schedule. These checkpoints were used by the facilitators to monitor progress and provide feedback to the groups. Generally there would be two checkpoints one early in the week (either Monday or Tuesday) to ensure that the group had organised themselves and one later. The first checkpoint took the form of a short discussion with the group in which the group would present the current state of the design plans and their approach for achieving those plans. This included ensuring that the group had put in place an organisational structure i.e. group leader, had assigned tasks to each group member and had developed a time plan for the week. This first checkpoint also often occurred at an important decision point, where the group needed to justify a choice to the facilitator in order to progress to the next stage, e.g. in Scenario A the students needed to justify their choice of battery and wire gauge to the facilitator before they were given the wire to construct the coil.

The second checkpoint (generally on Thursday afternoon) involved presentation or demonstration of the group's solution to the scenario. To make this more interesting/motivating for the students this was often arranged as a competition in which all groups were present e.g. who could lift the heaviest weight in scenario A or the first to recover the unknown phone number and call the unknown phone it in scenario X. However, the results of these competitions did not contribute in any way to the grade that the students received. In addition to the excitement and motivation that the element of competition provides the exposure to the solutions of the other groups and the comments provided by the facilitators at these sessions provides feedback which can be incorporated into the final report. This is particularly evident in the presentation session of Scenario Y, where the other groups who are the audience get to see the work of their colleagues and the questions/suggestions that are provided by the board/facilitators, as well as question the presenters themselves.

All scenarios made use of 1-2 page reflective commentaries in which the students were asked to:

- Comment on or give details of their own input into the design process and summative tasks.
- Reflect on a personally significant aspect of the task.
- Identify and critically evaluate those aspects of the scenario that they consider successful and those that were less successful. Suggest how things might be improved in subsequent scenarios.

The purpose of the reflective commentaries was twofold firstly, and rather bluntly, they provided a mechanism for assessing the input and contribution of the individual students to the group based scenario. Secondly, and more importantly they get the students to reflect on and analyze those aspects of the process that worked well and those that didn't and to take these thoughts forward to improve their own performance in the subsequent scenarios. In addition, the commentaries provide a wealth of feedback with respect to what the students liked about the scenario, what their concerns where and what aspects of the scenario design they thought worked well.

V. Student Evaluation

Student evaluation of the scenarios was obtained in a range of ways the first and most immediate form of feedback came from informal chats, during and after the scenario, with tutorial groups and various students in the departmental corridors. The general feeling from these was that we had certainly developed something that they found enjoyable and challenging, however, there were a number of concerns expressed over effective group working strategies and fairness of awarded grade based on group work. Common responses included:

"We had one group member who barely turned up and when we tried to assign him/her a task it was not completed so someone else had to do it making it hard to complete the task. Will this penalise the other group members?"

"I hope I get a better group next time."

After each scenario the students were asked to complete a simple online feedback to the following questions:

1. What aspect(s) did you like most about this scenario?
2. What aspect(s) did you not like about this scenario?
3. What would you change to improve this scenario?

The analysis and presentation of the findings, from this style of questionnaire, is somewhat more challenging due to the unconstrained nature of the responses. Common themes in the responses to each question have been identified and scored based on the number of occurrences normalised to the total number of respondents. To get an overall feeling for whether the feedback was generally positive or negative, and what areas worked well and those that needed improving the categories identified in the 'like', 'change' and 'dislike' responses are plotted against the frequency of response to each of the identified themes. A negative value is assigned to 'change' and 'dislike' comments to indicate that this is an area that needs to be improved in future and give way of visualising whether the feedback is generally positive or negative.

VI. Case Studies

A. Scenario A: Electromagnetic lifting

This scenario aims to enhance the learning of basic concepts from electro-magnetics, circuit analysis, and mathematics. Students are required to design and build an electro-magnetic system to see which team can lift the heaviest weight. At the end of the week an Olympic weightlifting style competition is was held to test the designs.

One of the difficulties and major question raised by staff with running a practical scenario, such as this, where the students are expected to construct something is: 'Can you achieve something that is realisable, draws on the taught material and is sufficiently challenging within a week?' In order to make this scenario practical to run in a week the design was constrained by restricting the mechanical design of the electromagnet and limiting the choice of battery to either a 9V PP3 or a 1.5V C battery. The students were provided with a wide range of possible wire gauges to wind the coil with. These restrictions whilst constraining the possible solutions somewhat meant that by the Thursday afternoon when the testing competition was due to take place all groups had produced an electromagnet.

This scenario is essentially an optimization problem where the students need to determine and apply appropriate theory to produce a mathematical model of the system. They need to use both, tabulated and experimentally determined parameters in the model, and make various assumptions. The optimum solution, determined from the model, is then constructed and tested. In this case the optimum solution involves choosing the optimum wire gauge and battery.

In order to ensure that the students applied their theoretical knowledge to this problem and didn't just use trial and error experimentation a checkpoint was used on Tuesday. The students had to justify their choice of wire gauge and battery based on their theoretical calculations. They were then given their chosen wire and battery. This worked particularly well as all groups produced a theoretical model showing an optimal solution. Interestingly, at this checkpoint most were not convinced that it was possible to lift the weight that their models predicted (in the range of 40-80 kg) and were quite surprised when the best group lifted 53kg on the competition day. This observation highlights the importance of giving students the opportunity to apply and test theory.

The findings from the student evaluation of this scenario are illustrated in Fig. 2.

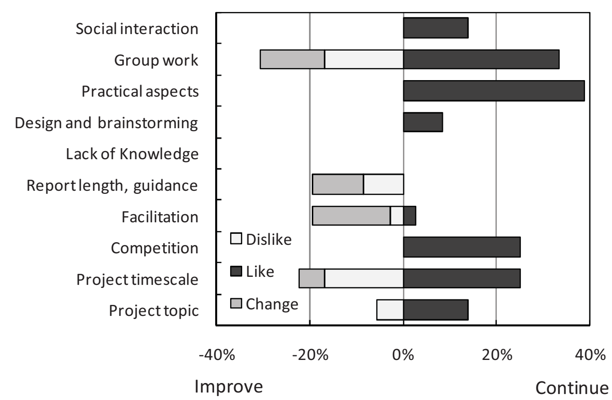

Figure 2. Scenario A: student response rate by theme (Total responses = 36).

Immediately we see that the feedback is generally more positive than negative. Surprisingly, given earlier comments, the students particularly valued the group work and social interaction involved with this. The 'dislike' and 'change' group work comments were related to issues arising with poor co-ordination between group members leading to a breakdown in efficient group working, or trouble with group members who did not contribute. The design, practical application and competition elements of this scenario were unanimously liked. As this was their first university project report students expressed some apprehension towards what and how much was required. They did not seem to appreciate the close alignment between the provided report structure, associated marking grid and assessment criteria. The students were fairly neutral on the quality of the facilitation that they received from the academics and would prefer to have more rather than less facilitation.

Generally the students were happy with the one week timescale and focusing solely on the project for the week, however, some students felt it could have been slightly longer.

B. Scenario B: Software development for identity recognition in an airport security system in Java

This scenario involved writing a program to apply mathematical transformations to an image in order to first scramble the image and then descramble the image. This scenario was designed to build on the mathematics and programming modules. Before commencing this scenario the students had completed their first year programming module in Java. The scenario requires the application of two main skills: algorithm development and programming. The first stage, algorithm development, requires the students to turn the problem statement into a series of commands that a computer can execute. This involves working out a method that can be used to apply the mathematical concepts such as rotation to an image that is constructed of pixels. The second stage, programming, requires the students to convert the algorithm into a formal programming language, in this case Java.

Algorithm development is a very generic skill that is fundamental to most problem solving tasks, however, in the context of computer programming it often gets entwined in the syntax of the programming language, which results in confusion amongst students. To reduce this confusion a checkpoint was used to break the week into two parts. On Monday and Tuesday each group of students was given a working space with a white board and it was suggested that they did not begin programming until after the Tuesday afternoon checkpoint. At the checkpoint the groups needed to explain, to the facilitators, their high level project design showing how the various parts of the program would work together and describe the algorithms that they had developed to implement each part.

The student evaluation, shown in Fig. 3, of this scenario indicates that the project topic was liked and the students enjoyed the group work. The main issue with group work was the fairness of work allocation and reward for actual contribution to the project. More worryingly are the comments related to a lack of prior knowledge. However, within the scenario week most groups produced a working solution which tends to suggest that the scenario was pitched at the right level and they did in fact have sufficient knowledge to complete the task.

In this scenario, unbeknown to the students, the groups were engineered to have at least one strong programmer, based on the assignment results from the programming course. This strategy was chosen to maximize the potential for collaborative learning especially for the weaker programmers. Student feedback from their reflective commentaries indicates that this was particularly successful for developing the programming skills of the weaker programmers, and the team management skills of the stronger programmers as the following comments indicate.

Comment from strong student.

"As I do have previous programming experience I did my best to explain algorithms, object oriented programming, Java and general programming basics to the team members. It was a rewarding teaching experience, as most team members did understand my explanations and learnt from them."

Comments from weaker students.

"During the course of the scenario, I had the opportunity to learn from my group members as I approached them for help whenever I was stuck on a task."

"Once the Scenario B teams were announced, I instantly felt relieved. I was never good at programming to begin with and there in my group is 'student A', a good programmer and someone who really can get the job done. I now have a new insight into programming as I did not realise simple codes are enough to program something I presume as difficult."

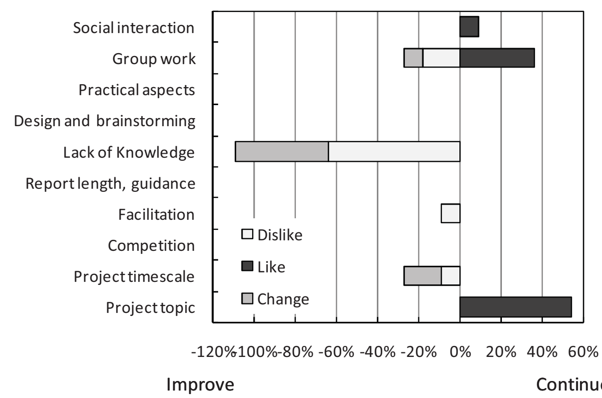

Figure 3. Scenario B: student response rate by theme (Total responses = 11). Note, the same categories used in figure 2 are used here for comparision.

However this did result in some issues with work load distribution and input into the project, with the more capable team members contributing far more. This scenario was designed to have elements suitable for the weaker students, more challenging elements for the stronger students. The problem with this is that the stronger students often perceive their contribution as been more significant to the project. To improve on this the testing of the software solutions will be designed to be more incremental, so that weaker groups will be able to meet some of the specifications and stronger groups will be challenged by the more advanced specifications. As with the previous scenario a few students would have liked it to be slightly longer.

C. Scenario Y: Due Diligence Report on Broadband Access Solutions

This scenario was introduced to the second year students in the form of a memo from the board of a company that was commissioning them to carry out a due diligence report on the technological, economic and social merits of three different technological solutions, and to inform the company which solution had the most potential.

This was a paper based study that required the students to use and apply their knowledge from the communications courses, and carryout further research into aspects of each technology. The introductory session included a presentation from an industrial expert who gave the students an overview of the problem and introduced some of the regulatory, economic and social issues involved in this problem.

The thought behind the design of this scenario was to give the students a free range and as such there were only two formal contact and evaluation sessions planned for the week as well as submission of a final group report. The first was an informal chat with each group on Tuesday afternoon at which they had been instructed to describe how they had organised themselves in terms of dividing the problem between the group members and their schedule for the week. The second was a 12 minute presentation to the board on the Thursday afternoon, where the board asked fairly challenging questions. There were also one hour facilitation sessions if the students wished to avail themselves of them on Monday afternoon, Tuesday and Thursday morning, however, few made use of these.

During the running of this scenario a number of things were learnt. Firstly, it was a observed that during the presentation from the industrial expert the students still appeared somewhat shell shocked by the task that had just been introduced and weren't altogether sure what they were meant to do or what relevance this presentation necessarily had to the task. Thus at the end of the presentation they did not ask many questions and as such did not make the best use of the opportunity.

Secondly, the Tuesday afternoon check point was intended to ensure that the students had thought about the issues involved and got themselves sufficiently organised to be able to meet the Thursday afternoon presentation deadline. Ideally they should have as a group developed a framework with which to analyze and compare the three company's technologies. In practice by this stage most of the groups had simply divided the tasks four ways using the obvious split of tasks, i.e. each company, and the social and economic impacts, as set out in the memo. This meant that rather than working as a team towards a common goal, they tended to immediately split the tasks and then retreat into their own silos to research and write their own sections of the presentation and final report. As a consequence both the presentation and the final group reports tended to be somewhat disjointed rather than a coherent piece of work that lead to a single conclusion. Thus in this project it is important that each group works together to create a well structured plan and schedules regular group meetings with all members present.

To ensure that the groups develop such a strategy and work as a team the following changes are planned. The first day will be much more structured. After the introduction the groups will have a group brain storming session before lunch, then the presentation from the industrial expert, a group reassessment session to incorporate what they have learnt from the expert presentation, followed by a formal feedback session with the facilitators. At the Tuesday checkpoint the students need to present the framework and criteria that they plan to use to assess the three solutions, along with a justification of the criteria chosen. This Justification will also be part of the final report.

VII. Conclusions

The trial has shown that it is realistic to complete a practical engineering design project - 'from concept to product', that both excites the students and enhances the material covered in lectures, within a week.

The use of staging and checkpoints throughout the week was particularly successful in guiding and providing feedback so that the students applied the knowledge and theory gained from lectures to the design problems. This was reflected in the quality of the reports, which are actually more important than the actual solution/device produced, far exceeding the expectations of the staff involved in assessing them. It was also reflected in the need to provide more structure in Scenario Y to encourage a more collaborative approach to the assessment of the technologies. Student feedback on the week long project timescale was also generally positive.

The group working aspects of the scenarios were particularly successful, despite the reservations, based around contribution, that come with using group work for summative assessment. The students particularly liked social aspects of this learning process. In particular, it was clear that the weaker students gained enormously by learning from their peers and the stronger ones learnt much about leading a team. Daily group progress meetings will be introduced in future scenarios to encourage a more collaborative approach. Peer assessment for moderation the individual marks will also be introduced to ensure that the credit received more accurately reflects the contributions of the individuals to the team performance.

The student feedback on the scenario topics, practical and design aspects was very positive. Their engagement and participation in the scenario weeks was high with the competitions generating a real excitement amongst the groups.

Mechatronics E-course for regular students and adults: realization and comparison of efficiency

Andreja Rojko, Darko Hercog, Karel Jezernik
Faculty of Electrical Engineering and Computer Science, University of Maribor, Institute of Robotics
Maribor, Slovenia
{andreja.rojko, darko.hercog, karel.jezernik}@uni-mb.si

Abstract— **This paper describes execution and gained experience with two practically oriented E-courses from mechatronics. Both courses have in common that they include remote experiments and are executed completely online, which is still rarity in the practically oriented engineering education, especially in non-university education. The execution details and educational approach applied in each course were adjusted to two specific target groups. The target groups of a first course 'Control of nonlinear mechanisms' is a group of regular local and regular international students of mechatronics. The target group of second course 'Basics of mechatronics' are employed and unemployed adult professionals from various engineering fields who have already finished their formal education but want to acquire new knowledge. For both courses interactive E-materials and E-tests in Slovene, English and partially also in German language are available within two learning portals, also adjusted to the needs of each target groups. First course was tested with 40 regular students and the second course with the group of 70 adult professionals mostly from industry. While adult professionals appreciated the fact that the course was executed completely online, the regular students have still preferred conventional lectures and especially conventional laboratory exercises over remote ones. Based on the teaching instructor's observances and on the results of anonymous questionnaires, the advantages and disadvantages of the replacement of traditional laboratories with remote laboratories are discussed from a critical point of view.**

Keywords-education; remote laboratory; mechatronics; adult education; vocational training; distant education

I. INTRODUCTION

Until recently the distance education courses for engineers were quite rare, although the distance education is due to its many advantages already quite widespread in other no-engineering disciplines. The main reason for this is that efficient engineering education should include experimental work on real devices, which usually takes place in laboratories and therefore requires personal presence of the learner. This has recently changed with the introduction of distance laboratories that enable remote execution of experiments from anyplace and at anytime [1],[2],[4]-[6],[10],[14]-[17],[19]. However the establishing and maintenance of the remote laboratories is technically very demanding and mostly also costly. Therefore, the practical use of such laboratories in regular education of higher number of learners is still not very common. One of the possibilities to ease the burden of establishing remote laboratories with high number of experiments and courses is to share it between few partners. An example of such shared laboratory is laboratory established within the Leonardo da Vinci EDIPE (E-learning Distance Interactive Practical Education) project [1], [17]. Here the courses are offered by thirteen universities from eleven European countries within the same portal and with some common functionality like booking system. However, beside technical problems, which can be at least partially reduced by sharing of the remote laboratory, there are also many educational problems. Those problems differ according to the target group of learners. In this paper applied educational approach and results will be presented for two courses, each with its own target group.

Both in the paper presented courses aim toward offering practical experience by incorporation of remote experiments. First course was developed within EDIPE project [1], [17], [19] and is intended for education of regular students of mechatronics from eleven European countries. This course 'Control of nonlinear mechanisms' introduces the students to modelling, simulation and motion control design and implementation for nonlinear mechatronic devices. The course was already successfully implemented in the regular education process of 40 local students. Students' feedback was obtained by anonymous survey and is analysed in the paper.

Second course which will be presented and analysed was developed within Leonardo da Vinci MeRLab (Innovative Remote Laboratory in the E-training of Mechatronics) project [9], [12], [13]. Course 'Basics of mechatronics' is designed for employed and unemployed adult professionals who have already finished their official education. This course was tested by the adult participants with very different background knowledge, various levels of official education and also very different interests. Obtained feedback shows that in contrary to the regular students, the adult professionals highly appreciate the possibility to participate in the completely online course as it can be easier fitted in their busy schedule.

The paper is organised as follows. Second section presents course 'Control of nonlinear mechanisms' developed for regular local and international students. Learning portal, course topics, execution of the course with educational approach and students' feedback are described. In third section the course 'Basics of mechatronics' for adult professionals is described. Details about learning portal, topics, educational approach and participants' feedback are given. Fourth section compares the experience of both courses and gives analysis of usability of completely remote engineering courses based on the participants' feedback obtained at the end of both courses. Last section draws some conclusions and presents plans for future work.

II. E-COURSE 'CONTROL OF NONLINEAR MECHANISM' FOR LOCAL AND INTERNATIONAL REGULAR STUDENTS

This course was developed within the EDIPE project as one of the 18 available courses developed in thirteen partners from eleven European countries [1], [17], and [19]. All courses contain high quality documentation with theoretical background for learners and teachers, simulations, various exercises, and remote experiments on real electrical or mechatronic devices and are at disposal to teachers and students of participating universities. Therefore they can be applied as regular courses at the universities. Courses include topics from fundamentals of electrical engineering, power electronics, electrical machines, electro-mechanical and motion control systems. Here presented course 'Control of nonlinear mechanism' deals with modelling and motion control of mechatronic devices with nonlinear dynamics.

A. *Learning portal*

Learning portal named PEMC Weblab, Fig.1, is Moodle based and therefore offers all necessary functionalities for distance learning to the instructor and learners. Basic Moodle platform was completed by very efficient booking system [3] which enables the learner to book time slot for execution of remote experiments in advance and prevents multiple simultaneous accesses to the same experiment. The page of the course 'Control of nonlinear mechanism' is shown in Fig.2.

B. *Course 'Control of nonlinear mechanism' topics*

The 'Control of nonlinear mechanism' course covers an extensive topic of modelling, simulation, planning and practical implementation of the motion control of mechatronic device with nonlinear dynamics. All this is important part of the modern education of electrical engineers, machine engineers and mechatronics engineers.

In the course, all basic elements are included which enable the student with adequate pre-knowledge an insight into the problem, an acquisition of some new knowledge, and practical experience in motion control of mechatronic devices. Beside in PEMC Weblab the course is also available within frame of DSP based remote control laboratory, Fig.3. [3], [7], [8], [11].

Figure 1. PEMC WebLab learning portal, selection fo courses

Learning objectives of the "Control of nonlinear mechanism" course are:

- Modelling of the mechatronic device with the nonlinear dynamics.
- Planning, implementation and optimization of the linear regulator with the cascade structure (cascade P position, PI speed and PI current controller) for the position control of the mechanism with nonlinear dynamics.
- Planning, implementation and optimization of the nonlinear position controller based on the mechanism dynamic model.
- Understanding the reasons for variations in efficiency of the use of linear and nonlinear control methods in the case of nonlinear mechanism control.

As a practical example in the course, the mechatronic device called mechanism with a spring with a DSP-2 control system is used, Fig.4, [3]. The direct current motor shaft is covered with a silicon material and drives the Plexiglas disc. The disc is fastened to the bearing, while on the other side of the bearing the spring is attached. The whole mechanism is fastened on Plexiglas housing. This mechanism is very suited for remote experiments due to its smaller size, no limit and end switches and minimal wear and tear at the long time operation.

C. *Execution of the course*

The first part of the course is intended for familiarization with the theory. Each chapter is also supplemented with an example that represents the use of theory on a practical example. For example, in the chapter dealing with a basic dynamic mechanism model, the dynamic model of the mechanism with a spring is derived and explained. Corresponding MATLAB/Simulink simulation model is also built and tested afterwards. Then, the theory concerning the motion control problem follows, together with the design of suitable controllers and their implementation for the motion control of the mechanism with a spring. After the theoretical part with the simulations, the experiments in the remote laboratory follow.

When ones obtain unsatisfying results, the additional correspondence with tutor or literature study follows. The course flow is schematically shown in Fig. 5.

Figure 2. PEMC WebLab course documentation

Figure 3. Remote laboratory web page

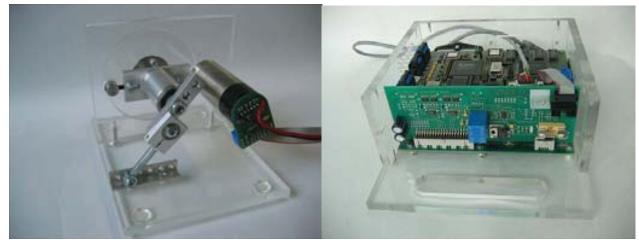

Figure 4. Mechanism and DSP-2 controller

D. Students' feedback

In the course altogether 40 students of mechatronics in two consecutively years were involved. 18 of them have filled anonymous questionnaire which they were handed after conclusion of the course. The feedback was as follows:

- 94% of students think that remote laboratories are a useful addition to ordinary laboratory exercises, while only 22% are of the opinion that remote experiments could entirely replace conventional laboratory exercises supervised by assistant.
- 94% of students are of the opinion that remote experiments are suitable for the strengthening and repetition of knowledge which they have already gained. Further, 72% have the opinion that remote laboratories are suitable also for acquiring completely new knowledge.
- 39% of students performed remote experiments for the first time.
- Despite the fact that remote experiments can be performed independently of the place and time, 61% of the students still prefer executing the experiments in the laboratory to remote experiments, 33% of students could not decide for one option and 6% prefer remote experiments.
- As much as 78% of students have the opinion that they learn more when executing the same experiments in laboratory as when they execute equivalent remote experiments. The rest 22% of students could not decide for one option.

III. E-COURSE 'BASICS OF MECHATRONICS' FOR ADULT PROFESSIONALS

Second E-course which is going to be described in this section is professional mechatronics E-training for employed and unemployed adult professionals from engineering and natural sciences. The emphasis is again put on the practical expertise, since this is the basic need of the participants from this target group. Therefore, the training includes many problem based exercises and high share of the work effort has to be put into execution of remote experiments.

The pilot training was executed with 70 participants from Slovenia in March-April 2009. Additionally the training was executed for small group of 4 participants from Austria. The majority of the participants were workers from the industry.

Also 20 primary and secondary school teachers were participating the training. Around 40% of the participants have finished vocational secondary school, around 25% vocational high school, 20% university study, while the rest provided no data concerning their educational background. Average age of participants was around 45 years. 90% (63) of the participants have successfully finished the training since intensive tutoring has minimized the drop-out rate.

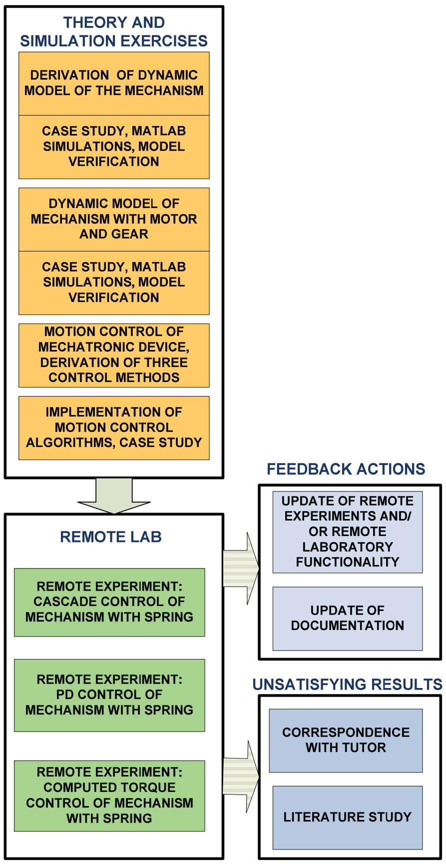

Figure 5. Course flow

A. *Course topics*

The training is composed from four modules; Introduction to mechatronics, Servomotor in mechatronics, Electrical circuits and Mechatronic devices. The whole training requires around 50 hours of intensive work. Each module is given with complete e-materials (in English, Slovene and partially also in German language). Exercises are given for each chapter and there is also an extensive e-test for each module, which is scored. Questions for self-evaluation are given for each unit. Each module also includes remote experiments. The experiments are performed on three devices: two degree SCARA robot, servomotor and circuit with different type of filters including switched capacitor filters, Fig. 6. All experiments are implemented within DSP-2 based remote laboratory [3], [11]. The content of each of the four modules is as follows:

- In the first module 'Introduction to mechatronics', the meaning of the term mechatronics and its short description is given. Then, the historical development from the pure mechanical systems to the state-of-the-art mechatronic devices is described. The structure of mechatronic systems and the role of each element of such a system are also discussed. Required time for the module is about 2 hours.
- In the module 'Servomotor in mechatronics' the role and application of the actuators with motion control in mechatronics is described. Description of the motion control problem and of few frequently used controllers is discussed first. Then, the basic operation principles of direct current motor are presented. Short description of its construction, static characteristics and equations is also given. Finally, the case study of the servomotor is performed trough the remote experiments. Required time for the course modules highly depends on the participant's initial knowledge. However, it is 15 hours on average.
- In the module 'Electrical circuits' first the fundamental elements of electrical circuits, including new fundamental element memristor, are presented. Then AC and DC electrical circuits are briefly described. The frequency characteristics and its graphical presentation in the form of the Bode plot are discussed next. Further filters are presented in the details as one of frequently used electrical circuits in the mechatronics. Emphasis is put on the passive and active low-pass, high-pass and band pass filters. Switched capacitor filters and digital filters are also described. Basic operating principles and frequency characteristics of the filters are studied trough the remote experiments executed on the passive and switched capacitor filters. Required time for the module is 15 hours on average.
- In the last module 'Mechatronic devices', the structure and operation principles of complex mechatronic devices are described. First, mechanical elements, such as the gears, the belts and the joints, are considered. As a simple mechatronic device and building block for more complex devices, a joint drive system is presented. Next, it is shown how joint drives are used to build a robot. The operation principles of the robots are explained in the case study. Finally, the real world problems in the control of complex mechatronic devices are demonstrated by executing the remote experiments with the SCARA robot. Required time is 15 hours on average.

  User front end for the executing the remote experiment with SCARA robot is shown in Fig. 7 (similar are also user front-ends for other experiments). Front end is available in English and Slovene language. The user can choose between three motion controllers and tune the controllers' parameters. Most important signals are shown in the user front end in graphical form. The live picture of the experiment is also transmitted by using Webcam client.

B. *Learning portal*

The e-learning platform implemented in the training is built by using eCampus system developed by a Slovene company B2, [18]. The eCampus is simpler to use then Moodle; therefore it was better choice, since some training participants were not very skilled in working within learning portals. Also visual design of eCampus system is superior to the in Moodle. For MeRLab training the original platform was partially customized to fit the requirements of the training and to enable direct connection to the remote laboratory. Fig. 8 shows the MeRLab Learning web portal [12]. Example of typical learning unit with text, scheme and question for self-assessment can be seen in Fig. 9.

Figure 6. Mechatronic devices for remote experiments

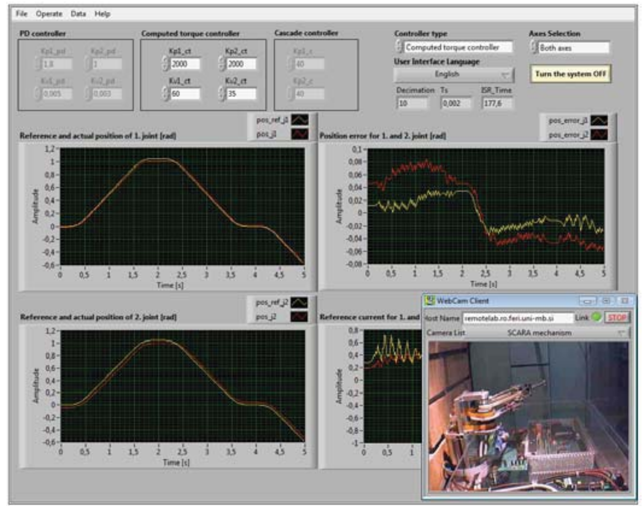

Figure 7. User interface for remote experiment with SCARA robot

C. *Execution of the course*

The training flow is shown in Fig. 10. Before the training one live meeting, about three hours long, was organized with all the participants. During the meeting the participants meet the instructor, have learned how to use learning portal, what will be the training flow and what exact contents of the training are.

Directly after the first meeting the online part of the training has begun. The learners were aimed to self-study the materials and answer questions for self-assessment. After each chapter there was at least one practical exercise which the participants had to solve and send the results to the instructor. The instructor then gave them the feedback about their success, additional aims and instructions for further work. The participants also had to finish assessment test for each module with number of questions from the materials and exercises. The last exercise in each module was remote experiment. The report concerning experiment also had to be send to the instructor. To pass the training, the participants had to complete all the tasks and tests in all modules with at least 50% of success.

During the training, a lot of attention was put to the communication between instructors and participates. Typically the answers to the participants' questions and feedback concerning the solved tasks and remote experiments reports were provided within few hours, while the maximal waiting time was always less than 12 hours. This was most likely also the main reason while the motivation of participants remained high during whole training. Most of the communication was done by sending the personal messages. Also phone communication was encouraged, although the learners didn't use it very much and preferred the communication through the messages. For some participants with weaker knowledge additional live meeting was organized in order to help them at understanding of specially demanding concepts.

The participants were already between the training and especially after the training asked to provide feedback and comments to the materials and training itself. Based on those some additions and improvements of the materials were made already during the training. Formal evaluation was executed at the end of training and lead to the additional changes.

Figure 8. Portal for adult learners

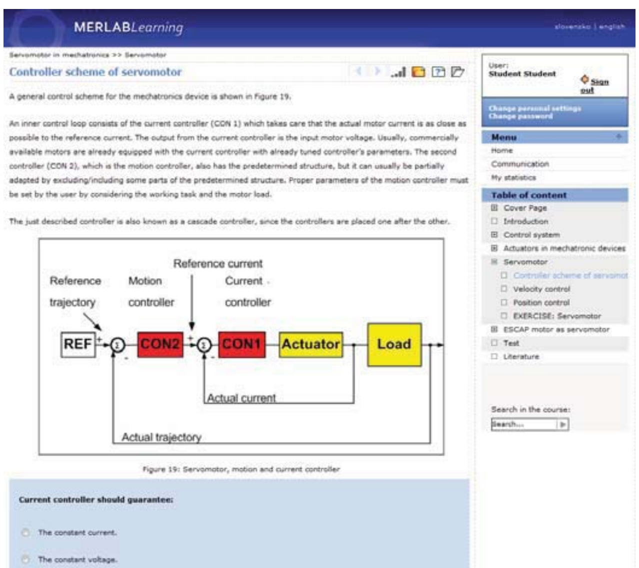

Figure 9. Learning unit

D. Participants' feedback

At the end of each module an evaluation was conducted based on the results of the anonymous survey questionnaire. Since the target group was different as in first course, also questionnaire was adapted. Overall the learners have responded very positively about all aspects of the training. The questionnaire was composed of statements that could be ranked from 1-Strongly disagree to 6-Completely agree. 55 participants took a part in the survey.

Following was found out:

- Almost all participants (92%) have executed remote experiments for the first time. Further, almost everybody have completely agreed (64%) or agreed (23%) with the statement 'I appreciate the possibility to execute remote experiment from anywhere and at anytime.' This really highlights the importance of introduction of the remote labs instead of local labs in the adults' education.
- Then 68% have completely agreed and 23% have agreed with the statements that installation of required software is easy and that the booking systems, as well as user front-ends for remote experiments, are easy to use. From this, it can be concluded that the whole system for execution of remote experiments is user friendly and that learning of how to operate it do not present additional burden for the participants.
- There have been some mixed answers concerning the statement 'Remote experiments were operating without any problems', where only 79% have chosen completely agree, agree and mostly agree, while 21% have disagreed. However this was caused by the antivirus programs and firewalls, which, if present, can block the access to remote experiments. However after those two obstacles were removed, everybody has been able to work with the experiments. The questionnaire's results also show that most of the participants have used the possibility to execute remote experiments for more than once.
- Almost everybody have completely agreed (76%) or agreed (17%) with the statements that the learning portal is clear and well organised and that the contents are clear and concise. Also, over 80% have completely agreed (49%) or agreed (32%) that the gained knowledge will be useful in their further career and that the contents of training correspond to the training goals. Those results are a good indicator that given content is up-to-date and also enough practically oriented.
- The participants have been very positive when valuing the E-training in general. 73% have completely agreed, 20% agreed, 7% mostly agreed with the statement 'I think the whole E-training is excellent'. No one has disagreed. Similar results have also been for the statement 'I will recommend the training to the colleagues and friends.' where 81% have completely agreed, 17% have agreed and 2% have mostly agreed. Again, there has been nobody who has disagreed.

In the free-worded feedback also collected in the survey, the participants have expressed the wish to include even more links and animations into materials. Some commented that they have lacked the time to participate in forum discussion, but overall no greater problems at the training were mentioned.

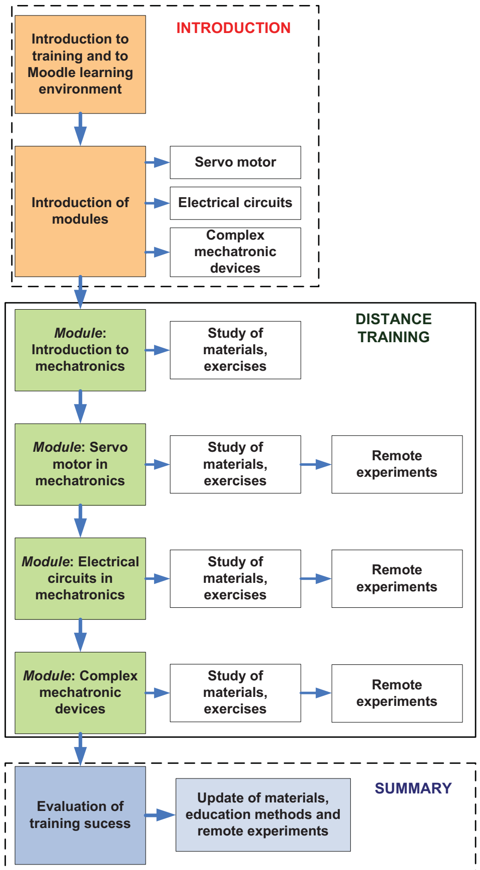

Figure 10. Training flow

IV. COMPARISON OF PARTICIPANTS' FEEDBACK FOR BOTH COURSES

Although the E-learning in both in the paper presented courses was very well accepted by participants, there are still significant differences between two learning groups. In this section we will try to discuss the reasons for difference in obtained feedback.

First, somehow surprising finding was that the majority of regular students (61%) still prefer conventional laboratory exercises over remote one, although they are very accustomed to the use of web. The situation was completely different in the group of adult participants, who have very much appreciated (what is believed to be the main advantage of remote laboratories) the time and place independency that such approach offers. Based on the experience from in-the-lab exercises with local students, the main reason for this might be that most of the students still do not come well prepared to the laboratory. Assistant, who is present in the laboratory, usually helps them with additional explanation. On the other side, at the remote exercises the students have to do everything by themselves and there is no one to provide the immediate feedback concerning the correctness of results. Then, the second reason is still the fact that remote experiments do not cover all aspects of local laboratory work since there is no direct physical contact with the experiment. For example the students do not have to deal with setting up equipment like connecting the cables or performing the measurements by analogue measuring instruments.

Also from instructor's point of view it must be said that the current technology of remote laboratories still do not enable the remote experiments to be equivalently good as the local ones. Therefore it should still be used only as supplement to laboratory exercises (also 94% of students have agreed with that) and in order to strengthen already gained knowledge (again also as 94% of students). However remote exercises are better choice then only simulation at the cases where there is not enough of available laboratory equipment or in other circumstances that make impossible to execute laboratory exercises. Such circumstances were however present in the second target group of employed professionals and in this case remote experiments were really high appreciated.

Concerning the operating specifics of remote laboratory which was used in both courses, both groups had no significant problems. This is a good indicator that booking system, software installation and operation of remote experiments are user friendly and suitable also for unskilled user.

V. CONCLUSION

Remote laboratories are believed to be a good solution in education in the cases when there is not enough available experimental equipment, when the participants have limited time, are distant from laboratory, or they have some kind of physical disability. Also introduction of remote experiments is considered as an optimal exploitation of the available technical resources.

While all this is true to great extent, in the paper described experience shows, that it is still essential to realize what limitations of such an approach has. Working with remote experiments still do not completely equals the laboratory experience, as no direct contact with instrumentation is included. Moreover, the students' answers which were gained via the questionnaire show that although the students find the remote experiments useful and an interesting supplementation of regular laboratory work, there is just a few of those who are of the opinion that such an approach could entirely replace conventional laboratory exercises. Likewise, a great majority of students are of the opinion that they learn more in laboratory than when executing remote experiments.

On the other side, the remote experiments show their usefulness when applied in the education of adults. In this case the time and place independence were much appreciated.

In the paper presented two courses are going to be implemented and regularly updated also in future. The training from basics of mechatronic which was developed for adult professionals is also going to be commercially offered to the companies for the supplementary education of their employees. Therefore, it can be expected that the training will, in the future, at least partially fill the gap between low number of available formally educated mechatronics and high market requirements in Slovenia.

***Abstract*—This work aims at suitably combining hands-on and remote practices in the teaching of automatic control subjects. Virtual and Remote Laboratories in Automatic education have increasingly become a method utilized by universities in their efforts to offer greater schedule flexibility and operation of available resources. This paper discusses the implementation of remote experiments for Automatic Control through both the Distance Laboratory System (SLD), developed at the Universidad Central Marta Abreu de Las Villas, and AulaWeb, developed at the ETSI Industriales of Universidad Politécnica de Madrid.**

The SLD allows users (i) to learn and adjust predefined controllers, (ii) to design new controllers, and (iii) to test and analyze the performance of the predefined/designed controllers over a set of physical devices. The SLD uses MATLAB-Simulink for the distance laboratory, i.e. testing the predefined/designed controllers for practice and the Real Time Workshop Toolbox (RTW) as a real time kernel.

AulaWeb is used as an aid for students and teachers of academic subjects. AulaWeb has been tested at several engineering schools and has been used by over 2000 students each year.

This work shows the results using SLD and AulaWeb in Regulación Automática I of the Universidad Politécnica de Madrid. The distance and virtual practices, made in SLD, are combined with the question in AulaWeb to form Web self-assessment tools.

Keywords- education of control, remote control, remote laboratories, virtual laboratories, innovative education

I. Introduction

Laboratory experiments are an essential part of engineering education. They complement theoretical lectures, as well as illustrate and validate analytical concepts which introduce students to professional practice, social development and teamwork skills in a technical environment [1]. These reasons explain the student's high expectations for laboratory activities.

Simulation tools for training have been popular mainly due to the high cost of maintaining and operating lab equipment. However, despite the advantages – low cost and relatively ease of use – simulators cannot efficiently replicate noise, frequency responses, D/A conversion and other physical phenomena that characterize real systems [2].

The advent of computer technology, particularly the arrival of the Internet, has presented new opportunities to the sharing of expensive software and hardware resources. Consequently, virtual [3] and remote control [4] applications have been developed. These new applications offer the capabilities and flexibilities of simulation tools; while keeping important characteristics of physical systems [5], and distance laboratory applications. Remote experimentation facilities, offered as part of a web-based learning approach, afford a number of critical benefits. For engineering distance education courses, remote facilities constitute the only realistic method of performing many experiments. They allow remotely located students, no longer constrained by time or geographical considerations, complete lab assignments. Thus, it is fair to conclude that remote experimentation facilities enhance the development of skills in the use of real systems and instrumentation [6].

In [7], the authors provide a literature review of modern remote laboratories. In addition, they identify possible evolutions for the next generation of remote laboratories which are under a strong current of evolution. Such labs would no longer be restricted to a single educational topic, where Automatics and Robotics constitute the most frequently used tools.

In the majority of cited remote control experiments, remote users can run an experiment and adjust the process or controller parameters from a set of predefined controllers. This limits the practice to some type of controllers (PI, PID, space of state, etc.).

The Automatic Control Telelab (ACT) enables students to choose a control law, change the control parameters online, and even design their own controller [8]. Our developed Distance Laboratory System (SLD) allows learning and adjusting predefined controllers, designing new controllers, and testing and analyzing the performance of the predefined/designed controllers over a set of physical devices [9].

SLD exhibits some features in common with most distance laboratories in operation at present, such as ease of use, availability and accessibility. Some additional characteristics such as user-friendly and fast user interface, management of multiple requests in parallel form, controller development using MATLAB and Simulink in a remote way and reference change are also added [9]. The SLD incurred in various technological updates aiming to improving its performance and security [10].

AulaWeb [11] is a Web self-assessment tool (WSAT) which serves as an aid for students and teachers of academic subjects. AulaWeb was built by the UPM and has been tested at several engineering schools and used by over 2000 students each year.

The paper shows a suitable combination of hands-on, remote practices, virtual practices and variable questions in the subject of Regulación Automática I at the Universidad Politécnica de Madrid, using SLD and AulaWeb.

This paper is organized as follows: section II describes the subject of "Regulación Automática I". Section III shows the works that are performed by the students by using SLD, taking into account their possibilities of use in Automatic Education. Section IV focuses on the methodology used in the subject. Section V shows the results obtained in the last course. Statistics about the time devoted by the students is summarized according to the survey completed at the end of the course. Finally, section VI summarizes important conclusions.

II. SUBJECT ANALYSIS OF REGULACIÓN AUTOMÁTICA I

The Regulación Automática I contents have been adjusted to cover the important aspects of the subject assuming a realistic balance between workload and dedication of the student [12].

The subject is made up by 144 hours, 78 of which are study hours (Figure 1). They are equivalent to 4.8 credits ECTS.

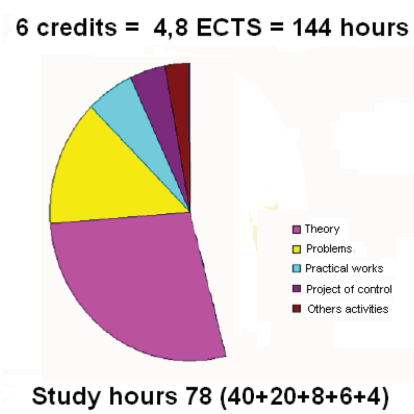

Figure 1. Study hours of students.

The program of the subject is made up by fourteen lessons and eight practical works [12]. This equates to an approximate average of a lesson per week and a practical every fortnight. The studied matters are dedicated to model and analyze discreet systems, as well as to study the feedback systems, with emphasis in the calculation of regulators. One of the chapters is concerned with the methods of system identification using algorithms based on square minimums.

A. Hands-on practices in Regulación Automática I

The subject has three real experiments in the laboratory of automatic.

The first practical work developed by the student consists of the implementation in real time of a system of control with continuous regulator. By means of this practice, the student will be able to analyze the advantages of operation of classic regulators P, PI and PID on a real system. The interface used is Simulink executed in real time with Real Time Target Windows.

In a second practical work, the student makes a model of Simulink in real time testing on a physical system.

The implementation of discreet regulators R (z) is made in a third practical work. In this activity, the student tries to design a discreet regulator by means of some of the techniques studied in class.

The laboratory of practices, where these activities are carried out, is formed by eight positions, each equipped with a computer, a data acquisition card (AD622 of Humusoft), two scale models, a thermal system and DC motors.

B. Practical activities in AulaWeb

The subject has five activities in AulaWeb. In each of them, the student only needs Matlab.

Before making a practical work, the student must complete a self-assessment exercise through AulaWeb.

C. Project of control

The control project is an activity that is made so that the student applies the knowledge acquired in the accomplishment of a control system. The student must choose what technique of modeling and what control tools has to use at every moment.

III. USE OF THE SLD IN THE SUBJECT REGULACIÓN AUTOMÁTICA I

The SLD has the capacity to support any type of practice where measurement and control are electrical signals; at present, the experiences developed, use DC motor and a robot manipulator [13] at UCLV and a thermal system at UPM.

A DC motor and the thermal system are single input and single output process (SISO) that lets to carry out identification, position control, velocity control and temperature control, experiments without loading disturbances.

The robot manipulator is a system with multiple inputs and multiple outputs (MIMO) that exhibits very coupled and stronger non-linear dynamics. It permits to carry out more complex positioning and trajectory tracking control.

The Table I summarize some topics, in Automatic Control Systems Education [14], where the SLD could be effectively used.

TABLE I. TOPICS WHERE THE SLD COULD BE EFFECTIVELY USED

Subjects	Topics
Modeling and simulation	Experimental Identification of SISO Systems. Transient Response Analysis.
Classic Control	Control System Design by Transient-Response. Control System Design by Frequency-Response. Tuning of PID Controller.
Modern Control	Design of Control System in State Space. Design of Regulator-Type by Pole Placement. Design of

	State Observer. Optimal Control Adaptive Control.
Digital Control	Sample Time Selection. Selection and Tuning of digital Controller. Digital Leg Compensation. Digital Lag Compensation.
Robotic	Dynamic Modeling of Manipulators. Trajectory Planning. Independent Joint Control. Computer Torque Feed forward Control. Control with Compensation. Adaptive Control

The SLD is used to make virtual practices and real practices remotely. It is also utilized in the development of the integrated project.

As exposed in [9], the SLD allows the performing of simulated and real practices in two variants: with predefined controller and with controller user defined. In this subject, all the variants for the design of the practices are used.

A. *Real and virtual practices in a remote way*

Real and simulated practices were designed in the SLD for the thermal scale model present in the laboratory (Figure 2). The theoretical transfer function of the thermal system shows in (1).

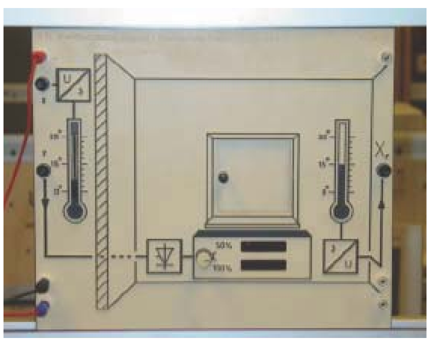

Figure 2. Thermal model

$$G(s) = \frac{0.9}{(1+7s)^3} \qquad (1)$$

Firstly, a practice was made which allowed the adjustment of a regulator PID to obtain the desired results (Figure 3).

This practice agrees with the first practice developed by the student. The reason behind making it remote is that it allows the student to perform new tests and see the effects in the answer of the system.

Figure 3. Web Page of thermal system practices with regulator PID.

The students have numerous possibilities to test the effects of proportional, integral and derivative control actions on the system step transient-response, first by simulation and then in real way.

The simulated and real answer of the thermal system with regulator PID, for Kp = 1, Ki = 0,067 and Kd = 7 as in (Figure 4).

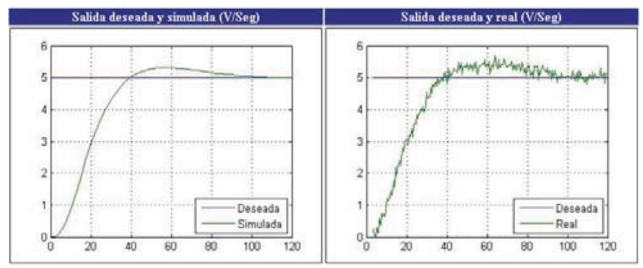

Figure 4. Simulated and real answer of the thermal system with regulator PID

In addition, a practice with controller user defined was designed. With this practice the students prove other algorithms of control and design their own regulators using MATLAB/Simulink.

When a practice with controller user defined is selected, a Web page is shown. This web page permits the downloading of a Simulink file (Figure 5). This file contains the block diagram of the practice. In addition, the user can modify the subsystems Reference and Regulator using software Matlab/Simulink, altering neither the name nor the amount of entrances and exits of the subsystems (Figure 6).

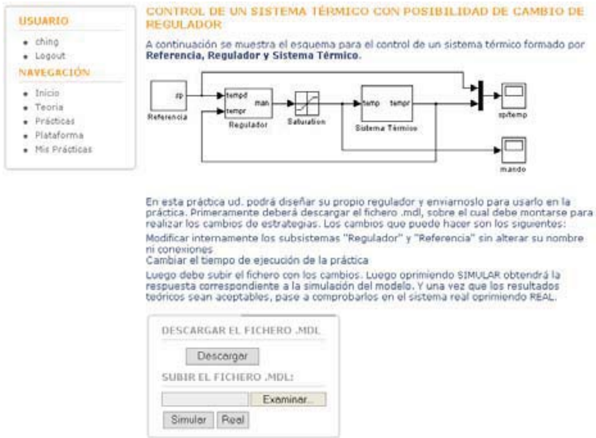

Figure 5. Web Page of thermal system practices with regulator user defined.

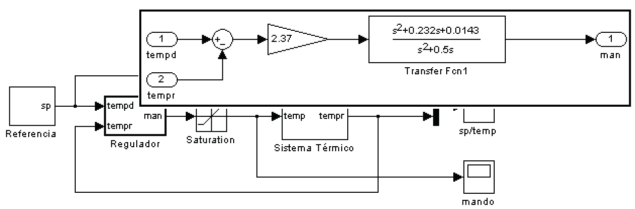

Figure 6. Simulink diagram of thermal system practices with regulator user defined.

B. *Practices developed for the integrated project.*

The integrated project was formed by three parts. In the first the student identified a system that varied depending of its registration number. A practice was designed that showed the answer of the system with white noise in the reference and step in the disturbance (Figure 7). The student identified the different blocks that formed the system, using the methods learned in class.

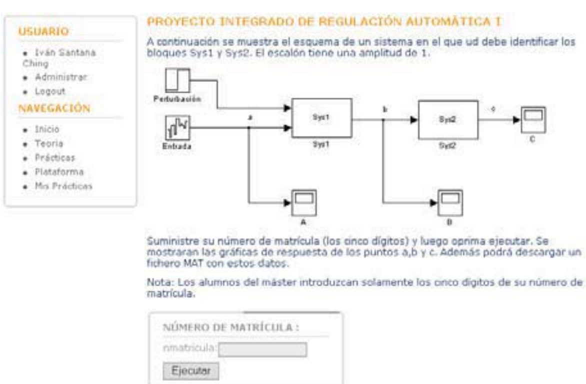

Figure 7. Web Page of integrated project part one.

In the second part, the student designs regulators for the identified system fulfilling some requirements in the answer. The designed practice is of controller user defined. This is the reason why the student designs his regulator and test with the real system comparing the answers.

In the third part, students make designs of compensation such as feedback and cascade compensation. The designed practice is of controller user defined like in the second part.

IV. METHODOLOGY USED IN REGULACIÓN AUTOMÁTICA I SUBJECT

As mentioned previously, this work shows the suitable combination of hands-on experiments, remote practices and activities of self-assessment.

The practical activities with AulaWeb were made several courses ago and allow a continuous assessment of the subject.

The combination of hands-on practices in the laboratory and remote practices was used as methodology, taking advantage of both variants. Hands-on practices have a great formative value for the students. They allow them to know and manipulate the physical equipment with which they work.

Once the student is familiarized with the systems they use, they can work at a distance with them, with the advantages of completion and optimization of the resources. Since the programming and capturing of data require between 10 and 20 minutes, the effective time using the devices is usually reduced. The accomplishments of remote works include time savings for the student and the sharing of resources. This is particularly important when the number of students is large and the equipment is expensive.

Another interesting aspect, that arises when combining hands-on and remote practices, is that the time of use of the equipment is not limited. The students can use them until they consider that they have reached the desired objectives.

In the integrated project, the statement of the different parts took place at AulaWeb, whereas the taking of data, graphs and the test of the regulators at SLD. The practices considered the registration number, thus they guaranteed a different game of data for each student which ensured the project's personalization. The delivery of the information took place through AulaWeb. This allowed the students to continue using the normal method of work and adapt to the SLD without difficulty.

V. RESULTS OBTAINED IN THE SUBJECT

The results obtained in the subject were good. The students were motivated with the use of the SLD for the integrated project. Nevertheless the access to the remote practices was modest, perhaps caused by the lack of information and ignorance of the possibilities that this method presents.

A survey on the subject was carried out. It took into account the following aspects:

- Dedication to the subject.
- Practical works.

Practical activities represent the most important aspect of this work. Items treated from this point of view include:

1. All practical works foster understanding of the subject.
2. The practical works and theoretical classes are balanced.
3. The integrated project contributes to the better understanding of the subject.
4. The time for the accomplishment of the integrated project was sufficient.
5. It was easy to use the Distance Laboratory System (SLD) in the integrated project.

Survey results, in a scale from 1 to 5, behaved as follows (Table II).

TABLE II. RESULTS OF THE SURVEY

Items (1 to 5)	Average	Median	Standard deviation
All practical works foster understanding of the subject.	3.94	4	0.85
The practical works and theoretical classes are balanced.	3.29	4	1.32
The integrated project contributes to the better understanding of the subject.	3.46	4	1.26
The time for the accomplishment of the integrated project was sufficient.	2.23	2	1.17
It was easy to use the Distance Laboratory System (SLD) in the integrated project.	3.19	3	1.22

The results obtained are positive. The students value the practical works which they consider to have a good balance with the theoretical activities. The students positively evaluated the integrated project; however, they considered that the time assigned to carry it out was not sufficient. Conversely, the professors agree that it lacked dedication on the students' part. Finally, the valuation of the SLD in the integrated project may be considered as acceptable, taking into account that it is used for the first time.

It was approved as an educative innovation project aimed at developing and evaluating the impact of new educative tools for learning subjects of Systems Engineering and Automatic.

VI. CONCLUSIONS

The accomplishment of practical works in the subjects of Automatic is a fundamental to achieve quality of teaching. The concepts explained in these subjects have an immediate impact in the implementation of control systems. The type of experiments to make is another important aspect. That is whether the student directly performs them on the physical equipment of the laboratory – as in the traditional way – or experiments accessing equipment remotely or using virtual models that simulate the physical behaviour of the systems.

The adopted option is that the students of the specialty will combine the execution of hands-on and distance practices. This allows them to know the operation of real equipments during the hands-on sessions, as well analyze different schemes from control at distance sessions. This methodology assumes no more than 100 students per classroom.

On the other hand, the students who are not of the specialty will work with virtual laboratories that simulate the behaviour of physical systems. This allows that large groups (classrooms with more than100 students) make several experimental works. In the case of hands-on practices, it would only be possible to make one or two during the course due to the limitation in the number of equipment.

In summary, the use of the SLD brings about a more flexible use of hands-on laboratories and a more rational use of the resources available. In addition, SLD offers the students great possibilities of development and investigation while trying studied algorithms of control in physical plants. The main benefit obtained to date is the reinforcing of the students' learning process when using the combination of hands-on and remote practices. This is derived from the fact that the real hours allow them to familiarize and manipulate the physical equipment directly, whereas remote working hours permit them to test different algorithms and techniques from control without the schedule restrictions.

This methodology increases the practical activities. In addition, students devote more time to the subject during the semester and this effort is rewarded in the final mark.

Abstract— **The paper presents a web-based tool designed to give support to teaching and learning of UML class diagrams. The proposed UML environment is capable to correct automatically UML class diagrams exercises providing feedback to the student immediately. The tool is part of a more general framework, denoted ACME, which provides the main functionalities of an e-learning platform. The tool has been used in a first experimental group of an introductory database course.**

Keywords: UML class diagrams, web-based tools, e-assessment

I. Introduction

Traditionally, a database course uses entity-relationship diagrams (ERD) when teaching conceptual modeling. Describe ERD and how to use them to illustrate conceptual database design is one of the main objectives of an introductory database course [1]. But, despite the popularity of ERD, in last years, different authors have proposed the UML (Unified Modeling Language) class diagram as an alternative to be used instead of ERD notation.

The UML [2] is the standard language for modeling object-oriented applications and is commonly used in the development of software applications. Although, this methodology was developed mainly for software design, a major part of software design involves designing the databases that will be accessed by the software modules. Hence, an important part of the UML is the class diagrams. A class diagram is a type of diagram that describes the static structure of a system by showing the system's classes and the relationships between them. Therefore, it can be considered that class diagrams are similar to ERD in many ways [3]. Moreover, UML provides an advantage with respect to entity-relationship model (ER) since it is widely understood within the computing community, whereas ER is limited primarily to the database community.

In non-academic environments, UML has emerged as an effective modeling tool for database design. On the contrary, it is still rare to see UML class diagram as the primary notation when teaching conceptual data modeling [4]. In academic textbooks the primary modeling techniques are based on ER notation. However, this tendency is changing in recent versions of the books, and chapters presenting UML methodology for conceptual modeling are included [5]. There are also different books focused only on the use of UML for database design [6,7]. These books claim that UML make closer database design with the real business applications.

We agree with [8,9] that this new tendency has to be taken into account in basic database courses, and hence UML class diagram notation has to be taught as well as ERD. Since building UML class diagrams is a complex process, we decided to develop a web-based tool to support its teaching and learning. This tool has being integrated in a more general e-learning framework, denoted ACME-DB, used in database courses of our university. The ACME-DB is used as a support for teaching and learning of the main topics of the course, amongst them, entity-relationship diagrams, relational database schemas, database normalization, SQL and relational algebra. This environment also provides the functionalities required to automatically correct exercises, continuous assessment, etc. The goal of this paper is to present the UML developed tool.

The paper is organized as follows. Section 2 describes related work on UML class diagrams and presents the ACME-DB e-learning environment. Section 3 presents the proposed UML correction tool. Section 4 describes experimental results. Finally, Section 5 presents the conclusions.

II. Related Work

In this section, we review the main concepts of UML class diagrams and their equivalences with ERD. Then, we present previous work on UML modeling tools and finally, the ACME-DB environment where our proposed tool has been integrated.

A. UML class diagram and ERD

There are many similarities between UML class diagrams and ERD [3]. Below we describe them by considering the examples extracted from [5] and illustrated in Fig. 1 and 2, where the same database has been modeled using UML and ERD, respectively.

The entity types in ER are modeled as classes in UML notation. An entity in ER corresponds to an object in UML. In UML class diagrams, a class is displayed as a box that includes three sections: the class name, the attributes and the operations that can be applied to these objects. Operations are not specified in ERD.

Relationship types in ERD are called associations in UML terminology, and relationship instances are called links. A binary association is represented as a line connecting the participating classes and optionally may have a name. A relationship attribute is placed in an association class that is connected to the association's line by a dashed line.

The cardinality in ER model is equivalent to multiplicity in UML terminology and denotes the number of objects that can participate in the relationships. Multiplicities are specified in the form *min..max*, and an asterisk (*) indicates no maximum limit on participation. Possible multiplicities are 0..1, 1..1 (or 1), 1..*, n..m and 0..* (or *).

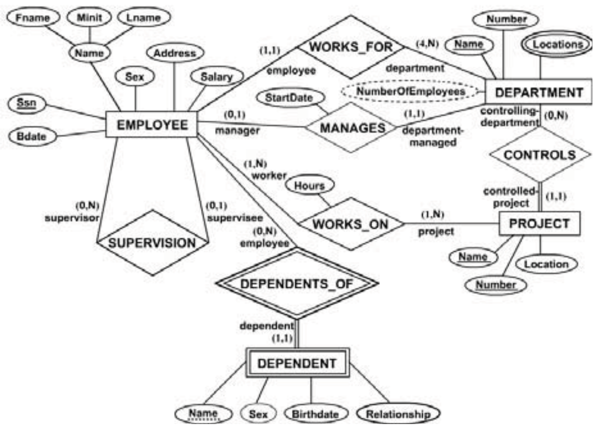

Figure 1. Entity-Relationship diagram of a company database from [5]

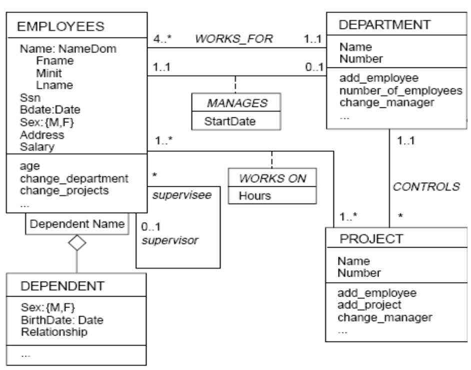

Figure 2. UML class diagram of a company database from [5]

In UML, there are two types of relationships: association and aggregation. An aggregation is meant to represent a relationship between a whole object and its components parts. In UML, it is graphically represented as a hollow diamond shape on the containing class. A composition is a stronger form of aggregation where the part is created and destroyed with the whole. The composition is drawn like the aggregation, but this time the diamond shape is filled. UML also distinguishes between unidirectional associations, which are displayed with an arrow to indicate that only one direction for accessing related objects is needed, and bidirectional that are the default. Weak entities in the ER model can be modeled using the construct called qualified association in UML that can represent both the identifying relationship and the partial key, which is placed in a box attached to the owner class. UML has the ability to specify methods, but when modeling database this feature is not needed as we only deal with data.

The UML is the standard notation for modeling business and software application needs. The main advantage of UML with respect to ER is that it can serve as a unifying framework that facilitates the integration of database design with the rest of a system design.

B. UML modeling tools

Building diagrams is a complex process and different modeling tools have been proposed for creating them. The majority of these tools has been designed for advanced users and only gives support to diagram drawing requirements. In the case of beginners, these tools are not appropriate since more advanced features are required. For instance, it is desired to obtain automatic correction of the diagram and feedback in case of detecting errors. In this section, we will focus on this second group of tools that can be very valuable in the academic context, i.e., tools that not only support drawing needs. Below we describe some of them.

Hoggarth and Lockyer [10] proposed an automated student diagram assessment system that provides a verification mechanism where the student manually compares his solution with the one designed by the teacher. At the end of the comparison process, the system generates a list with the differences with comments that can be used by the student to improve his diagram. H.Ali et al [11] proposed a UML class diagram environment that using notation extraction compares two Rational Rose files. The first file is a description of the UML class diagram proposed by the student and the second one the description of a correct solution defined by the teacher. The system compares these files line by line and generates a list with the differences. Feedback is returned according to this list. Baghaei, Mitrovic and Irwin [12] presented a constraint-based tutoring system for learning UML class diagrams. The system observes students' actions and adapts to their knowledge and learning abilities. The system compares the student solution with the ideal one proposed by the tutor. The comparison process is based on a set of rules. They proposed a single user and also a collaborative version of the tool. Virvou and Tourtoglou [13] proposed an environment for the adaptive support to a software engineering trainer. It considers two users, the trainer, considered an expert, and the student. The system assigns a degree of knowledge to the student and also an expert to monitor his work. N.Le [14] proposed an extension of the ArgoUML tool that allows creating UML class diagrams in a free-form way, i.e., with any restriction with respect to the name of the classes or the attributes. The system provides a set of guidelines to the student to create the diagram.

Despite the capabilities of these tools, in the academic context, it is desired that the e-learning tools provide not only the functionalities for which have been designed but also other functionalities related with academic issues such as continuous assessment, tracking student work, etc. Another limiting factor of these tools is that all of them requires to be installed and the majority requires an additional software for drawing the diagrams [10,11,14]. On the other hand, the tools are independent in the sense that they can not be integrated in a more general framework for giving support to different topics of database courses.

C. The ACME environment

ACME is a web-based environment developed in our university to give support at teaching and learning of different subjects. Originally, it was designed for teaching mathematics in engineering and technical degrees. ACME has a common repository of problems. The teacher can select problems from it and the system automatically generates workbooks. The student enters solutions and the system corrects them returning feedback. All the work is stored in a database and the teacher can extract information for continuous assessment. For a detailed description of the platform please see [15].

The good academic results obtained when applying ACME, encourages us to extend the platform in order to support other subjects. Currently, amongst others, it supports mathematical [15], computer programming [16], database problems, etc.

The set of modules of the platform related with database topics is denoted ACME-DB. We started to develop this environment in 2003 with the development of the relational database schemas module [17]. Since then, normalization [18], entity-relationship diagrams [19], SQL and relational algebra [20] correctors have been developed and integrated in the environment.

Compared with other e-learning platforms, ACME-DB presents, amongst others, the following advantages: (i) It integrates in a single environment, different tools for different database topics; (ii) supports automatic correction of exercises, providing feed-back and (iii) supports automatic student assessment.

Taking into account the limitations of current UML class diagrams tools and the advantages of our environment, we decided to develop the modules required to support UML class diagram correction. Such functionality will be a very valuable tool for teaching and learning conceptual database design in database courses.

III. THE UML CLASS DIAGRAM TOOL

In this section, we present the proposed tool for teaching UML class diagrams. First, we introduce the main design decisions that have been taken into account to develop the tool. Then, we describe the tool from a technical perspective, giving a detailed description of the main modules that compose it.

A. Design decisions

The proposed tool has to be capable of automatically correct UML class diagram exercises in order to reinforce teaching and learning of this topic. To design this tool, we consider that our system has to be able to assign UML class diagram exercises and also the tools required for the students entering the solution, i.e., a graphical interface that allows drawing UML class diagrams.

A second main requirement is the capability to support online correction. The system has to be able to automatically correct the exercises solved by the students. That is, when students enter a solution to a UML problem, it is desired that the system returns immediate feedback with detailed information about errors.

The system has to allow students to enter more than one solution until the correct one is obtained or a deadline is reached. The system has to record all student work, i.e. all attempts entered until the correct one is obtained. Such information will be very valuable for the teacher to carry out a tracking the student progress. The information recorded in the system can be used for continuous assessment purposes. In addition usability requirements are also desired. For instance, the tool has to be easily accessible for teachers and students, no special installation has to be required, only a web browser. The system has to provide a communication channel that enhances student-teacher contact, whether students ask about doubts or teachers give hints about how to solve diagrams.

The ACME environment provides some of the desired requirements, such as, easy access, record of student work, continuous assessment and the student-teacher communication channel. Therefore, to reach our objective we have to focus on the functionalities not provided by the environment and required to support the correction of UML class diagram exercises.

At broad level, we can reduce our problem as it is illustrated in Fig. 3. Our system has to propose exercises, the student will enter solutions, the system will provide feedback according to the correctness of the solution, and this process will be repeated until a certain deadline or the correct solution is obtained. Hence, we have to design two main modules: the class diagram student interface and the class diagram correction module. Both are described in detail the next sections.

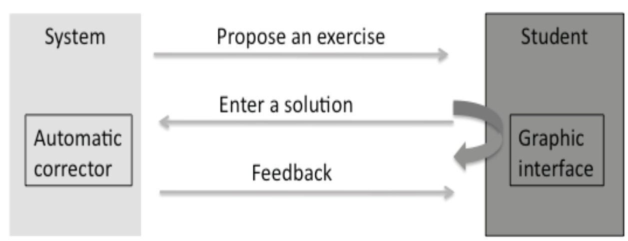

Figure 3. Main functionalities to be considered for the design of the UML class diagram correction tool.

B. The problem structure

Previous to the definition of the different modules that will compose our tool, we have to determine the structure of an UML class diagram problem. This structure is crucial for defining the correction strategy that has to be applied.

We define the problem structure following the guidelines used for the definition of the database problems that are also supported by ACME-DB. It is important to take into account that a UML class diagram problem can have more than one correct solution. The proposed structure is illustrated in Fig. 4. There is a first part with a description of the problem that has to be solved. It consists of a set of requirements for a real life application. A constraint of our approach is that attributes have to appear in the problem descriptor with a specific name and in brackets. Although, the identification of attributes is an important skill to be acquired, for students of introductory database courses we consider more important the capability to properly group attributes in the correct class or attach to the corresponding relationships.

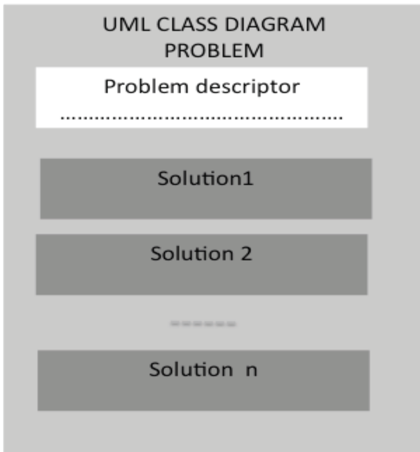

Figure 4. Main parts of a UML class diagram problem.

For each problem we also store a set of possible correct solutions. In Fig. 5, we illustrate the information codified for each solution. We have to specify all the classes and the relationships that define it. We assign one name to each one of the classes and also the list of all its attributes. In the case of association classes, we have to enter also the name of the association with which is related. For the relationships, we have to specify its name, the related classes, its multiplicity and the direction (unidirectional or bidirectional). We also have to indicate if it is an association, aggregation, composition or a generalization. In the case of qualified associations, we have to indicate the qualified class and the qualifier attribute.

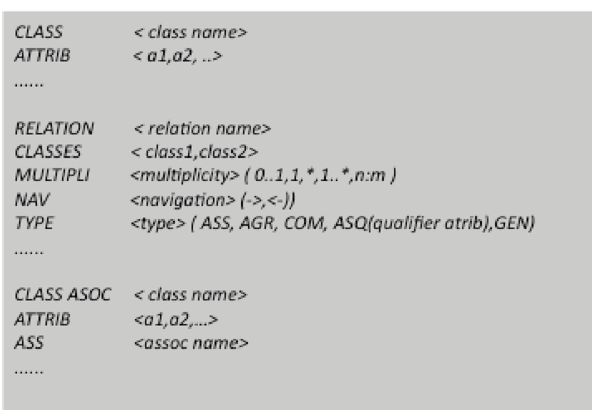

Figure 5. Parameters recorded for each correct solution

The teacher enters the problems and the solutions into the system using a specific editor integrated in the tool that makes easier this task. Each problem is recorded in an independent file, and once it has been created the system verifies that all the parameters have been entered correctly. If the system detects that the entered file does not fit the expected structure, it generates a message indicating where is the error. Problems are stored in a common repository and once saved they are available for being assigned to the students' workbooks. For creating the workbooks the teacher selects exercises from the repository and then the generation module assigns it to the students. Once the student has assigned a workbook, he can select exercises and solve them using the module presented in the next section.

C. *Class diagram interface*

Before presenting the UML class diagram student interface, just to put in context, we briefly describe how the information is showed to the student. Students enter into the ACME environment by using their password. Then, the system presents a list of topics and one of them corresponds to UML class diagram exercises. The student selects this and then accesses to the list of class diagram exercises that have been assigned to his workbook. When he selects one of these exercises it appears an interface with all the information and the tools required to solve it.

In Fig. 6 we illustrate the student interface. Its main parts are: (i) At the top, the problem descriptor area that is the space where the system displays the problem descriptor. (ii) On the left, there is a button bar with the drawing tools that contains a set of buttons where all the elements required for creating a diagram are represented. (iii) In the middle, the working area where the student design the UML class diagram. In this example we show the UML class diagram designed for a database problem from [5]. Since the dimension of the class diagram can be larger than the working area, there is a zoom button to select the part of the diagram it has to be displayed in it. (iii) At the bottom, there is an area with different tabs, each one related with a diagram element. This space is designed for entering the information and the main parameters related to it. For example, when defining a class we enter the attributes, for an association the multiplicity, the type of association, etc. In this example, the association between the two highlighted classes has been selected and hence the corresponding tab allows entering the type of association, related classes, etc.

The student enters the solution and then presses the correct button. In this moment, the correction process (described in next section) starts and when it finishes it returns feedback to the student. Feedback messages appear in an independent window jointly with the sent solution. If the solution is not correct, the returned message gives some advice of how to solve it (see Table I).

D. *Correction module*

The correction strategy is based on a comparison process that proceeds as follow. The solution entered by the student is compared with the possible correct solutions of the problem stored in the repository of the system. If any one of the correct solutions coincides with the one of the student, the solution is considered incorrect. In this case the feedback module selects the solution of the repository more similar to the one proposed

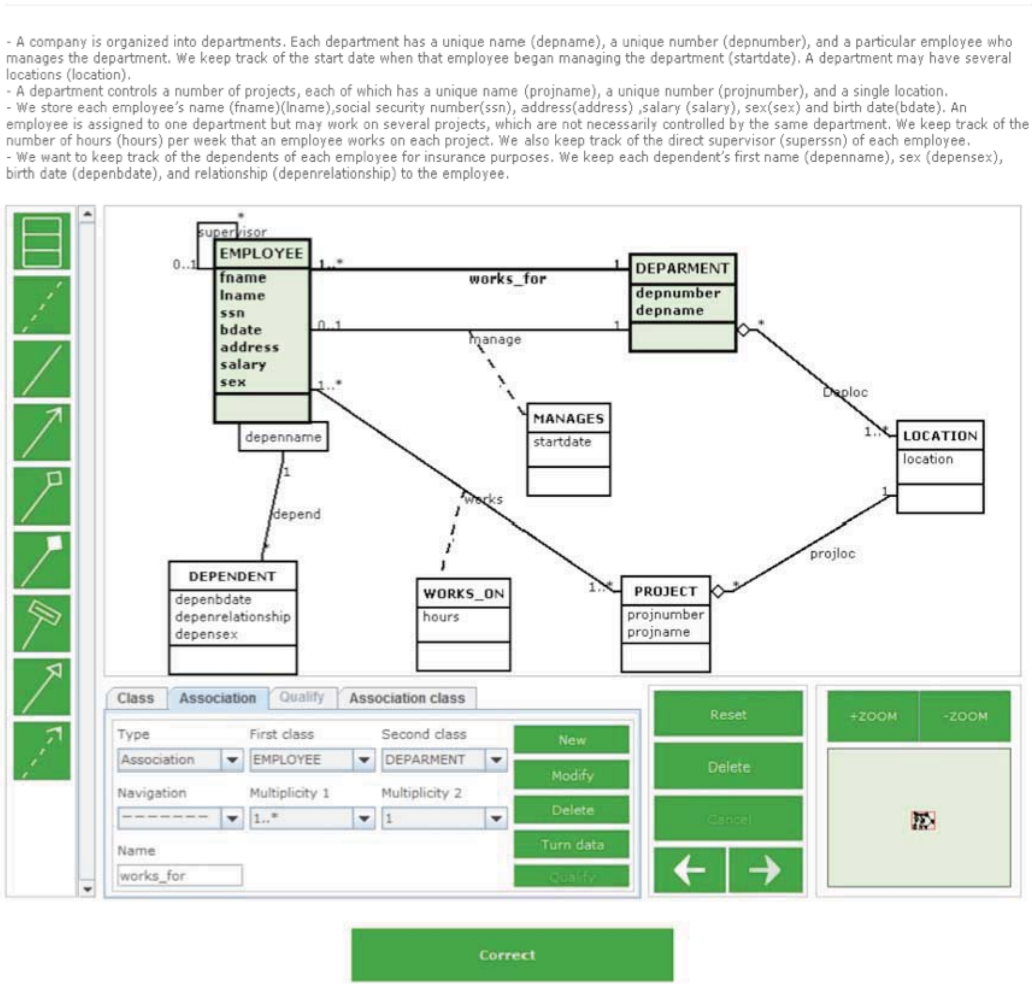

Figure 6. Student interface designed for entering a UML class diagram.

by the student and sends a feedback message to the student. The content of the message aims at driving him to the selected correct solution. The student can enter a new solution and repeat the process until the correct solution is obtained or a deadline has been reached.

The key of the correction process strategy is on the name of the attributes. Note that the only restriction it has been imposed to design the solution is that only attributes marked in brackets in the problem descriptor can be used. There is not any restriction on the names of the class nor the relationships. Classes are corrected by considering the set of attributes attached to it. Relationships are evaluated in terms of the classes they relate, its multiplicity and its type (associations, aggregations, compositions and generalization).

The differences between the correct solution and the student solution determine the message it has to be sent. We have classified the different types of errors that can be found and we have assigned a message to each one of them. The feedback module maintains this set of possible messages and according to the type of error detected by the correction module it automatically selects the message to be sent. In Table I, we report some the message errors.

TABLE I. ERROR MESSAGES GENERATED WHEN AN INCORRECT SOLUTION IS PROPOSED.

TYPE OF ERROR	RETURNED MESSAGE
Number of classes is incorrect	More/less classes are required
Number of associations is incorrect	More/less associations are required
Incorrect class	Class named … is not correct
Association type not correct	Association named … is not correct
Multiplicity error	Multiplicity of association named … is not correct
…	…

E. Integration in the ACME-DB

All presented modules have been integrated in the ACME-DB platform. The modularity of the platform allows such integration to be done easily.

The main advantage of this integration is that ACME-DB becomes a framework capable to give support to main topics of a database course. The student can use it to solve entity-relationship diagrams, relational database schemas and normalization, SQL and relational algebra queries. With the integration of the new tool, now it can also solve UML class diagrams. As far as we know, this is the unique environment that integrates all these features in a single framework.

IV. EXPERIMENTAL RESULTS

To evaluate the proposed tool we consider two groups of students of an introductory database course. The 48 students of the course were divided into two groups of 24 students. In the first one, we used the proposed tool and in the second one any tool was used. In both groups to teach UML we spent the same number of hours. The teacher introduced main UML concepts and then the same exercises were proposed to the students to acquire practice. These exercises require for being solved UML class diagrams with a number of classes that range from four to eight and from six to twelve associations.

In the first group (group A), the teacher introduced some example exercises through the proposed UML tool. Then, a personalized workbook with four different UML exercises was assigned to each student. In the second group (group B), the teacher presented the same examples of group A, but without using the tool. The students solved the exercises by hand. The teacher encouraged students to solve all the exercises and in case of questions, to go to his office.

For each group we collected the number of student and the number of exercise that they solve correctly. The obtained results are reported in Table II. Note that the best results are obtained using the tool.

TABLE II. NUMBER OF STUDENTS AND NUMBER OF PROBLEMS CORRECTLY SOLVED

Number of problems	4	3	2	1	0
Group A	16	4	2	1	1
Group B	10	2	4	4	4

We also evaluate the advantages of the tool from the teacher's point of view. The tool provides information of the type of student's errors. For instance, we detected that the 34,2% of errors are multiplicity errors, 31,3% are association type errors, 17,5% are definition class errors and 17,0% other errors. We also detect that to solve a problem correctly the student requires in average 3,2 attempts.

At the end of UML sessions, students of both groups have to pass an exam. The exam consists in one exercise similar to the exercises assigned to the students. The exam was the same for both groups. In Table III, we illustrate the obtained results, where capitals from A to D represent from excellent to failing the exam, respectively. Although, these results are experimental and need further evaluation with more students, we detect that the students that used the tool obtained better results than the other ones.

TABLE III. EXAM RESULTS

Mark	A	B	C	D
Group A	12	6	3	3
Group B	10	4	6	4

From the teacher's first impressions, we can remark that the environment is easy to use. It does not require any installation, only a web browser. More importantly, it provides gains with respect to the classical teaching methodology in the sense that it offers a system for the continuous assessment of the student's progress, makes personalized attention to the student easier and assesses the degree of participation of the students. The students' impressions have also been positive especially the fact that to access the system they only need an internet connection. During the different sessions students were asked to comment on the problems they faced while using the system. The responses were very positive. The students feel motivated to solve the proposed problems. The possibility to correct a problem in real time encourages them to work until a correct solution is found.

V. CONCLUSIONS

We have presented a UML class diagram tool that provides support at teaching and learning of this topic. This tool has been integrated in the ACME-DB, an e-learning framework for database topics. The tool has been used in a first experimental group with very satisfactory results.

Abstract—**This work presents the application of subgroup discovery techniques to e-learning data from learning management systems (LMS) of andalusian universities. The objective is to extract rules describing relationships between the use of the different activities and modules available in the e-learning platform and the final mark obtained by the students. For this purpose, the results of different classical and evolutionary subgroup discovery algorithms are compared, showing the adequacy of the evolutionary algorithms to solve this problem. Some of the rules obtained are analyzed with the aim of extract knowledge allowing the teachers to take actions to improve the performance of their students.**

Subgroup discovery; educational data mining; e-learning systems; evolutionary algorithms; fuzzy rules

I. INTRODUCTION

For almost as long as LMSs exist, researchers have been interested in study how the usage logs of these systems can be used to improve the learning process. The more used approach to exploit this data uses automated evaluation of system logs and databases [1] using data mining techniques to provide additional information for teaching staff about the quality of the student experience. In this sense, data mining techniques can be applied to analyze student's usage data in order to identify useful patterns and to evaluate web activity to get more objective feedback for instruction and more knowledge about how the students learn on the LMS [2].

Educational data mining is an emerging interdisciplinary research area that deals with the development of methods to explore data from an educational context [2]. It is concerned with the development of mining methods to explore the unique types of data in educational settings and, using these methods, to better understand students and learning settings. A data mining algorithm can discover knowledge using different representation models and techniques from two different perspectives: predictive induction, whose objective is the discovery of knowledge for classification or prediction [3]; or descriptive induction, whose main objective is the extraction of interesting knowledge from data. In this area, attention can be drawn to the discovery of association rules following an unsupervised learning model [4], subgroup discovery [5] and other approaches to non-classificatory induction.

Association rule mining [4] is one of the better-studied descriptive data mining methods whose objective is to discover descriptive rules about relations between attributes of a set of data. It has been applied to LMS in order to reveal which contents students tend to access together, or which combination of tools they use [5].

The extraction of association rules has been successfully applied in e-learning systems to discover relationships or associations between the different visited web pages, activities performed, marks obtained, etc. A pioneering work in applying web mining techniques to e-learning systems is [6] which proposes the use of agents [7] to recommend online learning activities or shortcuts in a web course based on access records of students, thereby enhancing the online learning process. Another work that uses association rule mining techniques and collaborative filtering is [8] with the aim of discover helpful navigation patterns and propose a navigation model. The use of methods such as linear regression in combination with association rules to obtain learning transferring patterns of students from the log files in intelligent tutoring systems is proposed in [9]. In [10] is described the use of fuzzy association rules to discover relationships between patterns of student behavior, including access time, number of pages read, questions answered, or read and sent messages. Evolutionary algorithms are used in [11] as a technique for discovering useful information for the authors of such courses, in order to make improvements of the contents, the structure or the adaptation of the courses. Another work using evolutionary algorithms is [12], where an association analysis is performed to predict student performance. Association rules can be adapted to subgroup discovery, a new and very interesting task in educational environments. In fact, this paper proposes the application of data mining techniques for subgroup discovering over educational data.

Subgroup discovery (SD) is a descriptive inductive learning area in which, given a set of data and a property of interest to the user, an attempt is made to locate subgroups which are statistically "most interesting" for the user [13]. A subgroup is interesting if it has an unusual statistical distribution with respect to the property of interest. The objective is to discover interesting properties of subgroups by obtaining simple rules, which are highly significant and with high support.

A rule describing a subgroup has the form:

Condition $\rightarrow$ *Class_label*

where the property of interest for subgroup discovery is the value of the variable (*Class_label*) which appears in the consequent of the rule, and the antecedent of the rule (*Condition*) is a conjunction of features (attribute-value pairs) selected between the features describing the instances of the data set.

Genetic Algorithms (GAs) are beginning to be used to solve SD problems [14], [15] because they offer a set of advantages for knowledge extraction and specifically for rule induction processes. A fuzzy approach in a SD algorithm, which considers descriptive fuzzy rules, allows us to obtain knowledge in a similar way to human reasoning, and so the obtaining of more interpretable and actionable solutions in the field of SD, and in general in the analysis of data in order to establish relationships and identify patterns.

In this work we apply the evolutionary subgroup discovery algorithms SDIGA [14] and MESDIF [16] to obtain fuzzy rules which describe relationships between the student's usage of the different resources provided by the e-learning systems and the final marks obtained. The objective is to characterize subgroups of students whose final marks are significantly different from those of all students, and use this knowledge to improve the learning process. The results obtained by these algorithms are compared with the ones obtained by classical subgroup discovery algorithms, showing the suitability of the evolutionary approach to this problem.

The work is arranged in the following way: Section 2 introduces the subgroup discovery and describes the evolutionary rule induction algorithms used, SDIGA and MESDIF, and the classical subgroup discovery algorithms Apriori-SD and CN2-SD. Section 3 describes the e-learning case study using the Moodle e-learning system implanted in the University of Cordoba, the experimentation carried out, the analysis of the results and of some of the rules obtained. Finally, the conclusions and further research are outlined.

II. Subgroup Discovery: Classical Approaches and Evolutionary Algorithms

In the literature, several different proposals for the extraction of rules in the area of subgroup discovery can be found. Two of the most used classical algorithms for subgroup discovery are adaptations of the well-known algorithms Apriori (used for the extraction of association rules) and CN2 (used for the extraction of rule bases for classification), which are named Apriori-SD and CN2-SD respectively.

There are also evolutionary proposals for the SD task. SDIGA [14] is an evolutionary algorithm for the induction of fuzzy rules which uses linguistic rules as description language for the specification of the subgroups, and adaptations of the measures used in the association rule induction algorithms as quality measures for the subgroup discovery task. MESDIF [16] is a multiobjective evolutionary algorithm using the same quality measures as SDIGA.

A. *Classical subgroup discovery algorithms*

The most widely used state-of-art SD algorithms are described below:

- Apriori-SD [17] uses the weighted relative accuracy as quality measure for the induced rules, using support and significance of each individual rule for the evaluation. It is an adaptation for subgroup discovery of the classification rule learning algorithm Apriori-C [18], based in the original Apriori association rule learning algorithm [4].
- CN2-SD [19] is a modified version of the CN2 classification rule algorithm [20] which induces subgroups in the form of rules using as quality measure the relation between true positives and false positives. As Apriori-SD, it uses a modified weighted relative accuracy measure for the selection of the rules.

B. *Evolutionary rule induction*

In any data mining process there are different tasks or problems which can be approached and solved as optimization and search problems. GAs are general purpose search algorithms which use principles inspired by natural genetics to evolve solutions to problems [21].

GAs have several advantages as a rule induction method: they tend to cope well with attribute interaction (because they usually evaluate a rule as a whole), have ability to scour a search space thoroughly, or allow to find complex interactions due to the implicit backtracking in its search of the rule space. This makes GAs particularly suited for the SD task.

The genetic representation of solutions is the most determinant aspect of any rule induction GA. In this sense, the proposals in the specialized literature follow two approaches in order to encode rules within a population of individuals [22]:

- The *"Chromosome = Rule"* approach, in which each individual codifies a single rule.
- The *"Chromosome = Set of rules"*, also called the Pittsburgh approach, in which each individual represents a set of rules.

Within the "*Chromosome = Rule*" approach, three generic proposals can be found: the *Michigan* approach, the *Iterative Rule Learning* (IRL) approach and the *cooperative-competitive* approach. A complete description of the different proposals for the evolutionary induction of rules can be found in [22].

In processes aimed to the extraction of rules for the subgroup discovery task, the "*Chromosome = Rule*" approach is more suited because the objective is to find a reduced set of rules in which the quality of each rule is evaluated independently from the rest, and it is not necessary to evaluate the set of rules jointly.

Among the different proposals of GAs for the description of subgroups, below are described two focused in this approach.

C. *Evolutionary rule induction algorithm SDIGA*

SDIGA (Subgroup Discovery Iterative Genetic Algorithm) is an evolutionary model for the extraction of fuzzy rules for the subgroup discovery task. This algorithm is described in [14], including here a brief summary of its key features.

In the subgroup discovery task we must distinguish between a set of descriptive variables and a single target variable which describes the subgroups. As the objective is to obtain a set of rules describing subgroups for all the values of the target variable, the GA of this proposal discovers fuzzy rules with the consequent prefixed to one of the possible values of the target variable. In this way, each run of SDIGA obtains a set of rules corresponding to the value specified for the target variable, and the algorithm must be run for each one of the possible values of the target variable.

In this proposal, each candidate solution is coded according to the *"Chromosome = Rule"* approach representing only the antecedent of the rule in the chromosome (since all the individuals of the population are associated with the same value of the target variable). The antecedent of a rule is composed of a conjunction of variable-value pairs. The information related to each rule is stored in a fixed length chromosome using an integer representation model (in which the i-th position indicates the value of the i-th variable).

The core of SDIGA is a GA which uses a post-processing step based on a local search (a hill-climbing procedure). The hybrid GA extracts one simple and interpretable fuzzy rule. The post-processing step is applied in order to increase the generality of the extracted rule. The optimized rule will substitute the original one only if it overcomes minimum confidence.

The GA uses a modified steady-state reproduction model, with the aim of increasing the diversity of the population, in which the original population is modified through the substitution of the worst individuals by individuals resulting from crossover and mutation. A two-point crossover operator is applied to the two best individuals of the population, obtaining two new individuals, who will substitute the two worst individuals in the population. Mutation is carried out by means of a biased random mutation operator applied to the gene selected according to the mutation probability. The mutation can eliminate the variable selected or assign a random value.

This hybrid GA is included in an iterative process for the extraction of a set of rules describing different parts (not necessarily apart) of the search space. A set of solutions generated in successive runs of the GA is obtained, corresponding with one value of the target variable. This is accomplished by checking the instances covered by the obtained rule, preventing a new rule to cover exactly the same examples. Thus different fuzzy rules are obtained, although they may be overlapping.

The model uses fuzzy rules, which provide better interpretability for the rules extracted by means of the use of a knowledge representation near to the expert, also allowing the use of numerical variables without a prior discretization. The fuzzy sets for the linguistic labels defined by the corresponding membership functions can be specified by the user or defined by a uniform partition if there is no available expert knowledge (using uniform partitions with triangular membership functions).

The evaluation function of the GA combines, according to the following expression, three factors: confidence (*Conf*), support (*Supp*) and unusualness (*Unus*):

$$fitness(c) = \frac{\omega_1 \cdot Conf(c) + \omega_2 \cdot Supp(c) + \omega_3 \cdot Unus(c)}{\omega_1 + \omega_2 + \omega_3} \quad . 1$$

in which w_i are the weights assigned to each measure, allowing to establish the importance of each one of the measures.

These measures are computed in the following way:

- *Confidence*. Determines the relative frequency of examples satisfying the complete rule among those satisfying only the antecedent. In this paper we use an adaptation of Quinlan's accuracy expression [23] in order to generate fuzzy rules [24]: the sum of the degree of membership of the examples of this class to the zone determined by the antecedent, divided the sum of the degree of membership of all the examples that verifies the antecedent part of this rule (irrespective of their class) to the same zone.
- *Support*. It is a measure of the degree of coverage than the rule offers to the examples of the class. This measure aims to promote the extraction of different rules in successive runs of the hybrid GA. This, for the computing of the support we only consider the examples not covered by rules obtained in previous runs of the GA. This way, support is defined as the quotient between the number of new examples covered by the rule and the number of not covered examples of the data set.
- *Unusualness*. It is also known as the weighted relative accuracy. It measures the balance between the coverage of the rule and its accuracy gain and is normally used as a measure of the interest of the rule.

The overall objective of the evaluation function is to guide the search towards rules that maximize the accuracy and the interest of the rule, also minimizing the number of negative and not covered examples.

D. *Multiobjective evolutionary algorithn MESDIF*

This multiobjective evolutionary proposal [16] extracts rules using the same representation as the SDIGA algorithm, and its objective is the extraction of a variable number of different rules for each value of the target variable. The algorithm allows the extraction of fuzzy and/or crisp rules, for problems with continuous and/or categorical variables.

The multiobjective GA follows the SPEA2 approach [25], and so applies the concepts of elitism in the rule selection (using a secondary population) and the search of optimal solutions in the Pareto front (the individuals of the population are ordered considering if each one of them is or not dominated by others using the concept of Pareto optimal). Any multiobjective GA must be designed aimed to reach two objectives: obtaining of good approximations to the Pareto front and maintaining the diversity of the solutions in order to adequately sample the space of the solutions and not to converge to a single solution or to a bounded section of the Pareto front. To preserve diversity at a phenotypic level the algorithm uses a niche technique that considers how close the values of the objectives are. Table I shows the operation scheme of the proposed model.

In this subgroup discovery process the objective is the extraction highly descriptive capacity, comprehensible and interesting rules. So, three objectives have been defined in this multiobjective proposal: support, confidence and unusualness. Confidence and unusualness are defined in the same way as in SDIGA, but a different definition of support is used because the algorithm obtains sets of different rules without using an iterative model. In his case, support is defined as the quotient between the number of examples of the class described by the rule and the total number of examples of the class.

This algorithm uses an elite population with a fixed size, and so it is necessary to define functions for truncation and filling. The truncation function allows the elimination of non-dominated solutions from the elite population if it exceeds the defined size. For this purpose it is used a niche schema defined around the density measured by the distance to its k-th nearest neighbour, in which, in an iterative process, in each iteration it is eliminated from the elite population the individual that is nearest of others respect of the values of the objectives. The fill function allows adding dominated individuals from the population and the elite population until the exact size of the set is reached (ordering the individuals according to their fitness values).

The algorithm uses the following reproduction model:

- Join the original population with the elite population obtaining then the non-dominated individuals of the joining of these populations.
- Apply a binary tournament selection on the non-dominated individuals.
- Apply recombination to the resulting population by a two point cross operator and a biased uniform mutation operator in which half the mutations carried out have the effect of eliminating the corresponding variable, in order to increase the generality of the rules.

TABLE I. OPERATION SCHEME OF THE PROPOSED EVOLUTIONARY ALGORITHM

Initialization: Generate an initial population P_0 and create an empty elite population $P'_0 = \emptyset$.
Repetir
Fitness assignment: Compute fitness values for the join of the individuals in population P_t and in elite population P'_t.
Environmental selection: Copy al non-dominated individuals in population P_t and in elite population P'_t in the elite population P'_{t+1}. If the size of P'_{t+1} is bigger than the number of individuals to store, reduce P'_{t+1} by a truncation operator; otherwise, if the size of P'_{t+1} is lower than the number of individuals, fill with dominated individuals of P_t and P'_t.
Mating selection: Perform binary tournament selection with replacement on elite population P'_{t+1} applying later crossover and mutation operator to fill the matting pool. The result is the population P_{t+1}.
While stip criteria is not verified.
Return the non-dominated individuals in elite population P'_{t+1}.

III. E-LEARNING CASE STUDY: USAGE DATA OF THE MOODLE E-LEARNING SYSTEM OF THE UNIVERSITY OF CORDOBA

In this section we examine the e-learning case study. First, we describe the problem and then the experimental results obtained in the execution of the different subgroup discovery algorithms are shown. Finally, an analysis from the point of view of the teacher of several of the rules obtained is performed with the aim of improving the e-learning courses.

As we have mentioned previously, we have used student's usage data of the Moodle system [26], one of the most used web-based e-learning systems. Moodle is an alternative to proprietary commercial online learning solutions, is distributed free under open source licensing and has been installed at universities and institutions all over the world.

The aim of the use of subgroup discovery in this problem is to analyze the possible relation between the usage of complementary activities of a course and the final marks obtained by the students. The final mark is used as the variable to characterize, using the different marks to divide the data into classes and codifying them as values of the consequent of the rules.

We have run different subgroup discovery algorithms in order to compare the results and show what type of algorithm discovers more useful knowledge for the course teacher. The objective is to present the results to the teacher in the form of rules in order to allow the use of this knowledge in the decision making concerning the complementary activities of the course. For example, the teacher can decide to promote the use of some type of activities to obtain a high mark, or on the contrary eliminate some activities because they are associated with low marks.

The Moodle system contains a great deal of detailed information on course content, users, usage, etc., stored in a relational data base keeping detailed logs of all the activities performed by the students. We can use these logs in order to determine which students have been active in the course, what they did, when, or if everyone has done a certain task or spent a required amount of time online within certain activities [27].

We have available information corresponding to 192 different courses of the University of Cordoba. Among all these courses, we have chosen 5 courses, corresponding to the subjects with the highest usage of the activities and resources, involving a total of 293 students. Although our approach can be applied to just one course we have selected courses with high student participation in order to generalize the results. However, there is no a minimum amount of students to obtain any rule.

We have applied a pre-processing step to the information, obtaining a summary table with the most important information related to our objective. Table II shows this summary table, including the activities completed and the mark obtained by each student in an e-learning course. We have discretized the marks into classes (fail, pass, good and excellent) in order to codify them as the values of the rule consequent. The information obtained has been exported to a text file using the structure of the KEEL platform files [28] because the subgroup discovery algorithms used are implemented for the KEEL data mining platform.

TABLE II. ATTRIBUTES USED FOR EACH STUDENT

Name	Description
course	Identification of the course
n_assigment	Number of assignments completed
n_assigment_a	Number of assignments passed
n_assigment_s	Number of assignments failed
n_quiz	Number of quizzes completed
n_quiz_a	Number of quizzes passed
n_quiz_s	Number of quizzes failed
n_messages	Number of messages sent to the chat
n_messages_ap	Number of messages sent to the teacher
n_posts	Number of messages sent to the forum
n_read	Number of forum messages read
mark	Discretized student's mark

A. *Experimental results of the application of subgroup discovery algorithms*

The experiments had been performed using four different algorithms in order to compare their results and determine the most appropriated approach: the classical subgroup discovery algorithms Apriori-SD and CN2-SD and the evolutionary algorithms SDIGA and MESDIF.

We have performed several runs of the different algorithms in order to obtain the average values of the measures used to evaluate the quality of the rules.

For the classic deterministic algorithms Apriori-SD and CN2-SD we have performed a set of runs, varying one of their parameters each time. In the case of Apriori-SD, we have used 4 minimum confidence values (0.6, 0.7, 0.8 and 0.9) varying the minimum support value (0.03, 0.1, 0.2, 0.3, and 0.4). In the case of CN2-SD, we have used the γ parameter (0.9, 0.7, 0.5 and additive) varying the star size (1, 2, 3, 4, 5).

For the evolutionary algorithms, we have performed 5 different runs for each of the values of the target variable (fail, pass, good and excellent) using a population of 100 individuals, a maximum number of evaluations of individuals in each GA run of 10000, a crossover probability of 0.6, a mutation probability of 0.01, and 5 linguistic labels for the continuous variables (very high, high, medium, low, very low).

In addition, the weights used for the fitness function in the SDIGA algorithm are: 3 for accuracy, 1 for coverage and 4 for significance. This set of weights has been chosen according to the results obtained in an experimental study. For the SDGA algorithm, different values of the minimum confidence (0.6, 0.7, 0.8 and 0.9) are used. For the MESDIF algorithm, different elite population sizes are used (3. 4, 5 and 10).

Table III shows the results obtained by the classic algorithms with their different parameter values and the averages of the 5 runs of the evolutionary algorithms with each value of minimum confidence. The table shows the total number of rules obtained, the number of attributes in the antecedents of the rules and the values of their quality measures (support, confidence, unusualness and significance).

In order to analyze de results with respect to the number of rules and the number of variables of the rules, we have to take into account that a key aspect in our problem is the interpretability of the results. In this sense, we are interested in the extraction of a reduced set of rules with a low number of attributes. This will facilitate the understandability of these rules for the teacher.

TABLE III. EXPERIMENTAL RESULTS OF THE ALGORITHMS

Algorithm	*Number of rules*	*Number of attributes*	*Support*	*Confidence*	*Unusualness*	*Significance*
SDIGA MinCnf 0.6	5.4	3.1600	0.7418	0.7709	0.0340	20.0671
SDIGA MinCnf 0.7	4.8	2.8000	0.8096	0.5716	0.0378	23.1872
SDIGA MinCnf 0.8	5.4	3.2583	0.6534	0.6805	0.0319	21.4395
SDIGA MinCnf 0.9	6.2	3.1821	0.3815	0.7769	0.0200	14.4846
MESDIF Elite 3	12.0	3.2000	0.9795	0.4466	0.0173	21.7596
MESDIF Elite 4	16.0	3.4125	0.9890	0.4242	0.0234	24.7158
MESDIF Elite 5	20.0	3.6500	0.9884	0.4517	0.0241	23.6884
MESDIF Elite 10	40.0	3.6950	1.0000	0.4732	0.0284	23.8734
Apriori-SD MinCnf 0.6	9.8	1.0400	0.5924	0.6157	0.0183	27.3901
Apriori-SD MinCnf 0.7	10.4	1.3238	0.5513	0.6301	0.0176	31.4304
Apriori-SD MinCnf 0.8	5.0	0.8294	0.3734	0.3842	0.0205	21.2968
Apriori-SD MinCnf 0.9	4.6	1.1692	0.2089	0.3787	0.0192	21.0734
CN2-SD (γ=0.5)	15.6	5.6406	0.9342	0.7143	0.0264	45.8554
CN2-SD (γ=0.7)	18.4	5.6857	0.9876	0.7177	0.0349	47.0058
CN2-SD (γ=0.9)	25.2	5.7177	0.9890	0.7184	0.0315	47.2862
CN2-SD (add)	31.5	5.7741	1.0000	0.7129	0.0273	54.7134

Thus, in this aspect the results of SDIGA are better than the results of the classical subgroup discovery algorithms.

With respect to the quality measures, it can be seen that:

- For the support measure, MESDIF and CN2-SD obtain the best results, obtaining rules with a high generality, so covering most of the students. MESDIF obtains the same results as CN2-SD but with a lower number of attributes. SDIGA also obtains high values in this measure.
- Related with the confidence or precision of the rule, which indicates the number of students covered by the antecedent of the rule and which correspond to the class associated to the same, the best results are obtained by SDIGA and CN2-SD, which obtain rules with a good level of precision.
- For the unusualness, the best results are obtained by the SDIGA algorithm, but all the algorithms obtain similar values in this quality measure.
- Finally, significance measures the relevance and interest of the rule. CN2-SD is the algorithm that obtains the best results in this measure, and both evolutionary algorithms obtain results very similar to that of Apriori-SD.

The most desirable algorithm with regard to the values of these quality measures would be an algorithm that simultaneously shows the highest values for all the measures. As we have seen there is not a single algorithm which achieves this. Then we have to consider the interpretability of the results for the teachers. In this sense, the evolutionary algorithms offer knowledge with a reduced number of rules and variables. In addition, the use of fuzzy rules in SDIGA and MESDIF contributes to the interpretability of the extracted rules due to the use of a knowledge representation nearest to the expert, also allowing the use of continuous features without a previous discretization.

B. Analysis of the comprehensibility of the rules obtained by evolutionary algorithms

According to the results shown in the previous section, the evolutionary algorithms for subgroup discovery take advantage over the classic algorithms in relation to the comprehensibility of the rules extracted when using them in the decision making of the teacher of a course. This is due to the use of attributes of the form “LABEL = VALUE”, where VALUE are linguistic labels provided by the expert, which allow an easier interpretation for the teacher.

On one hand, rule induction algorithms are normally also considered to produce comprehensible models because they discover a set of IF-THEN classification rules that are a high-level knowledge representation and can be used directly for decision making. Some examples of rules obtained by a rule induction algorithm are:

IF n_assignment < 6 THEN mark = FAIL

IF n_assignment > 10 AND n_quiz_a > 9 THEN mark = GOOD

IF course = 29 AND n_quiz_a = 0 THEN mark = FAIL

IF course = 110 AND n_quiz_a > 7 THEN mark = GOOD

On the other hand, fuzzy rule algorithms obtain IF-THEN rules that use linguistic terms that make them more comprehensible/interpretable by humans. So, this type of rule is very intuitive and easily understood by problem-domain experts like teachers.

Below are shown a few examples of rules discovered by the evolutionary algorithms, analyzing their meaning a applied to the improvement of the courses.

IF course = 110 AND n_assignment = High AND n_posts = High
THEN mark = Good
Support: 0.7045 Confidence: 0.7231

For the course 110, students who have done many activities and have sent many messages to the forum have obtained a high mark. The teacher of this course should continue promoting such follow activities as they have been proven effective in the final mark obtained by the students who carry them out.

IF course = 88 AND n_messages = Very High
THEN mark = Fail
Support: 0.1930 Confidence: 0.9444

For the course 88, students who have sent a lot of messages to the chat have failed. The teacher of this course should eliminate the chat because it has no provided any benefit to the students, but on the contrary it can be seen as a source of distraction.

IF n_read = High AND n_messages_ap = Very low
THEN mark = Fail
Support: 0.1176 Confidence: 0.7500

For any course, if the number of messages read from the forum is high but the number of messages sent to the teacher is low, then the final mark is fail. This rule provides information on a small group of students who tend to fail. The teacher can then pay more attention to these students trying to motivate them in time to pass the course.

Finally, in our educational problem the final objective is to show the instructor interesting information about student marks depending on the usage of Moodle courses. Then, the instructor can use the discovered knowledge for decision making about activities. For example, some of the rules discovered show that the number of quizzes passed in Moodle was the main determinant of the final marks, but there are some others that could help the teacher to decide whether to promote the use of some activities to obtain higher marks, or on the contrary, to decide to eliminate some activities because they are related to low marks. It could also be possible for the teacher to detect new students with learning problems in time to remedy (students predicted as *Fail*).

IV. Conclusions

In this work the application of subgroup discovery techniques to data from a real world problem of knowledge extraction in e-learning systems.

After testing the proposed algorithms by comparing them with other classical subgroup discovery algorithms, it appears that evolutionary algorithms are well suited for solving the proposed problem. They obtain a reduced set of understandable rules (due both to their small size and to use of linguistic labels) that make them more interpretable to the teacher, in addition to obtaining similar values in the other quality measures. Based on the rules obtained, teachers can make decisions about course activities to improve the performance of their students.

***Abstract*—Computation for Science and Engineering is an introductory computer science course for students majoring in fields other than computer science. This course, which was previously taught as a traditional introductory course focusing on syntax of C, will be offered with its new curriculum in Spring 2010. The new curriculum defocuses syntax and involves students in analyzing dynamic systems, which are frequently not deeply understood by students attending science and engineering courses. This course aims at attracting more non-computer science majors into computing disciplines and providing students with a deeper understanding of dynamism of real-life situations.**

Keywords-dynamic systems, programming, computing fields

I. Introduction

Motivated by Mark Guzdial's observation that programming is more accessible when examined in the context of interesting and engaging problems [1], we have recently developed at the University of Texas at El Paso (UTEP) a programming course offered to entering college students titled "Introduction to Computational Systems" (ICS) that examines the mathematics underlying familiar physical phenomena such as ballistics and resonance [2].

A typical project in ICS will be a short (4-15 line) program simulating a simple dynamic system whose output is drawn as a raster image. While the plots generated by these programs are essentially equivalent to the display of a graphing calculator, it appears that student definition of the system's evolution as a simple iterated sequence of instructions provides a heightened visceral-level understanding of the mathematics underlying a system's evolution. Furthermore, much like manipulatives used in math courses, the programs are sufficiently simple to be easily analyzed and repaired when a student discovers that their program evolves in an inappropriate manner. The preliminary evaluation of this course indicates that attendees quickly develop competency at basic programming tasks and have favorable attitudes towards learning about the mathematics of dynamic systems using computation in this manner [3].

Driven by the early success of ICS course, we are developing a new curriculum for the introductory computer science class for students not majoring in computer science. Computer Programming for Scientists and Engineers (CPSE) is a course at UTEP intended to teach basic computer programming skills to undergraduate students majoring in STEM disciplines other than computer science. The previous curriculum was a traditional introduction to programming that focused on the syntax and semantics of the C language and did not draw connections to attendees' majors. CPSE attracted too few students to be offered regularly.

We describe a new curriculum for CPSE, now titled "Computation for Science and Engineering" (CompSE), which will be introduced in Spring 2010. CompSE offers a more problem-oriented approach to learning programming concepts and uses the pedagogical approaches of our ICS curriculum to introduce programming as a tool for understanding the dynamism of systems of relevance to attendees' science-technology-engineering-math (STEM) academic majors.

One of the main goals of CompSE is to attract students not majoring in computer science to computational sciences courses and stimulate their interest in continuing study of computation. To achieve these goals, CompSE aims at attaining three main learning objectives.

1. Students will examine and understand the basis of analytical techniques that they have probably seen and memorized in mathematics or science courses but have frequently not been comprehended deeply enough to be able to apply them to real-life problems.
2. Students will learn how computation can be used to analyze problems that are difficult or impossible to understand using only analytical techniques, and
3. Students will realize that real-life problems expose common challenges to simulation such as catastrophic errors due to effects of round-off error or inappropriate simulation interval.

II. Motivation for Computation for Science and Engineering

While programmed computation is a key tool to understanding the evolution of dynamic systems across the sciences, it is unusual for students in traditional science majors to attend a course that teaches programming skills. Furthermore, traditional introductory programming courses rarely expose the relevance of computation to these disciplines. In order to engage a larger number of students from traditional scientific disciplines in computational sciences, CompSE focuses on the development and examination of programs that simulate dynamic phenomena drawn from these disciplines. These simulations typically compute the sum of finite differences that are computed at each simulated time-step and also provide an alternate learning pathway for understanding underlying mathematical concepts.

Through this approach the course exposes the utility of simulation in examining the evolution of realistic systems whose complexity limits the accessibility of analytical evaluation. CompSE thus motivates the use of computation to the study of compelling realistic situations rather than hypothetical or simplified examples frequently found in coursework.

In order to stimulate students' interest to continue study in computational systems, CompSE aims at improving students' understanding of real-life dynamic systems by use of computer simulations. One of our key objectives is to provide a visceral level understanding of the characteristics of stable, periodic, and unstable systems that include feedback effects such as investment, production-consumer markets, predator-prey models, muscle contractions, impact of environmental conditions on living organisms, and the development of cancer.

Families of dynamic systems are examined as threads of inquiry drawn from various disciplines in which layers of complexity are progressively added to increase the realism of the computational model. We begin with a financial modeling thread, and continue with examining threads in other fields including environmental science and molecular biology.

Besides the mastery of basic programming concepts, anticipated learning outcomes of this course also include an understanding of the power and limitations of simulation, visceral understandings that simple systems can have highly dynamic behavior, and interest in continued study of computational systems.

Our planned evaluation for the success of this curriculum will examine both the effectiveness of the course in achieving student learning objectives, and student interest in continuing multi-disciplinary studies that include computation and programming.

III. COMPUTATION FOR SCIENCE AND ENGINEERING

The new curriculum will be offered for the first time in the Spring of 2010. By this curriculum, like ICS, rather than initially focusing on syntax, CompSE will instead immerse students in problem solving and incrementally introduce language features in an as-needed manner. Python is selected as the initial programming language due to its simplicity to convey major programming skills, and C is introduced later in the semester to demonstrate to students the ease of learning a new programming language once they are comfortable using Python.

The new curriculum still examines foundational programming concepts such as input and output, branching and loop statements, and objects. However, the presentation of these concepts is driven by the needs of the projects being examined rather than following a more traditional approach in which programming concepts to be taught are determined first, and the examples to demonstrate these notions are chosen based on the concepts that are to be explained.

Dynamic systems are examined in modules chosen from various disciplines including physics, finance, biology, and environmental science. Each dynamic system is originally presented under simplifying assumptions, which make it easier for students to understand the basic principles of the system at hand. After the initial comprehension of the underlying dynamic system, layers of complexity are progressively added to modeling of the system to increase the realism of the computational model.

Below, we describe several modules of CompSE. Each examines an evolving sequence of challenges that permit students to engage in discovery-learning as they first understand and implement simplistic models, discover their naïve assumptions, and then discover and apply successive refinements that reflect deepening understandings of the problem.

A. Investment Module

We begin with a financial modeling thread that first implements simple interest that might be offered by a bank. It is clear that, using this approach, the amount of money in a bank account is represented by a linear function. However, the students are asked to simulate the balance in consequent years, for a given initial investment and interest rate, without finding the exact equation of the line. Only after experimenting with different initial amounts and interest rates, students become familiar with expected behavior of the investment system in the case of a simple interest rate. Moreover, students are asked to relate the behavior of the system to known mathematical functions, which is expected to deepen their understanding of simple mathematical functions, such as linear functions.

The next layer of complexity is added by considering compound interest, which yields an exponential function. Students are led through similar steps as in the case of a simple interest in order to understand a more realistic investment system and, at the same time, understand the behavior of exponential functions.

Subsequent labs examine the selection of alternative investment instruments such as stocks and real estate. We first consider two criteria for investing in stocks – return and risk, for which we can define a stable (possibly linear) relationship: if the return of a stock increases, the risk of investing in this stock increases as well [4]. However, in reality, when the risk reaches a certain high point, no one will invest money in the stock even if it offers high return, and therefore the established (linear) relationship between return and risk becomes invalid. The course explores how this new phenomenon could be modeled. Naïve models are demonstrated to be inadequate when the resulting system reaches an absurd state. Various approaches to refining the models are examined such as piece-wise corrections, higher-order approximations, or alternate models.

In the first case, boundaries of the regular behavior are established (i.e., until which point the relationship between risk and return is linear), and the branching condition is placed at this point. The already built model is used until the boundary condition is reached, and a new model is built for the remaining part of the problem.

In the second method, the existing model is thrown away and a new model is built to address the new situation. Instead of using a linear relationship between return and risk, possibility of using mathematical functions that tend towards some horizontal asymptote are examined, such as exponential and logarithmic functions.

Furthermore, the course explores models of how a financial system can continue to evolve including the risks of oscillatory behavior, market crash, and various approaches that can lead to stable recovery.

The effect of simulation granularity and utility of mathematics in modeling these systems is also explored. Market crashes could result in losing money, thus the amount of money in investment instruments decreases rapidly in this situation. If appropriate/sufficient/enough attention is not taken during the simulation, this amount might become negative, which is not an adequate representation of the real-life situation. In order to repair the simulation, students need to determine when exactly the value becomes zero. However, it might not always be possible to find the exact value due to granularity of the simulation. Thus, students are forced to accept an approximate value as the solution, therefore facing the round-off error in this particular problem.

The finance module of CompSE is accessible to students with a variety of academic backgrounds. The course assumes that students have only a superficial understanding of investment and familiarity with high-school algebra. As in ICS, each type of dynamism and its effects are incrementally taught and examined through incorporation into students' simulated computational systems.

B. Environmental Science Module

CompSE continues by examining dynamic systems from other disciplines including environmental science and the impact of environment on living organisms.

Through the simulation of a simple agricultural ecosystem, the lab sequence examines the nature of random processes, their effect on dependent stateful dynamic systems, and the Monte-Carlo method. At each time step, the evolved health (state) of the plant population is modeled as a function of current health and current climate conditions. For example, a simplistic model of a healthy plant will transition through several states of diminished health when subjected to drought, and its recovery to a healthy state will similarly require a prolonged period of adequate irrigation.

Lab exercises will examine the nature of randomness in climate models. For example, in an early lab, the simulation of irrigation water availability is naively simulated as an independent random daily event with fixed probability. Students can run multiple Monte-Carlo experiments and determine the relationship between expected availability of irrigation water and probability that the crop will fail.

Subsequent exercises challenge students to develop more realistic climate models and to examine their effect on plant resilience. In addition, projects can model or simulate more complex models of ecosystems such as ones that include reproduction or competition.

C. Molecular Biology Module

In contrast to the familiar finance and environmental science examples described above, it is unusual for students not studying biology to be familiar with the processes of molecular biology. This section offers most students the opportunity to understand unfamiliar biological processes and approaches to simulating uncertainties and constraints.

One of the problems that we model in CompSE is development of cancer. For example, four types of cells' mutations are understood to contribute to development of cancer [5]. These four types of mutations are explained to students with enough details to offer understanding of the problem and the opportunity to develop at least a starting point in building a meaningful model for prediction of cancer given a current state of a patient.

Since the prediction of cancer is an ongoing long term project in medicine, the students are not expected to build the entire model, but rather brainstorm about possible approaches, and consider limitations of particular techniques through simulation of the system on a smaller scale.

Since many cell mutations remain unexplained nowadays, students are faced with a somewhat random generation of mutations. Based on the existing literature on cell mutations, it is not known when a mutation will occur. However, the rate at which each mutation occurs is well-studied and documented. Thus, even though the mutations are random, the students need to simulate these mutations taking into consideration the estimated rates of each mutation.

While students' models of cancer growth will necessarily be simplistic, students will be exposed to key concepts and will be familiar with the dynamism of such systems and how they are studied.

IV. Comparison to Old Curriculum

In the past, CompSE (then titled CPSE) was taught as a traditional introductory computer science course, which focused on teaching students the syntax and semantics of C programming language. While learning basic concepts of programming is of great importance, it also could be boring for students who do not plan to major in computer science.

Because of the focus on syntax and semantics, traditional programming courses are organized around programming concepts such as input and output, branching and loop statements, and often objects. Lab assignments for these courses are selected in accordance to the topic that was just learned, and are often hypothetical or very simplified real-life problems. Students are often faced with using computer programming to solve problems that could easily be solved with pen and paper, a calculator, or a simple spread sheet, thus not getting the right feel for the importance of programming and computer science in general.

Moreover, programming is often taught without mentioning limitations of certain programming language or limitations of programming in general. Students are only introduced to viable concepts and asked to solve problems whose solutions could be obtained in a straightforward manner.

In contrast to the previously taught curriculum of a traditional introductory programming course, which focuses on syntax of a language, the new curriculum for CompSE offers a more problem-oriented approach to learning programming concepts. As described in the previous section, the focus of the new curriculum of CompSE is on introducing students to behavior of dynamic systems. A system is studied in phases starting from its simplified versions to more complex and more realistic behaviors. Besides learning programming tools, students also learn different dynamic systems, some of which come from their fields of study. Students are introduced to a variety of dynamic behaviors, some more stable than others, and are expected to transfer this knowledge and experience to other non-programming courses that they take.

Unlike traditional methods for teaching programming, students in the CompSE course face limitations of programming and simulation techniques. They realize that not everything could be simulated exactly as it happens in reality, and learn how to set reasonable assumptions. In the second half of the semester, students are also forced to determine which of the learned techniques suits best a given problem.

Similarly to the old curriculum of the CPSE course, CompSE covers all basic programming concepts. However, these concepts are not taught to just show to students that these particular tools exist, which is often the case in traditionally taught curriculum. Computer programming concepts in CompSE are taught when needed to solve a particular problem, and thus clearly show to students the need, usage, and implementation of these concepts.

V. Expected Learning Outcomes

Anticipated learning outcomes of CompSE include mastery of basic programming concepts, deeper understanding of the dynamics of real-life systems, understanding of common simulation techniques, and interest in continued study of computational systems.

Since it is currently almost impossible to study, understand, and analyze dynamic systems without the aid of computers, one of the main goals of CompSE is to involve a larger number of students from various disciplines in computational sciences. By providing a more problem-oriented approach to teaching introductory programming, CompSE examines examples that are more related to attendees' field of study. Thus, the expectation is that the new curriculum will not only attract a larger number of students to study the first course in programming, but also increase the interest of these students to continue enrolling in computing classes.

Moreover, CompSE aims at improving students' understanding of real-life dynamic systems by the use of computer simulations. Since simulations allow students to quickly evaluate the impact of different parameters in a model, the behavior of dynamic systems is better understood by experiments. Furthermore, students are challenged to develop these simulations on their own, thus a thorough understanding of the dynamic system at hand is needed.

Even though the focus of CompSE is on modeling dynamic systems, basic computer programming skills are covered in this course. They are introduced through simulation of dynamic systems under reasonable simplifying assumptions. The complexity of computer programming is gradually increased through addition of layers of complexity of the dynamic system at hand.

Students are exposed to different modeling and simulation techniques. As an outcome of this course, students should have a good understanding of the advantages and disadvantages of different modeling techniques with respect to their accuracy, simplicity, and speed. Students are also expected to understand the benefits and drawbacks of small scale simulations of large dynamic systems as well as limitations faced during simulation phase.

VI. Evaluation

Our planned evaluation will examine both the effectiveness of the course in achieving student learning objectives, and student interest in continuing multi-disciplinary studies that include computation and programming.

The main student learning objectives include mastery of basic programming skills, understanding underlying concepts of dynamic systems, learning simulation techniques along with their limitations, and ability to use simulations to solve problems that are hard or even impossible to solve using only analytical techniques. The achievement of these objectives will be measured by applying in-class examinations as well as several lab assignments in which the students will be challenged to work through problems that have not seen yet and which are selected from different disciplines.

Students' interest in continued study of computation will be measured by pre- and post- class online surveys. These surveys will measure:

- Students' beliefs that computation is necessary in their field.
- Students' confidence that they have enough programming skills to write programs relevant to their fields.
- Students' confidence that they can learn (if not already possess) programming skills relevant to their fields.
- Students' confidence about understanding dynamic systems, and
- Whether students intend to take more computing courses.

The comparison of students' answers at the beginning and the end of the semester will determine the change of students' attitudes towards CompSE and other computation courses. These surveys and analysis of surveys will be prepared and applied in collaboration with an external evaluator.

Moreover, we will track down the students from CompSE classes to find out whether they have taken any additional computation classes after completion of our CompSE course.

VII. Synopsis

CompSE is an introductory computer science class for non-computer science majors. Unlike the previous curriculum it replaced, CompSE uses a problem-oriented discovery learning approach to programming and understanding dynamic systems. This approach is expected to attract students from various majors and stimulate their interest in continuing the study of computation. Moreover, the students are expected to learn basic concepts of programming, and understand the basic principles of dynamic systems and simulation techniques.

Engaging Weak Programmers in Problem Solving

Brad Alexander and Cruz Izu
School of Computer Science
The University of Adelaide
Australia
{brad,cruz}at cs.adelaide.edu.au

Abstract— **As with many schools attracting international students, our postgraduate degrees must cater for students with diverse backgrounds and skill-levels. It is not practical to accurately assess students' domain-skills prior to enrollment. Thus, we found a need for a compulsory bridging course with the dual objectives of improving the problem solving and programming skills of the weakest computer graduates whilst still challenging and improving the skills of experienced programmers. This paper describes our experience in refining such a course over six semesters, in order to meet these goals.**

Keywords: collaborative learning, programming, problem solving, self-reflection

I. INTRODUCTION

Like many computing schools exposed to the international market our school attracts students from a diversity of backgrounds and skill levels. The diversity of skills is most apparent in our postgraduate coursework students with many having good theoretical knowledge but lacking in practical programming skills. To address this weakness, we developed a compulsory course (named Specialised Programming) to be taken by all starting Masters students. The main challenge for this course was to help weaker programmers to reach a satisfactory level while also challenging and improving the skills of the more experienced programmers.

Inspired by ideas from Astrachan[1] in first year undergraduate teaching, we based our course on practical application of programming to small, but realistic, TopCoder[2][1] problems. To cater for our cohort, we modified his approach in two key aspects:

- the use of cooperative learning strategies[3] to support the transfer of skills between students.
- course assessment based *primarily* on graded sets of these realistic problems, to better assess and directly address specific deficiencies in problem-solving skill sets.

Although other courses use subsets of TopCoder problems to replace/extend coding assignments, our course aims to improve the programming skills of postgraduates by intensive practice at solving these problems. The design of this course is informed by principles of deliberate practice[4,5]: skill acquisition is based on high repetition, designed practice, with fast feedback, tailored to individual abilities. The requirement for fast feedback means that errors should be identified and corrected during practice. The acquisition of expert performance through deliberate practice typically takes years [5, 6] so we cannot produce expert programmers in a 12-week teaching semester. However, we should expect to see a measurable improvement in student programming skills, which may provide self-motivation for further practice.

This article describes our experience with presenting this course over six semesters and in particular the impact of a number of changes made at the start of 2009 based on the experience of students with weaker programming skills.

The remainder of this article is structured as follows. Section II describes the course structure followed by the results and insights made during its delivery in 2007 and 2008 in Section III. Section IV lists the changes proposed at the start of 2009 in order to engage weaker programmers. Section V shows the impact that changes made on performance, particularly on the bottom half of the class., followed by a summary of what we have learned in the process.

II. COURSE STRUCTURE

The course presentation consists of lectures, structured group practice sessions, and ad-hoc tutorial sessions as needed. Except where stated, the following description of course structure applies to all six semesters that have been presented so far. Refinements to this framework over time are defined in subsequent sections.

Lectures are run in two-hour weekly sessions presenting algorithmic techniques for various problem types, based on the textbook "The design and Analysis of Algorithms" by Anany Levitin. The end of each session is typically devoted to supervised programming practice.

Three hours of each week are devoted to either practical exams or structured group practice sessions. The group practice sessions offer a mix of new and familiar problem types. Each group, of approximately four students, is assigned one or more problems. After working on the problems for 60 to 90 minutes, a group representative is picked to present their algorithmic solutions to the rest of the class. Coding and submission is to be completed independently by each student after the practical session. A summary of the problems selected for each session is provided at [7].

Each TopCoder problem statement has a consistent style, starting with a precise and entertaining description of the problem; followed by a description of the class name and

[1] Questions used, with permission, from TopCoder Inc.

method signature required; input data constraints; and, finally, some sample input and output data. Hints are rarely given in problem statements and there are usually many good ways to answer each problem allowing room for creativity.

Testing sets for each problem are harvested from TopCoder data using scripts and converted into a Java driver program to be used in the School's automatic submission system. During submission, students get feedback on the number of test cases they passed and for the first test case they fail they are given the input and expected output. They can resubmit their code as often as needed.

Groups are initially allocated in week 2, based on the result of a diagnostic practical exam using a genetic-grouping algorithm, to maintain diversity of skill levels within groups and uniformity between groups. Group allocations may be modified based on the performance up until the mid semester break.

Students are expected to practice outside of class time. They are encouraged to practice problem-solving with their group, but code their solutions individually. Group work makes the experience less threatening and decreased isolation.

Assessment is primarily based on practical exam performance with smaller amounts of marks allocated to group participation. Assessment begins with a diagnostic exam early in the semester followed by practical exams every 2-3 weeks. The minimum requirement for a passing grade will be to solve at least one problem in each exam. The submission system remains active at all times and students are able to practice submitting any question from the practice sessions or previous exam sessions as part of their practice regime.

Practical exams are hosted in a reasonably secure online environment. During the practical exams, students' normal accounts are suspended and practical exam accounts activated. Network controls are put in place to restrict access in the laboratory only to the school web pages, the submission system, and individual subversion accounts, in which the students place answers to be harvested by the submission system.

Each practical exam consists of three problems of differing degrees of difficulty. The first problem would require simple algorithm techniques (i.e. sorting, searching, string manipulation) and basic knowledge of the java API (documentation for which is available on-line during the exam). The other two problems will use the techniques taught during lectures (i.e. brute force, greedy, recursion, dynamic programming). The exam time is set to 3 hours, including the reading time (compared to 75 minutes for a Top Coder competition), so there is time to correct and modify the solutions, although a student needs to be a good programmer to solve all three problems in that time.

III. Initial Results

In this section we describe the outcomes of the first four offerings of the course in 2007 and 2008 in terms of three areas: assessed results; the quantity and quality of student practice; and student performance in exams. We describe each of these in turn.

A. *Assessed Results*

All four initial offerings enjoyed reasonable success with almost all students being able to solve at least the simple problems and achieve a passing grade.

As an indication of the initial ability of each cohort, Table I shows the performance of students in the diagnostic exam for the six consecutive semesters it has been taught. The problems in the diagnostic exam cover a range of the basic problem solving schemes and we would expect a graduate student with average Java programming skills to solve two problems. In all intakes, there was wide range of programming skills.

TABLE I. Student Performance on the Diagnostic Exam

Problems Solved	**2007**		**2008**		**2009**	
	S1	**S2**	**S1**	**S2**	**S1**	**S2**
0	17%	18%	42%	22%	71%	40%
1	8%	12%	33%	11%	12%	30%
2	25%	18%	17%	41%	12%	20%
3	50%	53%	8%	26%	6%	10%
	original course				after changes	

The first cohort of the course and, to a lesser extent, the second cohort contained a number of students who were reasonably competent programmers with enthusiasm for problem-solving. These offerings worked well for these students, with several commenting positively on the opportunity to be challenged and learn new skills. The ability of these cohorts was, in part, reflected by a high number of credit and distinction grades in the first two semesters.

In 2008 the average skill of the cohort dropped significantly. This can be attributed to the fact that, 37% of students who enrolled in Semester 1, 2008 had deferred enrolment in that course during 2007. Similarly, the Semester 2, 2008 intake had 27 student of which 8 have already deferred enrolment at least once. In other words, the weakest programmers delayed taking this course until the end of their programs (the program rules made the course compulsory but did not enforce pre-requisites, so it could be taken any semester). The data for 2009 is included in Table I as a basis for later comparison.

Students initially lacking programming skills could solve few problems during their diagnostic exam and struggled to both solve and code simple problems in practical exams. The apparent causes of these problems varied. Some have issues understanding the problem descriptions but with help they were able to code the solutions on their own. Others had little experience with Java and needed help to process any non-trivial inputs values. Others had difficulty debugging. To address these problems we provided ad-hoc tutorial support for those who felt they needed it.

Student skill levels in each semester improved from the diagnostic, with low failure rates below 10% in all semesters (without including, as we will discuss later, those who failed due to cheating in 2008). Although some students showed low performance in the first two practical exams, as they improved on later exams they were offered a supplementary exam.

B. Student Practice

Practice is the core activity in this course and students were encouraged to practice individually and in groups on a broad range of problems. Over 5000 individual practice submission attempts have been made by the 93 students who have taken this course over the four semesters Practice problems, of graduated difficultly are set up in the same way as the exam problems. Students can access practice problems on the web and submit multiple times without penalty. In addition, previous exam problems remain online as an additional pool of practice problems.

Due to the limited time in supervised practical sessions, the last step of problem solving - the coding of the algorithm - is left for the students to do outside the class at their own pace. Unsurprisingly, the volume of practice undertaken outside of class varied considerably between students. Fig. 1 plots, for each student in each semester, the number of practice attempts in the automatic submission system versus the number of attempts achieving a 100% score.

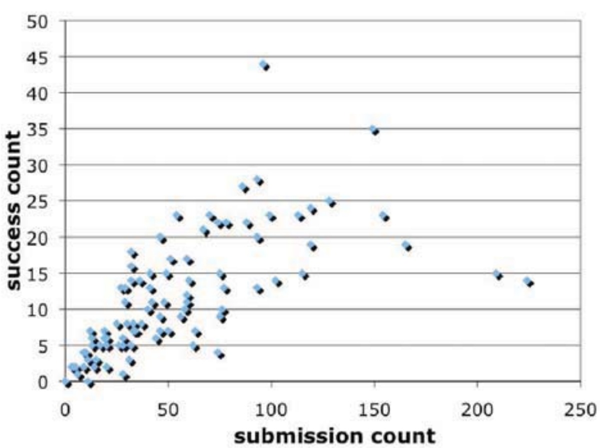

Figure 1. Number of practice problem attempts versus number of practice problems solved (2007-2008)

The plot shows that most students make about four total attempts for each successful attempt. This is not unexpected, even seasoned programmers sometimes fail to anticipate some test cases or make minor errors in their code requiring multiple submissions. The plot also shows the number of attempts made and the number of problems solved is highly correlated (correlation coefficient = 0.67) indicating that in most cases intensive practice is rewarded with a reasonable amount of success (or, conversely, that success encourages more practice). Last, but importantly, the plot shows that most students make less than 50 practice submissions solving less than ten problems – well below our recommended practice to students to solve 1 or 2 problem questions each week in a 12-week teaching semester.

Another observation about practice is that students did not practice consistently throughout the semester. Fig. 2 illustrates this issue in the 2008 semester 2 instance of the course. We observed students doing practice problems in the first few weeks leading to the first practical exam at the end of teaching week 4, but after that the amount of practice declines to very low levels in the second half of the course. This is in spite of the fact that that 3 of the 5 practical exams, which might benefit from practice, are held later in the semester.

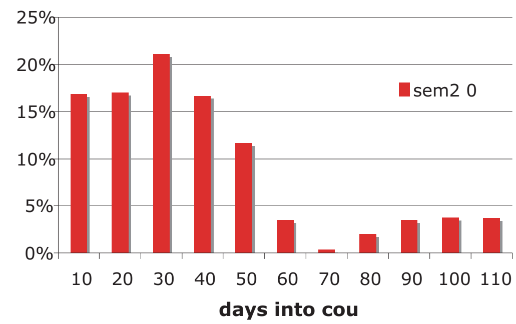

Figure 2. Histogram of practice submissions over duration of the semester 2 2008 course.

Motivation for practice also varied considerably between students. This variance was anticipated and, in the original design of the course, group members shared a proportion of their exam marks to create some of the positive interdependence needed for cooperative learning [8] and reduce the propensity for social-loafing [9]. Unfortunately, in the first instance of the course, a significant proportion of students - aiming for a bare pass - optimized their level of practice to the detriment of other group members. So, in the interest of fairness, the sharing of marks was quickly withdrawn under a no-disadvantage rule.

So far, we have seen that the amount of practice and the motivation for practice varies between students and across time. What about the impact of this practice on exam performance? As might be expected, the number of practice problems solved, by individuals is correlated with the number of exam problems solved by those individuals. Fig. 3 plots these metrics for each student in each semester. The maximum number of exam problems it is possible to solve in a semester is 15 (three problems in each of five practical exams).

The correlation between practice problems solved and exam problems solved (correlation coefficient = 0.34) is weaker than the relationship between practice submissions and practice success. This weaker relationships might be attributed to a number of factors: the time limit in the exam gives students more limited scope for experimentation; exam conditions restrict access to resources that may help with problem completion; some experienced students didn’t practice and simply turned up to the exams; some students aimed for a bare pass; and, finally, a minority cheated.

These *in-exam* performance factors bear closer scrutiny, thus next section will explore some of these aspects.

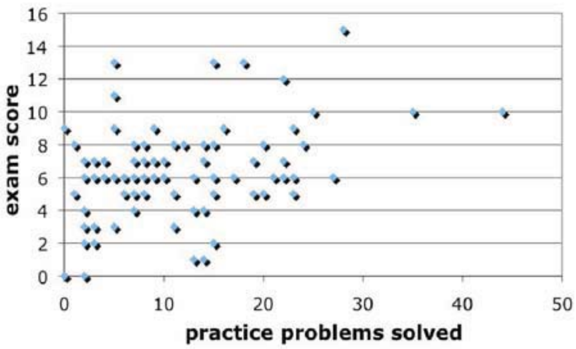

Figure 3. Number of practice problem solvedversus number of exam problems solved (2007-2008)

C. Student Exam Performance

In this section we describe aspects of student behaviour and performance during practical exams. In general, students are more prone to rush in the exams than during regular practice until they have solved the first problem, which keeps them in the pass range.

When submitting a coded solution, the student receives immediate feedback on the number of test cases passed, and when incorrect it can see the first test case failed and the expected output. For some students this feedback is sufficient to refine/correct their code, but weaker programmers spend most exam time fixing failed input cases one by one, breaking working parts of the code in the process. Their final solutions are longer that needed, and as the problems get harder, they cannot produce a working solution for all cases.

We present here as an example the analysis of the submitted solution for the problem *BoxesofBook*s, during a practical exam in semester 2, 2008. A solution to this problem requires a simple loop to iterate over the array of books to be packed into boxes, returning the number of boxed needed, and the overall code should take 20-25 lines at most (reducible to 15 lines if you don't use nice layouts). Good coders solved the problem in a short time interval, within 3 attempts or less and their code size was as expected. Other coders took longer and although they solved the problem their final solutions were complicated and their code size went up to 30-45 lines. As expected, later submissions increased code size; in only *one* case a submission reduced the code size, after the student worked out he was going in the wrong direction.

Four students (out of a class of 27) were not able to solve the *BoxesofBook*s problem. Two of them started with a reasonable solution but they keep adding code to solve each case and ended up with 50 and 82 lines respectively. One of the students submitted 23 attempts, with only a few minutes between them. Another student keep changing conditions within the loop but could not correct their code after 13 attempts.

The extent of this problem of repeated attempts is apparent in Fig. 4, which plots the number of exam submissions made by each student in each semester against the number of successful exam submissions for that student. The plot shows a worryingly low success rate for some students with, in one case, over 166 submissions for 3 questions solved.

The anatomy of successful and failing exam attempts is analysed in Fig. 5, which contrasts the pattern of attempts for exam problems leading to success (881 successful attempts) with those leading to failure (423 eventual failed attempts). As can be seen, most successful attempts at questions take three or less submissions to get it right. Failed attempts tail off considerably more slowly. Worryingly, more than 5% of failed attempts have more than 15 submissions. These high counts almost always indicate that a student is re-submitting by making minor unproductive changes in a desperate attempt to pass the automatic testing. We label this unproductive behaviour in practical exams as thrashing.

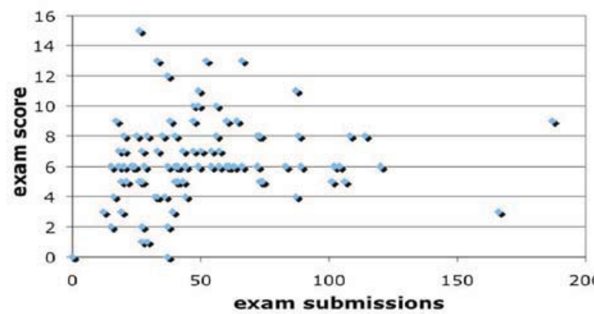

Figure 4. Plot of number of exam submissions made versus number of exam problems solved (2007-2008).

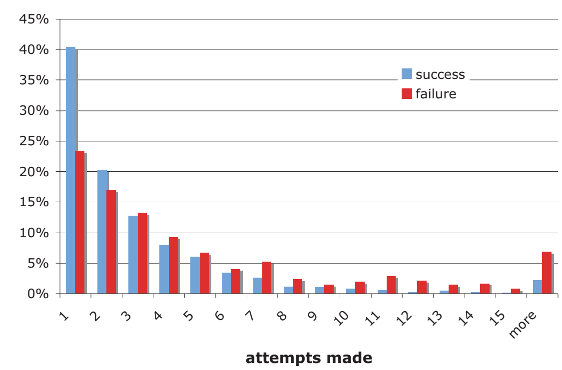

Figure 5. Histogram of submission patterns for successful and failed attempts at exam questions.

The impact of thrashing is significant. Given a conservative threshold for thrashing of three or more unproductive attempts in less than 15 minutes, 30% of the nearly 6000 submissions made in practical exams are instances of thrashing. As an aside, not every instance of multiple closely spaced attempts at a question constitute thrashing.

A small number of, eventually, successful attempts take a very large number of submissions. Sometimes a large number of submissions stems from an attempt to pass the automatic testing by the tactic of: (1) failing a case (2) harvesting the expected output value (3) inserting a print statement of the expected output value and (4) then resubmitting to harvest the next value and so on. Given that the number of test cases is usually high, in the range 60-120, the effort required for this tactic is considerable[2].

Because so much thrashing was occurring in exams and, to a lesser extent, during practice we decided to investigate this pattern more closely. In some practical exams we observed the weaker students attempted the first problem and after a few attempts to fix their code they gave up and move to the next problem. Again, they were able to produce a draft solution that passed the trivial cases but were not able to fix their code in order to pass the non-trivial cases. As the end of the exam approached, they panicked and jumped from one problem back to the other one, editing their code but their corrections were not well thought through. For example, they would panic and reverse the condition of a correct *if* statement to see if that passed more tests.

It is not surprising, given the pressure to complete their masters program, that some students resorted to cheating during practical exams. In Semester 1 2008, 10% of students failed due to documented cheating, although there was other doubtful cases which avoided being failed, due to the complexity of detecting and proving cheating as discussed in [10]. Although we have removed the submissions identified in any cheating incidents before analyzing the data, there is some doubt on the real performance of some students under different exam conditions for semester 1, 2008. Simple measures were taken to make cheating more difficult and the rates of suspected cheating have fallen in 2009.

Finally, two common behaviours for less-skilled programmers were a passive role in their group practice and diminishing attendance lectures as the material moved on to address more advanced concepts.

D. *Insights 2008 intake*

At the end of 2008, we reflected on the performance of the struggling students compared with those who thrived and gained the following insight:

> *All students were able to sketch a feasible solution for most types of simple problems. But weak programmers often overlooked one or two boundary cases and, thus, they failed some test and they were not able to identify the causes of their failure.*

We will list below the list of factors that prevent weaker students from solving non-trivial problem:

- Lack of debugging skills: although students do use debugging tools and print statements to find what their code is doing, they are slow in both indentifying the line(s) of code that are causing the problem and the changes needed to fix it. This is general caused by limited programming practice.
- Poor coding style: they code monolithic solutions, and rarely define additional methods to simplify coding and testing. For example, given a string manipulation problem in which they need to identify vowels, they would not define a method called *isVowel(*char x), instead they repeated the code needed to detect this condition as many times as needed.
- When their code fails after several changes, students are reluctant to go back and work through their solution on paper or change their strategy, as they felt this would take too long.

[2] And for naught - these cases are manually detected and given zero marks.

IV. CHANGES TO ENGAGE WEAKER PROGRAMMERS

This section will report the changes to the course delivery aimed at keep less-skilled programmers engaged, by addressing the set of problems identified above.

A. *Introduction to problem-solving*

From the analysis done, it was clear the course pace was too steep for those with low programming and problem solving skills.

The textbook assumed good programming skills and skipped over the range of problems that need simple algorithmic skills (sorting, searching, string manipulation, simple maths). Therefore, there was no support for the weaker student that lacked basic problem-solving skills. In other cases, students were not familiar with the Java API so they wrote their own code instead of using simple methods (such as *Maths.min* or *Array.sort*) to process the data.

So, the first change was to extend the coverage of basic problems types from one to three lectures. The additional time allowed to provide more examples and to describe ways to identify each basic problem type. Through the examples, we emphasized the need to reference to the Java API to find methods that may simplify coding. For example, when describing a string manipulation problem that uses prefixes we asked students to go through the String class and find methods that may be useful (such as *startsWith).*

B. *Step-by step problem-solving*

Weaker students write their code without prior testing of their strategy and made limited use of the given examples provided to see if their code will work.

To emphasize the need to devise a basic algorithm, we introduced a paper problem template, with sections to identify the problem type, write the basic idea of how to solve it, and then convert it into an algorithm. This template was provided at each lecture time, and we asked students to work on the template before coding the solution on the terminal. Instead of moving to the labs to do a problem-solving session at the end of each lecture, we ran them in the lecture room, forcing them to write their solutions on the template. We also introduced in the first practical session techniques to test the examples on paper, so we can see if the algorithm works for the examples given before coding it. The additional teaching materials and modified lecture schedule are provided in [7] for the interested reader.

These changes, combined with some one-on-one coaching, helped most students to focus on doing some development and testing of algorithms prior to coding.

C. Increase group practice and feedback

Another major goal to keep weaker programmers engaged was to enforce problem-solving practice every week, particularly on the second half of the semester. To achieve this, we ask each member of a group to fill an online report weekly, from week 4 onwards, describing the list of problems attempted and/or solved and the way the group tackled them. The report format is shown in Fig. 6. Each weekly report was worth 1% of the final mark (9% in total).

Although the reports are not compulsory, each student must complete at least 40% of each of three course components (1.practical exams, 2.practical sessions and 3,group reports) to avoid a failing grade.

By asking them to list the Java classes and methods used to solve problems, we reinforce each week the need to check and use the Java API. Thus, there is a minimum practice required outside the practical exam, which is monitored by the weekly reports. The second question provides feedback to lecturers on group dynamics, and by having to report on it, we encourage weaker students to participate in their groups. The last question encourages self-reflection so that each student could identify and assess the strategies they were using.

1. *List the problems you attempted, your scores so far for each problem, and which Java API Classes and methods you used to solve each problem. Remember that you must attempt at least two different questions each week. For example:*

   SlowKeyBoard: 90 out of 90

   - ArrayList (size, add, get)

   - Arrays.sort

   .

   FracCount: 7 out 100

   - HashMap (containsKey, put, get)

   - ArrayList (size, add, get, remove)

2. *Describe what happened during your group practice session. Who contributed and how did they help the group? Highlight the things that went well and/or any problems that arose.*

3. *Which steps of the problem solving process did you find easy?*

   Which steps did you struggle with?

   What approaches did you use to overcome those difficulties?

   Can you think of how you might approach the problem differently if you had to start again?

Figure 6. Weekly Group Report online questions.

We are able to provide feedback to their self-reflection when marking the reports. This refinement and review process is aligned with other methodologies for addressing problem solving in Computer Science [11].

In the first semester 2009 we focused on feedback and self-reflection, but noticed some students were claiming to complete problems they did not have submissions for. To counter this, in the second semester we policed their submissions and sometimes reminded them of the need to code their own solutions.

The weekly reports were also useful for the lecturers by providing feedback during the course on the topics and issues than students find more difficult so that teaching materials could be adjusted accordingly.

V. RESULTS

The new course structure has been used in both semesters on 2009. In this section we will evaluate the impact that the changes had both on regular practice and student performance.

There was some anecdotal evidence from two students repeating the course in Semester 1, 2009 that the gentle introduction to problem solving made the course content less scary; the examples provided in lectures were a good start to review the java API, and students felt more confident before taking their first practical exam in week 4.

We should note 2008 had the largest cohorts (36 and 27 students for semester 1 and 2 respectively) while 2009 had small cohorts (19 and 10 students). Particularly, students in the last cohort had nowhere to hide, they received more feedback and the chances of cheating being undetected were much reduced. In fact, two students cheated in the first practical exam, but as they exam results were so different from their class performance, they were easily identified and they decided to drop the course, so they are not included in the study.

A. Problem solving practice

The changes of the course encourage students to keep practicing during the whole semester. Groups meet outside the supervised practical session to solve problems and the weekly reports provide feedback of the interaction in the group. In the second semester, groups were more active. Although there where some issues with students who did not participate, 80% of the student agreed that working in a group was a valuable experience.

Fig. 7 shows number of practice problem submissions per student per term in 2009 versus the number of problems actually solved. The old 2007/2008 data from Fig. 1 is included for reference. Success rates in 2009 are similar to 2007/2008 but the average amount of practice per student is slightly higher and the correlation between practice attempts and practice success is higher (0.90, up from 0.67) this is partially due to there being fewer students getting little reward from their practice attempts.

This better success rate also appears to be reflected in exams. Fig. 8 plots the number of exam submissions per student per term in 2009 versus the number of problems solved in exams. The old 2007/2008 data from Fig. 4 is included for reference.

The plot shows that there are comparatively few students making many submissions with limited success. This is also borne out in the higher correlation between exam submissions and exam success in 2009 (0.76) than in 2007/2009 (0.51). Overall, the amount of thrashing in exams was reduced.

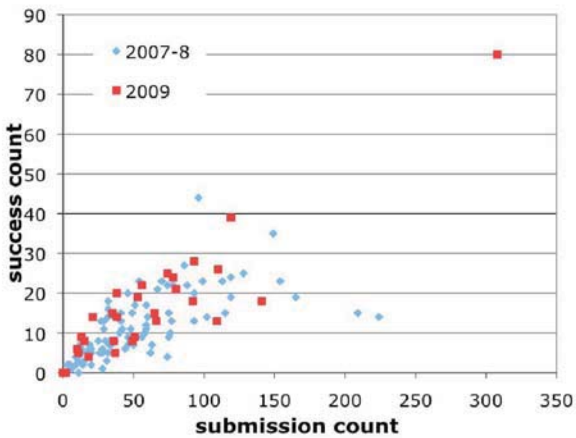

Figure 7. Number of practice problems attempted versus the number of practice problems solved in 2009 (2007-2008) data included for reference.

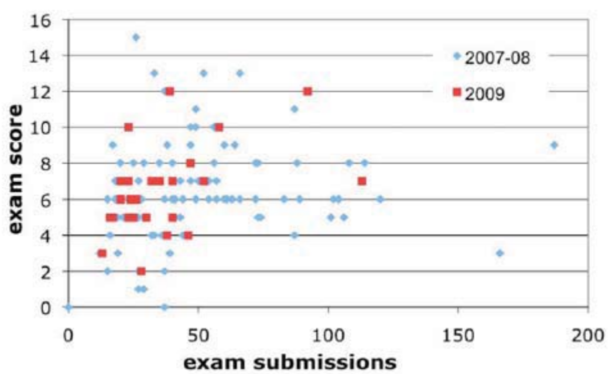

Figure 8. Number of exam submissions made versus the number of exam problems solved in 2009 (2007-2008) data included for reference.

Practice habits also improved somewhat in 2009. Fig. 9 shows the amount of practice over the semester for semesters 1 and 2 of 2009 with the data for semester 2 of 2008 from Fig 2. included for reference. Some improvement in second half practice is apparent.

Table II shows the number of problems solved both during practice and during the exam for all students who remain enrolled for the whole semester. We should note that we can only measure practice done using our submission system, which may be lower than expected if students practiced at the TopCoder website. Our local problem pool had approximately 40 problems in 2007, and grew by 15 problems each semester, so in the latest semester there are more than a 100 problems to choose from. Only two out of 10 students in the last semester reported using TopCoder to source additional problems.

The rise on problem-solving practice is more pronounced in semester 2, as we reminded students on the need to code their solutions via the report feedback. Consequently, the number of problems solved raised to 20 - within course expectations as they must submit 9 weekly reports, in each of them they should report on solving two problems. As the problem sets in the practical sessions become harder, some students choose to solve problems from previous year's practical exams[3], which is in line with deliberate practice.

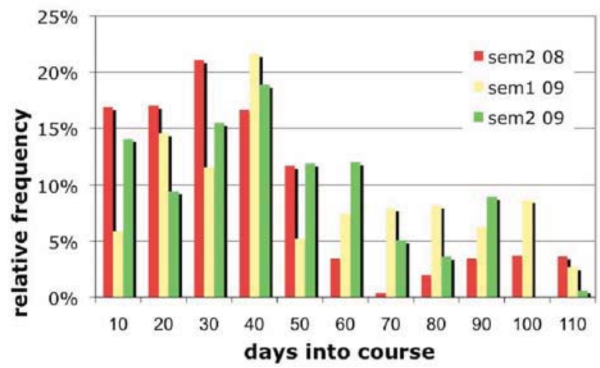

Figure 9. New practice patterns in 2009 as compared to semester 2 2008.

TABLE II. AVERAGE PER-PERSON SCORES

Average per-person	2007 S1	2007 S2	2008 S1	2008 S2	2009 S1	2009 S2
Practice attempts	80	41	53	48	55	77
Practice solved	11	9	13	12	14	20
Exam Attempts	54	38	58	44	37	32
Exam solved	6	5	8	6	6	7
Course Score	71	62	63	51	65	67
	original course				after changes	

B. *Exam performance*

Row four of table II shows the number of problems solved during practical exams. The number of problems solved is a good indicator of performance, although the higher value in 2008 S1 is a possible reflection of the cheating problems that were detected in the middle of the course.

We can see the number of exam attempts is lower in 2009 compared to 2008, this is an indication of reduced thrashing.

[3] In all our analyses we count these attempts at old exams as practice attempts rather than exam attempts.

It is difficult to measure class coding speed as each problem set may be more or less challenging depending on the type of problem chosen and the Java skill-set required. Figure 10 compares the speed to solve the first problem for three consecutive cohorts, one before the changes to the course, and two after. To reflect the problem complexity we chose the second fastest solution in each exam as representative of the top of the class and compared that time with the time needed by the bottom half of the class. We measured the speed of the bottom half of the class using two metrics:

- *half-solved* is the average time taken by those in the bottom half of the class who manage to solve the problem
- *half-all* consider that those who did not complete will take at least 3 hours to do so, and include them in the average.

Thus, a higher half-all (the green bar) compared to the half-solved (red bar) indicates some students failed to pass that exam. We can see this is the case in all exams in semester 2, 2008, except for exam 3.

The exam performance for the bottom half of the class was, in general, better in both semesters of 2009. Students in semester 1 did not show significant improvement compared to the previous cohort, but considering their initial low skills (please, refer to Table I), there was a clear improvement as the semester progressed. At the end of the semester all students were confident they could solve at least one problem, which may have also helped to keep them calm and do better.

Although exam difficulty is variable, we can see that the difference in speed between the best coders and the bottom of the class is narrowed in the last semester. The best performance in 2008-S2 was for exam3, problem 1, when all but one student solved the first problem. The question was simple and it took 13 minutes for the second fastest coder, and the slowest one took 2 hours and 46 minutes. A similar type question was used in 2009-S2 exam 5, and as the figure shows, it also took 13 minutes for the second fastest coder, but the average for the bottom half was 28 minutes and the slowest student took only 37 minutes.

We believe there were two reasons why the last cohort solved some problems faster:

1. they were able to identify the problem type (brute force) as they read the problem description,
2. they needed less time to debug/correct their code.

We should note than in exams 3 and 5 of semester 2, 2009, all students managed to complete the first and second questions, compared with exam 2 in which 3 students could not solve one problem. Exam 4 had a harder first problem but most students were able to complete it.

There is also evidence in the practical sessions that students became better at problem-solving, and could identify the problem type and some basic algorithms to be applied. However, their problem-solving skills were ahead of their Java programming skills so they could not code their solutions.

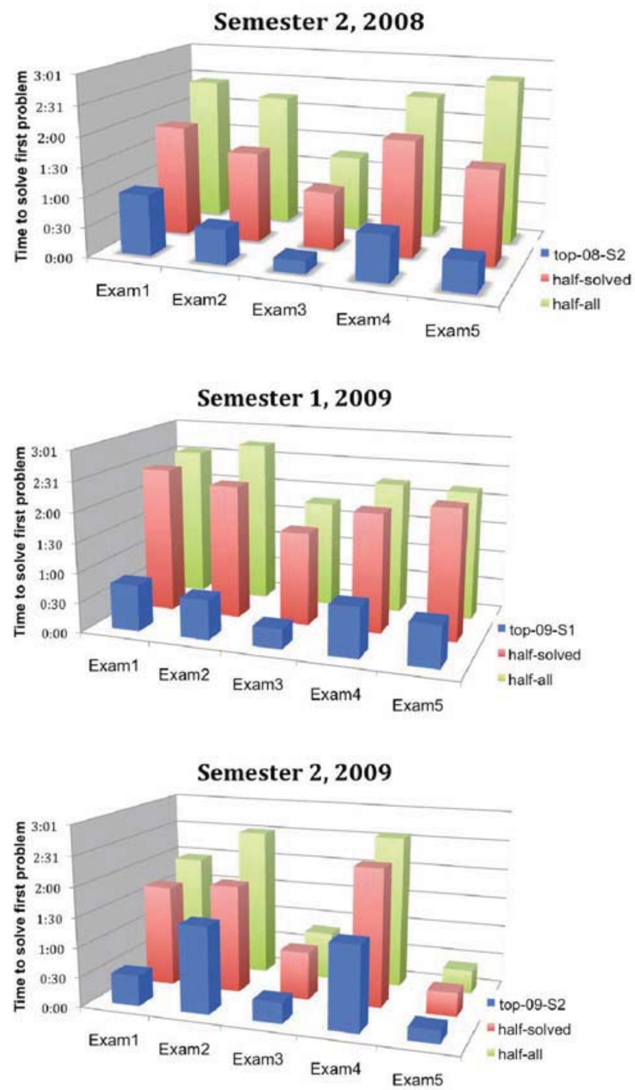

Figure 10. Time to solve the first problem at a practical exam, for 3 consecutive semesters.

In particular, they found hard dealing with complex input data that needed to be stored in another format to simplify coding of the solution. For example, the textbook and the course lectures cover graph algorithms such as Breadth Search First in detail. In the last practice session many students could work out that the given problem could be solved by (1) building the graph and (2) finding the shortest path from a given node to another. But only 3 out of 10 students were able to construct a graph from the given input information. Thus, we need to add more support material for the second part of the course to support coding for complex problems.

C. *Student feedback*

As expected, the better class performance in semester 2, 2009 is accompanied by positive feedback from the small group of students who took the course. We will report here on some of the comment received and their suggestions for further improvement.

All students agreed the course have improved their problem-solving skills and their ability to work independently. Below are two quotes (printed with permission) from students that show we have achieved one of our main goals by providing the programming skills needed for their Master degree:

"During the initial stages I took 90-120 minutes to solve a single above problem. But now I take 30-60 minutes to solve the problems. SP eased me in doing assignments of Computer Vision, which are actually very tough to do"

"Although most of the tasks for this course have been finished, I still need to keep on practicing, since I have noticed that the practice we have done during the whole semester really helps me with coding and debugging"

All students thought the practical sessions have a good mix of problem types and they were positive about working is a group. One student suggested including peer-review on their coding as part of the group work. Antoher student made the following suggestion:

"My only problem was that some of my group members wouldn't attend group meetings. The course could have a forum that listed weekly group attends, and how many times you met outside your Practice Sessions to work on problems. That way, people might feel more accountable to attending group sessions".

During the course, most students reflected on their weekly reports on their need to work on pen and paper to check if their idea worked before coding. In the course feedback, a student reported on the importance of developing an algorithm first:

"The real power of the problem solving process comes down to pen and paper - first test out the examples on paper, by trying to "solve" the problem. Then try and figure out what you are doing to solve the problem. Make sure that you have examined all the EXTREME cases, base cases, boundary cases, before you implement it."

However, during exam time some students skipped this step and coded straight to the terminal with variable success. Thus, we need to do more work to reinforce this concept.

VI. Conclusions

We believe the strategies used in this course, based on aspects of deliberate practice [4], would be applicable to other technical courses with mixed cohorts.

Students are more likely to improve their skills if we provide clear expectations of what is needed to reach each grade level, and encourage the practice needed to achieve good grades.

It is important to assess students' initial skills in the first week, in order to help target support for the weaker students. We should note the review of basic techniques and debugging skills is also useful for stronger students, as it encourages self-reflection and good practice. Most students respond positively when they see some improvement early on the course.

By identifying the factors that cause failure and monitoring student performance, we could provide a tailored process for each student to achieve their objectives. The group reports provide good feedback on individual progress and chances to tailor their practice but this may be too onerous on the lecturer for a large cohort. As one of the main benefits of the reports was self-reflection, we will consider using blogs as a tool for students to report and reflect on their progress.

Future work on this course will focus on bringing more aspects of deliberate practice into the learning process including the selection of more questions designed to find and address particular skill deficiencies and more infrastructure to lecturers to monitor each student's progress and, just as importantly, to allow students to monitor their own progress.

Acknowledgments

The authors would like to thank their fellow lecturers Katrina Falkner, Peter Kelly, and Joseph Kuehn who helped us work through all the instances of this course. We also thank the supervisors who provided valuable feedback on the practical sessions.
Aspects of course development are part of an ongoing project to develop a problem-solving curriculum sponsored by a Google Research Award. Finally, we'd like to thank the people at TopCoder for letting us use their questions.

***Abstract*— Teaching of programming is crucial in every engineering course and particularly in computer courses. Students failure in this domain has led to the development of Portugol IDE, a tool for teaching/learning algorithms. This tool allows algorithms to be coded in mother tongue of portuguese students (portugol) or in flow diagrammatic language (flowchart) and its automatic execution. This paper presents generation 3.x of this tool and describes the advancements therein.**

Keywords-component; programming learning; portugol; flowchart; computer science education

I. Introduction

All courses in computer science related areas include in their curricula an introductory module on programming, which usually has high rates of failure. The concepts taught in this introductory module will be used in many other course disciplines and the rates of failure are deemed as one of the major reasons for student drop-out from these courses [1] [2] [3].

This serious drop-out rate has been a subject for research and several recommendations from computing professional associations (e. g. ACM e IEEE) [3]. Many different strategies and tools have been proposed to improve the teaching/learning process of programming basics [1]. With this in mind, faculty members and students of the School of Technology of the Polytechnic of Tomar have developed an innovative environment for teaching/learning algorithms - Portugol IDE.

This freeware and open source environment has been used in the Polytechnic of Tomar, in national and foreign higher education institutions and in high schools and professional schools.

Given its success and in order to broaden its scope of application in the teaching of programming, the authors have developed generation 3.x which features a more advanced language and a new environment.

This paper includes an overview of this tool (Portugol IDE) and the pedagogical characteristics that make generation 3.x an asset for the teaching of programming.

II. Portugol IDE project

Portugol IDE is an environment for algorithm exploration designed for the teaching of programming created in the Polytechnic of Tomar in 2005 as the final project by finalist students of the degree in Computer Engineering. This teaching/learning tool is available free of charge (http://www.dei.estt.ipt.pt/portugol) and its source code is accessed through the GPL licence. The tool has been developed using Java technology which makes it transferable to any computer platform that supports this technology.

Portugol IDE uses a Portuguese lexicon-based language for encoding algorithms (the portugol) and a graphic language (flowchart). These languages have been defined in a manner that allows their execution by the computer and are equivalent among them [4].

Flowcharts are a graphic language consisting of parameterized geometric shapes and arrows representing the flow of execution between those shapes. As it is a graphic language, the algorithm is designed and thus form parameters have a minimal syntax, thus being less prone to coding errors. This language is specially intended to teach the foundations of computer programming. Figure 1 shows the Euclid's algorithm coded in portugol and in flowchart.

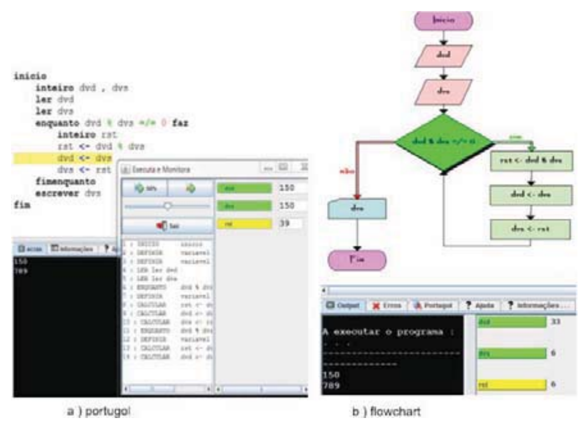

Figure 1. Euclid's algoritm in portugol (a) and flowchart (b) executed in the Portugol IDE environment.

Portugol has a small set of instructions and operators with a flexible syntax which make it easily understandable and powerful enough to perform complex reasoning. Although the flowchart is executed through portugol language, it is transparent by the student.

Portugol IDE also has some features that improve the efficiency of the programming learning process. Its environment allows the students to encode, execute and check algorithm correction in an iterative way within a simple intuitive environment (Figure 1). These activities can be performed in both languages and the system allows the translation of the algorithm into the complementary form providing an alternative representation of it. The environment allows formal verification of the algorithm through step-by-step execution of computer instructions. Portugol IDE also allows visualization of the state of real-time memory variables and to control algorithm execution speed. By analyzing automatic execution of the algorithm the students can recognize algorithm correction or the instructions that make it incorrect. Thus students can execute, change, correct and test their theories to solve the problem contributing to an active experience-based learning.

III. PORTUGOL IDE V 3.X

Advancements in Portugol IDE have reflected the needs and suggestions from faculty and students regularly invited to contribute to its development both at the level of system encoding and at the level of introduction of new tool features. This symbiosis between the two parts of the teaching/learning process causes Portugol IDE to be a widely used and appreciated tool by the whole academic community in the Polytechnic of Tomar.

The first generation of Portugol IDE was developed in 2005. The second generation was launched in 2006 and was characterized by the introduction of the flowchart module and its inclusion in portugol language. The generation 3.x of Portugol IDE featuring an enhanced language and a new environment will soon be launched

Previous generation of Portugol IDE was designed to teach learning modules: data manipulation, decision structures and repetition structures. For this purpose basic data types and arrays have been defined.

A. Core Enhancements

New features of generation 3.x include the possibility of defining complex data for the tuition of algorithms involving the definition of the arrangement for conceptual data (structures).

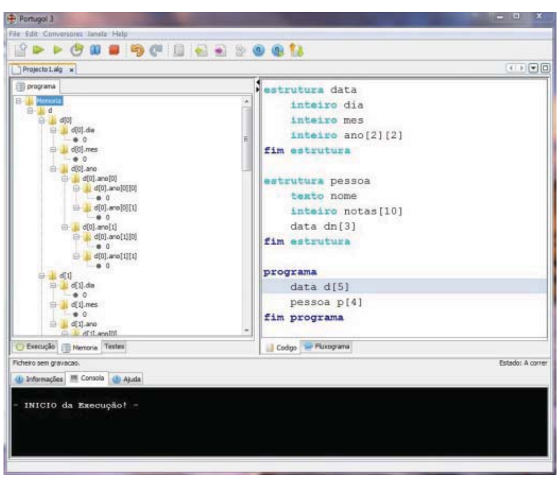

Figure 2. Complex data types in Portugol IDE v 3.x

The concept of reference is one of the most complex issues of computer programming [5]. Today this is introduced to students through complex computer languages such as C making learning of this subject even more difficult.

In order to illustrate this concept within the Portugol IDE environment, a new feature (&) has been introduced in variable definition to support values or addresses. Manipulation of the referenced variables follows a pattern that is similar to that of normal variables in which memory operations are displayed in the learning environment as can be observed in the referenced variable pb whose attribution value is like a normal variables (figure 3).

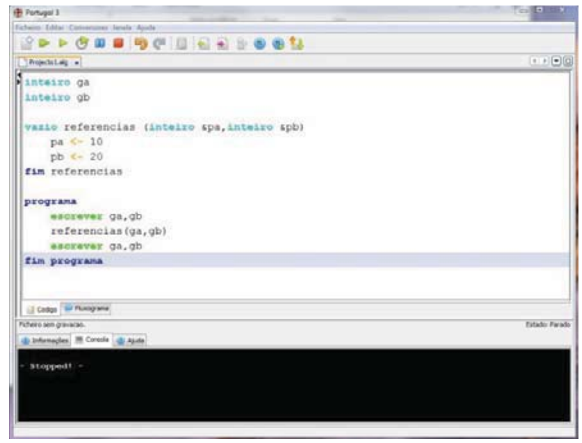

Figure 3. References in Portugol IDE v 3.x.

The new generation of Portugol IDE was equipped with a feature that allows the use and definition of iterative and recursive functions. Function definition enables problems to be divided into several modules that can be solved separately thus allowing new techniques for the development of algorithms to be learned such as top-down and divide-to-conquer.

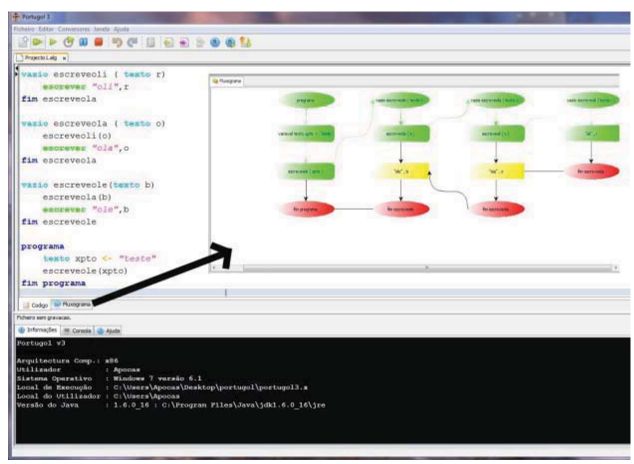

Figure 4. Functions in Portugol IDE v 3.x in the form of portugol and flowchart

The ability to include Java-compiled function libraries enables the utilisation of the learning environment in pedagogical contexts which were not initially predicted. These libraries can be developed by the students and external contributors so as to increase the functionalities of Portugol IDE without putting at risk the stability of the tool.

B. Development Environment

Classroom context is hazardous to any software because there is, more than often, an intensive unpredicted use of it.

To equip the tool with a sound basis an RCP (Rich Client Platform) architecture has been used. This type of architecture is very powerful due to its modular structure which is constituted by a nucleus containing several modules surrounding it and provides different features. As nucleus the NetBeans Platform RCP by Sun has been used. The stability of Portugol IDE nucleus has thus been ensured through a platform whose code has repeatedly been tested for years in IDE NetBeans, that shares this same platform.

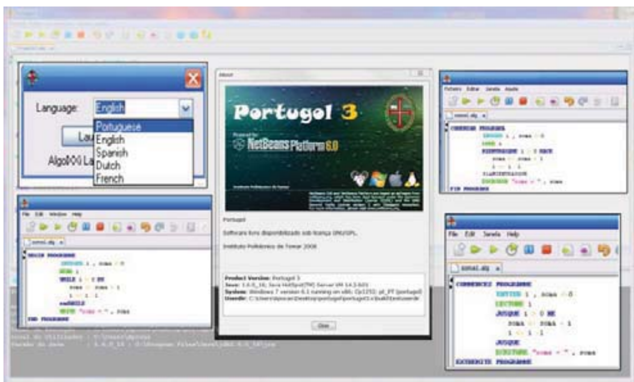

Figure 5. Multi-language suport of the Portugol IDE v 3.x

Previous generations of Portugol IDE have only been made available in Portuguese, this feature being hardcoded in the source application code, which made implementation of a new language very difficult. In Portugol IDE v3.x the interface language can be changed in a dynamic way as well as the language used in the source code syntax written by the student. Thus the students with different mother tongues will always write in their natural language. The source code in all the languages is the same, and the tool have an intelligent module that identifies the language of the source code and translates it to the desired language. This feature allows the exchange algorithm regardless of the language they were written.

This feature allows the coexistence of different language-speaking students in the same classroom solving the same exercises and cooperating among them.

In order to implement functions and complex data types it was necessary to redesign the overall system used to represent both local and global memories. The tree layout has revealed to be the best way to represent complex data structures allowing the user to collapse and expand different memory levels, thus turning the representation more organised and understandable (Figure 2).

To represent the different memories (global and local) a tabbed interface has been used in which each memory has an independent tab with a tree layout in the inside as can be observed in Figure 7. Tabulations of local memories are added and removed according to program execution. Only active local memories and the global memory are visualised.

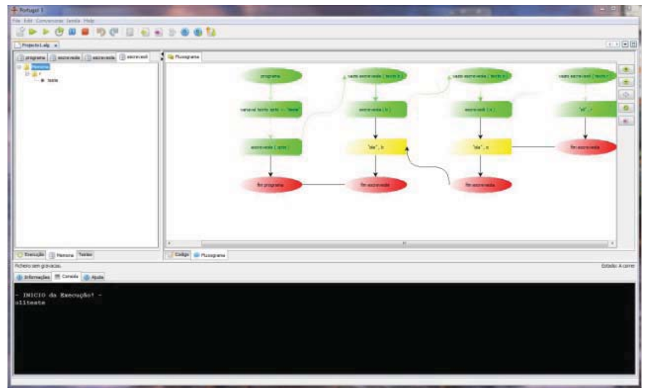

Figure 6. Running the algorithm in Portugol IDE v 3.x

To implement the new language features in flowchart no new graphic elements have been introduced, thus maintaining easiness. In function call, the process icon functionalities have been redefined in which execution of a function starts the construction of a new flowchart for the execution of the algorithm implemented therein. The transfer function parameters are now represented in the start icon and the return value in the end icon.

This new functionality generates a new local memory which in turn is generated by the start icon and destroyed by the end icon.

IV. EDUCATIONAL APPLICATION

Portugol IDE allows the student to be more active in the learning process, improves the effectiveness of development and verification of algorithms and promotes algorithmic reasoning.

Portugol IDE is currently being used in Engineering degrees and vocational programmes of the Polytechnic of Tomar, in various higher education institutions of the Portuguese-speaking community (e.g. Integrated Regional University and UDF – Brazil University Centre) and in several high schools (e.g. Sertã and Foz Côa High Schools).

In order to assess Portugol IDE's capacities, i.e. its utility and usability, a survey has been carried out involving students attending the 1st year of the Computer Engineering programme in the School of Technology of the Polytechnic of Tomar [1]. The participants have revealed to be very pleased with Portugol IDE viewing its innovations as extremely useful to learn programming. They also consider this learning environment as effective, user-friendly and easy remindable.

We believe that with launching of version 3.0 Portugol IDE has made great progress and advancements. This version allows the use of iterative and recursive structures and functions. With this functionality students will be able to learn more complex study contents in a simpler way.

The easy change of interface application language and the language used in the source code syntax enables the students with different mother tongues to always write in their natural language. Portugol IDE generation 3.x promotes algorithm distribution through learning management systems and Web repositories.

With this enhanced version it will be necessary to know the behaviour of future users. We intend to collect students opinions about Portugol IDE 3.0 and also to assess the implications of this new version in learning by carrying out a quasi-experimental survey [6] involving two different groups: Group A (use of Portugol IDE 3.0) and Group B (use of traditional table tests)

V. CONCLUSIONS

Learning how to program is a complex task involving high levels of abstraction and logical thinking which, as a rule, has high rates of failure.

Portugol IDE has been designed in a manner as a support tool for teaching and learning the basic foundations of programming. The definition of a minimal set of instructions for portugol and flowchart languages facilitates the learning of commands and icons but they are also sufficiently powerful to construct complex algorithms.

Furthermore, generation 3.x. of Portugol IDE also allows to define complex data types, to use iterative and recursive functions, to include Java-compiled function libraries, to change the language of application interface and the syntax language, to represent different memories, among other functionalities.

We believe that Portugol IDE is a good option for all those who are involved in the teaching/learning of programming as it facilitates active learning inside and outside the classroom environment while it validates algorithms, facilitates error depuration and supports two languages: portugol and flowchart [7]. Instructors are no longer the holders of the solution and become more available to their students.

New features are already being studied with the aim of promoting a virtual ecosystem in the framework of Portugol IDE, including its articulation with learning management systems, learning content management systems and learning objects repositories.

Abstract— **Competition is evident throughout our society, lives and work. "It transcends time and place, as well as all manners of people". In this paper, we present a study and a framework proposal for a mixed collaborative-competitive learning environment, applied to a programming course in a University level engineering program. While neither collaboration, nor competition, is inherently good or bad in supporting the learning process, the way teachers employ these strategies in classrooms determines their value in preparing "soon-to-be" professionals. We believe this mixed-based learning approach best serves students as they are able to achieve academic success both in working with others and on an individual basis. Besides the traditional theoretical lessons and laboratory practices of the course, the integration of the framework automates all the support and evaluation processes. It implements both an individual competitive setting and a collaborative one, where intergroup competition occurs, by means of two interconnected modules. We discuss our results and findings in its preliminary use, concluding that the framework promises to have a good impact in the way we teach some programming courses in our Institute.**

Keywords-competitive learning; collaborative learning; programming language innovation; automated evaluation framework.

I. INTRODUCTION

Competition is evident throughout our society, lives and work. "It transcends time and place, as well as all manners of people" [1]. In this matter, Universities play an essential role in preparing students for their professional lives, and courses should be adapted to an increasingly competitive and challenging world outside of them. Therefore, although different teaching/learning methods and styles exist nowadays, we emphasize, and describe in the current work, teaching as a mixed collaborative-competitive setting.

While neither collaboration nor competition is inherently good or bad in supporting the learning process, the way teachers employ these strategies in classrooms determines their value in preparing "soon-to-be" professionals [2]. An effective classroom must have the right mix of cooperative learning and competitive learning (along with individualized learning) [3]. This mixed-based learning approach best serves students as they are able to achieve academic success, both in working with others and on an individual basis, enhancing learning opportunities for students pursuing a professional career [4]. These two learning techniques do relate to the workplace of our times. Often in the business world people work on a variety of team settings, thus, collaborative activities in a classroom can prepare students for the experience of their professional lives. With these activities, students may also engage in learning because they enjoy cooperating with others. Similar to a collaborative structure, employing competitive learning has a complementary potential to engage students. Once they are faced against each other, their competitive instincts can encourage them to increase their commitment towards the learning process. Even students who initially may not be inspired by the subjects may begin to be interested once they have to compete. We also believe that this is particularly useful for students who are not prone to be competitive, since they should be confronted with this reality as soon as possible.

This work presents a study and a methodology proposal for a collaborative and competitive learning setting. It is based on a computational framework currently being under development for a programming course on a Polytechnic Institute engineering program. This methodology relates to learning in competition with others, achieving individual goals with or without collaboration from peers [5, 6]. Besides the usual theoretical lessons and laboratory practices, the integration of the framework in the course automates all the support and evaluation processes. It implements two competitive settings instantiated by the Champions League (CL) module and the Automated Test and Group Ranking (ATGR) module. The first module targets an individualized type of competitive learning, where students are selected to participate in a tournament with a group stage and a knock-out phase, similarly to the well-known UEFA Champions League. The later module aims at an intergroup competitive setting, in which balanced student groups are formed, competing among them. A third module is predicted to be implemented in the future, where the actual programs coded by the students compete in an arena, but its scope of applicability isn't as broader as the other two – only in artificial intelligence-like programming courses – and will not be further discussed in this paper.

The paper is structured as follows: in Section II we report some related work and studies with competitive and collaborative learning, while the methodology and supporting framework are presented in Section III. In the following section, we discuss our findings and present student opinions for this methodology, based on empirical and questionnaire results. Finally, in Section V, overall conclusions are taken and future work is presented.

II. Related Work

Concrete, reflective, abstract, experiential and active learning are some terms used to describe alternative pedagogical methods that fit different learning styles. Hence, there are several learning styles proposals and mixed applications described in literature [3, 7]. Obviously, learning styles are individual preferences and tendencies that influence the learning process [8]. Johnson and Johnson [3] refer a close relationship between learning styles and attitudes towards learning, including motivation to learn, involvement in learning activities, attitudes towards teachers and self efficacy. Students learn better if contents are presented to them through a medium that matches their preferred learning style [3, 7, 9]. Moreover, independently of the area of knowledge, recent innovations in pedagogical techniques have led to the introduction of new instructional methods in the classroom. These innovations include, for example, educational and on-line games [10, 11], asynchronous instruction (e.g., email, electronic bulletin boards and podcasting) and computer-based teaching [12]. Therefore, the different learning approaches are basically applied by teachers according to their experiences, the ambience where they find themselves teaching and the concepts they want to pass through.

Based in our experience in teaching programming courses, we have found that a mixed collaborative and competitive method is an adequate approach for such courses. Competition has been defined as “a social process that occurs when rewards are given to people based on the basis of how their performances compare to the performances of others doing the same task or participating in the same event” [13]. Competitive learning holds both positive and negative aspects. Lam et al. [14] found that competition had a positive impact on performance goals and learning motivation in the classroom. Also, it has been stated that “learning by loosing” was a valuable process for students preparing themselves for professions where working under pressure was necessary [15]. On the other hand, some handicaps related to competitive learning have been identified in literature, like high anxiety levels, self-doubt, selfishness and the interference with the capacity to solve problems [3]. Nonetheless, these issues can be attenuated if one establishes different competing environments, being one of them the competition between groups of students, during which elements of a group cooperate in achieving personal goals, hereby introducing collaborative learning. Collaboration, or cooperation, has been defined has “a social process through which performance is evaluated and rewarded in terms of the collective achievement of a group of people working together to reach a particular goal” [13]. As with competition, collaboration also yields positive and negative aspects. Duetsch [16] suggested that collaboration embodies positive interdependence and found that college students solved more problems in a collaborative environment than students in a competitive environment. The main problem that we identify with collaborative learning is the possibility of an uneven engagement in learning by individual students within a group, translated into uneven contributions for the group's final grade. Nevertheless, with our methodology, the individual merit of a student can be assessed in the individual competitive setting.

Programming courses offer good conditions for the implementation of a competitive environment, based on both collaborative and individualized learning. Structuring a problem-based competitive project, wherein collaborative student teams compete against each other, is a way by which teachers can ensure both collaborative and competitive learning opportunities for students [4]. These methods have also previously been applied to other engineering classrooms [17, 18, 19].

Previously to the work presented in this paper, some experiences of learning through competition and collaboration were carried out in our Institute. The implementation of a market based on software agents was the main goal of a curricular innovation experience in an advanced course on Distributed Artificial Intelligence [20]. The task was prepared to enhance the learning experience through collaboration and competition among the students. The project involved the creation of a community of agents capable of modelling a market of goods and competences. For each producer agent (with reasoning capabilities implemented by a group of students), the goal was to maximize its production capabilities and earn more money, by means of competition with other producer agents. This proved to establish a rich and challenging collaborative-competitive environment for the students, supported by their opinion and developed works. In another case of competitive learning evaluation, groups of students were asked to implement a representation of the horse game, the game operators (piece movements) and a search algorithm. The horse game is a simple game that finds its origin in the chess game and is played by two individuals on a ten per ten square boards. Essentially, the groups of students would play against each other and the first tree ranked groups of the tournament would benefit from a bonus translated into a higher subject grade. The introduction of the competitive element in the course motivated the groups to care and look for better implementations of their programs. By testing them against each other, they automatically started to explore new heuristics and to improve their algorithm's implementation to get better results in the competition.

As for related frameworks, *Mooshak* [21] is the only one we know about and is interesting because it presents some similarities with modules and functionalities of our proposal. *Mooshak* is originally a system for managing programming contests on the Web and its basic features include automatic judging of submitted programs, answering to clarification questions about problem descriptions, re-evaluation of programs, and tracking printouts. The system was originally intended for contests, but it is increasingly being used in programming courses, used to give instant feedback on practical classes, to receive and validate assignments submissions and to partially evaluate and mark assignments.

However, in competitive programming field there are several examples on the web like *Robocode* [22], *Top Coder* [23] and *ProjectEuler.net* [24]. *Robocode* is a game where a programmer codes the behaviour of a robot that is put into battle with others around the world. *Top Coder* is more targeted for professionals, since competition happens with programmers solving problems for customers and getting paid for the job in case they win. Finally, *ProjectEuler.net* is composed of hundreds of mathematical problems in which computer programming skills are required to solve the majority of them. By solving one problem it will expose the programmer to a new concept that allows him to undertake a previously inaccessible problem. So, a determined participant will slowly, but surely, work his way through every problem [24]. We find this interesting because the idea is similar to our “hints” mechanism in the proposed framework (next Section).

III. Methodology and Framework

This section details the methodology proposed, highlighting the main principles, the supporting computational framework’s architecture and the development of the two competitive modules. The followed learning methodology implementation is explained along with the framework’s architecture and modules description.

A. Main Principles Requirements

When implementing a new methodology and designing a framework like the one presented with this work, we first establish guidelines for the design. Some principles requirements that must be regarded in the conception of our proposal are the following:

a) To implement different competitive learning settings (competitive and collaborative), but with a strong interdependence between them;

b) To insure flexibility with regard to time and location, the framework should be available in a permanent manner, i.e. anywhere, anytime;

c) To present teaching and assessment materials in a language that is simple, clear, direct, adequate and attractive to the target for which the courses are intended;

d) To create auto-evaluation functionalities, in the form of evaluative exercises and tests that allow students to evaluate their own progress;

e) To continue introducing a variety of competitive components, such as games and challenges, to stimulate the student to engage with the learning solution;

f) To allow, in case of failure, the repetition of the studying process as well as the practice and auto-evaluation, yet with a different set of exercises;

g) To use the information obtained from evaluation moments and every time students use the system to define measures that allow guaranteeing the existence of an adequate component of support and feedback from the system and from teachers;

h) To devise adequate analysis that allows teachers to become familiar with students who are really learning from this methodology.

B. Overall Architecture

The framework supports a methodology divided in two different competitive settings. As mentioned in the Introduction, these settings are mapped into two modules of the architecture (Fig. 1) – the Champions League (CL) and the Automated Test and Group Ranking (ATGR).

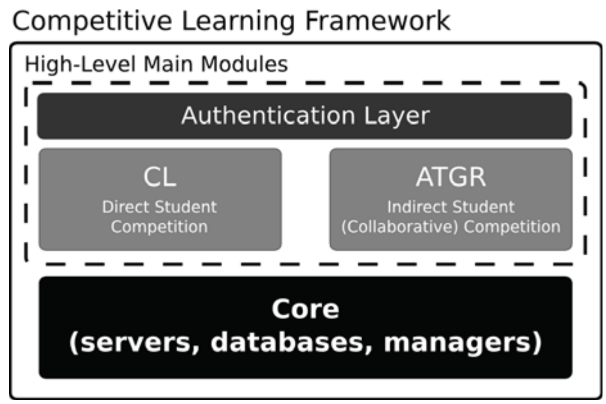

Figure 1. Overall architecture of the presented framework.

The CL module implements an individualized type of competitive learning, while the ATGR module is related with intergroup competition where collaboration occurs within groups. An Authentication Layer, for controlling the access to the system, is an independent module because it depends on the information system used at the Institute. This way, we do not keep duplicate information about users, but instead use the information already available in the information system, e.g. student's number, name, course, number of enrolments, etc. It is only necessary to map the users’ unique identification on that system to the information stored in this learning framework.

These high-level modules are strongly interdependent, not only because they are used in conjunction to evaluate and to teach the students, but also because the results taken from the CL are used to configure groups in the ATGR module. The groups of students are generated upon results from the CL to ensure homogeneous grouping, maximizing the chance of winning for all groups. Homogeneous grouping allows the groups to be as evenly matched as possible to provide a challenging environment for competition. We discuss this grouping methodology in Section IV. Therefore, the output from a module is used as input on other modules, despite being used in an indirect way. This means that the output data from a module must be stored in the core of the system.

The core is composed by the necessary servers, like web and database servers, and the manager modules, which are used to configure the system to a learning case. This configuration is made by advanced users, e.g. teachers with an administrator course role, who determine exactly how to apply the proposed methodology through the supporting framework.

In addition, the framework also integrates contents modules for the lessons and for the students study, being a complement for the competitive learning. These modules have a strong emphasis on multimedia contents with audio, video and animations. They are presented through web interfaces and a multimedia interactive DVD-Rom.

C. The Champions League (CL) Module

The first main module implements a competition where the students are selected to participate in a tournament similar to the well known UEFA® football Champions League (CL), with a group stage and knock-out rounds. The architecture for this module includes four main sub-modules (Fig. 2).

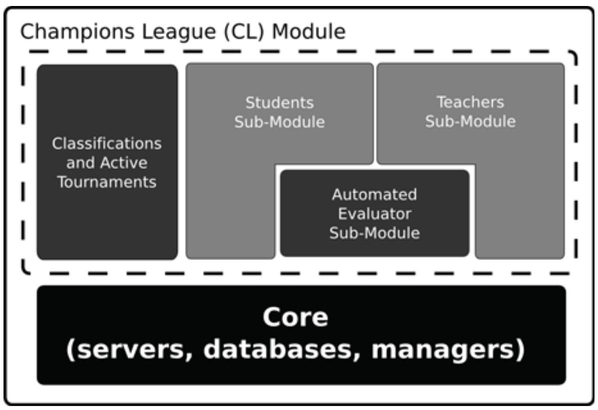

Figure 2. Detailed architecture of the Champions League (CL) module.

One of them is the manager of Classifications and Active Tournaments (CAT). All the information is gathered from the corresponding database. The CAT module is a Web-based application where it is possible to get information about past and present competitions. Students have access only to data related with competitions where they have participated. Teachers can export results from competitions designated as assessments, which are configured according with that. In short, it presents tournaments classifications and matches results, detailing the obtained goals for each student player, and statistics that can be obtained through a set of queries.

The module related with teachers integrates all the functionalities necessary for the correct management of the competitions. One teacher can add new exercises, with the corresponding type descriptors, to the database and configure CL tournaments, which may be of the formative or assessment type. Through this sub-module, teachers access the Automated Evaluator (AE) sub-module, configuring it according to the class of students they have in mind to compete. Additionally, this module has access to another sub-module integrated in the CAT module. Through it, teachers can determine which and how results and statistics data should be presented to students, with the possibility to decide if they are made public.

The AE module crosses the submitted results (programs resolutions) with the configuration made by teachers and the exercises descriptors taken from the database to evaluate how many goals were achieved by each student in the scheduled match. Each exercise has a set of goals to be achieved that are specified by a teacher when submits them to the database.

For the competition, students use the laboratory computers to implement the proposed code for each programming exercise (a "match"), where they compete against an opponent and the clock. Using the Students sub-module, students must submit a file with the implemented code to the framework at the final of a match, or when they finalize it. They also have to use this Students module to access their areas in the CAT module.

The AE module automatically evaluates the obtained results of the matches, updating the repository and giving feedback to the participants. Briefly, the result of a match is dependent on the evaluation of each exercise resolution submitted by each student that participates in the match. When a submitted exercise is evaluated, the number of goals obtained by the student is counted and stored. This is important information not only for statistic purposes, but also for course evaluation purposes. If both students obtain the same number of goals, then it is necessary to look up for the timestamp relative to the moment when files were last saved. If this item is also equal then the match result is a draw, resulting in one point for each container, otherwise, three points for winner and nothing for the loser.

The competition can take place for several sessions (lessons, marked days, etc.) and a teacher can configure it by choosing, for example, the starting time of the different group games, the level of the games (exercises to be implemented), the submission type, the competition mode (auto-evaluation/training, assessment, or friendly), among other parameters.

In addition, another sub-module under development will permit that students submit to the database exercises to be implemented by their colleagues in a determined CL competition. This is one of the most interesting functionalities in our methodology, since we think this may improve the learning performance of a student, as he has to find and know adequate exercises for accomplishing this specific task. Although not necessary, this can be a parameter in an evaluation.

D. Automated Test and Group Ranking (ATGR) Module

This module is responsible for automatically evaluating the correct implementation of functionalities within a final course project. The module architecture is depicted in Fig. 3.

One advantage of this module is that it relieves teachers from manually testing each group project, which can be very time-consuming, particularly in courses that easily scale up to hundreds of students. This way, they only have to complement the automatic evaluation by evaluating the quality of the code produced by the groups of students. The second advantage is that student groups may use the system to do periodic checks to their implementations and see if they are doing things right, i.e. if their algorithms are producing the correct results. While doing so, they are competing with the other groups for being the first to achieve correct implementations of the different functionalities/tasks that compose the overall problem assigned to them. During this process, they are awarded points for a correct implementation, plus bonus points for being the first, second or third groups to achieve each individual goal.

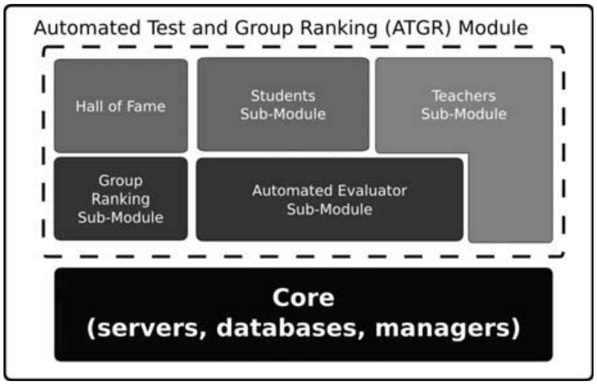

Figure 3. Architecture of the Automated Test and Group Ranking (ATGR) module.

As an incentive, each time a group submits a correct implementation, for a particular functionality, they receive clues ("hints") for solving other harder functionalities. At the end of the submissions – the deadline – the final ranking table (Hall of Fame) elects a winner group to whom is given a bonus grade, as well as to second and third runners-up. Nevertheless, the ranking table is available to the students throughout the implementation phase as a means of direct competition.

In order to sort out if some kind of plagiarism or code-sharing occurred, all final implementations are submitted to the Moss system [25], a software plagiarism system from Stanford University, upon which a Hall of Shame can be generated. This list is not a priority to us, but in severe cases it must be used and it can even act as a deterrent measure for future course editions, or for other Institute courses.

The front-end of the sub-modules that interact with users are web-based. In order to avoid abuse, teachers are responsible for group information submissions and assign themselves to those groups, using the Teachers module. Through this sub-module teachers also upload the code, which will be used for automated testing of project implementations, to the Automated Evaluator sub-module, in the same way they do for a CL competition. Authenticated groups (any student assigned to the group can do so) submit their implementations code through the Students specific sub-module. After that, they can obtain feedback from the AE sub-module, including the aforementioned clues for solving what is left of the problem.

The Hall of Fame sub-module is responsible for retrieving the information from the database and for generating the rankings table. When the delivery deadline is reached, all the final versions submitted are sent to the Moss server and results can be made public. All data relative to group performance, submission history and rankings are stored in a specific-module database, with modularity in mind, at the core.

IV. RESULTS AND DISCUSSION

In this section, we summarize and discuss our findings and student opinions during this early use of the proposed methodology and supporting computational framework. These experiences were conducted with laboratory classes of an introductory Java programming course. The final grading of this subject is calculated by summing 50% of the exam grade (written exams cannot have a weight inferior to this percentage in our Institute) and 50% of the grade provided by the framework adding its two settings.

A. *The CL Pilot Experience*

In terms of the competitive learning provided by the CL module, the results obtained with the first application of the methodology were very positive. Students thought it was a very interesting initiative, giving to them some fine moments where they were able to combine the concerns of an assessment with the joy of participating in a game. Not exactly the feelings to expect from an evaluation moment, but they were much nearer of situations from the real World. For teachers, it clearly showed them that better prepared students were the ones obtaining the best results in the final classification.

Figure 4. First CL edition results. Legend: G (Group), W (Wins), D (Draws), L (Losses), GF (obtained Goals), GA (suffered Goals), SF (Semi-Final).

As an example for an easy understanding, it is possible to analyse a small laboratory class of eight students that took place in the first CL edition. Fig. 4 presents the competition progression with all the obtained results.

First, it is important to summarize how students got placed in the groups/pools and the organization of the competition. They were split into two groups of four students/teams (each student chose a team name to relieve the pressure of competition and evaluation), who played "home" and "away" against each of their pool opponents to decide which two teams from each pool would advance to the first knock-out round. In these rounds, the last 16 until the semi-finals, teams played two matches against each other on a "home" and "away" basis. In this case, after the groups stage we ended up with only four teams, the best two from each pool. So, the first round was not the last 16, but immediately the semi-finals round, and group winners played against runners-up other than teams from their own group. In this application, it was not necessary to make a draw because the number of participants was limited. The final game was decided by a single match.

The tournament results help to understand the reason why the student with the team name "Net_Azelha Beta" won the competition. Besides being the winner of her pool, this student also "scored" the highest number of goals after six games played, considering that the games/exercises were the same for the two pools. "Net_Azelha Beta" has reached a total of 24 programming goals present in six proposed exercises. It was an excellent result since it was above 95% of the goals represented by the six Java programming exercises. However, the same appreciation can be made for the second best team. Moreover, the course final written exams proved that the semi-finalists students in this CL edition were really the best students of their class. This is an important conclusion because it proves that a competitive learning environment does not prejudice the best students.

After the realization of the competition, with duration of approximately one month and five laboratory lessons, we also carried out a questionnaire survey. It was carried out among all the students in order to determine their satisfaction and opinions regarding the CL competition. The questionnaire was designed to gather information on students' attitudes towards aspects of the competitive learning they experienced as well as towards some more specific aspects of testing. The questionnaire had six questions:

1. How much do you like it?
2. How useful is it?
3. How much pressure do you feel when participating?
4. How fair is it?
5. How much do you want to maintain this CL format?
6. How functional is the CL module of the framework?

Students had to answer with a number that ranged between 1 (a little) and 5 (a lot) for each question. In Table I we present the mean value of the ratings on each question.

TABLE I. STUDENT'S OPINION QUESTIONNAIRE ABOUT CL MODULE

Students	Questions					
	Q1	*Q2*	*Q3*	*Q4*	*Q5*	*Q6*
Testing Class	4,62	4,88	5	4,88	4,75	4,62
All Classes	4,37	4,63	4,82	4,55	4,13	4,67

One row of the Table I has the questionnaire results from the eight students of the previous CL example, while the second row refers to the answers from all students (60) of all classes. We believe that these results traduce perfectly what the CL competitive methodology brought to the course: "more demanding with more fun".

Moreover, in the classrooms, teachers felt that students were positive about the introduction of this evaluation method and the questionnaire results confirm that informal and empirical conclusion.

B. *The ATGR Module Application Example*

In regard to the collaborative setting – intergroup competition – the reception by the students was also positive. One of the features they liked the most was the possibility of checking their implementations at home in an autonomous way, rather than just believing that it was correct with their own testing or with the help of teachers.

One of the first things to be set in the ATGR module, besides preparing it for a particular course project, is the composition of the groups. Initially, it is common for students to be somewhat reluctant to being assigned into groups. However, explaining to them that employees in an organization rarely get to choose their co-workers and are often put in situations where they have to work with people they do not know, the students come to understand, accept and benefit from the situation. We first thought in achieving balanced groups, in terms of chance in winning the competition, by pairing the first ranked student in the CL competition with the last, the second with the next-to-last and so on. But soon we found out that this was not the correct approach, because some students would be concern about being paired with an underachiever or that did not have good results in the CL competition. A purely random composition of the groups is preferred [4]. However, upon this random composition process, we used the information gathered from the CL competition, along with our own knowledge about the students, to correct the composition of some groups when we detected that the original ones did not benefit them or the competition. Our main concern is to engage all groups in a healthy competition, even if it happens separately in clusters of those groups.

The competition begins after the groups have been set. One of the interesting things we concluded was that it turns out that it is not beneficial to let the students make all the submissions they want to the framework. This is a negative side-effect that we must take into account for the following courses and competitions. It leads to a kind of frantic development by which they do not reason about what is wrong with their code, but embrace a trial-and-error approach until the system tells that their implementation is correct. In a few cases, it really became a game of fortune. We believe this is not desirable and we chose to limit the number of permitted submissions per-day, e.g. five submissions. This forces the students to use them wisely and also prevents them from reaching a correct algorithm "by chance" in the hurry of being the first ones to implement that functionality.

The students enjoyed the "hints" provided by the system during their submissions. They found them particularly useful to overcome the harder functionalities implementation as they approached the submission deadlines. Teachers liked the automatic evaluation of the projects since they are able to know beforehand the different levels of completion of each project. This is also particularly useful in giving grades, because students immediately have a tangible way of comparing their expected grades with others. All of this is obtained at the expense of a greater workload on behalf of the teachers during the initial setup of the framework for a particular course, but we believe that it is compensated during all the teaching/evaluating process and provides a rich and challenging environment to students for learning and preparing themselves for their professional lives.

V. Conclusions and Future Work

In this paper we presented a study and a proposal for a collaborative and competitive learning methodology, applied to a university level programming course. Due to an increasingly competitive professional world, where at the same time people are put to work with others in teams, we provide a mixed setting between these two learning methodologies with the expectation that it will somewhat prepare them to their professional careers, as well as providing a rich and challenging learning environment.

Opinions gathered form students during the initial use of the methodology and supporting framework were positive and we have discussed our findings and suggestions for such systems. In summary, these preliminary results showed us that this kind of mixed competitive-collaborative learning methodology has the potential to become a solid and reliable approach in learning programming languages. We believe that the developed framework is a valuable tool for the support of both teaching and learning activities. It will have a key impact on how some programming courses are taught in our Institute.

The modules presented for the framework have been implemented, but separately, and are now being integrated and unified in the proposed framework. This obviously leads to some refinements in modules that were independent, particularly in terms of a uniformed user interface, a common authentication layer and database sharing. Depending on the internal success of this framework, we intend to release it as an open-source project so others may benefit from it while, at the same time, helping in the process of perfecting it and/or adding new features.

As future work, a third module that targets artificial intelligence-like courses is planned, whereas the students' actual implementations of some projects will be put into an arena to compete with each other. Later on, we intend to publish another paper describing the technical issues and technologies involved in the computational supporting framework development.

Acknowledgments

We thank our colleague Cédric Grueau for the great job produced while working with us on the first approach to the proposed methodology.

We also thank the anonymous reviewers for their invaluable comments and suggestions regarding this paper.

Abstract— **This work is focused on the syntax error recovery visualization within the compilation process. We have observed that none of the existing tools, which display some views of the compilation, give a solution to this aspect. We present an educational tool called VAST which allows to visualize the different views of the compilation process. Besides, VAST allows to display different syntax error recovery strategies.**

Educational technology; Visualization; Computer science education; Languages

I. Introduction

Language processors or compilers are considered by the students as ones of the most difficult subjects in Computer Science degree. One of the most difficult parts in these subjects is the syntax error recovery.

In the syntax analysis points out the syntax tree (ST) comprehension. The ST concept is basic for syntax analysis and syntax directed translation. The understanding of both topics can be improved using visual representations of the ST. Moreover, the tree representation of the ST is quite similar to student's mental representations of the ST.

Card et al. [7] defined visualization as the "use of computer-based, interactive visual representations of data to amplify cognition". Visualizations, which show the behavior of the internal parsers structures, can be used to make easier the comprehension of the syntax analysis. Nowadays, we have not found any tool which displays the syntax error recovery.

Some syntax error recovery (SER) strategies are difficult to understand for students. Also their implementations in the parser generating tools (e.g. The panic mode error recovery of Yacc): "Proper placement of error tokens in a grammar is a black art…" [13].

Lexical error recovery (LER) is simpler than SER. LER consist in transforming an unmatched string of characters in a valid string using single character modifications (insertion, deletion or modification) or just reporting the error and then restart the lexical analysis process with the next character. However, SER has more implications; sometimes it does not work properly creating new nonexistent syntax errors because the parsing task cannot be interrupted. Furthermore, it is necessary to choose the synchronization point which can force to ignore a part of the input stream or to change it virtually.

The main syntax error recovery strategies are error production, which consists in extending the grammar adding new erroneous productions. Panic error recovery strategy allows the parser to ignore the input stream until find any synchronization token. Finally, the phrase level strategy can make local changes assuming that an unexpected token is correct, for example inserting it into the stack.

Parser generators are commonly used in language processing courses, but the implementation of error recovery methods is far from theory. Obviously, error productions can be used with all parser generators. But, the phrase level is mostly used by LL parser generators, e.g. ANTLR[1]. And the panic mode method is mostly used by LR parser generators, e.g. Yacc[2], Bison[3], and Cup[4]. Even changing the concepts, because the parser developer must specify synchronization points with a special error token, instead of specify synchronization tokens associated with productions.

Visualizing the error recovery process will improve students' understanding of these methods. We have developed VAST [2,4], an educational tool devoted to syntax analysis visualization. VAST has been evaluated in both an educational and observation way [3]. One of the most important features of VAST is its generic approach. It can be used with different parser generators; our students have used it with Cup and ANTLR parser generators. Here we describe how VAST visualizes the different error recovery strategies implemented in both parser generators.

The rest of the article is structured as follows. In the section 2 we describe the related work. In the section 3 we describe the different strategies of error recovery. In the section 4 we explain the visualization of the error recovery with VAST. In the section 5 we describe other characteristics of VAST. Finally, in the section 6 we state our conclusions and future work.

II. RELATED WORK

There exist numerous tools to display some aspects of the compilation process. These tools have been divided according to the use that they are thought for. On one hand there are tools designed to be used mainly with a theatrical aim. However, with this kind of tools the user cannot generate his/her own parsers. Some examples of this type of tools are JFLAP[16], THOTH[8], BURGRAM[9] y SEFALAS[10]. All of them have in common that they animate some aspects of the compilation process such as the table's construction, recognition of the input stream, generation of the syntax tree, etc. On the other hand, there are tools designed to be used with a more practical aim. Some examples of this kind of tools are, ICOMP[6], VisiCLANG[17], APA[12], TREE-VIEWER[19], VCOCO[18], CUPV[11], LISA[14], ANTLRWorks and JACCIE. These tools have two remarkable problems. On one hand they only work with a particular generation tool. On the other hand, they display only certain parts of the compilation process.

There is not any tool that covers the entire parsing algorithm and visualizes all the dimensions –algorithmic behaviour and ST-, therefore it is possible that a teacher has to use more than one, switching between different notations, organizations and visualizations. In this context, the students have to learn how to use more different tools: specification notation, construction process, interpretation of output messages –conflict reports, transitions matrix or items sets-. Furthermore, the teacher has to dedicate time to become familiar with the different environments, and to plan their integration in the course. This makes more difficult their use in educational environments [15].

Focusing on both kinds of tools which have been found, and trying to display the error recovery process, we have realized that except ANTLRworks, none of them visualize this process. In the specific case of ANTLRworks, the visualization of the error recovery process is limited. On one hand, it only allows the visualization for parsers built with the parser generator ANTLR, which also mean for LL(1) parsers. Moreover, it only displays a specific kind of error recovery, the ANTLR one, which consists in inserting the unexpected symbol into the parser's stack. Finally, sometimes the visualization generated can be confusing.

In the Figure 1 it is shown the partial ST built by ANTLRworks when a syntax error occurs. In this case the error is produced because the parser expects a symbol which is not in the input stream, so that ANTLR inserts into the stack all the symbols that it founds although there are not correct. In this case as the error cannot be recovered it reaches the end of input stream, finishing the analysis.

III. SYNTAX ERROR RECOVERY, AN OVERVIEW

The main objective of a parser is to build the ST. But if the input stream is erroneous, then the parser must detect as much existing errors as possible. Therefore, the parser cannot stop the analysis after the first syntax error. Instead, it must move to a correct state and continue with the parsing. This is the main idea of SER.

Typically, four SER methods are taught: phrase level recovery, error productions, panic mode and theoretical [1]. Next we briefly describe each method, note that when we qualify a method as simple or complex we are talking about the student's point of view (understanding).

Phrase level recovery is one of the simplest methods. It tries to transform an incorrect phrase into a correct one by inserting/deleting tokens in/from the input stream. Every state of a parser has a list of expected tokens; they can be used in this recovery method. A common example can be found in most C/C++ compilers, the insertion of the forgotten semicolon at the end of sentences.

Error productions detect specific errors by specifying erroneous grammar productions as they would be correct ones. This recovery is directly specified by the language designer/parser developer. The error treatment is defined in the associated actions of the error production.

Panic mode is more complicated because it simultaneously and explicitly, involves the stack, the input stream and the ST.

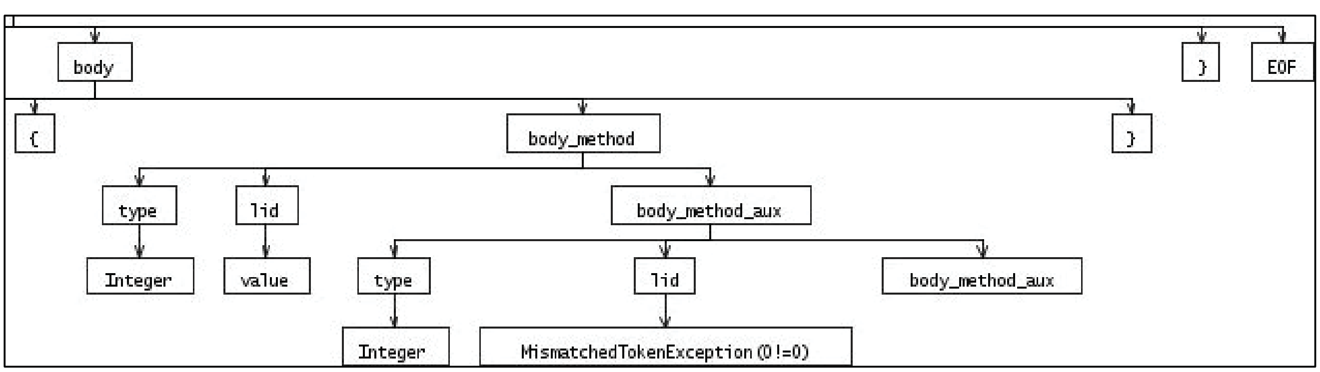

Figure 1. Error recovery visualization in ANTLRworks

This method is based on synchronization points. When an error is detected, the parser discards input tokens until it reaches to a synchronization point. This point is defined by a group of synchronization tokens. To master this method, one must know what are the state of the stack, the input stream and the ST just after the recovery. Besides, it depends on the synchronization token used to recover from the error.

IV. VISUALIZATION OF SYNTAX ERROR RECORY

Visualizing the error recovery process will improve students' understanding of these methods. We have developed VAST [4], an educational tool devoted to syntax analysis visualization. One of the most important features of VAST is its generic approach. It can be used with different parser generators; our students have used it with Cup and ANTLR parser generators. Here we describe how VAST visualizes the different error recovery strategies implemented in both parser generators.

A. *A note about VAST*

VAST has been designed to cope with any parser generation tool independently from the type of the parser generated (LL/LR). In order to get this independence and keep the easy of use as a fundamental requirement, VAST has been divided in two parts: VASTapi and VASTview.

VASTapi is the part encharged of the language processing, its target is to interpret the actions made by the parsers. Finally, it has to create an intermiddle representation, in a xml file, with the content of the ST and the neccesary information which allows it visualization.

VASTview is the part encharged of the visualization. Its function is to interpret and represent visually the content of the xml created by VASTapi.

In order to make this process work correctly, it is necessary to perform an annotation process. This one consists in inserting calls to the methods of VASTapi using semantic actions inside the parser specification. The information needed by VASTapi is the syntactical rule which has been executed. To make this task, the user has to use the method *addProduction("Antecedent", "Consecuent")* of VASTapi. For each syntactical rule is necessary to add the semantic action which communicates, to VASTapi, the rule which has been used.

In the Figure 2 it is shown the user interface of VAST. In the central part it is displayed the ST and in the bottom the different views of the compilation process (input stream, stack, grammar and actions performed). Besides, it includes a global view to make easier the interaction with the ST. Note that in this figure it is used the horizontal distribution. In the Figure 3 it is shown a scheme of how to work with VAST. The process has been divided in design time, which include the annotation process; execution time, when the parser processes an input stream and as a result of the execution of the VASTapi methods, it is built an intermeddle representation in xml; and finally, visualization time, where VASTview interprets the content of the xml file.

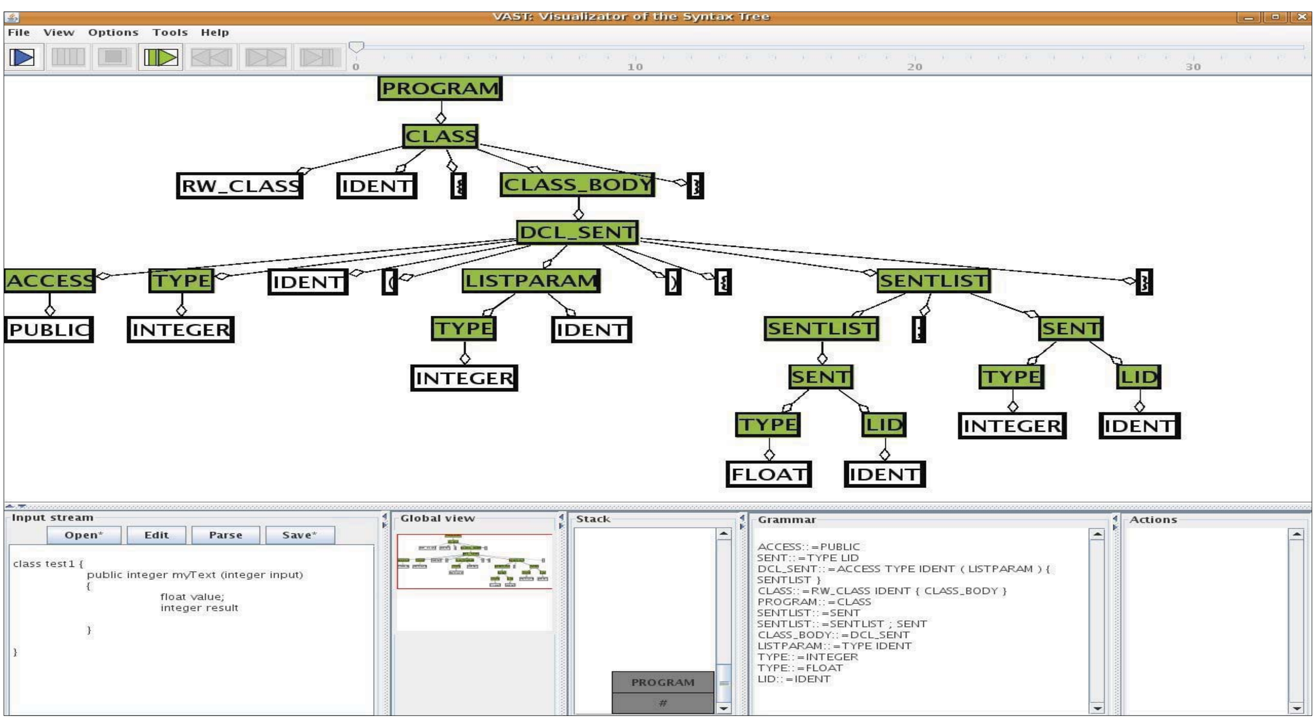

Figure 2. User interface of VAST

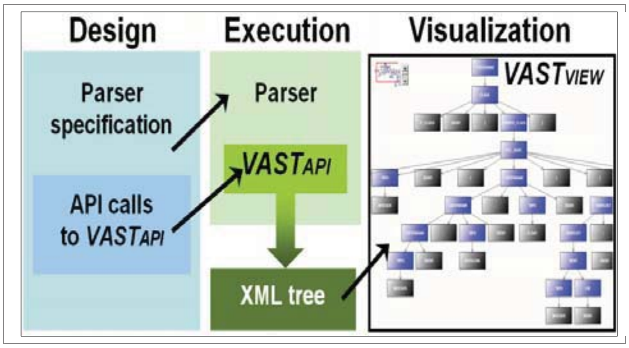

Figure 3. Working with VAST

B. *Visualization of the phrase leve errorl recovery method*

This method is based on token insertion/deletion in/from the input stream. The ANTLR parser generator implements this method by inserting expected tokens. ANTLR allows the parser developer to overload the syntax error recovery method *displayRecognitionError.* We have inserted code that identifies the inserted tokens in the ST.

The main effect of this method is that the terminal nodes of ST (the leaves of the tree) don't correspond to those present in the input stream.

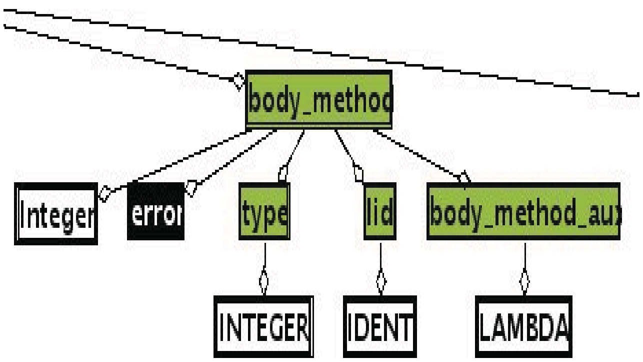

Figure 4. Phrase level recovery with VAST

With VAST we highlight the existing tokens of the ST that have been inserted by the phrase level recovery method.

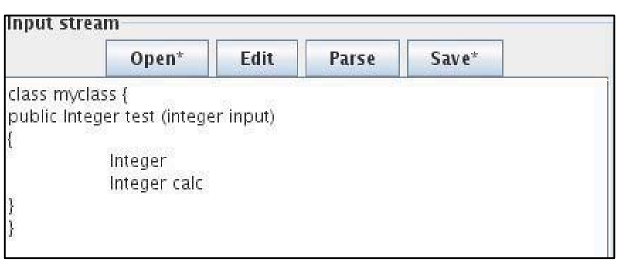

Figure 5. Input stream for LL recovery

In the Figure 4 it is shown an example of an erroneous input stream for a parser generated with ANTLR. As we can see in the input stream in the Figure 5, there is an error in the identifier declaration, so it produces a syntax error. Visualizations can help to understand how this method of error recovery works. When a syntax error occurs, the symbol is shifted into the stack and the analysis continues. In the Figure 6 it is shown the grammar used in the example of the Figure 4.

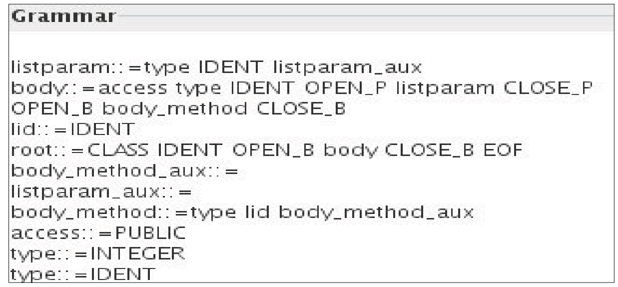

Figure 6. Grammar for LL parsing

C. *Visualization of error productions*

Taking into account that sometimes the error recovery methods implemented in the generation tools are very generic, using error productions allows to perform a more specific error recovery.

In order to make VAST recognize the error productions, it is necessary to communicate it, which productions are used for this error recovery strategy. To obtain this functionality it has been necessary to add a new method called *addErrorProduction("antecedent", "consecuent")* to VASTapi. As we can see, the information communicated to VAST is exactly the same in both cases, in normal productions and in error ones.

VASTview displays an error production highlighting the whole production in a different colour. As result, the user can distinguish that a specific error recovery has been performed.

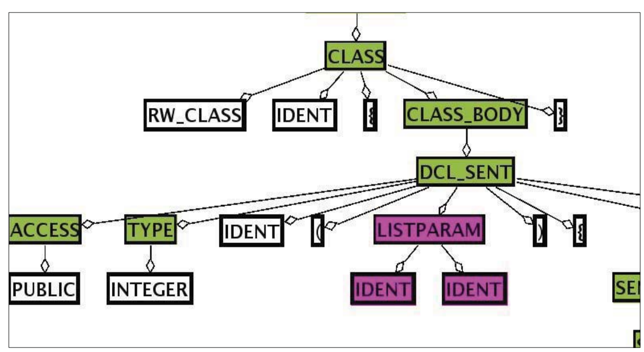

Figure 7. Visualization of error production

In the Figure 7 it is shown an example of error recovery using the error production method. In this case the parser recovers from a specific error produced by an erroneous input stream in the parameters declaration of a method. In the Figure 8 it is shown the input stream using for this example. We can see an error in the parameters declaration of the method *myText.* In the Figure 9 it is shown a fragment of the annotation of the Cup specification to implement this behaviour using error productions. Note that we are using an error strategy not implemented by the generation tools. However, VAST can distinguish this kind of productions, so the visualization adopts the correct aspect.

Figure 8. Input stream for error production recovery

D. *Visualization of panic mode method*

Normally, the panic error recovery is implemented in the generation tools using a special symbol, usually called "error" symbol. This recovery method allows to define easily the synchronization points, however, sometimes it can be extremmely complex to understand how the error recovery strategy works[1].

```
LISTPARAM ::= LISTPARAM COMA TIPO IDENT
| IDENT IDENT
 {:parser.inter.addErrorProduction("LISTPARAM", "IDENT IDENT");:};
```

Figure 9. Annotation for error production recovery

In the specific case of the Cup generator, the panic error recovery is implemented using the Terminal symbol "error". When the parser detects an error in the input stream, it commutes to an internal error stage, inserting into the stack the "error" symbol. To extract this one from the stack it is necessary to find a production which allows to shift the error. If the error can be shifted, then the parser has recovered correctly and the analysis continues. However, if the parser reaches to the grammar axiom and the error has not been shifted, it has not recovered from the error and the analysis will conclude.

To display correctly this process in VAST, it was necessary to implement new functionalities in VASTapi for ascendant parsers. There exist two problems when trying to visualize this process. On one hand, when the parser enters in the error mode, it does not perform any reduction, so that VASTapi does not receive any information of the task done by the parser. On the other hand, as the parser is in an error mode, it does not communicate the ignored symbols to VASTapi. Due to these problems and to obtain these information, it was necessary to modified VASTapi.

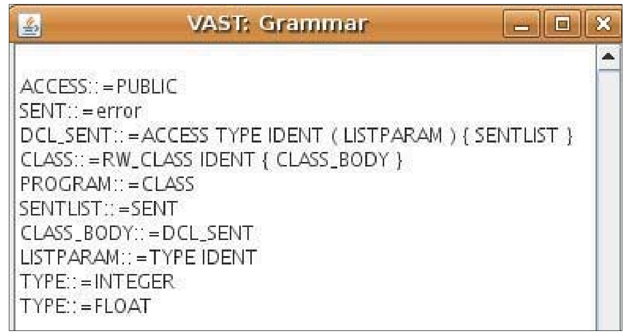

Figure 10. Grammar used for panic error recovery

Instead of solving these problems independently, we have chosen a global solution, which allows to solve both of them. When the parser enters in the error mode, it calls to the *syntax_error* method, which has been overload to communicate to VASTapi that the parser is in the error mode. Besides, in this context, although the parser is in the error mode, it continues asking for symbols to the lexer using the *scan* method.

When VASTapi receives the symbols from the lexer, it marks them indicating their mode (normal or error). Finally, when the error production is performed and the "error" symbol detected, VAST has all the necessary information. On one hand there are the subtrees processed. On the other hand it is the ignored input stream. With this information VAST can create the visualization of this error recovery method.

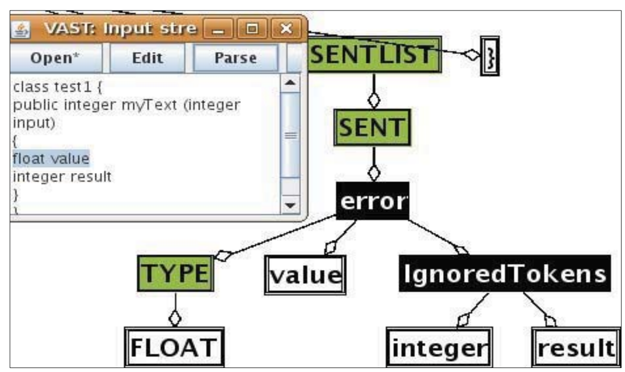

Figure 11. Visualization of the panic error recovery with 1 error

To this end, firstly it is necessary to obtain the synchronization symbol. This one shows the point in which the parser continues the analysis without ignoring the input stream. We obtain this symbol acceding to the last one received when an error production is applied. Secondly, to obtain the ignored symbols it is necessary to access to the received symbols since the parser commuted to the error mode until it received the synchronization symbol. With this information VAST builds a subtree, which root node is the error symbol. The sons of this node are the subtrees processed correctly just before the error occurred and an additional node with the ignored symbols

("IgnoredTokens" node), which contains each one of the ignored symbols.

In the Figure 11 it is shown an example of the panic error recovery. In this case there exists only an error in the input stream, produced because the symbol";" is not after the identifier "*value*". The error recovery implemented used the symbols ";" y "}" as synchronization symbols, so that the parser ignores the input stream until it finds one of those symbols. In this example the parser ignores the "*integer*" and "*result*" symbols. When the parser reads the symbol "}", it recovers from the error and continues the analysis.

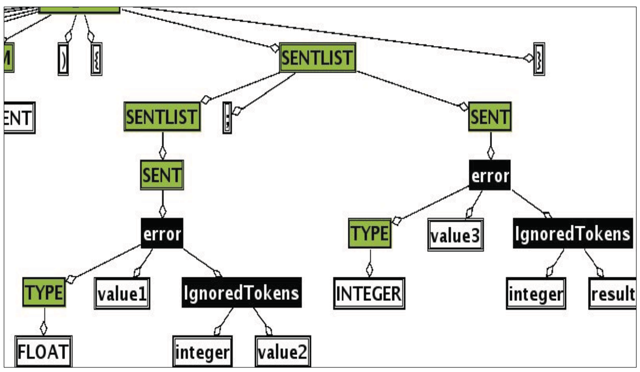

Figure 12. Visualization of the panic error recovery with 2 errors

In the Figure 12 it is shown an example of panic error recovery in which the parser recovers from two errors in the input stream, both produced because there is not ";". As in the previous example, the parser implemented uses the ";" and "}" as synchronization symbols. The first error is produced because after the symbol "value1" it is expected the ";" symbol. However, the parser reads from the input stream the "integer" symbol, so that it enters in the error mode, from which it exits only when reads the ";" symbol. In this case the ignored symbols from the input stream are "integer" and "value2". The second error is produced because as in the first case, there is not ";" symbol. In this case the parser ignores the "integer" and "result" symbols from the input stream. In the Figure 13 it is shown the input stream used to generate the tree of the Figure 12.

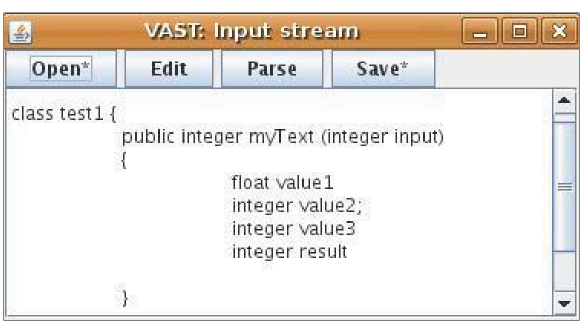

Figure 13. Input stream for panic error recovery with 2 errors

In the Figure 14 it is shown an example in which there are two consecutive errors. In this case as there is not synchronization symbol between both errors, the parser ignores more symbols from the input stream. In the Figure 15 it is shown the input stream used to generate the visualization of the Figure 14.

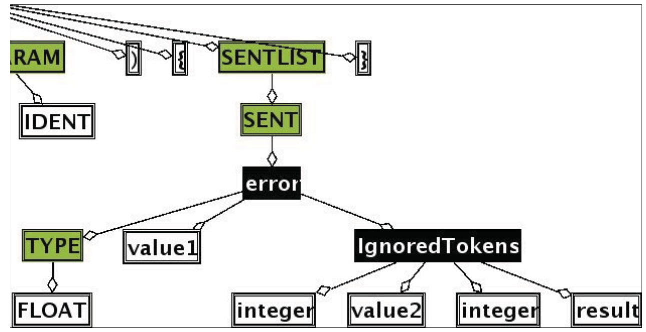

Figure 14. Visualization of panic error recovery with 2 errors consecutive

V. OTHER CHARACTERISTICS OF VAST

Visual representations are not effective educational resources by default, they must be carefully designed. VAST has passed a number of evaluations. As a consequence, we have designed VAST to provide a number of useful features.

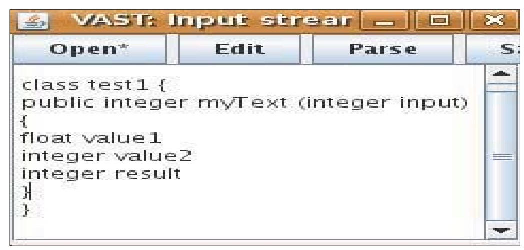

Figure 15. Input stream for error panic recovery with 2 errors consecutive

Apart from inserting additional functionality in VASTapi to interpret the error recovery, we have modified VASTview to handle new functions. It has been improved those characteristic which allow to distribute VAST wider and easier. To this, the user interface has been internationalized into Spanish and English. Besides, we have worked in the platform independence, allowing to work with VAST in Windows, Linux and Mac OS systems. Moreover it has been performed some improvements to work easily with the tool and also to display some specific aspects of the error recovery process that cannot be treated by VASTapi.

A. Visualization of the ST

The graphical representation which has been chosen to visualize the ST is the tree structure resulting of the processing of the input stream. In previous versions of VAST, it can be distinguished three types of nodes: terminal nodes (T), non terminal nodes (NT) and error nodes (EN).

The T nodes are the leaves of the tree, the NT are the internal nodes of the ST and the EN represent the synchronization points in which the parser can recover from an syntactical error. The last one allows to determine the exact place where it is recovered (if possible) a syntactical error. Furthermore, they allow to guess the amount of recognized elements, so the elements recognized before an error occurs will be sons of the corresponding error node.

Due to the changes performed to improve the visualization of the error recovery in panic mode, it has been necessary to create an additional type of nodes, ignored nodes (IN). This kind of nodes has only sense when it is implemented a panic error recovery strategy. When the parser detects an error, it ignores the input stream until it finds a synchronization symbol. The function of the IN is to group the ignored symbols until a syntactical error is recovered. In the graphical representation they appear as sons of the EN, containing all the T ignored.

B. Reproduction of the construction of the ST

The animation of the construction process of the ST is performed using different intermeddle stages generated and ordered by VASTapi. The animation of this process helps the students to understand how the input stream is processed using shifts and reductions.

To reproduce an animation, VASTview has a VCR controls and a slide bar which allows to reach easily to a specific point of the reproduction. During the construction process the ST change its shape, area and content. Due to this behaviour the interface could adapt to each stage using a “best-fit” policy, which would change the location of the nodes of the tree and consequently affect the user. According to this, we have decided to keep the location of the nodes of the tree as the construction process of the ST is reproduced.

The reproduction process is synchronized with all the views offered in VAST, so that when the state of the ST changes all of the views have to act consequently.

In the Figure 16 it is shown an example of the reproduction process of the construction of the ST. In this case the parser is descendant, so as VAST constructs the ST the current node is remarked. In this figure we can see two intermeddle stages of the reproduction.

C. Different distributions

Probably the ST generated by the parsers designed by the students are huge and without any specific structure (symmetric, width and height). For this reason, VASTview has an user interface which make easier the visualization and interaction of the ST.

The interface of VASTview offers three different distributions: horizontal, vertical and float. The horizontal and vertical distributions are used for horizontal and vertical ST respectively. In the case that a ST cannot be classified in any of these types, VASTview offers the float distribution in which the user can change the position of the different views.

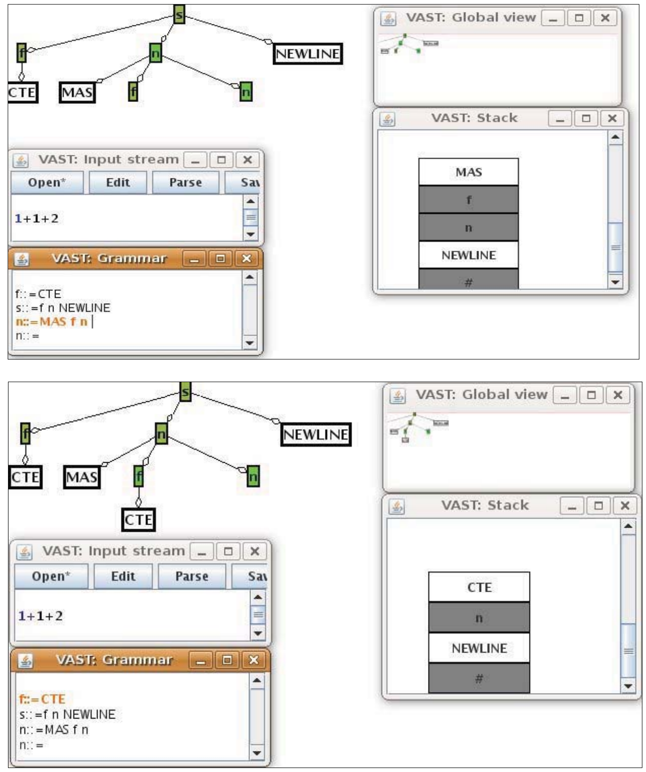

Figure 16. Reproduction of the construction process for LL parser

Independently of the distribution used, the interface of VASTview has a global and detail view of the ST, all together with the zoom and aggregation functionalities. The global and detail view allow the user to manipulate easily the ST. The global view indicates the visible part of the ST in the detail view. The functionalities of the global view give the students the opportunity of examining the ST with zoom, and aggregation, keeping always the synchronization with the global view.

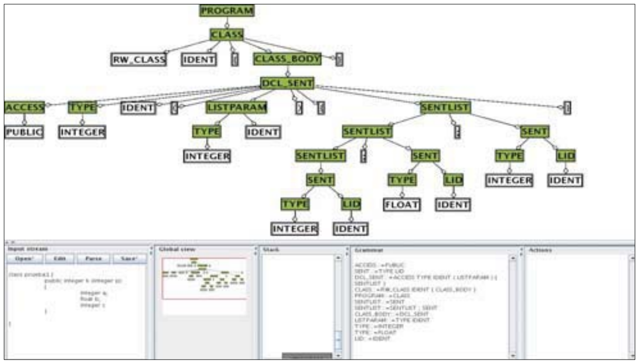
The aggregation allows the user to hide those parts of the ST which are not interesting. In this case, when a node is resumed, we used a “best-fit” policy to redistribute the ST.

In the Figure 17 it is shown the different distribution of the VAST interface. Figures 17a, 17b and 17c show the horizontal, vertical and float distribution of the user interface respectively.

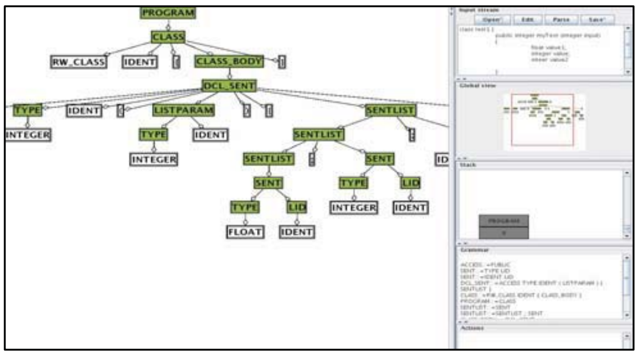
D. Views of the compilation process

Apart from displaying the ST, VASTview visualizes the input stream, the stack of the parser, the used grammar and textual explications of the performed actions. Each of these views have a different aim, however, all of them are really important when the construction process of the ST is animated.

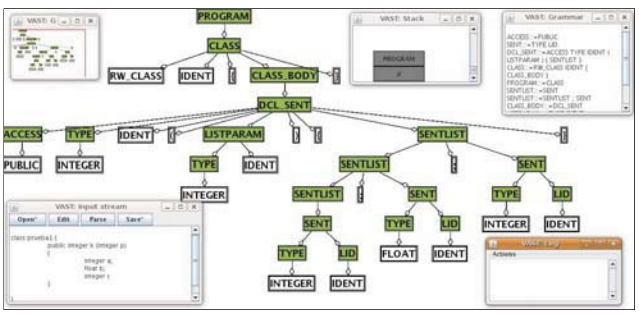
In case of the input stream, it is remarked when the construction process is reproduced. When in the parser is



(a)



(b)



(c)

Figure 17. VAST interface distributions

implemented a method of error recovery, the input stream can distinguishes between the process symbols and the ignore ones. Besides, when the ST is displayed in a static way, if a T node is selected, then in the input stream is remarked the part which corresponds with that node.

The stack view simulates the content of the stack of the parser. It is compatible with both LL/LR parsers and it is really important in the error recovery process, so it is possible to make predictions about the recovery point just observing the content of the stack and the grammar. This view allows to display a stack history, which allow the user to display the different stages of the stack during the analysis.

The visualization of the grammar allows to indicate which syntactical rule has been used in a reduction/derivation. In this case it is necessary to distinguish between the grammar of the specification and the grammar used. The grammar of the specification refers to the set of rules that implements a parser. However, the grammar used is a subset of the previous one, so it is the part of the specification grammar used to process a specific input stream. According to the way of work of VASTapi, it is easier to get the used grammar. So that, when it is displayed the set of rules, it is important to have into account that it refers to the used grammar.

The textual explication was a characteristic asked by the students during the evaluation sessions of VAST. In this case, it has been added the explications of the actions performed during the construction of the ST, including the error recovery process.

Finally, it has been improved the way of showing the views of the VASTview. In this version is possible to hide or change the workspace of each different view. This solution has been necessary to work with low resolution screens.

E. *Importing parsers*

According to the results of the usability evaluation of VAST [5], it was necessary to implement a global integration which consists of two functionality integrations.

The first integration allows to anote a syntactical specification, generate and compile it. The second one allows to execute a parser and visualize the result of this execution.

As result of the implementation of VAST, it has been developed a first approximation of the importation of parsers. In the case of the second integration it has been developed in a generic way. However, the first integration has been implemented just for the ANTLR specification. This limitation does not involve VAST, but the necessity of creating metaparsers which can annote automatically the specification including the VASTapi calls.

VI. CONCLUSIONS

In this work, we has presented the educational tool VAST, which allows to visualize the ST and the different views of the compiling process. The main characteristics of VAST are the independence from the generation tool and the easy of use.

Specifically, within the visualization of the ST, we have studied the existing tools and realized that the existing tools to display the compilation process, give a partial or/and particular solution. On one hand, these tools are particular because they only allow to display the parser created for a concrete generation tool. On the other hand, they give a partial solution because they do not show all the views of the compilation process.

In this context when we focus on the syntax error recovery visualization, we observe that none of these tools give a solution for it. We has found only one tool, ANTLRworks, which give an approximation of the syntax error recovery visualization. However, as in the other cases, the solution implemented is particular and partial. Taking into account that SER is one of the most difficult points in the language processor courses, and the pedagogical effect that visualizations have in education, we have decided to use the visualizations technologies to improve the comprehension process of the syntax error recovery.

We have added new functionalities to VAST, in order to display the syntax error recovery. We have detailed the different characteristics of each error recovery strategy. Afterwards, we have explained how they are implemented in VAST. As a result VAST allows the visualization of the insertion error recovery, error productions and panic mode error recovery.

Furthermore, in this work we include the functionality of importing parsers specifications. This one allows to display any parser in a very easy way.

The work with VAST has not finished yet. As future works we plan different evaluations of the new functionalities. Moreover, we will work on the exporting of animations to be used in different contexts (e.g Powerpoint). Finally, it will be necessary to improve the importation of parsers, so this version allows only to import automatically ANTLR specifications.

Abstract—**Tokyo Institute of Technology has been active in academic collaboration with Asian countries, and we opened our overseas offices in Bangkok, Manila, and Beijing, in 2002, 2005, and 2006, respectively. International distance education has also been conducted since 2002. Backed up with those experiences, in 2007 we started a new graduate program allied with National Science and Technology Development Agency (NSTDA) and Thai universities. The program is called Thailand Advance Institute of Science and Technology (TAIST) - Tokyo Tech. TAIST will serve as a virtual institution and focal point. NSTDA provides researchers to act as adjunct professors, research projects and scholarships for graduate students. Thai universities provide an academic framework, academic staff to oversee and guide students and degrees for the successful candidates. Currently two master programs are running; Automotive Engineering (AE) and Information and Communication Technology for Embedded Systems (ICTES). Tokyo Tech is responsible for most of its coursework. To get rid of long travel between Tokyo and Bangkok (separated by 4,600km), distance education is effectively utilized. In the ICTES program, 7 lecture courses out of 18 are entirely taught from Tokyo, and some others combine distance education. All the course materials are uploaded on the e-learning site, where lecture videos are also available for some courses. TAIST-Tokyo Tech is expected to initiate the start of a positive spiral of human resource development system in Asian region. TAIST-Tokyo Tech aims to harmonize advanced technology with the environment and to realize research and human resource development for global sustainable development. Operations of this graduate program and distance education activities are introduced.**

Keywords- Allied graduate school; distance education; international collaboration

I. INTRODUCTION

Information and communication technology can suitably be used to overcome not only physical distance but also mental distance between learners and teachers as well as among learners. Tokyo Institute of Technology (Tokyo Tech) installed Academic Network for Distance Education by Satellite (ANDES) system in 1996, and utilized it for various kinds of distance education programs; university - high school collaboration, lecture exchange with Hitotsubashi University, lecture distribution to workplace engineers, and international distance education. In some parts on the globe, internet is not yet developed well, and satellite communication is important. On the other hand, in many other places (especially in big cities) broad-band internet connection is well established and even high-definition video communication is possible. Internet environment is considered to gradually develop and distance education will become easier to conduct from the viewpoint of communication channel.

II. TOKYO INSTITUTE OF TECHNOLOGY

Tokyo Tech is ranked No. 55 in the Times Higher Education-QS World University Rankings 2009 (No. 19 in engineering and information technology).

Among about 10,000 graduate and undergraduate students, there are 1,100 foreign students. This ratio of foreign students is one of the highest in Japanese universities.

Tokyo Tech started International Graduate Program in 1993, in which students can take entrance examinations and lectures in English. Students are enrolled in October, unlike regular enrollment in April. Currently, a choice of seven curricular programs in which students can obtain a master's or doctoral degrees in English is provided in the International Graduate Program. More than 100 courses are currently taught in English. The program now makes it possible for qualified students with little or no knowledge of Japanese language to pursue a full degree-course of advanced study in this country. The provision of such a program not only eliminates the previous language requirement but also, thereby, significantly shortens the period of study. It can thus be said that the program provides qualified overseas students with another option for admission to graduate schools. Since lectures and seminars are given in English, it is no longer essential to master the Japanese language. However, since Japanese is the language of daily life, students in the program are encouraged to attend a few Japanese classes per week on a regular basis for further enrichment.

Tokyo Tech Open Course Ware (Tokyo Tech OCW) [1] is a platform maintained by Tokyo Tech for providing free access to course materials for users around the world aiming at releasing the Tokyo Tech's high-level educational resources on science and technology as the world's public property. Tokyo Tech OCW is one of the core material of the web-based electronic knowledge system. Starting in May 2005, Tokyo Tech OCW covers all of 1,910 undergraduate and 1,581 graduate courses, for which course outlines are shown. Lecture materials are shown for more than 551 courses at this moment, and we will cover almost all the courses in the future. This number of 551 courses is more than half of the total lecture materials released by Japanese OCW Consortium consisting of major Japanese universities in cooperation with Massachusetts Institute of Technology. Tokyo Tech OCW pages get more than 6,000 hits per day, which is about 20% of the whole accesses to Tokyo Tech web pages.

III. DISTANCE EDUCATION AT TOKYO TECH

The Center for Research and Development of Educational Technology (CRADLE), established in 1973, set up the ANDES system in 1996, for the use in lecture deliveries via commercial communication satellite. The ANDES system has been used for lecture exchange with Hitotsubashi University, famous national university in social science, open lecture delivery to workplace engineers, and high-School university collaboration in which undergraduate lecture courses are transmitted to high-school students all over in Japan who are interested in science and technology. Since 2002 some of the courses taught in English in the International Graduate Program are transmitted to Thailand using ANDES system [2]. We use 3Mbps or 6Mbps MPEG2-DVB for video transmission. The lectures were received by NSTDA, Asian Institute of Technology (AIT), and King Mongkut's Institute of Technology Ladkrabang (KMITL). The courses to be transmitted are chosen by the request from the Thai side and willingness of lecturers. All the courses had been taught in English and not much load is added to the lecturers. Lecturers are requested to put their lecture notes on the Tokyo Tech OCW (or send them to the students) in advance of the lecture. Since 2006 we use a Japan-Thai land link of Japan Gigabit Network 2 (JGN2, and it is JGN2plus since 2008), an open testbed network environment for research and development, which is operated by National Institute of Information and Communications Technology (NICT) [3]. JGN2 is an ultra-high-speed testbed networks for research and development collaboration among industry, academia, and the government with the aim of promoting a broad spectrum of research and development projects, ranging from fundamental core research and development to advanced experimental testing, in areas including the advancement of network-related technologies for the next generation and diverse range of network application technologies. We mainly use H.323 audio-visual communication sessions with about 500 kbps, but we are testing the use of high-definition (1920x1080) video transmission [4].

To manage the international distance education and research collaboration, Tokyo Tech Office (Thailand) was established in 2002 in the NSTDA building in the Thailand Science Park (TSP). In 2005 Tokyo Tech Office (Philippines) opened at De La Salle University, Manila, and Tokyo Tech Office (China) opened at Tsinghua University in Beijing in 2006. Those offices act as communication hubs for people in those areas. Through these offices remote students are taken care of. The Offices also handle research partnerships and information about studying at Tokyo Tech, and offer guidance for academic-industrial collaboration.

IV. TAIST TOKYO TECH

Based on those experiences and MOU with NSTDA, we established a new graduate program named TAIST. TAIST is based on the idea of collaboration among Tokyo Tech, NSTDA and partner universities to develop the human resources. TAIST will serve as a virtual institution and focal point. NSTDA provides researchers to act as adjunct professors, research projects and scholarships for graduate students. Tokyo Tech provides world class background, expertise and experience, academic instruction and research advice. Thai universities provide academic frame work, academic staff to oversee and guide students, and degrees for the successful candidates. The viability of the idea is nicely demonstrated by the creation of TAIST Tokyo Tech.

The main objective of TAIST Tokyo Tech is to establish an institution for human resource development to foster and support world-class researchers and high-level engineers through a combination of advising from Tokyo Tech professors, excellent facilities and research staff in NSTDA, and established resources of Thai universities. The participating Thai universities are KMITL, Sirindhorn International Institute of Technology (SIIT), Kasetsart University (KU), and King Mongkut’s University of Technology Thonburi (KMUTT).

NSTDA is an agency under the Ministry of Science and Technology and supports research in science and technology and their application in Thai economy. It promotes innovation and research activities in Thailand. Its mission is research and development to strengthen Thailand's sustainable competitiveness, complemented by technology transfer and the development of human resources and science and technology infrastructure, with outcomes that have positive impacts on society and the economy. It is affiliated by 4 research centers;

- National Center for Genetic Engineering and Biotechnology (BIOTEC)
- National Metal and Materials Technology Center (MTEC)
- National Nanotechnology Center (NANOTEC)
- National Electronics and Computer Technology Center (NECTEC)

NSTDA and those 4 research centers are located in the TSP about 40km north of central Bangkok. The TSP is the country's leading integrated R&D hub which came into operation in 2002. The TSP is also located close to three of Thailand's leading universities; AIT, SIIT, and Thammasat University. Tokyo Tech Office (Thailand) is a tenant of TSP.

NSTDA prepares TAIST classrooms in the TSP with distance education equipment and internet infrastructure. It also lends a notebook PC to each of TAIST students.

.

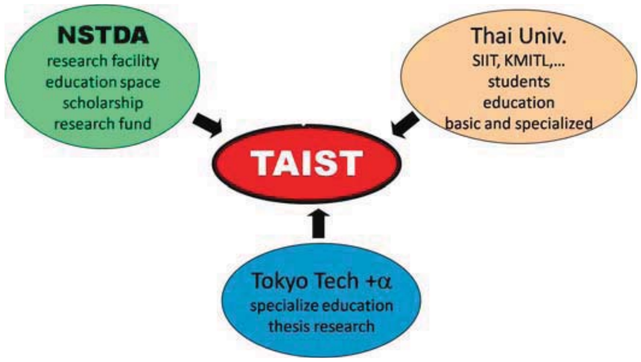

Figure 1. Concept of TAIST Tokyo Tech

The TAIST Tokyo Tech project aim to attain world top level performance by mobilization of whole institutional resources based on long history of education and research of participating institutions. Tokyo Tech and TAIST Tokyo Tech share the same philosophy of education and research - "human resource development by promoting cutting-edge research activities".

It is expected that TAIST Tokyo Tech will initiate the start of a positive spiral of human resource development system in Asian region. TAIST Tokyo Tech aims to harmonize advanced technology with the environment and to realize research and human resource development for global sustainable development. Looking back at the history of modernization through industrial development, factors such as global warming, unusual weather and the pollution of air, water and soil indicate that there is a real risk of serious destruction of nature and life in the near future. It is urgent for us to recognize this paradigm shift in science and technology and concentrate our effort and intelligence on technologies which are in harmony with the environment. In Thailand, development and industrialization have been so drastic, compared with developed countries, that problems derived from these factors are much more serious as they become obvious. In light of such a situation, expanding research and education to harmonize advanced technology with the environment effectively and efficiently will be quite necessary and the outcome of such effort will be valuable for Thailand, as well as other countries of the world.

All first year students receive full scholarships for tuitions and fees. In the second year, researches for dissertations will be carried out mainly in NSTDA various laboratories with NSTDA researchers acting as supervisors or co- supervisors. The second year students are expected to receive scholarships for tuitions and fees from research projects of their supervisors. Professors from Tokyo Tech will actively participate in the educational process of the students throughout each program. After a successful completion of both course work and thesis, the students receive degrees from the host universities and certificates from Tokyo Tech. These programs are:

1. Master's Degree Program in Automotive Engineering. The program started accepting the first group of students in the Academic Year 2007. The host universities are KMITL and KMUTT, and the host institute at NSTDA is MTEC.

2. Master's Degree Program in Information and Communication Technology for Embedded Systems (ICTES). The program started accepting students in the Academic Year 2008. The host universities are SIIT and KU, and the host institute at NSTDA is NECTEC.

3. Master's Degree Program in Environmental Engineering. The program is expected to start in the Academic Year 2010.

4. Master's Degree Program in Biotechnology is now under discussion for its start.

Each program accepts 30 students every year. TAIST students are not restricted to Thais. In fact there are students from neighboring countries in AE program, and we hope more students will come to TAIST programs from various countries.

V. TAIST ICTES PROGRAM
