CD-ROM Edition - IEEE Catalog Number: CFP10EDU-CDR - ISBN: 978-1-4244-6569-9
USB Edition - IEEE Catalog Number: CFP10EDU-USB - ISBN: 978-1-4244-6570-5

CONTENTS

WELCOME FROM IEEE EDUCON 2010 CHAIRS

It is well documented that our modern society is characterized by rapid developing and ever-changing political, social, economical, technological and environmental situations. Consequently, our society of the 21st century makes great demands on its members in virtually every aspect of their lives. Members of the society must now keep pace with these mutable situations, adapt their skills and expertise with agility, collaborate, and compete to provide value to society. Technology subjects and the engineering domain are, in particular, affected by this situation.

As a result of this, educational approaches have changed over the last century from remedial repetitive learning to today's learning, which focuses on acquiring an understanding of how to become more independent in the learning process. Learning is no longer concentrated mainly in the first stages of human life through formal education and specific training in business, but it becomes a day-by-day routine over a human's life cycle. This situation requires new forms and channels in the learning process. Additionally, modern learning approaches must account for social and cultural aspects as well as the individual's profile including task and role-based aspects, interests, knowledge state, short-term learning objectives and long-term career goals. Thus processing and acquiring knowledge is a key to a modern learning pedagogy, but also content creation, collaboration and community-based practice for knowledge and skills development are important success factors.

IEEE Education Society partnership with the IEEE Region 8, is beginning a new global engineering education conference, IEEE EDUCON, held each year in selected cities throughout Europe, the Middle East, and Africa. The conference provides an interdisciplinary forum for academic, government and industrial collaboration on teaching methods, practical experiences and research toward improving the future of global engineering education. The IEEE EDUCON conference will attract participants from all over the world and will provide an interdisciplinary forum for academic, research and industrial collaboration on teaching methods, practical experiences and research towards the future of global Engineering Education.

The conference will cover papers in the categories of: research, development, evaluation and best practices that deal with learning Engineering Education in academic, organizational, and life-long learning settings including, but not limited to the following areas and their associated topics:

- Area 1: Infrastructure and Technologies for Engineering Education
- Area 2: Innovative Materials, Teaching and Learning Experiences in Engineering Education
- Area 3: Knowledge and Competencies in Engineering
- Area 4: Educational Methods and Learning Mechanisms in Engineering Education
- Area 5: Attracting, Engaging and Retaining Human Talent to Engineering

Manuel Castro (Spanish University for Distance Education, Spain), Edmundo Tovar (Technical University of Madrid, Spain) and Michael E. Auer (Carinthia Tech Institute Villach, Austria)
EDUCON 2010 Conference Chairs

IEEE EDUCON 2010 CONFERENCE PROGRAM

Wednesday, April 14th, 2010 – Madrid
CONFERENCE VENUE: UNED. Faculty of Humanities and Faculty of Sciences
Location: Campus "Senda del Rey", close to "Puente de los Franceses"

9:00 - 9:30 - EDUCON 2010 Opening Ceremony

9:30 – 10:30 - Keynote Speaker Session – Susan Lord - IEEE Education Society: Global Leader in Engineering Education

11:00 - 12:00 - Session: 01A Area 4: Learning Models - Competency and Teaching methodologies

Session: 01B Area 3: Specific Engineering Disciplines - Researches

Session: 01C Area 1: Collaborative and Social Technologies - Social Computing

Session: 01D Area 1: Computer and Web based Software - Web based services

Session: 01E Area 1: Computer Supported Collaborative Learning - For use in projects

Session: 01F Area 1: Intelligent Learning Systems

Session: 01G Area 3: First Year Courses and Programs

12:15 - 13:15 - Session: 02A Area 3: Skills Development: Technical Writing, Presentation, Teamwork

Session: 02B Area 3: Knowledge and Competencies Management - Competencies

Session: 02C Area 2: Innovative Engineering Courses and Labs - Laboratories

Session: 02D Area 2: Laboratory Experiences: on-site and remote environments - Remote Labs

Session: 02E Area 5: Lifelong Learning and Nontraditional Students - Theories and Courses

Session: 02F Area 4: Pedagogies

Session: 02G Area 1: Learning Objects reusability and digital repositories

14:30 - 15:30 - Session: 03A Area 2: Innovative Competitions and Laboratories - Detectors and robotics

Session: 03B Area 2: E-Assessment

Session: 03C Area 4: Rethinking Pedagogy in Engineering Education Multidisciplinary issues

Session: 03D Area 1: Computer and Web based Software – Physics Applications

Session: 03E Area 1: Wireless, Mobile and Ubiquitous Technologies for Learning

Session: 03F Area 1: Open Source, Open Standards, and Federated Systems

Session: 03G Area 3: New Frameworks for Engineering Education

15:45 - 16:45 - Session: 04A Area 4: Learning Models - Learning tools

Session: 04B Area 4: Active Learning - Project based learning

Session: 04C Area 2: Virtual Worlds for Academic, Organizational, LifeLong Learning and training - Virtual environs

Session: 04D Area 4: e-Assessment and new Assessment Theories and Methodologies - Methods

Session: 04E Area 1: Computer Supported Collaborative Learning - Proposals and Methodologies

Session: 04F Area 3: Degree Programs and Curricula

Session: 04G Area 5: Gender Issues in Engineering Education

17:00 - 18:30 - Session: 05A Area 1: Learning Systems Platforms and Architectures - Platforms and Learning Tools

Session: 05B Area 3: General Issues in Engineering Education - Improving students performance

Session: 05C Area 2: Innovative Engineering Courses and Labs - Courses

Session: 05D Area 1: Computer and Web based Software - Programming

Session: 05E Universia Special Session: International Engineering Cooperation

Session: 05F LiLa Special Session: Library of Labs - LILA Project

Session: 05G e-Madrid Special Session- eMadrid: Research and Development of e-Learning Technologies in the Madrid Region

Thursday, April 15th, 2010 – Avila
CONFERENCE VENUE: Avila's Conference Center (Centro de Congresos y Exposiciones Lienzo Norte de Ávila)
Location: Avenida de Madrid, 102 - 05001 Ávila

9:30 - 10:30 - Session: 06A Area 1: Uses of Technology in the Classroom – Engineering Applications

Session: 06B Area 3: Specific Engineer ing Disciplines - Prac tical pro jects in Engineering

Session: 06C Area 1: Collaborative and Social Technologies Experiences

Session: 06D ICOPER Special Sessi on: Assessing Assessm ent For mats - ICOPER Network

11:00 - 12:00 - Session: 07A Area 2: Inn ovative Competition s and Labora tories - Dig ital, Communication and analytic issues

Session: 07B Area 3: Knowledge and Competencies Management - Knowledge

Session: 07C Area 4: Rethinking Pedagogy in Engineering Education - Project based learning and research

Session: 07D Area 2: Laboratory Experiences: on-site and remote environments - On-line Labs

Session: 07E Area 5: Attracting and Retaining practices in Enginee ring Education

12:15 - 13:15 - Session: 08A Area 1: Learning Systems Platforms and Architectures – Virtual and Remote Labs

Session: 08B Area 4: Active Learning - Methodologies and analytic studies

Session: 08C Area 2: Design Experiences - Subject methodologies in design

Session: 08D Area 3: General Issues in Engineering Education – Innovative Experiences

13:45 - 14:30 - Keynote Speaker Session – Patricia Manson - Learning in the 21st century: Technology-Enhaced Learning and European research

14:30 - 14:45 - EDUCON Awards Ceremony

IEEE EDUCON 2010 Meritorious Service Award - Dr. Russel Meier

IEEE Education Society Chapter Achievement Award 2009 - Portugal Chapter - Jose Salvado, Jose Carlos Metrolho, Co-Chairs

Friday, April 16th, 2010 – Madrid
CONFERENCE VENUE: UPM. School of Forestry Engineering and UPM's Central Headquarters
Location: Campus of "Ciudad Universitaria"

9:30 - 10:30 - Session: 09A Area 1: Uses of Technology in the Classroom - Learning Experiences

Session: 09B Area 4: Active Learning - Collaborative learning

Session: 09C Area 1: Collaborative and Social Technologies - Collaborative and projects works

Session: 09D Area 4: e-Assessm ent and new Assessm ent Theories and Methodologies - Theories

Session: 09E OCW-Universia Special Session : OCW and Open Educational Resources

Session: 09F VISIR Special Session: W orkshop on VISIR electrical and electronic remote lab: Principles and educational view

11:00 - 12:00 - Session: 10A Area 1: Adaptive and Personalized Technology-Enhanced Learning

Session: 10B Area 3: S pecific En gineering Disciplines - Proffesional Developments

Session: 10C Area 2: Virtual W orlds for Academ ic, Organizational, L ifelong Learning and training - Virtual media and tools

Session: 10D Telefónica Special Session: T elefonica University Chairs Network

Session: 10E Area 5: Lifelong Learning and Nontraditional Students - Practical experiences

Session: 10F VISIR Special Session: Practical Workshop on VISIR electric and electronic remote labs

12:15 - 13:15 - Session: 11A Area 4: Learning Models - Methods

Session: 11B Area 3: General Issues in Engin eering Education - Theories and studies about learning layouts

Session: 11C Area 2: Design Experiences - Tools and procedures

Session: 11D Area 1: Computer and Web Software - Security and Data Bases

Session: 11E ANECA S pecial Session: New Directions in Engineering Accreditation, Quality and Course Design

Session: 11F Area 2: Laboratory Experiences: on-site and remote environments - Didactics for experimentation

13:15 – 13:45 - Keynote Speaker Session – Javier Uceda - Innovation in Engineering Education

14:30 – 15:00 - Educon Closing Ceremony and Awards

IEEE EDUCON 2010 ORGANIZERS

Manuel Castro - IEEE Fellow, IEEE Education Society AdCom

IEEE EDUCON 2010 Areas and Topics

Areas

- **Area 1:** Infrastructure and Technologies for Engineering Education
- **Area 2:** Innovative Materials, Teaching and Learning Experiences in Engineering Education
- **Area 3:** Knowledge and Competencies in Engineering
- **Area 4:** Educational Methods and Learning Mechanism s in Engineering Education
- **Area 5:** Attracting, Engaging and Retaining Human Talent to Engineering

Area 1: Infrastructure and Technologies for Engineering Education

- Learning Systems Platforms and Architectures
- Adaptive and Personalized Technology-Enhanced Learning
- Intelligent Learning Systems
- Computer Supported Collaborative Learning
- Open Source, Open Standards, and Federated Systems
- Standardization, Reusability and Interoperability Issues
- Learning Objects reusability and digital repositories
- Experiences in OpenCourseWare Engineering Education
- Computer and Web based Software
- Uses of Technology in the Classroom
- Semantic Web and Ontologies for Learning Systems
- Web 2.0 and Social Computing for Learning and Knowledge Sharing
- Data Mining and Web Mining in Education
- Collaborative and Social Technologies
- Synchronous and Asynchronous Technologies
- Wireless, Mobile and Ubiquitous Technologies for Learning
- Ambient Intelligence and Smart Environments for Learning
- Standardization, Reusability and Interoperability Issues

Area 2: Innovative Materials, Teaching and Learning Experiences in Engineering Education

- Laboratory Experiences: on-site and remote environments
- Undergraduate Research Experiences
- Design Experiences
- Innovative Engineering Courses and Labs
- Digital Game and Intelligent Toy Enhanced Learning
- Affective and Pervasive Computing for Learning
- Human-Centered Web Science and its Applications to Technology-enhanced Learning
- E-Assessment
- Virtual Worlds for Academic, Organizational, Life-long Learning and training
- Innovative Competitions and Laboratories

Area 3: Knowledge and Competencies in Engineering

- Knowledge and Competencies Management
- Accreditation Issues
- Assessment and Feedback
- Degree Programs and Curricula
- First Year Courses and Programs
- General Issues in Engineering Education
- Specific Engineering Disciplines
- Faculty Development
- Globalization: Preparing Faculty and Students
- Graduate Curricula and Programs
- New Frameworks for Engineering Education
- Skills Development: Technical Writing, Presentation, Teamwork

Area 4: Educational Methods and Learning Mechanisms in Engineering Education

- Rethinking Pedagogy in Engineering Education
- e-Assessment and new Assessment Theories and Methodologies
- Active Learning
- Learning Models
- Pedagogies

Area 5: Attracting, Engaging and Retaining Human Talent to Engineering

- Lifelong Learning and Nontraditional Students
- E-learning in the Workplace
- K-12 Initiatives and Partnerships
- Study Abroad Programs
- Attracting and Retaining practices in Engineering Education
- Technology Enhanced Learning for students with special needs
- Accessibility in On-Line and Technology Enhanced Learning
- Gender Issues in Engineering Education
- Cultural Issues in Engineering Education
- Attracting Women to the Engineering Profession

IEEE EDUCON 2010 COMMITTEES

IEEE EDUCON Honor Committee

President:	Royal Highness the Prince of Asturias, Felipe de Borbon y Grecia
Esperanza Aguirre	Madrid Autonomous Community President
Ángel Gabilondo	Spain Education Ministry
Celestino Corbacho	Spain Labor and Immigration Ministry
Cristina Garmendia	Spain Science and Innovation Ministry
Alberto Ruiz-Gallardón	Madrid City Mayor
Juan A. Gimeno	Spanish University for Distance Education (UNED) Rector
Javier Uceda	Universidad Politécnica de Madrid (UPM) Rector
Thomas Klinger	Systems Engineering Faculty Dean, Carinthia University of Applied Sciences
Pedro Ray	IEEE President 2010
Susan Lord	IEEE Education Society President
Jozef Modelski	IEEE Region 8 Director
Manuel Sierra	IEEE Spanish Section Chair
Zulima Fernández	ANECA (Agencia Nacional de la Evaluación de la Calidad y Acreditación) Director
Richard Straub	European Society eLIG (European Learning Industry Group) General Secretary
José I. Ustarán,	Spanish Society APEL (Asociación de Proveedores de e-Learning) President

IEEE EDUCON Steering Committee

Michael Auer	Chair, Senior Member IEEE, President and CEO IAOE Carinthia Tech Institute - Villach, Austria
Rachida Ajhoun	IEEE, ENSIAS MohammedV-Souissi University - Rabat, Morocco
A.Y. Al-Zoubi	IEEE, Princess Sumaya University for Technology - Amman, Jordan
Manuel Castro	IEEE Fellow, IEEE Education Society AdCom, Spanish University for Distance Education (UNED) - Madrid, Spain
Mohamed Jemni	IEEE, University of Tunis - Tunisia
Russ Meier	IEEE Education Society Meetings Committee Chair, Milwaukee School of Engineering - USA
Rob Reilly	Senior Member IEEE, Secretary IEEE Education Society, MIT Media Lab - USA
Marian Kazmierkowski	IEEE Region 8 Conference Coordinator, Warsaw University of Technology - Poland
Edmundo Tovar	Senior Member IEEE, IEEE Education Society AdCom, Universidad Politécnica de Madrid (UPM)- Spain

IEEE EDUCON International Advisory Board

Rob Reilly, Chair,	Secretary IEEE Education Society, MIT Media Lab, USA

Chairs

Technical Program Chair:
Manuel Caeiro, Universidade de Vigo, Spain
Special Sessions and Panels Chair:
Andreas Pester, Carinthia Tech Institute, Villach, Austria
Peer Reviewing Chair:
Juan Manuel Santos, Universidade de Vigo, Spain
Publications Chair:
Jose Carpio, UNED, Spain
Workshops Chair:
Francisco Azcondo, University of Cantabria, Spain
Exhibits Chair:
Baltasar Fernandez-Manjon, Complutense University of Madrid, Spain
Web and Electronic Media Chair:
Sebastian Schreiter, IAOE (International Association of Online Engineering, France
New Faculty Fellows Chair:
Claudio Brito da Rocha, Council of Researchers in Education and Sciences, Brazil
Awards Chair:
Carlos Vaz de Carvalho, ISEP, Portugal
Publicity and Dissemination Chair:
Raquel Portaencasa, UPM, Madrid, Spain
Special Activities Chair: Jaime
Sanchez, University of Chile, Chile
Other Related Societies Chair:
José Salvado, Instituto Politecnico de Castelo Branco, Portugal
Region 8 - Europe - Chair:
Arnold Pears, Uppsala University, Sweden
Region 8 - Middle East - Chair:
Amr Ibrahim, American University-Cairo, Egypt
Region 8 - Africa - Chair:
Mona Laroussi, Centre Urbain Tunis, Tunisia
International - North America - Chair:
Dan Moore, Rose-Hulman Institute of Technology, USA

International - South America - Chair:

Rosa M. Vicari, UFGRS, Brazil

International - Asia - Chair:

Diane Salter, University of Hong Kong, China

International - Australia - Chair:

Vanessa Chang, Curtin University of Technology, Australia

EDUCON CONFERENCES AND THE FUTURE

The Engineering Education Conference (EDUCON) will provide an interdisciplinary forum for academic, research and industrial collaboration on teaching methods, practical experiences and research towards the future of global Engineering Education attracting 200+ participants from all over the world. Participants will include university presidents, college deans, department chairpersons, faculty in engineering and engineering technology, and industry leaders from throughout the IEEE Region 8 (Europe, Middle East and Africa) and the world.

IEEE EDUCON conferences are organiced from the IEEE Education Society in collaboration with academic and professional entities of IEEE Region 8 (Europe, Middle East and Africa). For this reason the conference is expected to yearly move around IEEE Region 8 (2010 in Europe, 2011 in Middle East and 2012 in Africa, beginning again in 2013 in Europe).

IEEE EDUCON 2011

Amman, Jordan
IEEE EDUCON 2011 will be organized by Princess Sumaya University of Technology.
Chairs: Abdullah Y. Al-Zoubi, Michael Auer and Edmundo Tovar

IEEE EDUCON 2012

Africa

TOPICS AND SESSION CODES IN EDUCON 2010

The papers presented in EDUCON 2010 Conferen ce, have been organized in the following development areas and topics, mainly based in technical and educational resources. Every session has been addressed by a wide knowledge and extense experience chair.

Session	Topic and Area
01A	Area 4: Learning Models - Competency and Teaching methodologies
01B	Area 3: Specific Engineering Disciplines - Researches
01C	Area 1: Collaborative and Social Technologies - Social Computing
01D	Area 1: Computer and Web based Software - Web based services
01E	Area 1: Computer Supported Collaborative Learning - For use in projects
01F	Area 1: Intelligent Learning Systems
01G	Area 3: First Year Courses and Programs
02A	Area 3: Skills Development: Technical Writing, Presentation, Teamwork
02B	Area 3: Knowledge and Competencies Management - Competencies
02C	Area 2: Innovative Engineering Courses and Labs - Laboratories
02D	Area 2: Laboratory Experiences: on-site and remote environments - Remote Labs
02E	Area 5: Lifelong Learning and Nontraditional Students - Theories and Courses
02F	Area 4: Pedagogies
02G	Area 1: Learning Objects reusability and digital repositories
03A	Area 2: Innovative Competitions and Laboratories - Detectors and robotics
03B	Area 2: E-Assessment
03C	Area 4: Rethinking Pedagogy in Engineering Education - Multidisciplinary issues
03D	Area 1: Computer and Web based Software - Physics Applications
03E	Area 1: Wireless, Mobile and Ubiquitous Technologies for Learning
03F	Area 1: Open Source, Open Standards, and Federated Systems
03G	Area 3: New Frameworks for Engineering Education
04A	Area 4: Learning Models - Learning tools
04B	Area 4: Active Learning - Project based learning

Session	Topic and Area
04C	Area 2: Virtual Worlds for Academic, Organizational, Life-long Learning and training - Virtual Environs
04D	Area 4: e-Assessment and new Assessment Theories and Methodologies - Methods
04E	Area 1: Computer Supported Collaborative Learning - Proposals and Methodologies
04F	Area 3: Degree Programs and Curricula
04G	Area 5: Gender Issues in Engineering Education
05A	Area 1: Learning Systems Platforms and Architectures - Platforms and Learning Tools
05B	Area 3: General Issues in Engineering Education - Improving students performance
05C	Area 2: Innovative Engineering Courses and Labs - Courses
05D	Area 1: Computer and Web based Software - Programming
05E	Universia Special Session: International Engineering Cooperation
05F	LiLa Special Session: Library of Labs - LILA Project
05G	e-Madrid Special Session- eMadrid: Research and Development of e-Learning Technologies in the Madrid Region
06A	Area 1: Uses of Technology in the Classroom - Engineering Applications
06B	Area 3: Specific Engineering Disciplines - Practical projects in Engineering
06C	Area 1: Collaborative and Social Technologies - Experiences
06D	ICOPER Special Session: Assessing Assessment Formats - ICOPER Network
07A	Area 2: Innovative Competitions and Laboratories - Digital, Communication and analytic issues
07B	Area 3: Knowledge and Competencies Management - Knowledge
07C	Area 4: Rethinking Pedagogy in Engineering Education - Project based learning and research
07D	Area 2: Laboratory Experiences: on-site and remote environments - On-line Labs
07E	Area 5: Attracting and Retaining practices in Engineering Education
08A	Area 1: Learning Systems Platforms and Architectures - Virtual and Remote Labs
08B	Area 4: Active Learning - Methodologies and analytic studies

Session	Topic and Area
08C	Area 2: Design Experiences - Subject methodologies in design
08D	Area 3: General Issues in Engineering Education - Innovative Experiences
09A	Area 1: Uses of Technology in the Classroom - Learning Experiences
09B	Area 4: Active Learning - Collaborative learning
09C	Area 1: Collaborative and Social Technologies - Collaborative and projects works
09D	Area 4: e-Assessment and new Assessment Theories and Methodologies - Theories
09E	OCW-Universia Special Session: OCW and Open Educational Resources
09F	VISIR Special Session: Workshop on VISIR electrical and electronic remote lab: Principles and educational view
10A	Area 1: Adaptive and Personalized Technology-Enhanced Learning
10B	Area 3: Specific Engineering Disciplines - Proffesional Developments
10C	Area 2: Virtual Worlds for Academic, Organizational, Life-long Learning and training - Virtual media and tools
10D	Telefónica Special Session: Telefonica University Chairs Network
10E	Area 5: Lifelong Learning and Nontraditional Students - Practical experiences
10F	VISIR Special Session : VISIR Special Session: Practical Workshop on VISIR electric and electronic remote labs
11A	Area 4: Learning Models - Methods
11B	Area 3: General Issues in Engineering Education - Theories and studies about learning layouts
11C	Area 2: Design Experiences - Tools and procedures
11D	Area 1: Computer and Web based Software - Security and Data Bases
11E	ANECA Special Session: New Directions in Engineering Accreditation, Quality and Course Design
11F	Area 2: Laboratory Experiences: on-site and remote environments - Didactics for experimentation

KEYNOTES SPEAKERS

Susan M. Lord – Professor and Coordinator of Electrical Engineering, University of San Diego, San Diego, CA, U.S.A. President of the IEEE Education Society

Susan M. Lord received a B. S. with distinction in Electrical Engineering and Materials Science and Engineering from Cornell University and the M.S. and Ph.D. in Electrical Engineering from Stanford University. Author of over seventy publications, her teaching and research interests include electronics, optoelectronic materials and devices, service-learning, feminist pedagogy, lifelong learning, and engineering student persistence. From 1993-1997, Dr. Lord taught at Bucknell University. She is currently Professor and Coordinator of Electrical Engineering at University of San Diego (USD). Her research has been supported by several National Science Foundation (NSF) grants from various programs including a CAREER grant, instrumentation and laboratory improvement (ILI) grants, scholarships for STEM (SSTEM), gender in science and engineering (GSE), and innovations in Engineering Education. She is the Guest Co-Editor of a special issue of the International Journal of Engineering Education on Applications of Engineering Education Research. Dr. Lord has worked at SPAWAR Systems Center, NASA Goddard Space Flight Center, AT&T, and General Motors. She is a member of the IEEE, ASEE, SWE, and Tau Beta Pi. She has served on the national administrative boards of the IEEE Education Society (EdSoc) and the ASEE Education and Research Methods (ERM) Division. Dr. Lord served as the General Co-Chair of the 2006 Frontiers in Education (FIE) Conference and has served on the FIE Steering Committee since 2006. Dr. Lord served as Vice President of EdSoc for 2007-2008 and President for 2009-2010.

IEEE Education Society: Global Leader in Engineering Education

The IEEE Education Society (EdSoc) is pleased to be a sponsor of EDUCON and technical co-sponsor of TAEE. EdSoc leaders view this conference as vital for carrying out the mission of our society and believe that EDUCON will be at the forefront of global Engineering Education in the future. In this talk, I will describe some of the history of the Education Society, its recent strategic planning process, and its hopes for the future. What is the Education Society? In April 2009, EdSoc leaders developed new vision and mission statements to introduce EdSoc to the world. The vision of EdSoc is “The IEEE Education Society strives to be the global leader in Engineering Education”. The mission is “The IEEE Education Society is an international organization that promotes, advances, and disseminates state-of-the-art scientific information and resources related to the Society’s field of interest and provides professional development opportunities for academic and industry professionals”. Currently, EdSoc has about 3000 members globally including 30% from IEEE’s Region 8 (Europe, the Middle East, and Africa) and 10% from Region 9 (Central and South America). Strengths of the Education Society include being globally engaged, recognized, and sought after to collaborate in educational innovation, generating quality publications and conferences, and dedicated leadership.

Patricia Manson – Head of Unit, Cultural Heritage and Technology Enhanced Learning in the Directorate General Information Society and Media of the European Commission.

Patricia Manson has worked at the European Commission since the early 90s on ICT applications areas in the Community's research programmes and for the past 4 years has been involved in defining the research agenda and subsequent workprogramme for technology enhanced learning research and for its implementation through the funded projects. Prior to joining the Commission she worked in the UK on a research-funded post providing technology and market watch, as well as information and advisory services to the cultural heritage community on the adoption of ICTs.

Learning in the 21st Century: Technology-Enhanced Learning and European Research

The presentation will explore the challenges facing learning in the 21st century and describe the role of European research in technology enhanced learning in this changing context. Experience has revealed the importance of giving equal weight to the technologies, to the learning and to the improvements in learning and this balance is at the core of technology-enhanced learning.

Javier Uceda – Professor of the Automatic Control, Electronic and Computer Engineering Department at Technical University of Madrid. Rector of Technical University of Madrid

Javier Uceda received the M.Sc. and Ph.D. degrees from the Universidad Politécnica de Madrid (UPM), Madrid, Spain, both in electrical engineering. Since 1986, he has been a Professor of electronics with UPM. He has published several books and more than two hundred and fifty papers in international journals and conferences and he holds several national and international patents. He has been a member of the Editorial Board of the European Power Electronics and Drives Journal. His research activity has been developed in the fields of Power Electronic and Digital Electronic Systems where he has participated in numerous national and international research projects. His main contributions are in the field of switched-mode power supplies and dc/dc power converters for telecom and aerospace applications. In the year 2000 he was appointed Vice-Rector for Research and Institutional Relations of the Technical University of Madrid, a post which he occupied until his election as Rector of the same University in March, 2004

Dr. Uceda is currently Fellow of the IEEE and a Senior AdCom member of the IEEE Industrial Electronics Society. He is a member of the Editorial Board of the European Power Electronics and Drives Journal and belongs to the Executive Council of the European Power Electronics and Drives Association where he is Vice-President. He has been Associated Editor of IEEE Transactions on Industrial Electronics. He was the Technical Program Committee Chairman of the IEEE Power Electronics Specialists Conference in 1992 and the General Chairman of the European Conference on Power Electronics and Applications in 1995. Prof. Uceda is also member of the Scientific Advisory Board of the Center for Power Electronics Systems (CPES), sponsored by the National Science Foundation in USA. Has received several individual and collective awards among which stands out the IEEE Third Millennium Medal.

Innovation in Engineering Education

Engineering is changing as a consequence of scientific and technological evolution and society needs and demands. Engineers need to understand the structure and behaviour of matter from nanoscale to extremely complex systems. Convergence of scientific and technological disciplines requires also an interdisciplinary approach in education. In this presentation some of the challenges and possible orientations in Engineering Education will be discussed.

IEEE EDUCON 2010 AWARDS

EDUCON Meritorious Service Award

EDUCON Meritorious Service Award will honor outstanding contri butions to the adm inistrative and management efforts for the IEEE EDUCON conference.

- Prize: Plaque and Certificate.
- Funding: Funded by the EDUCON Steering Committee.
- Eligibility: Must be a member of the IEEE Education Society.
- Basis for Judging: Dedication, effort and contributions.
- Presentation: During the Opening Ceremony of the annual IEEE EDUCON Conference.

History:

IEEE EDUCON 2010 – Dr. Russell D. Meier

Best Paper Awards

Best Paper Awards are appointed in the following categories:

- Infrastructure and Technologies for Engineering Education
- Innovative Materials, Teaching and Learning Experiences in Engineering Education
- Knowledge and Competencies in Engineering
- Educational Methods and Learning Mechanisms in Engineering Education
- Attracting, Engaging and Retaining Human Talent to Engineering

and furthermore:

- Best Student Paper
- Most Innovative Paper regarding Engineering Education

- Prize: Certificate.
- Eligibility: Authors of accepted submissions of the IEEE EDUCON Conference.
- Basis for Judging: Review results and voting of the session chairs especially considering the quality, originality, and attractiveness of the presentation.
- Presentation: During the Closing Ceremony of the annual IEEE EDUCON Conference.

CONTRIBUTIONS TO IEEE EDUCON 2010

EDUCON 2010 Conference, has been structured in 57 normal sessions, 9 special sessions and a non tradicional paper session.

Session 01A Area 4: Learning Models - Competency and Teaching

Competency-Based Pedagogical Wrapping
Atif, Yacine
UAE University (United Arab Emirates)

Consequences of the Declining Interest in Engineering Studies in Europe

Abstract—**In this paper, we propose a novel learning-framework that is context dependent. We adopt a broad definition of learning context, encompassing learning domains and learner competencies. Context-based learning requires dealing with three major research thrusts: pedagogical categorization, learner modeling, and context matching techniques. The system architecture relies on a context matching engine and a set of pedagogical learning patterns to re-purpose learning objects according to contextual situations. A prototype is implemented on top of a common learning service registry, which supplies learning schema that map a given learning context and a learner profile, as well as instances of instructional learning services.**

Keywords-pedagogy; learning personalization; learning design; semantic Web; Web services; design patterns.

I. Introduction

Significant progress in reusability of learning resources have been made [1, 8, 4, 6, 2]. Learning however, is not just about contents but also about the process through which content is repurposed into personalized learning patterns [9, 5, 3], which map instructional contents into experiential learning activities. Yet, this external pedagogical know-how is not conveyed in a reusable manner to field experts and learning interface designers. Process-oriented learning (instead of content-based approaches) is facilitated in this paper through adaptive learning patterns.

Figure 1 shows a taxonomy of learning specification models, where learning operations are highlighted. At design-time, content is provisioned and related patterns are advocated. Learning patterns are encapsulated into learning schema to reflect a subject-related learning prescription. A learning schema models possible evolutions of learning styles and constraints throughout an instruction process. The annotation of learning resources to standard packages, such as IEEE LOM (Learning Object Metadata which specification is available at *http://ltsc.ieee.org*) and the publication of related active services used to retrieve those packages are performed in the implementation-time phase of learning specification. Finally, run-time specifications address interfacing issues to accommodate accessibility requirements, and provide means for context-acquisition to trigger further dynamic pattern reconfiguration.

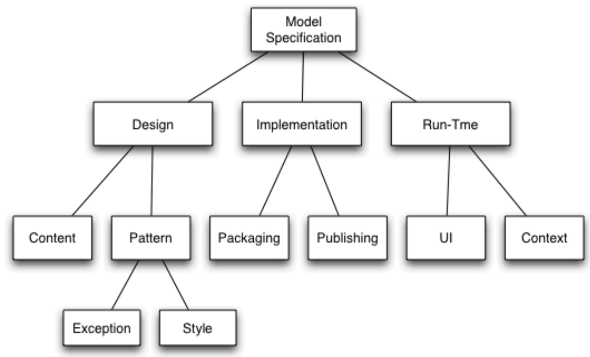

Figure 1. Learning Taxonomy

This paper proposes an approach to learning design which integrates learning patterns as standard learning services with tuning configuration parameters based on learner profiling criteria through standard LIP (Learner Information Package) specification. A learning process schema is introduced as a learning modeling capability to map contextual-dimensions via predefined pattern templates. The remaining sections of this paper are as follows: first, we provide some background and related work, which are relevant to the presented work in this paper.

In the remaining sections we first provide some background and state the problem addressed in this paper. Then we specify in Section 3 learning patterns as reusable educationalist-devised pedagofical templates, followed in Section 4 by learning designs to model learning patterns. We conduct an system prototype implementation in Section 5 as a proof of concept, and conclude the paper with a summary of results and suggested future directions.

II. Background and Problem Statement

Learning production is delivered in a standard layered-model shown in Figure 2. Typically, at the base level of the learning model is the domain model, which is an ontological structure to reason about the domain itself. It conceptualizes domain-related knowledge and defines semantic relationships, independently from pedagogical concerns. The subsequent layer of the learning model routes pedagogical goals and constraints via logical rules to operate over the domain model base layer. Goals refer to the sought-after competency levels, whereas learning-institutions, pedagogical requirements or personal learning-contexts may impose constraints.

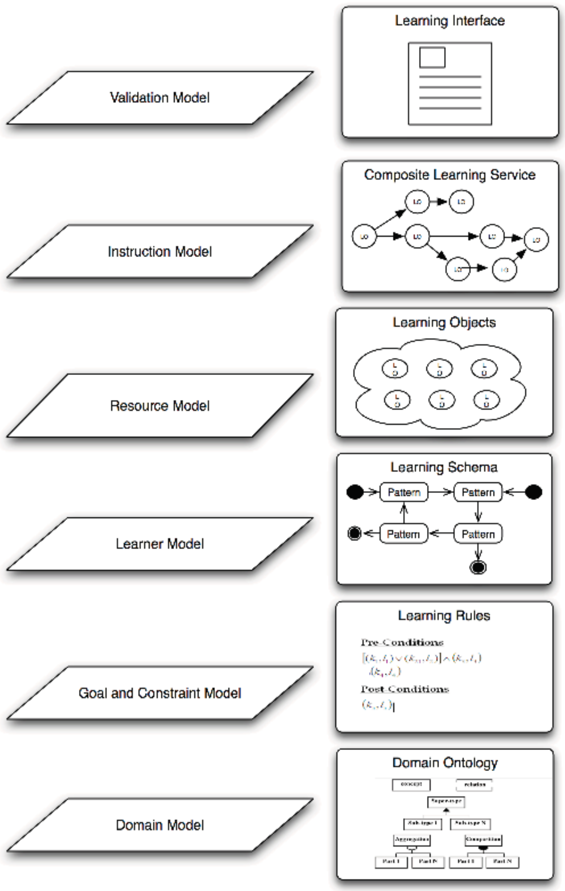

Figure 2. Learning Model

The third layer represents the learner model, which accumulates knowledge about learner profiles based on which, domain content can be wrapped into reconfigurable learning patterns. Pattern-specific learning tasks are prescribed at run-time to adapt to pedagogical recommendations and goals specification, based on pre-conditional rules consideration and post-conditional competency assessment. The learning resource layer shown in Figure 2 consists of learning services which access distributed repositories of Learning Objects or LOs. Learning services, implemented as standard Web services, subsume learning contents into standard packages defined by IEEE LOM specification. The course model choreographs a scenario of learning services as directed by a schema of learning patterns defined in this paper, through a service composition process.

The separation of functionalists into modular production units calls also for a separation of learning-provisioning roles, giving an opportunity to contribute at different levels of learning design. Learning content is tuned at each level to fit variety of profiles. Domain expert for example, may configure content to fit varying degrees of background. Pedagogues may instead mold learning content into activity patterns to adapt to a wider range of learning style. Instructional designers may package learning patterns into standard units and publish related services for learning distribution. Another possibility is for an HCI designer to advocate a presentation facade that is adjusted to specific learning services or customized to specific learning profiles.

Trends in providing personalized learning can be achieved by developing an open composition scheme of versatile learning-services provision within a multilevel enterprise integration framework such as the one shown in Figure 3. There is a lack of approaches today that enable open, enterprise-wide integration of learning, which empowers passive learning-structures such as LO to display a polymorphic behavior to fit learning patterns. In the learning architecture shown in Figure 3, lower layer modules are passive data structures that encompass raw learning-data at the bottom level, as well as structured learning resources and knowledge to package and reason about learning domain, at the upper level.

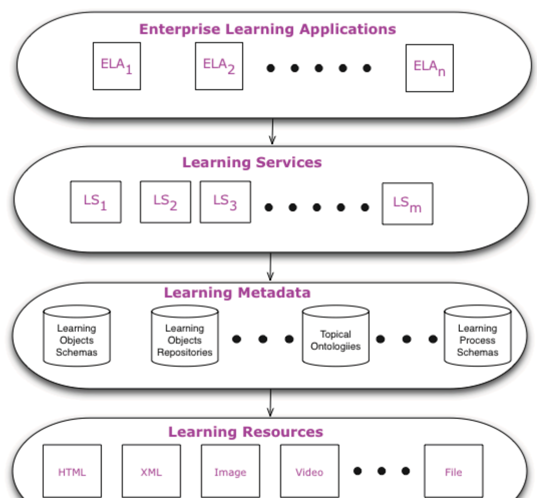

Figure 3. Enterprise Learning Architecture

III. LEARNING PATTERNS

As highlighted earlier, authors from different expertise horizons, like Content Experts, Instructional Designers, Pedagogues, etc, statically design instructional instances in each dimension of learning processes. In doing so, they retrieve an exiting instance of a given learning dimension and enumerate all possible instances across another dimension that fall onto their domain expertise. For example. A "Computer Science" pedagogue may consider an "Operating System" learning content and develop related activity patterns such as experiential learning cases through laboratories, pointers to discussion forums on the subject, problem-based practice lessons, etc. This authoring process may require an exhaustive enumeration of possible learning patterns, to match a wider range of typical learning profiles.

A. Learner Profile

Working out a learner's profile through some stereotypes can happen using the standard IMS Learner Information Package (LIP). This would permit to identify appropriate capability-enabled learning services. LIP is a specification of standard means for recording information about learners. It is designed to access information about learners, as well as their progress records. In doing so, LIP facilitates the transfer of learner-related information across different learning services or applications. As shown in Table 1, IMS LIP specification is structured in eleven groupings aimed at personalizing learning experiences in a general form. These groupings include Identification, Goal, QCL (Qualifications, Certifications or Licenses), Accessibility, Activity, Competency, Interest, Affiliation, Security Key, and Relationship.

TABLE I. LEARNER INFORMATION PACKAGE SPECIFICATION

Category	Explanation Explanation	Tag
Identification	Key bibliographic and demographic data about learner	<identification>
Goal	Career and other objectives and aspirations of an individual learner	<goal>
Qualifications	Qualifications, certifications and licenses granted by recognized authorities	<qcl>
Activity	Any learning-related activity in any state of completion	<activity>
Transcript	Summary of academic achievements	<transcript>
Interest	Hobbies and other recreational activities of a learner	<interest>
Competency	Skills, knowledge and abilities of a learner	<competency>
Affiliation	Learner's membership in different professional organizations	<affiliation>
Accessibility	Learning preferences as well as language capabilities, disabilities and eligibilities	<accessibility>
Security Key	Set of passwords and security codes assigned to a learner	<securitykey>
Relationship	Relationship between core data structures	<relationship>

Our approach exploits the inter-relationships between LIP elements to define learning patterns for an individual learner, within cognitive preferences, acquired competencies and expected learning goals, as shown in Figure 4. Competencies could be communicated in a suitable format to match learning patterns.

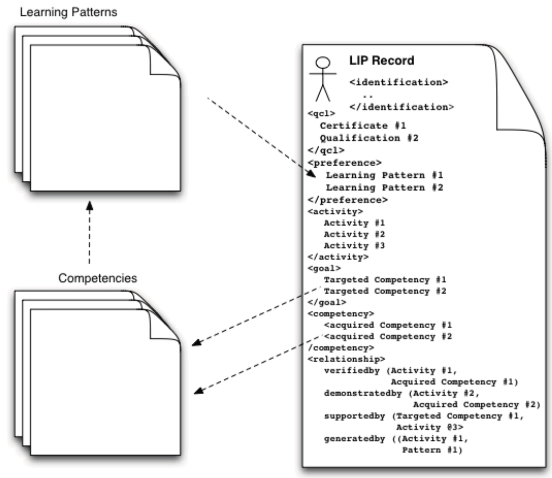

Figure 4. Learning Pattern

B. Learning Styles

Just as some people are left-handed, we learn better following different styles. A renowned educationalist David A. Kolb, has made an inventory of possible Learning Styles [7]. These learning modes are deemed to be responsive to contextual demands. According to Kolb, learners perceive and process information in a continuum from a concrete experience to testing implications as follows:

- Concrete Experience (CE): being involved in a new experience (feeling)
- Reflective Observations (RO): watching others or developing observations (seeing)
- Abstract Conceptualization (AC): creating theories to explain observations (thinking)
- Active Experimentation (AE): using theories to solve problems and make decisions (doing)

Depending upon the situation or the environment, learners may enter the above learning modes at any point. Below are some brief illustrative examples in applying Kolb's styles within different domain contexts:

- Abstract conceptualization - Listening to explanations and theoretical presentations.
- Concrete experience - Going step-by-step through an equation.
- Active experimentation — Practice on solving problems.
- Reflective observation - Recording thoughts about algebraic equations in a learning log.

Kolb's model offers both a way to understand individual learning styles, which he named the "Learning Styles Inventory" (LSI) [7], and also an explanation of a cycle of "experiential learning" that applies to all learners. Hence, our motivation to consider Kolb's model for defining learning patterns that can suit a variety of learning profiles. Kolb developed four learning styles: Diverger, Assimilator, Converger, and Accommodator. Learners generally prefer some of the four styles above the others or may move between styles in different learning domain contexts to reinforce retention. Kolb thought of these learning styles as a continuum that one moves through over time and hence, these are the main styles that instructors need to be aware of when creating instructional materials, particularly domain pedagogues. This instruction development approach results in four types of learning patterns:

1) Accommodators Pattern - (Concrete experience/Active experimenter pattern)

Learners who are exposed to this pattern are motivated by the question, "What would happen if I do this or that?" They look for significance in the learning experience and consider what they can do to move to the next stage. They like also to accumulate previous case scenarios elaborated by other learners. Example of instruction methods to create learning instances of Accommodators pattern include:

- Provide opportunities for independent discovery.
- Develop an active learning environment.
- Anticipate questions, such as "What if?" and "Why not?

2) Assimilators Pattern - (Abstract conceptualization/Reflective observer pattern)

Learners are eager to answer questions like, "What is there to know precisely?" They like accurate, organized delivery of information. They tend to pull a number of different observations and thoughts into an integrated whole. They also prefer to reason inductively and create models and theories before moving to design projects and conduct experiments. Instructional methods that suit Assimilators include:

- Lecture method (or video/audio presentation)—followed by a demonstration.
- Lab exploration, following a prepared tutorial for which answers should be provided.
- Independent study works and analytical exercises.

3) Convergers - (Abstract conceptualization/Active experimenter pattern)

For this type of learners, relevancy or the "how" of a situation are dominant learning-behaviors. Application and usefulness of information is increased by understanding detailed information about the system's operation. They tend to emphasize the practical application of ideas and solving problems. They like decision-making, processes and problem solving as well as practicability side of concepts. Finally, they prefer technical problems to interpersonal issues. Typical instruction methods that suit convergers include:

- Interactive instruction (i.e. not passive).
- Computer-assisted instruction.
- Exploring problem sets or workbooks.

4) Divergers - (Reflective observer/Concrete Experience pattern)

These learners are motivated to discover causality relevancy or "why" of a situation. They like to reason from concrete, specific information and to explore the information presented to them in a detailed, systematic and reasoned manner. They emphasize innovative and imaginative approaches in doing things. They view concrete situations from many perspectives and adapts by observation rather than by action. They like cooperative groups and brainstorming activities. Instructional methods that suit divergers include:

- Lecture focusing on specifics such as the strengths, weaknesses and uses.
- Hands-on examples. – Interaction sources with the instructor.
- Ready reference guides and organized summaries.

A learning profile may include several learning patterns. Content providers and pedagogues should use the above guide to develop learning packages. Each learning schema has one or more learning pattern. And each learning pattern belongs to exactly one learning schema. The line ended with a filled diamond between a learning schema and a learning pattern, denotes this composition relationship. This means, that a learning schema may encompass one or more learning patterns.

IV. Learning Design

We define a learning schema to encapsulate diverse learning pattern specifications, which are instantiated based on contextual information. Learning pattern models are behavioral approaches to learning. Learning schema is an overall structure that defines personalized learning processes. Learning schemas are reconfigurable to match the dynamic changes in learning patterns within a given learning experience. We represent a learning schema as a statechart, which is appropriate for modeling processes such as a learning process. Learning states are run-time reflections of learning patterns. As shown in Figure 5, a statechart is made up of states and transitions. States can be initial, end, basic, or compound. A basic state (representing in this paper a learning task) corresponds to an invocation of a learning service operation. Hence, patterns specify learning services and the service operations implement the pattern's learning tasks. Multiple operations may be invoked within a learning pattern, and several learning tasks may be invoked across learning patterns of a schema. Candidate learning services are selected based on their operations, which match a competency's functional requirements specified in a learning schema. A further selection among matching tasks is based on non-functional attributes such as QoS (Quality of Service) parameters or learning constraints to guide the matching process. Compound states in learning schemas provide a mechanism for nesting one or several statecharts inside a larger statecharts as shown in Figure 5. We use this abstraction to represent learning patterns as learning sub-processes within an overall learning process. This modeling technique facilitates dynamic transitions across learning states in a specific learning dimension, which may occur during a learning process. There are two types of compound states: OR and AND. An OR state contains single statecharts which represent alternative learning tasks, whereas AND states represent concurrent tasks separated by dashed line in Figure 5, which have to take place.

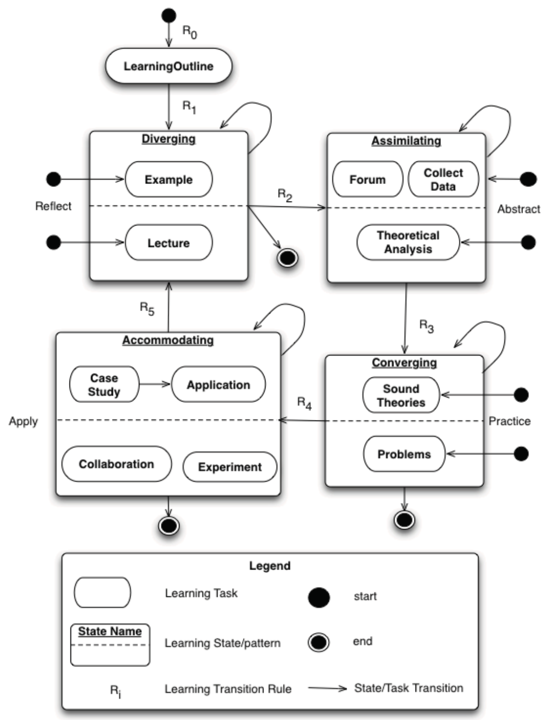

Figure 5. Learning Schema

Figure 5 presents an illustration of a simplified learning schema as a statechart diagram for a particular learning domain subject, which content have been designed. The elaboration of learning schemas may be devised by a pedagogue, in collaboration with the domain expert, or ideally by a domain-specific pedagogue, who could be seen as a senior domain expert with substantial accumulated experience in the subject instruction. In the example shown in Figure 5, learning may start from an overall outliner or from other learning unit instances. The closed circle shows the entry points leading to an initial state of a learning schema. The outliner task reveals the topical list of units modeled by this learning schema. The outliner task is followed by a transition to a Diverging pattern, where the learner may view hands-on examples concurrently with a focused lecture presentation. The learner may remain in the Diverging state for subsequent learning units (hence the loop at the compound box corner), or move to a new state. A transition to a new learning state is triggered by a condition and guided by a policy rule.

In this particular learning schema, the pedagogue advocates possible entry and exit points to fulfill the instruction outcomes. The bordered circle represents final states in the learning schema. For example, Diverging state may complete instruction requirements. However, assimilating state must be followed by converging state across a given learning unit to claim learning completeness in the subject matter, for which the schema in Figure 5 is advocated. Similarly, Accommodating state does not have an entry point (i.e. in this example, it cannot be the initial state). Hence, the learning schema is a learning guide rather than purely preferential style modeler.

Initially, learning schemas are designed and stored. A request for learning identifies a schema model. At run-time, matching learning services are matched to learning tasks in the schema. A coordinator agent sends the learning resources returned by the learning task to the context service along with the learning task policy. Learning reconfiguration is initiated by the learner context. Context data accompanies the reconfiguration event notification. The context-providing service verifies context data against learning-task post-conditions and updates the learner's (LIP) record of competencies accordingly. The next learning service invocation moves learner to a new state based on a schema of patterns description. If all patterns are exhausted or if learning services of the new pattern are unavailable, a new schema request is made.

V. Prototype Implementation

The prototype is implemented in Java on top of a common service registry, which supplies the learning schema as well as the learning service specifications. We used standard Web technologies such as XML, SOAP, WSDL and UDDI (Universal Description, Discovery, and Integration). Figure 6 shows of the prototype featuring the architecture of learning services as separate modules of objects. Learning Factory module generates a composite learning service to map a learning pattern specification and produces requested learning objects. Knowledge Factory module returns an XML specification of the learning schema, while the event-driven Context Factory module captures conditions for adaptations and triggers the reconfiguration process. Although simplistic, the prototype implementation is a proof of concept and a toolkit for usability evaluation. These three modules are further illustrated in Figure 6.

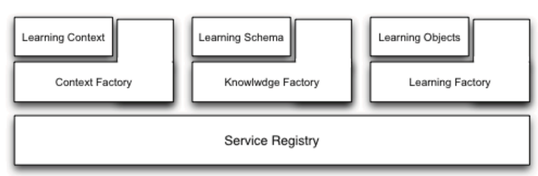

Figure 6. System Architecture

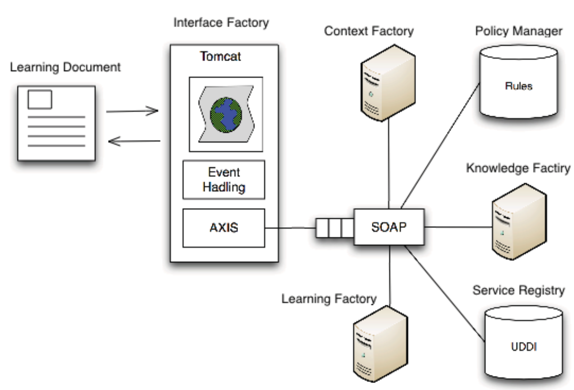
Services are deployed using Apache Axis. Apache Tomcat is used as a Web server where Apache Axis is deployed. Each service has a deployment descriptor that includes the unique identifies of the Java class to be invoked as well as the operations in the class that are available to clients. Learning Factory module uses a learning service registry, which is bound to learning objects repository. The service registry also includes a discovery and invocation facility implemented as SOAP calls (Figure 7). Learning services are simply used as a gateway to learning objects and may offer enhanced operations to deal with a learning object. When a learning service registers with a discovery engine, a UDDI SOAP request containing the service description in WSDL is sent to the UDDI registry. A learning service factory may deliver composite services from existing basic services in UDDI (for e.g. a case study followed by a collaborative project to match the Accommodating pattern description). The knowledge factory module accesses learning schemas stored in the UDDI as a tModels. tModel is a standard specification utility to represent a service type (a generic representation of a registered service) in the UDDI registry. Each learning service provider registered with UDDI maps all of its Web services according to a defined list of learning patterns within a schema (as specified in the example of Figure 5). An instructional designer can search the registry's learning schemas to create the enclosed pattern instances. The tModel organizes the service type's information and makes it accessible in the registry database. Each tModel consists of a name, an explanatory description, and a Universal Unique Identifier (UUID) . The tModel name identifies the service, such as, for example, "Computing Lecture" learning task.



Fi gure 7. Process Architecture

VI. CONCLUSION

The paper addresses learning personalization through adaptive patterns. We introduced learning schemas as means to design patterns of learning in a given instructional subject. Learning patterns encapsulate learning tasks, relevant to experiential learning processes, based on Kolb's foundations of learning theory. Learning schema specification use Statecharts and embedded patterns to reflect a learning style during instruction. Transitions across learning styles dictate learning reconfiguration through rules, which represent pedagogical requirements and personal constraints. Several directions could extend the presented work in this paper. First, we are currently building a portal application to enable learning producers at different level to participate in learning integration workflows. We could also export and share the accumulated learning services of advocated patterns to a public repository.

Consequences of the Declining Interest in Computer Science Studies in Europe

Katherine Maillet, Marcela Porta
Departement des Langues et Sciences Humains
Telecom & Management SudParis
Evry – Val - d'Essonne, France

***Abstract*—Official European statistics of education indicate that the number of students entering tertiary education have significantly increased between 2000 and 2006 [1], and indicate a trend that will continue. However, this increase is not reflected in every field of study; computer science and engineering are among those that have decreased each year, evidence of a decline of interest in following this career on the part of students. As a response to this disturbing fact, this paper aims to identify some of the possible consequences that this trend could produce in Europe. It will highlight the impacts in economic, social, political and pedagogical fields and explain how these segments will be affected if the decline in computer science persists. Supported by previous investigations and official reports, this analysis provides some examples of the problems already produced by the declining interest in computer science in Europe and proposes solutions such as teaching methods and learning strategies to attract more students to this field and therefore limit the negative effects in a near future.**

Keywords-component; Computer Science studies, learning methods, teaching methods

I. Introduction

The official European statistics reflected a low rate in the number of high school students choosing computer science as a career. While the number of students entering university is rising, this field of study represents just 9.9% and decreases each year [1].

Because of this, European countries might be affected by a low number of experts in technology that represents an important stake for industry. In France for example, people spent a total of 7,965 millions of Euros in technology in 2008 [18].

The relationship between the high demand of technology and the decreasing number of experts to support it, leads us to ask the following questions:

- How can Europe justify the decreasing interest in computer science studies when the demand from the technological industries remains stable?
- What are the main reasons that produce this decline in the choice of computer science as a domain of study?
- Is it important for Europe to promote Engineering school?
- What are the consequences of a reduced number of computer science experts in industry and research in Europe?

This paper aims to demonstrate the imbalance between the number of students choosing computer science as a domain of study in relation to the demand in the industry and points out the importance of attracting and retaining students to this field by highlighting the possible consequences that this decrease could produce in different sectors.

As a conclusion, this document will point to some solutions that could be used in order to bring alternatives to these issues and prevent the negative impacts.

II. Related Work

Certain studies are investigating related questions about the number of students enrolled in technology. Some of these studies highlight the fact of the low interest in computer science as part of their results.

In 2009 the Computing Research Association (CRA) remark that the number of undergraduate students majoring in computer science significantly increased [2]. This fact not only creates a concern about the future of technology in Europe, but also sustains the decline of interest in computer science.

A larger investigation by Mahar, J. [3] was dedicated to find strategies to attract women to computer science, expressing their concern about the low number of them in this scientific field. In 2008, the proportion of women opting for scientific and technological studies was lower than the 40% in Europe, concerning computer science as a part of the study [4].

These references affirm that investigating the reasons of this decline is essential in order to understand and control this problem. Some studies agree that the reason why a student does not pick computer science or does not feel attracted by technology as a domain of study is related to the image these careers reflect or to the degree of difficulty that these domains seems to represent: in 2006, a European orientation study suggested that "*The choice of the students is essentially determined because of the image of the professors in the scientific and technological areas and by the content and quality in the discipline*" [4].

Academics thought that vague and erroneous perception begins in high school and that industry could do more to improve the image of jobs and careers in this domain and help identifying a stereotype that has not been clearly identified yet [5].

Nowadays, the real reasons that produce the rejection of computer science as a domain of study is not yet discovered. However, the importance in the number of technology professionals in Europe is determined by the possible consequences that can take place if this decline is not controlled and this is what this paper will emphasize.

III. Population Results and Education Key Statistics in Europe

The official key statistics in Europe, delivered the results of the educational analysis in the European countries [1].

This study leads to understand the declining performance of computer science school in Europe and enclose general conclusions to better understand the importance on the evolution of this field and its consequences in case of failure.

A. *Education Statistics for Europe 2000-2006*

The statistics published in 2008 [1], indicated that the number of students that have access to tertiary education in Europe is increasing in a sustainable way. In other words, the number of students attending university after high school is rising as shown in Figure 1.

Unfortunately the increase in tertiary studies is not reflected in all domains of study. Graduates in science, mathematics and computing have decreased each year as shown in Figure 2 [1], reflecting the lack of motivation of following scientific careers from the part of students.

While analyzing the computer science results it is important to highlight two main concerns:

- Graduates in computer science and engineering are decreasing; while graduates from other fields of study are increasing or remain stable.
- We can presume that there are specific reasons which cause students to reject science, math, computing, manufacturing and engineering.

The declining interest in computer science education surprise the more when they come from developed countries in which an important part of their industries depend on the evolution of technology and constitute a significant change affecting labor demand [19].

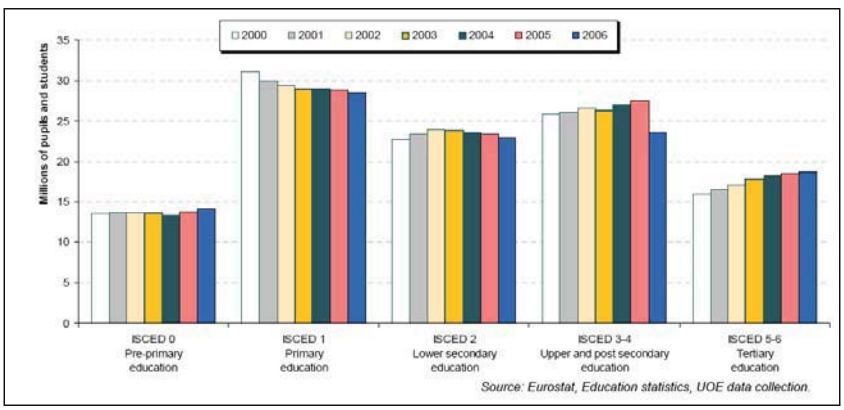

Figure 1. Distribution of tertiary graduates by field of education, EU27, 2000 and 2006, in %

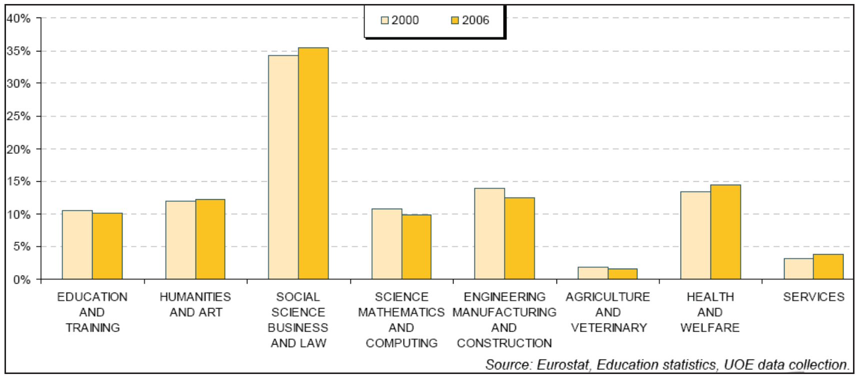

Figure 2. Number of pupils and students by level of education (in millions), EU27, 2000 to 2006

There are other analyses that reflect and confirm the declining interest in computer science, such as the one shown in Figure 3, provided by the Computer Research Policy Association [18]. It illustrates the continuous decrease in computer engineering and computer science graduates from 2001 to 2005.

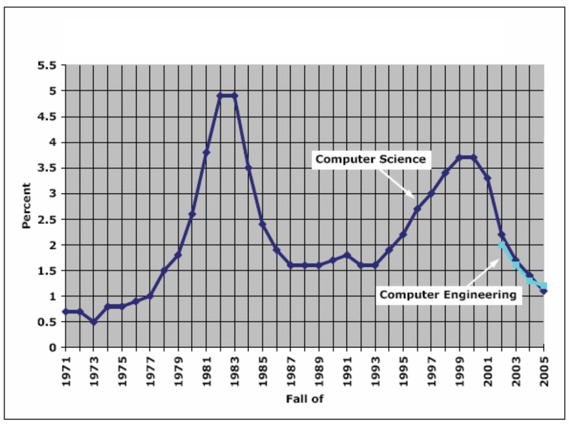

Figure 3. Development of computer engineering and computer science in persentage of university graduates during the last years

These statistics lead us to agree in the fact that the interest in computer science is declining and that this decline may alter and bring consequences in the technological field for European countries.

B. *Analysis and enclose of the situation*

The latest statistics show a reduction in the number of persons studying computer science in university. This decrease represents, as general consequence, the declining number of professionals in this field and thus involved in the development of local technology in Europe.

Other sectors such as the economic, social, political and pedagogical fields will reflect similar consequences. The next section will present the possible impacts of the declining interest in computer science studies in Europe.

IV. CONSEQUENCES OF THE DECLINING INTEREST IN COMPUTER SCIENCE STUDIES IN EUROPE

A. *Economic consequences*

1) A reduction in the number of computer science students will result in a decreaing number of experts in the technology field in the near future

In general, when the stakes of an industry are reduced in number of experts, it will cause an increase in the price of the good or service that these experts provide. The economic model on elasticity shows a comparison between the market price of a product or service and the offer of the same, i.e. less human force with the same demand is equal to a price increase.

The price P of a product is determined by a balance between productions at each price or supply S and the desires of those with purchasing power at each price or demand D. Along with a consequent increase in price and the quantity sold of the product [6]. This theory is quickly highlighted in Figure 4.

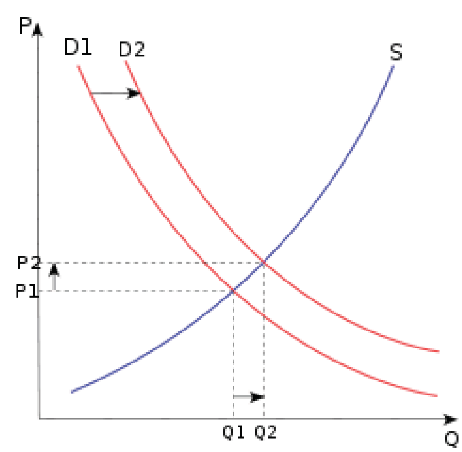

Figure 4. Elasticity of the price of a product

Explained from this point of view the number of students and experts in the technological field is crucial to balance prices and promote the progress of the nation's technology industry, because a low offer in the market of technology represent a more expensive product.

This increase in the price of computing development and the decrease of professionals in the industry can be related to the initiative of the companies that redirect or migrate their labor forces to foreign countries where development is not only as efficient as in Europe, but also where there is a greater available production capacity at a lower cost, e.g. India.

2) A migration in the labor force and technological development to foreign countries

The migration of the technology from a company that can not afford development in its own country is very common these days. Countries will buy the software and programs to other countries willing to maintain the low prices in operative costs.

This fact represents a great opportunity of development for those countries trusting technology as a development strategy. However, a negative impact will take place in the purchasing countries, because this migration can turn out in instability of the industry, due to: the migration of the human force and abolition of actual and future jobs, the reduction in local tax payment and most important, the absent of strategies to manage this impact.

Because of this, predictions of job losses from shifting high-technology work to low-wage nations with strong education systems, like India and China, were greatly exaggerated. As remarked by Lohr, S. 2006, "*The concern is that misplaced pessimism will deter bright young people from pursuing careers in computing, and, in turn, would erode the skills in a field that is crucial to the nation's economic competitiveness"* [7].

B. Social consequences

1) Increase in careers outside math, science, computing, manufacturing and engineering

As we previously understood, the number of university students is rising. This fact also suggests that university students that are not choosing technology as a career are selecting another one. As shown in the previous graphs, careers like business and social science are the ones increasing the most these days [1].

This fact can be related to an increase in the job opportunity needed for negotiating and purchasing technology from other countries. The global increase on the technology demand produces success in management careers such as purchasing and international commerce because the technology that is not being developed in Europe is being purchased from other countries.

This tendency will result in a higher proportion of professionals trained to be managers and businessmen and a lower number of engineers and producers of technology; which is not precisely a negative change, but represents an alteration that needs to be assumed.

2) The need to learn other cultures and languages

Due to the migration of the human resources, there is an increasing need to learn other cultures and languages to succeed in negotiations with other countries.

Nowadays a person speaking several languages has a large number of job offers in Europe thanks to the companies that need interlocutors for their commercial exchanges.

However, the culture and languages of the countries which are involved in technology development are not precisely related to the European. Therefore, Europeans might loose their strengths of speaking English, French and Spanish (more speak languages in Europe and in the world) and became weak when facing the opportunities that are presented to Chinese, Russian and other languages speaking countries [8].

Following this example, we may find a certain number of investigations considering the importance of integrating foreign languages and cultures to European countries, not only in the name of technology development, but also because unique educational modules, courses and programs are being designed and evaluated throughout the Asian region, evidencing issues, challenges, opportunities and initiatives related to the education of technology. [20]

One of the solutions could be to include these languages in the curricula offered to students seeking careers in business. This will permit students to gain opportunities in international job offers and be prepared to affront their professional lives after university. Some studies emphasize the importance of learning other languages to meet this demand and to adopt the economic change that Europe might be affronting [9].

Unfortunately taking as an example the program of study offered to students of one of the most popular careers (economics and management) at one of the best universities in Europe, we can see that the language options are limited to Europeans and neither Chinese nor Japanese, or other language that represent geographical expansion is offered as shown in Figure 5 [10].

Figure 5. Sorbonne University, 2nd semester Management Curricula

However in its many international exchanges, European universities are providing educational programs to foreigners, giving them the expertise and knowledge of the European market and enhancing the population that in some years will represent the strongest competition for local professionals.

This fact can be demonstrated by an example: In France the number of Asian students has tripled in five years; as published in its annual report on diplomacy in 2006.

Thus Asians represent the fastest growing group of foreign students highly incentive form the French government [11], however this document specifies as well that only 5% of these foreign students stay in France, while the rest of them return to their countries to work in the field contributing to the migration of the technology development.

By the other hand, the countries producing technology can appreciate a fast progress observed from a positive point of view. Some countries might find in this the occasion to expand their industries and create links with other cultures that will represent an economic profit for them.

C. Political consequences

1) General dissatisfaction causing political instability

The lack of opportunities in a country for a person that has concluded secondary studies can represent a menace to the economy and the stability of the country itself. The information about companies that migrates the development of technology out of Europe might guide us to ask ourselves about the future of thus professionals that might lose their opportunities to work.

Europe is already subject to several aggressive strikes that reflect the dissatisfaction of the local workers due to the migration of the labor force to other countries which is affecting their careers.

For example, the employees of JLG Industries, the world's leading designer, manufacturer and marketer of access equipment, went on strike as a result of a possible delocalization of the labor force. The employees threatened to explode the warehouse if the company did not stop the policy of firing a certain number of people at the end of the year [12].

Another related event was a demonstration organized by students of informatics engineering and other careers related to computer science, who manifested their concern about the lack of job opportunities in the field in Europe [13].

These demonstrations create an environment of insecurity, violence and material damages in Europe that can also harm political image.

2) Modifications in the national curricula

The political influences on education have been rapidly increasing over the past several decades. Recently, the power of the state has been expanding further into the domain of the university. Any curricular changes in teacher education must be planned with an eye toward the state's expected role. This may be the most crucial aspect of technology integration.

Curriculum developers may not be well versed in governmental matters and may have to change the ways they prepare for reform while facing changes in things such as: the budget, the importance to foreign languages and cultures and the political instability. [21]

D. Pedagogic consequences

1) Declining careers in engineering

If the number of graduates in a specific subject is reduced or simply modified, there will be a similar reduction or modification in the number of professors in this discipline. Therefore, the difficulty to find teachers that provide students the knowledge and expertise to develop technology will increase.

The success of computer science is based on the number of experts involved in the same geographic area, the entire development of technology depends on the persons who have the expertise to create and maintain technology because they are capable to create and maintain technology material.

2) Declining investment in the field of study

The fact of reducing the number of computer science students might represent less founds for the development of this educational sector, because institutions in charge of providing money to education will not invest in a career without students. As a catastrophic result this could eventually mean the complete elimination of this career in Europe.

One example of this fact is reflected in the European Commission that will sponsor a large number of contracts directed to technology research in order to the results that the partners conforming this contracts could offer, i.e. the number of publications in collaboration with students and professors. Therefore, with no experts working in the development of technology research, the funds coming from the European Union might be reduced.

V. CONCLUSIONS AND FUTURE WORK

After analyzing the consequences of the declining interest in computer science in Europe, two main conclusions can be appreciated:

A. Increase the number of computer scientist in Europe

The first conclusion refers to the fact that in order to maintain the development of computer science as a career and as the basis of technology in Europe it is necessary to attract and retain human talent in this field.

As a strategy to this matter, a future work can be directed to identify the reasons why a student does not feel the motivation to follow computer science studies as a career and to create methods that attract and retain people in this domain of study.

As mentioned previously, some studies blame the negative image this career reflects while observing the professionals working in this field [5].

Other analysis demonstrate that preventing young students from using technology in an early age might psychologically affect a child and cause him to reject this discipline his entire life. Parents forbid children to touch expensive equipment (that could be attractive to them in the first place), such as computers and televisions etc. and give them the wrong impression of being incapable to operate them and impede the development of their technological skills [16].

Other programs have directed their strategies to attract women to these scientific domains. The development of such strategies has made it possible to attract undergraduate students historically not enrolled in computing courses and therefore attract students to this field [15].

B. *Adopting the changes that computer science is affronting*

As specified before, a general recommendation to adopt the technological raising in other countries is necessary. The fact of learning other languages, expanding markets and modifying teaching/learning curricula was mentioned as a technique to affront the consequences of the migration of computer science and gain advantages in the international market.

Other initiatives have already launched strategies targeting a more specific area; they create teaching and learning methods to enhance e-learning and support students with the help of information technologies such as "Effective video clips for Web-based language learning" [14]. This study affirms that the opportunity of providing new technological features to existing teaching methods will help attracting users and students to the technological field.

Abstract—**The PAVEs Program (Profesores Asociados Vinculados a Empresa – Adjunct Enterprise Professors) of the University of Valladolid allows enterprises to offer a set of optional subjects dealing with the technological knowledge necessary for their operation. These subjects are not only very attractive for the students, as they are given the chance to get an insight of the world that will host them as employees in the future, but also could be studied to extract lessons about the future European Higher Education Area (EHEA). This work presents the PAVEs program, the lessons learned that could be applied to the plan adaptation to the EHEA, and how the PAVEs subjects could be better integrated with ordinary subjects in the upcoming EHEA.**

Keywords- ECTS; Adjunct Enterprise Professors; Practical Education; Learning Technology; EHEA.

I. Introduction

The PAVEs Program (Profesores Asociados Vinculados a Empresas – Adjunct Enterprise Professors) is aimed at bridging the gap in the educational plane between the industry and the academia [1]. This program represents a unique collaboration initiative in the Spanish landscape, and has revealed itself as a very efficient tool for the students of technical degrees in the University of Valladolid.

Traditional collaboration among industry and academia has been focused on research activities, either having universities as consultants or partners for research, development and innovation activities. There is an extensive literature describing this, for instance [2] and [3]. However, collaboration in the educational plane has not been typically addressed.

The industry has a very wide spectrum of very specific skills which are necessary for each of the activities carried out in the different areas. Traditional academic programs are limited in time, and priorities have to be assigned so all the basics of the profession can be taught. The idea behind the PAVEs program is to take advantage of some of this industrial knowledge and bring it to the University students, so they can have a first approach to the details of some of the real industrial activities and the necessary skills to perform them) that they will carry out during their professional lives, effectively bridging the transition from student to apprentice. The teacher of a PAVEs subject is an industry professional acting as Adjunct Enterprise Professor, classes could be conducted within that enterprise premises, and although students do not perform any practical industrial work during these classes, they learn the skills, techniques and knowledge to do so.

Therefore, when students obtain their degrees, they have already some contact with the skills, habits and best practices required in the industry, which are not always teachable by professors which have been involved in academic spheres for years.

The PAVEs program has been active since 2001, when the University of Valladolid and the Regional Government (with the aid of the Spanish Ministry of education and the Spanish Ministry of Economy) reached an agreement to integrate Adjunct Professors from the industry sector into de University hierarchy. This agreement, with an initial duration of 2 years, has been renewed several times, and a total of 50 professors coming from the technical and engineering areas are involved.

As the PAVEs program has had an eminently practical approach and has tried to avoid traditional unidirectional learning methods, it can be considered a great information source to extract experimental conclusions about the new orientation of the education system in the European Higher Education Area. This information could be used for instance to drive the design of educational programs on the different subjects for the future convergent European framework.

The PAVEs program could be considered an innovative experience with very similar aims to those of the EHEA (European Higher Education Area), in particular, the practical approach and the compatibility with the ECTS (European Credit Transfer System) credit systems, based on the students' workload required to reach the objectives of the subject instead of just hours attending classes. In this sense, the PAVEs program aims in the right direction to foster the implantation of ECTS credits, focusing directly on the students' efforts to learn the subject and letting the student play the main role in his own education.

II. Telefónica I+D in the Adjunct Enterprise Proffesor Program

Telefónica I+D, the Research and Development branch of Telefónica, the Spanish telco operator, is one of the most active companies in the PAVEs program of the University of

Valladolid, through its nearby premises in the Boecillo Technological Area (Parque Tecnológico de Boecillo). It has been offering a wide array of subjects inside the program for years with very good results [4].

For academic year 2009-2010, Telefónica I+D offers a total of seven different subjects, covering several areas like Multimedia, Next-Generation Networks, Web Programming and Service Provision [5].

The subject "Innovación: Servicios" (Innovation: Services) is a transversal course dealing with how the Research – Development – Innovation cycle is implemented in the enterprise. A first, generic block of the subject presents a description of the R+D+i cycle, its implications in the industry, and best practices, including the funnel diagram, typical procedures, publications and patents. The second content block presents the application of these concepts to several specific areas, including communications, mobility, digital home, etc.

The subject "Servicios Avanzados de Apoyo a Aplicaciones Telemáticas" (Advanced Services for Telematic Application Support) presents the innovative low-level services introduced by telco operators to support next-generation converged applications. Specifically, context-aware and location services, support for Mobile Ad-hoc Networks (MANET) and frameworks for Next Generation Network management.

The subject "Desarrollo de Aplicaciones Orientadas a Internet" (Development of Internet-oriented Applications) is aimed at preparing the students with the specific programming skills that the ICT (Information and Communication Technologies) industry is employing in the state of the art trends in the internet, including Web 2.0 and Web 3.0, Web Services, Service Mashups, RIA (Rich Internet Applications) [6]. This subject teaches how to develop a dynamic Web application accessing a database using Java as a programming language. Web servers, Development tools and environments, Web applications architectures, Servlets, JSP, JDBC, iBatis and AJAX are the technologies to be explained during this course.

The subject "Desarrollo de Componentes y Servicios en .NET" (Component and Service Development in .NET) aims at teaching how to create applications for the Windows operating system, ranging from traditional, simple ones like Microsoft Office expansions to more sophisticated ones taking advantage of innovative resources, such as N-layer applications or multi-touch interfaces. Technologies to be investigated within this course include .NET Framework v3.5, SOAP Web Services, ASP .NET, Windows Form, WPF, Silverlight, Windows Azure, Windows Surface and Windows 7.

The subject "Servicios Móviles sobre IP y de Tercera Generación" (IP-based and Third Generation Mobile Services) aims at providing an insight on how service development for mobile environments aimed at end users is carried out using the latest technologies. State of the art technologies in distributed mobile applications are presented, and popular environments such as iPhone and Android are investigated. Additionally, the innovative Scrum development methodology is studied, teaching the studies how to conduct team work and application development following its principles, and how it is employed in real world enterprises.

The subject "Fixed-Mobile Service Convergence on IMS" aims at teaching students how the converged Internet of the future is being shaped, how telco operators' infrastructures are changing to adopt IMS (IP Multimedia Subsystem) [7], and how the Quality of Experience concept is applied to network design. With an eminent practical approach, this subject will train students in several areas related to IMS and convergence, including IMS Testbed Installation and configuration; Femto-cells and convergent technologies; SIP and SIP-SIMPLE practical analysis with network analyzers; multimedia convergent service creation based on SIP (with session transfer); Quality of Experience model definition for messaging, interactive or streaming services; and studies on the technologies enabling the Internet of the future.

The subject "Redes de Cuarta Generación, Interconexión y Gestión de Red" (Fourth Generation Networks, Interconnection and Network Management) aims at introducing the fourth generation of mobile communications to the students, and teach them how implementation and management of fourth generation systems is carried out. The course is focused in the feature of heterogeneous 4G networks and Internet access protocols in high mobility environments, and includes practices on designing a management system for 4G networks.

III. Integration Within Official Degrees in the EHEA

A good integration of the PAVEs subjects into the programs of the official degrees, and together with the ordinary subjects is a key factor for its success. There is a risk that due to the fundamental differences in the matters covered by the PAVEs and the ordinary subjects, students can develop the perception that they account for two completely different, and even competing, realities. It is necessary to counter this risk inducing the idea that they are actually complementary, and that the same knowledge acquired in more theoretical subjects is actually applied in the industry activities shown in the PAVEs.

A very good approach to foster a coherent integration of both worlds is to actually create links among PAVEs and ordinary subjects. As the EHEA promotes a bigger presence of practical activities, ordinary subjects are also increasing the amount of this kind of practical contents. The approach suggested in this work is to take advantage of this fact, and interpret PAVEs as a kind of practical modules that can be optionally "plugged" with ordinary subjects in order to substitute or complement the ordinary practices.

This allows an intimate contact among the ordinary subjects and the PAVEs, and a direct, easy linking of the theoretical concepts with the industrial, practical knowledge. This brings a twofold benefit. First, the theoretical concepts taught give a good basis to understand the fundamentals of the technologies seen in action during the PAVEs. And second, the conceptual knowledge is better understood, as real world applications are presented as an example of the usefulness of the theory.

However, these links have to be carried out in a subtle manner, so as ordinary subjects are not interfered, hijacked or distorted by the industrial contents. University professors have to keep their workload and official study programs have to be fulfilled according to the defined specifications.

There are some options to implement this link among the different subjects, which have been actually tested within real experiences in the University of Valladolid. In the Polytechnic School [8], practical credits of degree modules are taught by PAVEs professors. But in subjects with very large student bases this approach could be difficult to follow, as industrial premises are not always adapted to host a big number of practicing students.

For these cases, another approach is suggested, which has been named "subject association". This approach implies a link between a specific ordinary subject and a specific PAVEs subject. The ordinary subject is a complete subject, including all the necessary theoretical and practical concepts, and the PAVEs subject is an industrial application of the concepts explained in the ordinary subject. Students are then given the chance to optionally take the PAVEs as a substitution of the practical credits of the ordinary subject.

An example of this subject association was carried out in the University of Valladolid [9]. The *Projects* subject, which deals with the project management discipline, is particularly suitable for an industrial approach in the practical credits. As a standalone subject, the teacher usually has to present use cases to illustrate the application of the management tools studied, and the nearer they are to real experiences, the better the subtleties of the problems encountered in the real world are captured. Therefore, through PAVEs subjects it is possible to offer real examples of project management to the students, specifically in this pilot *Voice over IP* and *Development of Internet oriented applications* were the PAVEs subjects which could substitute the practical credits of the ordinary subject.

The experiences carried out within the PAVEs program show that the achievements obtained are in line with the objectives of the EHEA. This means that the novel methodologies fostered by the EHEA are pointing in the right direction, and that the implementation of the PAVEs subjects could be used as a kind of guide to help modifying the study programs and adapt them to the EHEA.

Specifically, the PAVEs program has been monitored yearly since its beginning by conducting a series of surveys among the students implied in order to extract conclusions on the satisfaction level. These surveys have shown that students of PAVEs subjects are very satisfied with the experience, mainly because of the following reasons:

- Interesting and attractive contents, which depart a little from the traditional academic approach followed by ordinary subjects, and are usually focused on state of the art technologies instead of the basics and generalities that often form the core of ordinary study plans.
- Approach to a real world company, opening a whole new world of experiences, methodologies and procedures. The direct contact with this new world induces a bigger motivation and interest in the students.
- For students, the University often becomes a kind of bubble, with its own idiosyncrasy, which prevents them from actually experiencing the real world. This sometimes translates in ignorance about the kind of professional work that they will be performing after leaving the academia, and in the fact that very few students actually have clear ideas about their labor objectives in the long term, and how to orient their careers accordingly. Being in contact with the industry helps them to get an insight on the specificities of enterprises and the real work that they will be performing in the future, also helping in many cases to take personal decisions about the kind of jobs that they will pursue.
- The focus on practical tasks helps diversifying the kind of activities that a student has to ordinarily perform. This results in an increased interest and in fighting some of the student's negative feelings about the University and clarifying doubts about the actual usefulness of the studying activity. This is reflected in the fact that many students recognize PAVEs subjects as one of the most interesting activities within their degree programs and continue taking PAVEs courses during the following years.

The philosophy behind PAVEs subjects is quite in line with the new paradigm driving the EHEA. Specifically [10],

- The contents are mainly practical.
- Reduced student groups foster teacher-student interaction, while at the same time adapt better to the industrial premises which are often not adapted to big groups.
- Student-centric learning, meaning that the teacher acts like a guidance to allow the students "discover" the knowledge by themselves.
- Emphasis in group and collective work, sometimes even mimicking real team structure of the enterprise.
- Focus on industry-specific skills.

However, there is still some work to do in order to achieve a complete integration of the PAVEs program into the EHEA, mainly:

- Study of subject structure according to the formal conventions of the EHEA, namely distinction between on-site and off-site tasks, and a proper workload distribution among those tasks.
- Usage of English language.
- Introduction of transversal activities to foster the acquisition of side personal skills, including document search, organization and development, budget and team management, negotiation, etc.

IV. CONCLUSIONS

The PAVEs program of the University of Valladolid has revealed itself as one of the most attractive and innovative initiatives related to the courses offered to the students. Not only it comprises specialized and practical contents that are not frequently found in ordinary subjects, but also gives the chance to students to get in contact with the enterprises, a world that is mostly unknown for them, that they will have to join one day and that remains strange. Through this contact, students get an insight at the environment and practices in this strange world.

Additionally, some of the main characteristics of the PAVEs program have made it a very interesting experience to get some lessons for the adaptation of courses to the upcoming EHEA. The main driving philosophy, the idea that the practical contents should have a prominence and that the students should be playing the key role in their own education, is shared among the two initiatives. This means that while PAVEs subjects do not still fully conform to the conventions of the EHEA, they are a good value for extracting conclusions about the new orientation of the academic degrees.

Finally, letting the industries permeate somehow the University education may initially raise some concerns related to the influence and control they may exercise. Therefore it is worth mentioning that within the PAVEs program, the independence of the University as an academic institution is always guaranteed. PAVEs subject complete education programs introducing side knowledge into them as optional courses, never substituting the traditional base subjects.

Competence certification as a driver for professional development: A IT-related case-study

João Vasco P. Coelho
CIES-ISCTE
Lisbon / Portugal
vasco.jcoelho@gmail.com

Abstract— **Human resource managers have typically used certifications as an indicator of an individual skill set suitability for a specific position. Certifications act as a signal to hiring managers that a job candidate has achieved a level of knowledge and skill necessary to perform in a particular job role. In the IT (Information Technologies) sector, a recent study sought to determine if human resource managers (HR) and IT professionals perceived certifications differently in the context of the hiring process [7]. The purpose of this exploratory case study was to determine how IT professionals perceive certification programs as a professional training alternative, when compared with more traditional education settings, and the kind of effect the effective participation in one of the programs has in that judgment. The data for this exploratory study was gathered from a 58 employee sample of a Portuguese-based multinational software engineering company. An experimental *Competence Certification Effects Scale* (CCES) was used, and after a consistency analysis, the original 22 items were reduced to 17, grouped in a 4-factor structure: "*Intrinsic Value*"; "*Certification as Training*"; "*Career Management*"; and "*Effort Trade-off*". Cronbach`s alphas were .81, .81, .83, and .81, respectively.**

In short, the findings of the study indicate that there is a significant difference in the perceived usefulness of a certification, if an employee participates or not in a dedicated certification program. This difference is more significant in more senior, management-related roles, as for junior engineers that don't participate in a certification program, this participation isn`t seen as a professional development anchor or a valid education driver. The paper presents and discusses the study`s main results in points III to V, after describing methodological aspects and the underlying theoretical framework.

Keywords-component; Competency certification; Self-directed learning; Career management

I. Learning and training in the contemporary work space: The IT sector case.

In present contemporary workspaces, punctuated by severe competition pressures, the accelerated incorporation of technology in work processes, and the prevalence of high paced information exchanges and commercial trades in a worldwide scale, the individual, group and organizational differentiation that can co-exist in work organizations is a fundamental attribute in their current social development consolidation paths. Having this setting in mind, the certification of professional competences represent one of the available alternatives to adjust the workforce to flexible work processes demands, also responding to social and labour rights compliance needs ([1], [7], [14]).

It is fairly documented that the contemporary society is characterized by rapid developing and ever-changing political, social, economical, technological and environmental situations. Consequently, living in the 21st century is making great demands on its members in virtually every aspect of their lives. Technology subjects and the engineering domain are, in particular, affected by this situation. As a result of this, educational approaches have changed over the last century from remedial repetitive learning to today's learning, which focuses on acquiring an understanding of how to become more independent in the learning process [3]. Learning is no longer concentrated mainly in the first stages of human life through formal education and specific training in business, but it becomes a day-by-day routine over a individual's life cycle. This situation requires new forms and channels to animate learning processes.

Considering the set of institutional devices that is possible to trigger or implement to get a enriched adjustment of each worker to a particular job role, professional training currently occupies a prominent role, as it represents a strategic process to adapt the knowledge profile of a company`s workforce. Nowadays, corporate training and education services correspond to a fundamental regulation tool in the competence development domain, and must be understood not only as an economical or organizational redesign resource, but also as a personal change opportunity, in the sense that provides a setting to change a worker`s behaviour, beliefs and knowledge pool. In fact, according with Tajfel`s social identity theory [17], it`s reasonable to suppose that professional training practices act in order to enable positive social identity dispositions and a satisfactory self-image, as a training program participation has a positive effect in terms of self-esteem, in those that are enrolled and make part of it.

The current value that his given to learning processes in the workplace, has a different origin than the seminal 19th century goals that justified the emergence of skill enhancement measures, has a way to enable the industrial labour force cultural emancipation; currently, continuous learning and skill development are closed linked to productivity, quality and aggressive competition needs, that highlight the workplace as one of the most relevant social locus to support (formal and informal) learning processes. Authors like Lave and Wenger [12], and Billett [3] consistently state that a workspace, whatever its context or specificity, is the ideal social milieu to promote individual and group-related learning and social integration, due to the tight connection that it promotes, by articulating the theorical "world" with professional, concrete practices.

In this sense, it`s understood that formal education and training (and certification) contribute to only a small proportion of learning at work [10]; developing a understanding of situations, colleagues, the work unit and the organisation are examples where learning primarily occurs while working, rather than in a formal educational setting [3]. Similarly, much learning that occurs at work depends upon peer interaction and knowledge sharing, and the use of knowledge resources outside formal education and training settings.

The possibility of each individual become a co-creator of his/her education biography through the lifespan, is a tendency that reinforces the idea of multiplication and co-existence of multi-level learning locus in contemporary work organizations. When employee development budgets are being scrutinized, blending learning into the way work is done is more important than ever. Organizations need their learning approach to be more innovative and efficient than ever before - to make the most of technology advancement, reach geographically dispersed learners, and meet budget requirements. If what people need to learn is defined by organizational business priorities, new learner-centered mediums integrate this learning into the workflow.

Self-paced learning mediums depend of several individual cognitive attributes, such as self-management and learner control, self-direction and motivational dispositions [6], and particular development needs of each employee, with little or none external supervision. With this medium, individual motivation to engage in learning tasks and the external encouragement of their fulfilment, are primary drivers that enlarge education domains to virtual, technology-driven immaterial learning contexts, changing the way learning processes are seen, making them more accessible, dynamic and flexible [4]. Through technology and, in particular, web-based developments, it is easier to communicate, share ideas and specific knowledge.

Despite these changes, it`s rather relevant to teach people how to use the technology to have a social learning experience and collaborate in knowledge sharing, and, in a organizational setting, to learn how to mediate a process that has as drivers subjective and relational features. To some extent, learners need to learn how to capitalize knowledge on the social milieu, by learning to learn with and from others, and managers are asked to learn to mediate others' learning, not only for their sake but for what that will teach oneself, and learning to contribute to the learning of a collective.

Duderstadt [9] suggests that we are experiencing a shift from just-in-case to just-in-time to just-for you education, equivalent to a shift from synchronous, classroom-based instruction to asynchronous e-learning, to ubiquitous learning opportunities. This author uses ubiquitous learning to refer to a culture of learning in which people are continually surrounded by, immersed in, and absorbed in learning experiences; a necessity in a world driven by an expanding knowledge base and need for continuous learning.

Organizational training processes goals cannot be resumed to merely instrumental, business-driven targets that, despite the legitimacy, erode the emancipation and development potential associated with that processes implementation. Training practices are valued by stakeholders as inclusive strategies, a symptom of a organization`s maturity and concern to address its labour force particular skills and career development needs.

Promoting an autonomy and learner-centered culture opens the possibility for a organization to experiment different strategies for addressing skills adjustment needs, allowing individual initiatives in the definition of career and development projects. Self-paced instruction and computer-based training, training delivery forms that can be triggered within a anytime, anyplace approach, have been gaining visibility as valid alternatives to conventional instructor-led classroom training.

In this context, the particular question of how to validate new skills and knowledge informally build is frequently raised. Credentials and certification programs, used by HR managers as indicators of an individual skill set suitability for a specific position, currently are in the spotlight as career and skill development anchors [2]. The participation in certification program is recognized as faster, cheaper, and more focused education alternatives, yet, many questions arise around the issue of how occupation specific credentials compare with the more traditional educational qualifications.

According to Bird [4], a changing economy and job market places a higher value on knowledge and applied skills. In the IT sector, a domain where credentials and certifications are increasingly being valued, certifications act as a signal to hiring managers that a job candidate has achieved a level of knowledge and skill necessary to perform in a particular IT job role. The findings of a recent study [7] indicated that managers placed a greater emphasis on certifications when hiring for IT related positions. The question of whether certified individuals are better able to perform in an IT job-role, than non-certified individuals becomes relevant in the hiring process [1].

Existing theory provides a strong conceptual framework for examining the role of industry credentials in recruitment for IT positions. Qualifications and credentials have long served as signals for organizations. Signaling theory, originally developed in economics, suggests that employers require information (observable characteristics and attributes of an individual) about potential employees to determine the job positions and salaries offered to the employee ([15]; [14]). Some observable attributes of individuals are unalterable (e.g., age, gender), while others are subject to change usually at the initiative of the individual (e.g., education). Spence [15] referred to these alterable attributes as signals.

Presently, any individual can claim to be an "expert" in a particular process, subject matter or technology. But for employers, quality assurance is vitally important in this context. Since employers have incomplete information about the knowledge, skills, and abilities of applicants, they use qualifications and credentials as signals for making inferences about missing information in determining the likely suitability of prospective employees [14]. The value that organizations place on different qualifications can also act as a signal to applicants. For example, organizational preferences for either externally validated assessment of skills (IT or management certifications, for instance) or more traditional college qualifications provide applicants with information about what it would be like to be a member of that organization, and what type of skills and knowledge it values.

The demand for workers with specialized skills has placed a considerable pressure on traditional educational strategies to provide a qualified and sustainable workforce. In the IT sector, certifications have become a standard precursor to employment for many IT job roles serving as a "work ready" indication to HR managers, that specific precursory knowledge or competencies have been met.

Despite the growth in the use of these programs as institutional training alternatives, their success isn`t linearly guaranteed, as they depend, in a considerable scale, of the applicants` commitment to learn, their ability to control and pace learning activities, and the existence of external support and encouragement. These variables are particularly relevant if the certification programs success largely depend of self-paced learning efforts [6], a potentially conflictive context where learning activities can be seen by applicants as a result of personal investment, and not as a result of a corporate learning policy.

II. METHOD

The relevance of this study is associated with the raising importance of learner and individual-centered learning processes, and the diversification of training strategies and learning *foci* that can co-exist in contemporary workspaces; in particular, the study is centered in the growth of competency certification programs in the IT sector, and in the way these programs and concrete participations on them are perceived by certification applicants.

In terms of analytical focus, a case-study research strategy was applied in a portuguese multinational IT-based company, whose activity combines expertise in several engineering disciplines, enabling software solutions for demanding and crosscutting problems. The company's engagement model covers the whole software life-cycle, from planning and analysis, to design, development, integration, testing and maintenance, and focus on enterprise oriented solutions for different markets. This organisation fosters constant innovation and the use of training and learning management top notch practices, providing all workers the best possible training for a large range of job roles. As the job requirements are becoming increasingly specialised, the implementation of certification programs in technical, managerial and language skills domains has become, during the past years, a relevant training instrument.

These programs are supported by practical seminars, informal peer-based knowledge sharing, and, to some extent, self-directed learning that is encouraged by the organization`s team and area managers. In the past two years, more than 70 certifications were obtained, but, despite these success evidences, this exploratory case study aims to determine how IT professionals of this particular organization perceive certification programs as a professional training alternative, when compared with more traditional education settings, the personal investment implied in the participation in one of this programs, and the kind of effect the effective participation in one of the programs has in the global judgment made about its efficiency and relevance.

A. Participants

The data for this exploratory study was gathered from a 58 employee sample of a portuguese based multinational software engineering company. An experimental *Competence Certification Effects Scale* (CCES) was designed and applied using a web-based questionnaire management tool.

TABLE I. CASE STUDY PARTICIPANTS: GENERAL DEMOGRAPHIC CHARACTERISTICS (N=58)

		n	%
Gender	M	54	93.1
	F	4	6.9
Age	24-29	29	50.0
	30-35	22	37.9
	36-43	7	12.1
Participation in a certification program (past 12 months)	Yes	31	53.4
	No	27	46.6
Job role	Junior Engineer	26	44.8
	Project Engineer	11	19.0
	Senior Engineer	2	3.4
	Engineering Manager	5	8.6
	Business Developer	1	1.7
	Project Manager	13	22.4
Years worked in company	≤ 1 year	19	33.8
	2 a 3 years	25	43.1
	4 a 5 years	10	17.2
	6 a 7 years	1	1.7
	8 a 9 years	1	1.7
	10 a 11 years	1	1.7
Total		*58*	*100*

The primary criteria used to identify the study participants, was the effective participation in a competency certification program in the 12 months prior to the scale`s application, or a planned participation in the 12 months period subsequent to the

CCES application. The participants` age varies between 24 and 43 years old, and as is presented in *Table 1*, there is a larger, but non-significant, percentage of study participants that effectively engaged in a certification program (53,4%). *Table 1* also shows that 26 of the 5 study participants occupy junior engineer roles, and 77% of the participants work in the company considered in the study for 1 to 3 years.

B. Procedure

This study`s deployment implied the request for participation of a group of employees, according the criteria described in the previous topic. 60% of the enrolled study employees replied to the participation request, and 58 scale answers were gathered and considered in the analysis procedures. The participation in the study was voluntary. According with the research questions and hypothesis – the concrete participation in a certification program has a positive modulation effect, in the way these programs are perceived as relevant skills and career development anchors –, a 22 Likert-like items exploratory scale was designed, with 5 answer options available for each item [1], ranging between total disagreement (1) and total agreement (5). The original *Competence Certification Effects Scale* (CCES) had 22 items, but after a communalities analysis (h^2) (see *Table 2*), five of the original items pool (items CCES_1, CCES_2, CCES_12, CCES_14 e CCES_22) didn`t reach the required cut point, 0.40 [16], and due to this they were removed form the analysis procedures.

The items used in the scale were inspired or adapted of previous learning and competency certification-related studies of Lave and Wenger [12], Candy [6], Rainbird [13], Cegielski [7], Souza and Luciano [14], and Billett [3]. To compile statistical measures, SPSS 17.0 was used as support tool. In order to explore the proposed scale underlying dimensions a exploratory factorial analysis was used; factor extraction used the principal components method and orthogonal *varimax* rotation. The adequacy of the factorial analysis was evaluated by means of the Kaiser-Meyer-Olkin test and Bartlett's sphericity test.

The CCES 17 final items inter-correlations matrix was subjected to analysis, and a 4-factor solution was found, with a total explained variance of 65.48%; the underlying sense of each factor was interpreted, and the scores of the first factor (F1: ValInt) were used as a indicator of a certification perceived intrinsic value, the second one was related with the value of a certification program as a institutional training option (F2: ValCertTrain), the scores of the third were related with career management effects (F3: CertGestCarr), and the fourth linked with the investment and effort trade-off (F4: EffortTrade) implied in a certification program participation. In order to identify group differences, *t* and *one-way* ANOVA tests were made, according with the groups formed by the independent variables *certification program participation*, *age* and *job role*, variables with a relevant effect in the explanation of the differences that were found. The adopted level of statistical significance was $p \leq 0.05$.

[1] Some inverted items were included in the exploratory study scale (CCES).

III. Results

The standardised coefficient alpha was used to estimate internal consistency for the CCES final scale and the results obtained for the 4-factor structure solution – "*Certification intrinsic value*"; "*Certification as training*"; "*Career management effects*"; and "*Effort trade-off*" – were .81, .81, .83, and .81, respectively. All items were positively correlated with the scale with the target item removed, when their correlations were examined by standard alpha coefficient analyses, a result that confirmed the relevance of the scale`s final 17 items.

The adequacy of the factorial analysis was evaluated by means of the Kaiser-Meyer-Olkin test and Bartlett's sphericity test. The KMO test score (KMO = .807 [≥ .60]) validates data adequacy to take the factorial analysis solution in consideration; Bartlett's sphericity test is also statistically significant (χ^2 =590.714 p = .000 [≤ .05]). After a communalities analysis (h^2) (see *Table 2*), five of the 22 original items pool (items CCES_1, CCES_2, CCES_12, CCES_14 e CCES_22) didn`t reach the required cut point, 0.40 [16], and due to this they were removed form the analysis procedures.

In order to explore the proposed scale underlying dimensions a exploratory factorial analysis was used; factor extraction used the principal components method and orthogonal *varimax* rotation, with factor retention for factors with *eigenvalues* greater than 1. The analytical procedures revealed a 4-factor solution with an *eigenvalue* greater than 1 ([5]; [11]), accounting for 65.48% of total explained measure data variance. Cattell`s screen test corroborated this observation. *Table 2* shows the 4-factor solution found for the measures, the scale items and correspondent communalities. Significant loadings, superior to .50 [16], were found for all factors.:

A. Participation effect in the value perception of a competency certification program

In what concerns the effect of participating or not in a program, taking into consideration the data gathered, it`s possible to see in *Table 3*, that the effective participation in a program has a relevant effect in the way a certification is seen, in terms of its intrinsic value (see F1: ValInt scores), its efficiency as training alternative (see F2: ValCertTrain scores), the associated effects related with career management possibilities (see F3: CertGestCarr scores), and the personal effort implied in the learning activities inherent to a program participation (see F4: EffortTrade scores).

Table 3 also reveals that there is, in particular, a significant statistical difference in the perceived intrinsic usefulness of a certification (see F1: ValInt scores), if an employee participates or not in a certification program. Despite this evidence, the scores obtained in this domain aren`t very high, when compared with the scores related with the efficiency of a certification as a possible training alternative (see F2: ValCertTrain scores), or a participation associated effects related with career management possibilities (see F3: CertGestCarr scores).

This suggests, in our opinion, that certification-oriented training programs tend to be judged in an instrumental way, more by its positive effects, benefits or rewards in terms of career management or professional within-peers recognition, than by its intrinsic value as institutional or personal development drivers. Besides the displayed analysis, a ANOVA data variance analysis was made, taking as independent variables the participation in a program and the job role of the participant, in order to perceive the nature of these variables interaction in the perceived intrinsic usefulness of a certification domain.

The effect that was obtained is statistically significant ($t = 3.79$, $p \leq .05$)

TABLE II. FACTOR LOADINGS MATRIX, AND ITEM COMMUNALITIES (H^2).

Factor	*Item*[2]	*Loading*	*h^2*
F1 [ValInt]	(CCES_3). A certified professional has a better job performance than a non-certified professional.	.724	.642
	(CCES_8) [inv]. A certification doesn`t validate a professional`s past experience or competency.	.695	.570
	(CCES_11) [inv]. A professional that isn`t certified feels less confident in his/her work execution.	.670	.459
	(CCES_19). A certification increases a professional`s level of confidence and his/her ability to be more competitive.	.636	.615
	(CCES_7). A certification is a quality guarantee of a professional`s services.	.594	.571
	(CCES_18). To be certified is to be a member of a distinctive professional group.	.556	.616
F2 [ValCertTrain]	(CCES_17). The certification is a motivating mechanism, because it helps the professional to obtain new certifications by learning new abilities.	.819	.712
	(CCES_21) [inv]. A professional certification, when compared with other training mechanisms, is a bad investment for a work organization.	.777	.737
	(CCES_9) [inv]. A professional certification isn`t necessarily a good career development driver.	.730	.644
F3 [CertGestCarr]	(CCES_10). A certified professional can obtain better salaries and benefits.	.856	.756
	(CCES_4). A certification is a driver to win several professional battles.	.703	.659
	(CCES_16). A certification can help to get a new job, in a faster and more adjusted way.	.703	.731
	(CCES_15). A certification enables a professional development congruent with personal and professional project and aspirations.	.448	.605
	(CCES_20). A certification is a proof that a professional deeply knows a particular matter, product or technology.	.421	.530
F4 [EffortTrade]	(CCES_5) [inv]. There is a large amount of psychological effort in a certification program, and the benefits don`t compensate these costs.	.881	.822
	(CCES_6) [inv]. To get a certification demands a excessive effort, when compared with possible benefits.	.820	.746
	(CCES_13) [inv]. Getting a certification mainly result from industry and market pressures, not from personal or organizational benefits.	.675	.719

[2] The scale version used in the study was originally in Portuguese.

TABLE IV. VALUE PERCEPTION OF A COMPETENCY CERTIFICATION PROGRAM: JOB ROLE AND PROGRAM PARTICIPATION INTERACTION EFFECT (MEANS).

[Participation/No participation] ***F1 (average)***	***Junior Engineer***	***Project Engineer***	***Senior Engineer***	***Engineering Manager***	***Business Developer***	***Project Manager***	***Total (n=58)***
Participation in a certification program	2.81	3.02	3.17	3.25	n.a.	2.97	**2.96**
No participation in a certification program	2.68	1.79	n.a.	1.50	3.83	3.15	**2.69**
Total	2.74	2.58	3.17	2.90	3.83	3.08	**2.83**

The analysis of the differences obtained in terms of the perceived intrinsic usefulness of a certification, considering the participants job role (see *Table 4*), reveals that higher scores are registered in management-related roles, as for engineering roles, and in particular, junior roles that don't participate in a certification program, a certification isn`t intrinsically valued as a valid professional development anchor or education driver. In these cases, expectations are somewhat low, but the effective participation in a program, apparently has a positive effect in revamping previous (low) beliefs and expectations related with the perceived intrinsic usefulness of a certification; aligned with these observation, we can state that, for this study`s sample, participation itself helps to enhance the way a certification program is intrinsically valued.

III.B. *Age and job role effect in the value perception of a competency certification program*.

Checking the effect of the variable *age* in the value perception of a competency certification program, reveals that there are differences in the perceived usefulness of a certification, and higher scores are obtained in elderly participants

groups (in particular, in the measure domains F1 and F3); in a broad sense, the older the participant is, the more likely is him/her to value the participation in a certification program.

A remark must be made, however, about this assumption: for more senior participants, probably due to the position that they already occupy in the organization (40% are Project or Senior Engineers, and 30% are Project Managers), the effort trade-off implied in a program participation isn`t unequivocally favoured (see F4 scores). Statistically significant differences were obtained in this domain ($t = 3.98$; $p < .05$), as can be seen in *Table 5*.

It`s reasonable to suppose that the higher score obtained for the intermediate age group (30-35y) can be associated to the career development stage the participants are immersed in, in the sense that a ascendant career phase can help to perceive a personal learning investment as reasonable, desirable or manageable, having in mind possible future benefits; this doesn`t occur so clearly with younger or older participants, as these benefits aren`t so clearly projected, due to the junior, low-hierarchy or more senior, top-hierarchy roles these participants have. In this sense, the variation in the degree of engagement to reason and manage the personal effort implied in a program participation and correlated learning activities, is a important variable to predict the success of these programs, and must be seen with particular caution by those who promote them, as part of a corporate skills development strategy.

TABLE 5
Age effect in the value perception of a competency certification program.

		24-29y	**30-35y**	**36-43y**
F1 [ValInt]	***M***	2.70	2.87	3.29
	SD	.75	.86	.64
	t	1.65		
	p	.20		
F2 [ValCertTrain]	***M***	3.83	4.24	4.24
	SD	.92	.81	.50
	t	1.77		
	p	.18		
F3 [CertGestCarr]	***M***	3.66	4.00	4.03
	SD	.77	.70	.54
	t	1.66		
	p	.20

	SD	.91	.77	.78
	t	3.98		
	p	**.02**		

The efficiency of a program partially depends of the participants` commitment degree, and the foreseen career development opportunities associated with these participations.

Work division, organization structures and job roles career lines condition the scope and range of these opportunities, subjectively linked to promotions, functional mobility and compensation improvements. In this study, the effect of the variable job role in the value perception of a competency certification program was considered, when analyzing the differences obtained in terms of the perceived intrinsic usefulness of a certification, considering the participants job role (see *Table 4.2*); as referred, higher scores were registered in management-related roles.

This relation is corroborated by a ANOVA data variance analysis, taking as independent variables the participation in a program and the job role of the participant, in order to perceive the nature of interaction of these variables in the perceived effects of a participation in terms of career management opportunities (see *Table 6*). The effect that was obtained is statistically significant ($F = 3.69$, $p < .05$).

IV. DISCUSSION

The findings of the study fairly corroborate the initial research hypothesis related with a predicted positive effect of a concrete participation in a certification program, in the way these programs are perceived as possible skills and career development anchors. Significant differences were found in the perceived usefulness of a certification, if an employee participates or not in a certification program. The exploratory scale (CCES) presents satisfactory psychometric qualities in the used sample, but further studies are necessary with larger samples to further test the scale in other organizational contexts. In a overall sense, four specific remarks must be addressed, concerning the results that were found related with the perception of a certification program as a professional training alternative (when compared with more traditional education settings), the personal investment trade-off implied in the participation in one of these programs, and the kind of effect the effective participation has in the global judgment made about a certification program efficiency and relevance:

TABLE V. CAREER MANAGEMENT CERTIFICATION PROGRAM EFFECTS:JOB ROLE AND PROGRAM PARTICIPATION INTERACTION EFFECT (MEANS).

[Participation/No participation] ***F3 (average)***	***Junior Engineer***	***Project Engineer***	***Senior Engineer***	***Engineering Manager***	***Business Developer***	***Project Manager***	***Total (n=58)***
Participation in a certification program	3.51	3.91	4.00	4.10	n.a.	4.36	**3.85**
No participation in a certification program	3.83	3.70	n.a.	1.80	4.20	4.08	**3.82**
Total	3.67	3.84	4.00	3.64	4.20	4.18	**3.83**

a) In what concerns the effect of participating or not in a program, taking into consideration the data gathered, it`s reasonable to assume that the effective participation in a program has a relevant effect in the way a certification is seen, in terms of its intrinsic value, its efficiency as training alternative, the associated effects related with career management possibilities, and the personal effort implied in the learning activities inherent to a program participation. There is a significant statistical difference in the perceived intrinsic usefulness of a certification, if an employee participates or not in a certification program; despite this evidence, the scores obtained in this domain aren`t very high, a disposition that suggests, in our opinion, that certification-oriented training programs tend to be judged in an instrumental way;

b) The job role apparently has a modulator effect in terms of the perceived intrinsic usefulness of a certification, as higher scores were registered in management-related roles, and in particular, in engineering junior roles, a certification isn`t intrinsically valued as a valid professional development anchor or education driver. In these cases, expectations are somewhat low, but the effective participation in a program, apparently has a positive effect in revamping previous (low) beliefs and expectations related with the perceived intrinsic usefulness of a certification;

c) In a general sense, the older the participant, the more likely is he/she to value the participation in a certification program. A remark must be made, however, about this trend: for more senior participants, probably due to the position that they already occupy in the organization (40% are Project or Senior Engineers, and 30% are Project Managers), the effort trade-off implied in a program participation isn`t unequivocally favoured.

d)

e) The age-related and job role-related variations in the degree of engagement to reason and manage the personal effort implied in a program participation and correlated learning activities, is a important variable to predict the success of these programs, and must be seen with particular caution by those who promote them, as part of a corporate skills development strategy.

V. CONCLUSIONS

The relevance of this study is associated, we think, with the raising relevance of learner and individually-centered learning processes, the shift from *just-in-case* to *just-in-time* to *just-for you* education approaches [9], and the diversification of training strategies and learning *loci* that can co-exist in contemporary workspaces. Despite the growth in the use of these programs as institutional training alternatives, their success isn`t linearly guaranteed, as they depend, in a considerable scale, of the applicants` commitment to learn, their ability to control and pace learning activities, and the existence of external support and encouragement, and, for this study`s sample, the age and job role of the certification program applicants. These variables are particularly relevant if certification programs success largely depend of self-paced learning efforts, a potentially conflictive context where learning activities can be seen by applicants as a result of personal investment, and not as a result of a corporate learning policy.

Investing in formal self-paced learning efforts within the workspace imply a shift in the way training periods are conventionally planned in work organizations; creating multiple learning *loci* in contemporary workplaces, using, for instance, competency certification programs as a option, is a current managerial challenge, as it poses new involvement demands to managers and training promoters, the need for constant renewal of training materials and resources, due to high-paced knowledge erosion, and the systematic monitoring of individual, asynchronous skill adjustment efforts.

Abstract—**Work Internship Placements (*WIP*) is a transversal programme of enterprise internships for the engineering students of UdG which is focused on quality improvement, academic control and satisfaction of collaborating enterprises. The fundamental *WIP* infrastructure is a web-based intranet platform that provides a complete set of *WIP* tools, procedures and tasks involved in all internships stages for every participating agent: enterprises, students, coaching professors and administrative staff. Our new programme is centered on a broader, more holistic internship placement procedure than the traditional "career and academic goals" approach. The *WIP* programme has been found to be a valuable asset in addressing enterprise and student needs in the experiential project.**

Keywords: work integrated learning; engineering internship programme; quality placements; intranet web platform; internship coaching

I. INTRODUCTION

Exposing engineering students to a real working environment provides the student with a complimentary and fundamental view about engineering, being a key component in the Bologna process. This work integrated learning (*WIL*) approach could be included in the concept of "*WIL* as preparation for future employment" in the set of types of *WIL* explained by [1,5,7].

The quality of the practical placements is determined by the contents, duration, allotted credits and also by the quality of resources, the stage organization and the procedures of monitoring and evaluating the competences acquired by the students. As described in [4], the success of a practical placement model requires the design and accomplishing of a quality assurance system for the practical stages, which comprises: (1) establishing objectives and quality assurance policies, (2) establishing organizational structures and responsibilities, (3) drawing up documents and human resources assurance, (4) monitoring, analyzing and improving the quality of the educational process through practice stages.

There are no general patterns for elaborating a quality assurance system for practical placements, since their structure is influenced by the general management of the university, by the philosophy of the university regarding the place and role of the practical placements, by economic and politicalsocial factors both at national and international level. Whatever the adopted system is, in order to be efficient and functional, it must attract the participation of the whole staff and promote a new system of values in the university and in the company, specific to the quality culture, which includes continuous improvement, focus on clients, extended cooperation and partnership.

Enterprise internships have always had a great importance and interest in the bachelor engineering programs of the Polytechnic School (*EPS*) of the University of Girona (Spain). This preliminary professional training experience, carried out during the last academic year of the engineering studies, provides students with an opportunity to apply what they have learnt in a real environment and to acquire useful and efficient new work habits. Moreover, internships become a fundamental key factor in the student academic motivation, as also pointed out in [2].

Although the Polytechnic School understood internships as a key component of the academic curricula, some drawbacks were detected in the existing implementation of our internship programme. First of all, there was a lack of control of the working plan, due to a strong dissociation between the University and the enterprises. The coordinator of the engineering degree was formally responsible for the evaluation of the internships, among the many other tasks he had to carry out. Therefore, we could not effectively audit the academic contents of the internships. It should be noted that the coordinator's assessment was based only on a "*pass*/*don't pass*" strategy, and the student obtained a positive evaluation as far as he could prove that he had carried out the internship. Unfortunately, the university did not have a catalogue of companies offering internships. Therefore, the student had to look for a company, and the first contact between the university and the company was carried out by the student itself. With this situation, the offers could be too balanced towards the particular interests of either the enterprise or the student. Thus, in some cases, companies proposed working plans that were too biased towards their needs, sometimes without a valuable academic content for the student. The other undesirable situation with the existing internship model was that some students reached agreements with small companies were they had a personal/family contact, so that, in those cases, the student could not be objectively evaluated by the company. Finally, we had confirmed some cases of dissatisfaction with students regarding the academic content of their working plan, and with companies that were also disappointed because they were hiring students with the wrong profile and/or motivation.

For this reason, we started in 2005 a new transversal program of *EPS* internships that we named *Work Internship Placements* (*WIP*) which has been designed specifically to overcome the drawbacks of pre-existent programs while taking profit of their positive aspects. Thus, *WIP* is focused on internship quality improvement, increase of the academic control and, simultaneously, on promoting the interest and satisfaction of collaborating enterprises.

One of the key elements in the success of *WIP* is that it makes available to all internship participating agents (students, enterprises and university staff) a specifically designed intranet web platform which centralizes the set of tools, procedures and tasks involved in all internships stages: fluent communication among participants, partner contacts, information, registration, management, statistics and evaluation.

II. WIP METHODOLOGY

Before the deployment of *WIP*, the methodology to audit student internships was based on awarding some academic credits that were proportional to internship time. In contrast, in this new programme, students are enrolled in a specific *WIP* course –which is included in the engineering curriculum– having a selected team of coaching professors devoted to follow the advances of the student during the internship. A key point of the *WIP* programme is the adequate selection of these coaching professors, who not only monitor the internship, but also actively counsel students involved in this off-campus learning experience. For this reason, coaching professors should have experience in working with private companies, but should also know and understand the "culture" of every enterprise where a student is placed, guiding the student not only in the technical aspects of his work, but also in the typical way of behaving within the organisation. On the other hand, beyond providing support and guidance to the students, coaching professors also participate in the design of the internship activities, providing feedback to the companies and enabling synergies with existing research groups of the university that could add value to the company through technology transfer contracts. Therefore, adequate selection of coaching professors is one of the pillars for the success of the *WIP* programme.

The *WIP* programme works as follows: (1) participating entreprises and institutions propose online their *in situ* engineering placements, (2) placement proposals are revised and approved by *WIP* administration, (3) students access the web and apply for placements according the their curriculum and interests, (4) enrolled enterprises automatically receive an email with a link to examine the curriculum of the applicant every time a student selects that offer. Once the enterprise receives all the applications, the students are interviewed and, possibly with the help of coaching professors, the enterprise carries out its selection. (5) Whenever a student has been selected for a given placement, a coaching professor from *EPS* and an engineering coach from the entreprise are assigned to the student. (6) The internship starts with a meeting between the coaching professor, the enterprise coach and the student. During this meeting a working plan is defined in detail, pointing out the tasks that will be carried out by the student. (7) During the internship, those three partners are in contact at regular arranged times under the supervision of the coaching professor. (8) After the internship, the student is assessed by the coaching professor taking into account the enterprise opinion (this is carried out by contacting the enterprise coach).

III. WIP WEB PLATFORM

The *WIP* intranet Web Platform (*WIPWP*) has been designed, implemented and configured specifically by the *EPS* to satisfy the requirements of the *WIP* model (see Figure 1). From a technical viewpoint, the platform has been always hosted on a Red Hat Linux server of our faculty.

WIPWP has been developed mainly in PHP language while some user interacting functionalities had been implemented in Javascript and AJAX. *WIPWP* is supported by a MySQL independent database and performing temporary data connections with other university central databases for data interchanging.

Figure 1. *WIP* homepage. Public zone which main functions are enterprise registration and registered-user login.

Despite its faculty specificity, *WIPWP* design easily allows being adapted and configured to be used by other faculties either in our university or outside. For instance, at present, and due to the success of the *WIP* model, the Faculty of Economics of our university is finishing its own adaptation of our *WIPWP*.

Functionally and from the user point of view, *WIPWP* has been split into five "agent" zones corresponding to the actors playing a role in the *WIP* model: *public-common zone*, *enterprise zone*, *student zone*, *coaching professor zone* and *administrative staff zone*. Moreover, there is a "super-agent" zone of *administration-managing.*

The platform works always under HTTPS network protocol to provide users a secure data flow. Access to the registered "agent" zones is protected by means of user defined passwords and specific PHP authentication code, while the "super-agent" zone uses a particular HTTP authentication scheme.

A. Public-Common zone

This area is the public unregistered zone of the intranet and also the common login door to "agent" registered zones. Its main functionality is allowing the registration of new enterprises to the platform; but it contains also general information about the *WIP* performance, the list of coaching professors, the list of collaborating enterprises and the public news section.

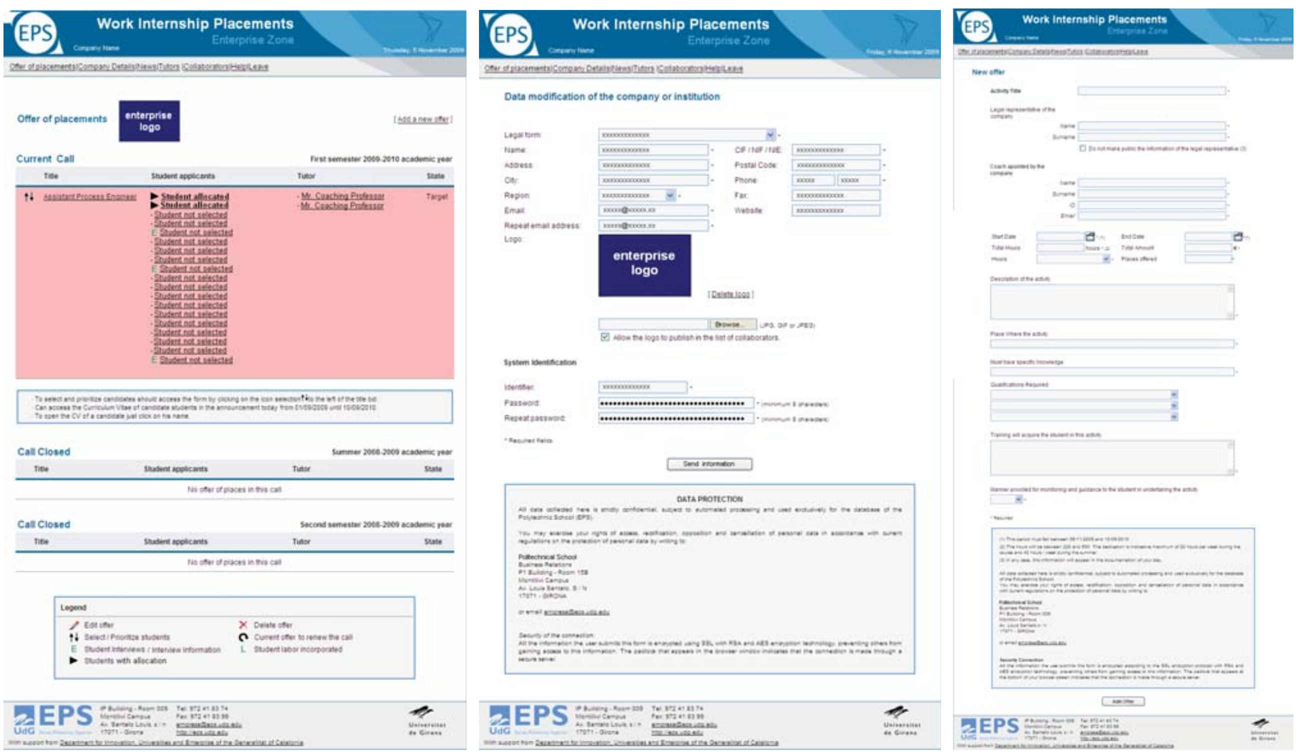
Whenever an enterprise has filled in the registration form it receives an email message to verify its email address. To verify the confidence of those registrations, the *WIP* platform administrators contact all new registered enterprises at regular intervals or whenever a new enterprise makes a placement offer.

B. Enterprise zone

As already stated above, enterprises require a compulsory registration to access this zone which is dedicated to participating enterprises (see Figures 2 and 3).

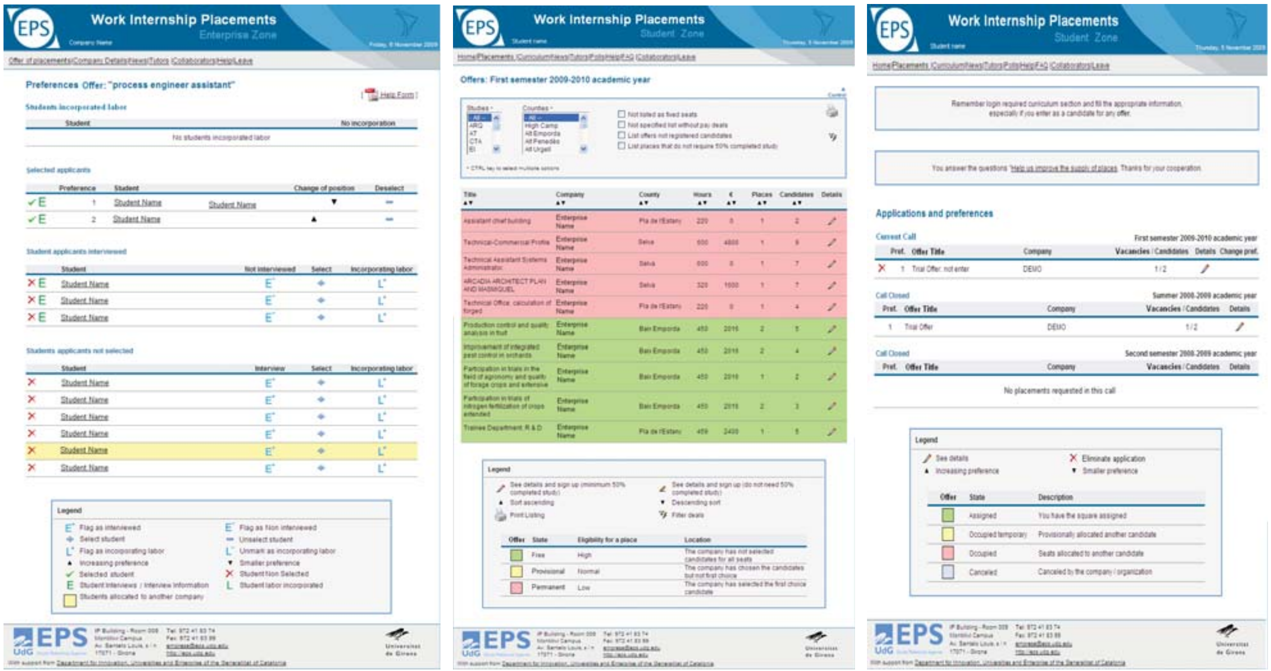
The *enterprise zone* includes the following enterprise devoted services:

- *Offers service*. It includes: adding offers, state of offers, full offer information, cancellation of offers, list of applicants for every offer, access to curriculum of the applicants, etc.



(a) (b) (c)

Figure 2. Sample web interfaces once the enterprise has registered online. (a) Information about the offers submitted by an enterprise; (b) Enterprise modification data form; (c) Placement offer form.



(a) (b) (c)

Figure 3. (a) Enterprise zone: The applicants'selection and preference setting form as seen by an enterprise. (b) Student zone: List of available placements seen by a student. (c) Student zone: A student application form

- *Selection service*. Includes: selection of applicants setting the preference order, interview information, etc.
- *Enterprise data service*. Data modification of every enterprise in the platform.
- *Coaching professors service*. The list of coaching professors (including contact information) in every *EPS* degree.
- There is also a news and documentation section, a collaborators section and a help section.

C. *Student zone*

Students, as members of the university community are already registered users of the university network, so EPS students do not need any specific registration in the *WIP* intranet and they should simply use their corresponding university intranet authentication data to access also our platform (see Figure 3 b-c).

The *student zone* includes the following student dedicated services:

- *Application service*. It includes: state of allocation, full application information, cancellation of applications, change of preferences, etc.
- *Curriculum service*. The personal data and *EPS* training data are automatically filled in, so the student needs to complete only his/her work experience and additional information.
- *Placements service*. The complete list of placement offers (details, vacancies, number of applicants, state of allocation, etc.) which can be filtered depending on student interests and the application form.
- *Coaching professors service*. The list of coaching professors (including contact information) in every *EPS* degree.
- As in the enterprise zone there is also a news and documentation section, a collaborators section, a help section, a FAQ section and a surveys section.

D. *Coaching professor zone*

As explained before in the case of students, specific registration for *WIPWP* professors is not required.

The *coaching professor zone* includes the following services (see Figure 4):

- *Coaching service*. Including: list of assigned student-enterprise pairs, partner contact information, assess form, placement documentation state, etc.
- *Enterprise service*. Complete list of enrolled enterprises with complete contact information.
- *Placements service*. Complete list of placement offers (details, vacancies, number of applicants, state of allocation, etc.) which can be filtered depending on user interests.

- C*oaching professors service*. List of coaching professors (including contact information) in every *EPS* degree.
- It also includes: a news and documentation section, a collaborators section, and a help section.

E. *Administrarive staff zone*

Administrative staff members are also users of the university network, so they do not require registration either. This zone is devoted to administrative staff services focused on providing information (list of placement offers, list of enrolled enterprises, list of coaching professors, administrative staff news, etc) and not on acting on the platform.

F. *Administration-Managing zone*

This zone is devoted to administrative and managing tasks of the *WIP* model and de managing utilities of the *WIP* web platform itself.

The *administration-managing zone* includes the following detailed and extensive management services: *enterprises, placements, applications, allocation algorithm, coaching assignments, placement documentation, coaching professors, students, emails, news, call for offers, statistics,* etc.

An interesting and useful functionality implemented in the "super-agent" zone is the possibility to emulate a login playing the role of any registered "agent" of the *WIPWP*. That login emulation is complete, in the sense that the "super-agent" could, not only monitor exactly what the emulated "agent" would see, but also act, if necessary, as the emulated "agent" itself. This emulation has several benefits: (1) instantaneous and exact monitoring of user's activities from their point of view, (2) efficiency in user problem solving, (3) executing actions on user demand, (4) testing new functionalities and (5) easiness of implementation by means of the correspondent "agent" zone services.

IV. WIP ALLOCATION ALGORITHM

Finally, *WIPWP* includes also an Automatic Allocation Algorithm (*WIP3A*) which, taking into account the declared preferences of the allocation's phase actors (placement offering enterprises and applicant students) performs the allocation.

From the *WIP3A* point of view, students can be in one of these three different allocation states:

- *Not allocated*, when the student does not have an allocation.
- *Provisionally allocated*, when the student has an allocation which he has not yet accepted, so that allocation could be replaced by other student's priority allocations.
- *Permanently allocated*, when the student has an allocation already accepted by him or an allocation which has the highest student's appliance preference.

And placements can be in one of the following four different allocation states, according to the allocation algorithm:

- *Free allocation*, the placement has no applicants or the algorithm has not set a different state to the placement yet.
- *Void allocation*, the placement does not have an allocated student after algorithm execution.
- *Provisional allocation*, whenever the placement has a *provisionally allocated* student.
- *Permanent allocation*, whenever the placement has a *permanently allocated* student.

WIP allocation proceeds as follows:

(1) Students can apply simultaneously to several placement proposals setting a preference order.

(2) Enterprises can also select several students from the corresponding applying offer list and set their preference order too.

(3) Every time *WIP3A* is executed, placements in the *void allocation* state are set to the state of *free allocation*. Then the algorithm looks for the set of placements in state of *free allocation*, which is named the *Free Placement Set* (*FPS*). One *free placement* is taken from *FPS* and named the *target placement* –i.e. the placement that the algorithm would try to allocate–. Therefore, accordingly to the enterprise preference order, the first selected *not allocated* or *provisionally allocated* applicant in a lower student preference placement, if any, would be allocated in that *target placement*; otherwise –i.e. the *target placement* has no applicants, has only applicants *permanently allocated* or *provisionally allocated* in a higher preference placement– the placement is set to the *void allocation* state. Any new allocation would be always *provisional* excepting those cases where the *target placement* has the highest student preference or the student has already accepted it; only in these above mentioned cases the allocation would be *permanent*. The target placement would be always removed from the *FPS*. One of the collateral effects of this procedure will be that some *provisional allocated placements* could be let into a *free allocation* state and added to *FPS*, because its students "had been stolen" by other placements which are more interesting for those students. The process is repeated, by taking another *free placement* from *FPS*, until *FPS* is empty (i.e. there are no *free placements* left).

(4) *WIP3A* could be executed automatically whenever any agent carries out an action or in a managing supervised scheme at regular time intervals.

Finally, it must be noticed that despite the fact that both (applicant students and offering enterprises) had pointed out its preference order and enterprises had carried out a selection of students, the final decision (placement acceptation) and the prevailing preference criteria (for instance, whenever several enterprises had selected simultaneously the same applicant student) would be, obviously, on the student side.

(a) (b)

Figure 4. (a) List of students allocated to a coaching professor. (b) List of placements (top) and list of applicants for a given placement (bottom) as seen by a coaching professor.

V. RESULTS

The Work Internship Placements programme has currently completed its fourth year of operation. Table 1 summarizes the obtained results. It should be noted that although the number of enterprises that joined the programme has been increasing at a good pace, the number of student placements has also increased, but it decreased on the last year. This decrease is explained because of the international economic crisis, which has especially affected several companies of our local industry. On the contrary, the number of students that participate in the programme has kept a constant growth, with 370 students on the last year, generating more than 850 applications. This compares to the 111 students of the first year that generated 174 applications.

One of the keystones that enables this growth is the efficient performance of our automated web service, which allows an optimal interaction between students, enterprises and academic staff. This web portal is scalable, and allows the increase of the number of internships and companies with a very limited overhead for the administrative staff.

	2005/06	2006/07	2007/08	2008/09
Enterprises in the *WIP* platform	45	100	195	230
Enrolled enterprises	35	70	130	90
Placements	76	122	213	151
Applicant students	111	171	245	370
Applications	174	288	529	869
Placements with allocation	37	55	90	78
Placements without allocation	39	67	123	73
Students evaluated as "optimum"	33	39	49	55
Students evaluated as "suitable"	4	16	24	22
Students evaluated as "unsuitable "	0	0	1	1

Table 1. Quantitative results for the first 4 years of the Work Internship Placements (*WIP*) programme.

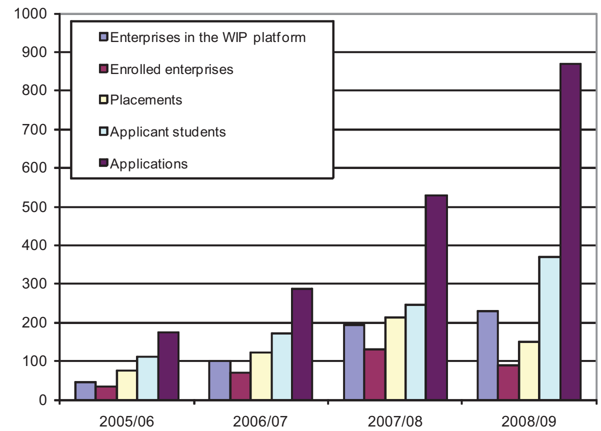
On the other hand, we observe that the performance of the students is very good. Since the students are qualified on a 3-grade system, most of them obtain the "optimum" grade, a few obtain a "suitable" and a much reduced number of students do not obtain a positive evaluation of the internship. In this grading, the coaching professors consult and take into account the opinion of the company before judging the work of the student. Finally, it should be noted that the allocation of placements works very well by automatically following the algorithm described in section IV.

It is also important to note that, currently, the programme is not pre-defined. On the contrary, it is constantly developing. Continuous interaction and dialogue between faculty and industry is the cornerstone of the internship programme. For this reason, the web service has dedicated zones to for interaction between the different participating agents (students, faculty and companies) to interact in an optimal way. Moreover, at the end of the internship, we collect the opinion and observations of the enterprise coach, the student and the coaching professor. This feedback is crucial to the success of the project and critical for adopting corrective actions in the benefit of the programme. Finally, and provided that coaching professors are a key element in the success of the project, it should be noted that efforts are also being made to obtain new faculty members with industrial experience who will eventually act as coaching professors.

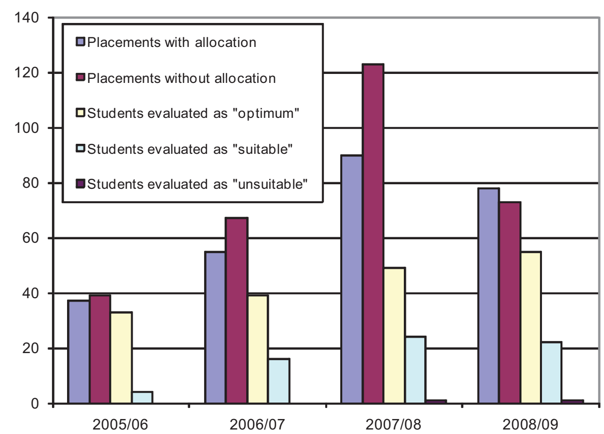
VII. CONCLUSIONS

Currently, the *WIP* course is not yet mandatory in our degree programmes, but according to the strategic guidelines of the Bologna process and as a result of its success, it will be mandatory in the near future for some of engineering degrees of EPS. This mandatory nature of the *WIP* is also supported by the regional environment business world main opinion that this course makes a very significant contribution towards providing industry with engineering graduates who are well-prepared to assume responsible and productive engineering assignments, with less need for on-the-job training and with generic skills through problem-based learning (as explained in [6]). This significant contribution agrees with many research works, for instance see the UK study presented in [3], where the author points out the positive effect of industrial placement schemes on future engineer students employability.

Moreover, it should be noted that the development of a web platform that automates and monitors the different steps of the internship process is a key tool to improve the quality both for the students and for the enterprises. This model is perfectly scalable, so that an increase of the number of internships carried out by the students of the Polytechnic School can be easily handled by the web platform.



(a)



(b)

Figure 5. (a) Evolution of the number of participating enterprises, internship offers, student demand, placements and evaluation results, for the first 4 years of the Work Internship Placements (*WIP*) programme. (b) Number of placements and evaluation obtained by the students.

Finally, we should remark that both enterprise and student feedback has been overwhelmingly positive for *WIP*, with a special emphasis in the functionality of the web application and the active participation of the coaching professors.

VIII. Future Work

The future main project related to *WIP* is the development of an automated *WIP* Survey Web Platform (*SWP*). The aim of *SWP* is obtaining useful and valuable feedback from the *WIP* participating actors (mainly enterprises and students) to improve the quality of the general *WIP* model in all its features (information, security, functionality, efficiency, etc). This survey platform, which at this moment is in a design and initial development stage, would finally be integrated in the general *WIPWP* project.

Acknowledgments

This project has been partially funded by the Catalan Government through project 2007MQD00163.

Abstract—**In this paper, a review of the educational research that is being developed in Spain is realized in the areas of Electrical, Electronics, Telecommunications and Informatics through the works presented to the prizes CESEI (Spanish Chapter of the Education Society of the IEEE) in his three editions. There are two categories of candidates to the prizes, one for the Doctoral Thesis and the second for the Final Degree (or Master) Projects. An analysis of the working areas, the subjects covered as well as the conferences and journals where the results are published has been done. The main goal of this paper is to have a general vision about the work done in such areas of educational research in Spain that will be very interesting for academic staff and researchers.**

Keywords- doctoral thesis; educational research; engineering

I. Introduction

The University plays a very important role in the Society as responsible for the education of future engineers and staff members of companies and Administration. University teachers must split their work in three fields: academic, research and management. For this reason, not always they can devote enough time to the academic activity.

Nevertheless, in the last years an effort for empowering the research and innovation in education is being observed. This effort has been reflected in the increase of the number of reviews and conferences dedicated to the higher education, as well as in the number of papers published and research projects developed in this field.

In the present paper, a review has been done about the research in education carried out in Spain in the areas of Electrical, Electronics, Telecommunications and Informatics through the works presented to the CESEI prizes (Spanish Chapter of the Education Society of the IEEE) in its three editions 2007, 2008 and 2009 and for both categories, best Doctoral Thesis and best Final Degree (or Master) Projects.

In section II Spanish Chapter of the Education Society of the IEEE, organizer of these prizes will be presented. In section III, the works (doctoral thesis and final degree projects) presented to the three editions of the prizes will be analyzed. An analysis of the working areas, the subjects covered as well as the congresses and journals where the results are published will be done.

In section IV other reviews and conferences, not mentioned by the candidates to the prizes, but of great interest in the fields of research of the IEEE Education Society will be reviewed.

Finally, section V presents the conclusions of the work.

The main objective of this paper is to have a general vision about the work done in such areas of educational research in engineering areas in Spain, that we think could be very interesting for academic staff and researchers.

II. CESEI Presentation

The IEEE is a non-profit organization and is the world's leading professional association for the advancement of technology. The IEEE name is an acronym for the Institute of Electrical and Electronics Engineers, Inc. Today, the organization's scope of interest has expanded into so many related fields such Automation, Telecommunication or Informatics, but it continues to be referred to by the letters I-E-E-E (pronounced Eye-triple-E) [1].

IEEE includes many unique technical societies, active in the areas of publications, conferences and building technical communities. Between these organizations, the Education Society (EdSoc), was created with the main aim of "shall be scientific, literary, and educational in character. The Society shall strive for the advancement of the theory and practice of electrical and computer engineering and of the allied arts and sciences, and the maintenance of a high professional standing among its members and affiliates, all in consonance with the Constitution and Bylaws of the IEEE and with special attention to such aims within the field of interest of the Society" [2].

Its fields of interest are: "Educational Methods, Educational Technology, Instructional Materials, History of Science and Technology, and Educational and Professional Development Programs within Electrical Engineering, Computer Engineering, and allied disciplines" [2].

In Spain in the year 2004 was created the Spanish Chapter of the Education Society of the IEEE (from now on CESEI). The CESEI has the same interests and aims that the IEEE EdSoc has and to whom it belong, but the CESEI tries to develop its interest and aims in Spain and in Spanish language [3].

At the moment, the CESEI is constituted by a Directive Board with a Director and three committees:

- Technical Committee of Accreditation and Evaluation (CTAE in Spanish).
- Committee of Activities, Dissemination and Web (CADW in Spanish).
- Committee of Members and Relationship with Associations (CMRE in Spanish).

and four work teams as shown in Fig. 1.

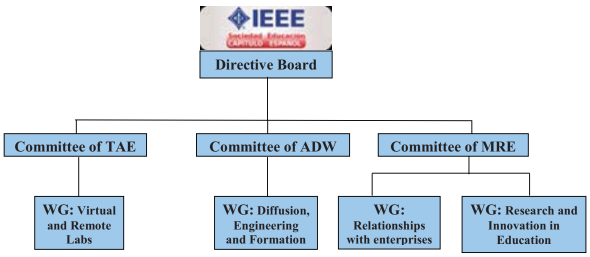

Figure 1. Structure of the Spanish Chapter of the Education Society of the IEEE (CESEI).

Since his creation in 2004, the CESEI has tried to be a meeting point for the responsible from the University as from the Enterprise that work for the improvement of the teaching of engineering and computing .

For that reason, between others, promotes the next activities:

- Edition of the International Review, edited in Spanish and Portuguese, IEEE-RITA (Latin-American Learning Technologies Journal) [4].
- Edition of the book: TICAI (TICs applied to learning of Engineering) [5]
- Collaboration with different congresses and workshops related with Higher Education.
- The prize to the best doctoral thesis and to the best final year project "Premios CESEI".

In the next section, the results of the last activity will be analysed.

III. The CESEI Awards

Among the activities promoted by the CESEI in the year 2006 one of the most relevant was the prize for the best doctoral thesis and for the best final degree (or master) project, being the thematic related totally or partially with the research or technological applications with the education in the frame of the disciplines of the IEEE, areas of Electrical Engineering, Electronics, Telecommunication Engineering and Informatics.

Since then, three editions of the prizes have taken place, covering the works developed between October 2004 and September 2008. The fourth edition, covering from October 2008 to September 2009, is running now. In those prizes, a total of 85 final year projects (PFC) and 21 doctoral theses have been presented, as it can be seen in the table I.

The number of works received as candidates to the prizes allow to do an analysis about the educational research that is being developed in Spain in the fields of interest of the IEEE and, in consequence, in the CESEI.

TABLE I. Summary of numbers of PFC and Thesis in the period

Year	PFC	THESES
04/06	19	5
06/07	39	8
07/08	27	8

First of all, the analysis of the working areas and the subjects covered by the works will be considered. In table II, data corresponding to the final degree projects are shown. With respect to the fields of interest, clearly three lines of work are more relevant: Tools and Strategies applied to the education, Special education and Virtual instrumentation-Remote laboratories.

Moreover the two first fields are very related with the area of Higher Education, it is important to remark the interest generated in Spain for the elaboration of educational materials to facilitate the education of disabled people (12% of the projects).

As well, the 35% of the total of the works is dedicated to education (tools, strategies, laboratories or virtual instrumentation).

TABLE II. Subjects – Final year project (PFC)

Topic	Percentage
Tools / Strategies applied to Education	24,7
Special Education	11,8
Remote laboratories – Virtual instrumentation	10,6
Several	10,6
Signal theory	7,1
Networks	5,9
Image Processing	4,7
Not related with the areas of CESEI	4,7
Computer architecture	3,5
Informatics Security	2,4
Web Semantics	2,4
Domotics	2,4
Electronics – Electronic Systems	2,4
Programmable Logic Devices	2,4
Electricity/ EMC	2,4
Antennas	2,4

In Figure 2, the fields of work of the doctoral thesis are shown. 76% of the thesis corresponds to Computer Engineering and Telematics-Telecommunications (38% for each one).

Up to now doctoral theses from the field of Electronics have not been received and only a 5% belong to the Electrical Engineering field. This can be due to two reasons:

- In these fields there is less research in educational topics related with engineering.
- Researchers of these fields are not interested in the prize.

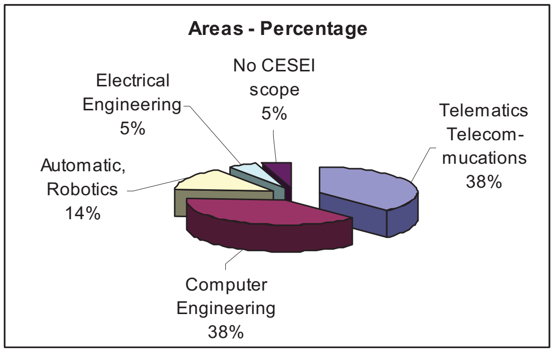

Figure 2. Percentage of doctoral theses in function of the field.

With respect to the doctoral theses, it could be of interest to know the journals in which the results of the research have been published. This information could help to the dissemination of the results of the research in education to other researchers.

Table III shows these journals. An analysis of this table allows concluding that the dissemination of the research results has been realized through specialized education journals, but as well, through other kind of technological journals non related directly with education. The reasons could be different:

- Several technical publications allow works related with the education.
- Researchers have separated the technical aspects of their doctoral theses from the educational aspects, sending each part of the work to a kind of review.

The number of journals where it is possible to publish a work in educational research for our areas of interest is very large (44 different journals identified).

With respect to conferences the information is relevant. In Table IV the conferences related directly with the education have been selected. Nevertheless, the authors of the doctoral thesis have published their work in more than 50 conferences not related directly with education.

It is important to note that, in Tables III and IV, it is possible to find English language publications as well as Spanish publications, so it is very easy for authors to publish the results of their work.

IV. OTHER PUBLICATIONS

Moreover the high quantity of conferences and reviews mentioned in previous paragraphs, there are other important publications where it is possible to publish the results of the research work in education and that can be of interest to the researchers.

Some of them are listed below [6]:

A. *Journals*

- International Journal of Technology and Design Education.
- Journal of Engineering Education.
- Journal of Educational Technology & Society.
- Revista Electrónica de Investigación Educativa (REDIE).

B. *Conferences*

- CAFVIR: Congreso Iberoamericano sobre Calidad de la Formación Virtual.
- CSCL: Computer Supported Collaborative Learning.
- CUIEET: Congreso Universitario de Innovación Educativa en las Enseñanzas Técnicas.
- ICCE: International Conference on Computers in Education.
- ICEER: International Conference on Engineering Education & Research.
- ICLS: International Conference of the Learning Sciences.
- IEEE - EDUCON: IEEE Engineering Education Conference.

- TAEE: Tecnologías Aplicadas a la Enseñanza de la Electrónica.

V. Conclusions

During the last years it has been possible to observe an increase of the interest for the research in education in particular in engineering areas. In this sense, since 2004 the Spanish Chapter of the Education Society of the IEEE (CESEI) is working for improving both teaching and learning of engineering and computing.

Among the activities promoted by the CESEI in the year 2006, the prize to the best doctoral thesis and to the best Final Degree (or Master) Project, being the thematic related totally or partially with the promotion of the research or technological applications in the education in the frame of the areas of Electrical Engineering, Electronics, Telecommunication Engineering and Informatics.

The number of works received as candidates to the prizes (106) allows performing an analysis about the educational research that is being developed in Spain in the fields of interest of the IEEE.

In the Final Degree (or Master) Project, in spite of the great variety of themes, there are three main areas of work: Tools and Strategies applied to the education, Special education and Virtual instrumentation-Remote laboratories. The second one represents the 12% of the total final year projects, that reveal the importance that this field is gaining in Spain in the last years.

The 76% of the doctoral theses received deal with Computer Engineering and Telematics-Telecommunications (38% respectively for each one). No doctoral theses have been received from the area of Electronics Engineering and only 5% of Electrical Engineering.

The results of the doctoral theses have been published in a large number of technical reviews and conferences (53 about education) so in English language as in Spanish or Portuguese.

The data allows encouraging the academic staff to work in this research field because they have a lot of possibilities to show and discuss the results of their work at the same time they increase the results for both areas of work the education and the research.

The main objective of this paper has been to show a general vision about the work done in such areas of educational research in Spain, that we think that could be very interesting for academic staff and researchers.

Acknowledgment

The authors wish to thank the help and support given by the Ministry of Science and Innovation (Projects TSI 2007-30679-E and TSI 2005-24068-E) and to the University of Vigo.

As well, they wish to thank the Spanish Section of the IEEE and the Department of Electrical Engineering, Electronics and Control of the UNED for their support and help.

Abstract— **This paper describes the Electronics curriculum in the Telecommunication Engineer degree at Rey Juan Carlos University (URJC) in Spain. Telecommunication Engineering started in the 2003-2004 academic year. In these years, all the electronic courses have been set up with a main practical orientation and with Project Based Learning (PBL) activities, both compulsory and voluntary. Once these courses have been successfully implemented we have reoriented some of the practical activities to be more interlaced. In this sense, projects involving students of different courses have been developed, as well as projects involving students from different years. All these activities fit in the principles promulgated by the Declaration of Bologna, which results in the actual updating of the university degree structure in Spain.**

Keywords: integral curriculum, Electronics, project-oriented, Bologna process

I. INTRODUCTION

This paper describes the Electronics curriculum of the Telecommunication Engineer degree at Universidad Rey Juan Carlos (Spain). Telecommunication Engineering was established in the 2003-2004 academic year. In these years, all the electronic courses have been set up with a main practical orientation and with Project Based Learning (PBL) activities, both compulsory and voluntary. In addition, the electronic curriculum has been consistently defined considering the contents and the relationships among the courses. These courses have been successfully implemented [1], [2].

Project-based learning is an instructional method that challenges students to think critically and enhance their ability to analyze and solve real world problems, develop skill in gathering and evaluating the information needed for solving problems, gain experience working cooperatively in teams. Successful implementation of Project Based Learning (PBL) strategies has been well documented [3-5].

Moreover, the regulatory modifications promulgated by the Bologna Process results in the implementation of new university degrees structures in Spain [6] and the adoption of the European Credit Transfer and Accumulation System (ECTS) [7]. This process implies a shift from traditional teacher-centered to a learner-centered approach, thus new teaching methodologies have to be introduced that focus on a more active participation of students in their learning process.

In this context, we have reoriented some of the practical activities to be more interlaced. Projects within more than one course and activities among students of different courses have been developed. Moreover, projects to be executed in more than one academic year have been planned. The implemented curriculum structure and the new activities proposed, allow a seamless transition to the Bologna Process.

This paper is structured as follows; section 2 presents the electronics curriculum context and the relationship among different courses and a description of the details, methodology, contents, evaluation data and organization of every course. Section 3 describes the recently introduced PBL activities among different courses. Finally, the results are summarized and discussed, and the conclusions are presented.

II. ELECTRONICS CURRICULUM IN TELECOMMUNICATION

Prior to the implementation of the Bologna Process, the Telecommunication Engineering degree was structured in five years, each one having two semesters. Each semester has an average of 36 credits. Each credit is equivalent to 10 hours of lessons including lectures and labs. A final degree project has to be presented (9 credits). The aim of this project is to develop a supervised complete engineering project, as a first approach to the student's future professional activity. It is equivalent to a MSc. Thesis.

Figure 1 shows the courses related to Electronics in the Telecommunication degree. All these courses are compulsory and, except for those shaded, are taught by the department of Electronics. Therefore, we have been able to elaborate a complete and comprehensive Electronics curriculum with no overlapping contents.

As can be seen, the courses cover both digital and analogue electronics. Besides, there are some other courses very closely related to the electronics curriculum. Computer Fundamentals, taught in the second year (fig. 1), are a required background for following courses. There is also a course on Communication Terminals, given in the fifth year, focused on the terminals basic specifications and internal block architecture.

Even though it is not shown in fig. 1, it is worth noticing that second year students also attend Photonics, covering the basis aspects of optoelectronic devices (LEDs, Photodiodes, Lasers…). This subject together with AE, will serve as background for Optical Communications I and II, which will be taught in the fourth and fifth years respectively.

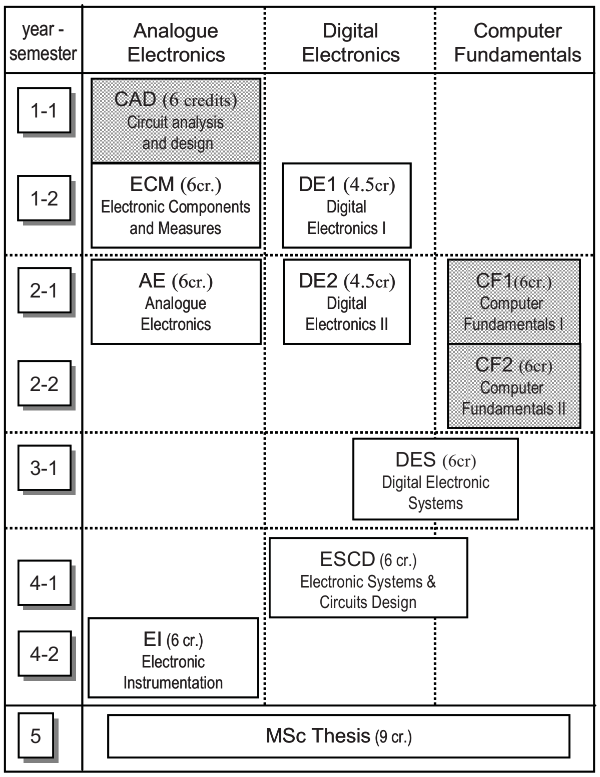

Figure 1: Electronic and related courses in the degree

On their fifth year, students who want to broaden their knowledge of electronics can work on their MSc. Thesis in our department.

Finally, it is also worth mentioning the approximate number of students attending electronic courses in each year. First year students attending ECM and EDI are around 150 divided in two groups, with one professor per group, and the support of another professor for laboratories. Second year students coursing AE and EDII are around 80 divided in two groups, with two professors both for theory and laboratory. Third year students coursing DES are approximately 60, with one professor for theory and two for the laboratory. Fourth year students coursing ESCD and EI are approximately 30, with one professor for theory and laboratory.

Following, a brief description of each course will be given.

A. Electronic Components and Measurements (ECM)

The Electronic Components and Measurements (ECM) course is a 6 credit second semester, first year compulsory course. ECM comprises theory (3 credits), practical exercises in class (1.5 credits) and practical work in the laboratory (1.5 credits). The essential background on circuit analysis is provided by the first semester, first year course on Circuit Analysis & Design (CAD) as can be seen in fig. 1. Therefore, students are familiar with linear circuit analysis with basic passive components, resistors, inductors and capacitors. On the other hand, this course provides the necessary knowledge on basic electronic components needed for the second year Analogue Electronics (AE) course.

According to the number of students and available laboratories, the students are divided in two groups for theoretical lectures and practical exercises classes and in three groups for laboratory work.

The aim of the ECM course is the learning of electronic fundamentals, including semiconductor principles and basic analogue circuits with individual components, and basic laboratory procedures, such us instrumentation use, measurements techniques and safety procedures. First, the Operational Amplifier is introduced, as a “black box”, in both linear and non-linear circuits. This allows the student to design fully functional basic circuits from the very beginning. Then, the principles of the rectifier and Zener diode and associated basic circuits are deeply studied, followed by other diode types (Schottky, LED, photodiode, tunnel) explanation. Finally, Bipolar and FET transistors are studied both following the same scheme; principles, models, DC analysis, applications and ideal-actual component comparison. The AC analysis is also explained as an introduction to AE course.

During theoretical lectures, multiple practical examples are used in the explanation. Practical exercises classes are reinforced with circuit simulations. Students have circuit simulation software available in free-access computer rooms. Laboratory work comprises a theoretical circuit to be studied analysis, circuit simulation, practical circuit implementation and critic practical-theoretical results comparison. This work is divided in five different guided sessions:

- Linear circuit analysis, where instrumentation use and measurement techniques are applied to simple linear circuit, so the student acquires the necessary skills
- Circuit simulation software, that will be used in the following sessions
- Operational Amplifier linear circuits implementation
- Basic rectifier diode circuits
- Bipolar transistor basic circuits.

The final mark is given by the exam mark weighted by 0.7 plus the laboratory mark weighted by 0.3. A minimum of 4 over 10 points are needed in the exam mark to pass the course. Laboratory work is evaluated in situ and, in addition, students must prepare a final report of each laboratory session.

B. Digital Electronics I (DE1)

The Digital Electronics I (DEI) course is a 4.5 credit second semester, first year compulsory course. DEI comprises theory (3 credits), practical exercises in class (0.5 credits) and practical work in the laboratory (1.0 credits). This is the first course on digital electronics in the degree, and provides the necessary knowledge on basic digital electronics needed for the second year Digital Electronics II (DEII) course, and for the higher level courses on electronic systems.

The aim of the course is to introduce the basic concepts in digital electronics, from numbering systems to simple sequential circuits. The following subjects are covered:

- Introduction to digital vs. analogue electronics. Review of sampling and quantification, advantages of electronics, brief history.
- Numbering systems and codes: Basic binary numbering systems (1's complement, 2's complement) and coding is presented. Binary arithmetics.
- Boolean algebra, logical functions and function simplification.
- Logical gates: Definition of the different logical gates, equivalences among them, and a short chapter on fabrication technologies and logical families.

The rest of the course deals is devoted to block design::

- Standard combinational blocks: review of the different blocks, practical designs using them. The chapter ends with the Arithmetic-Logic Unit, which serves as a review of the different block functions.
- Sequential circuits. Only biestables, registers and counters are studied, leaving more complicated designs for Digital Electronics II (DE2).

Students carry out two types of lab work. In the first session, they measure the features of several logical circuits and learn how to build simple circuits with discrete components. The second part of the course consists in designing and simulating circuits using schematics. We use the ISE-WebPack environment (Xilinx, San Jose, CA). Students are required to take three compulsory lab sessions and can also undertake several voluntary designs.

The final grade is given by the exam mark on top of which the laboratory mark is added (ranging from 0 to 1). A minimum of 4 over 10 points are needed in the exam mark to pass the course. Laboratory work is evaluated in situ and, in addition, students should send the project (schematics file) to be evaluated by the professor.

C. Digital Electronics II (DEII)

The digital electronic II (DE2) course is a 4.5 credit second year compulsory course. DE2 comprises theory (1.5 credits) and practical work in the laboratory (3 credits). Students taking this course have already a digital electronic background provided by the second semester, first year course on digital electronic I (DE1) where the have been taught the theoretical fundamentals of digital electronic design at logic level and logic-block level.

The aim of DE2 course is twofold: analyze and design sequential circuits and provide the necessary knowledge on the VHDL hardware description language. During the course, students will deep in digital design methodology. They will learn the methodology to design moderately complex digital circuits using finite state machines, computer-aided design (CAD) tools, VHDL and programmable logic devices (FPGAs). This course provides the necessary knowledge on digital design needed for the fourth year ESCD course.

The course takes place in a lab equipped for digital electronics. Designs are implemented in the Pegasus FPGA Board (Digilent, Pullman, WA) using Xilinx ISE. In this course students learn the design methodology and the hardware description languages (VHDL) in a practical way. This practical work consists of ten lab sessions where several FPGAs based systems of incremental complexity are implemented. The sessions are structured as follows:

- Introduction to development environment: Pegasus FPGA board and Xilinx ISE.
- VHDL design: concurrent sentences and process. The purpose of this session is to design standard combinational blocks: multiplexers, code converter and 7- segment decoder.
- VHDL sequential circuits: flip-flops, counters and shift register.
- VHDL for simulation: design of testbenches.
- Design of system based on finite states machines: door lock, vending machine and controlling the speed of a DC motor circuit using PWM.

The final grade is given by the exam mark on top of which the laboratory mark is added (ranging from 0 to 1). A minimum of 4 over 10 points are needed in the exam mark to pass the course. Laboratory work is evaluated in situ and, in addition, students should send the project (VHDL code) to be evaluated by professor.

D. Analogue Electronics (AE)

The analogue electronic (AE) course is a 6 credit second year compulsory course. AE comprises theory (4.5 credits) and practical work in the laboratory (1.5 credits). Students taking this course have already an analogue electronic background provided by two different first year courses (Circuit Analysis & Design (CAD), and Electronic Components and Measurements (ECM)) as can be seen in fig. 1. Therefore, students coursing AE possess significant knowledge of circuit analysis techniques, and deep understanding of simple analogue circuits with individual components.

The main aim of the AE course is to analyze and design fairly complicated amplifier circuits based on single components. First, standard parameters such as gain, input and output impedance of typical amplifier configurations using Bipolar and FET transistors are studied. This is followed by a deep analysis of frequency response and typical feedback networks. Finally, the course ends up with a quick review of power stage amplifiers.

During theoretical lectures, multiple practical examples are introduced in the explanation. Besides, in order to pass the course, students are obliged to attend practical work in the laboratory. This practical work consists of six guided sessions in the laboratory. Three different experimental setups are proposed, corresponding to the design and analysis of different amplifiers:

- Design and analysis of a voltage amplifier
- Design and analysis of a current amplifier

- Analysis of a multiple-stage amplifier (power amplifier).

Students are evaluated in situ in the laboratory and, in addition, they will hand in a final report of the laboratory work. Those with a good laboratory work can raise the exam mark up to one point (provided they obtained a minimum of 4 over 10 in the exam). Thus, the final grade is given by the exam mark on top of which the laboratory mark is added (ranging from 0 to 1).

E. Digital Electronic Systems (DES)

The Digital Electronic Systems (DES) course is a 6 credit third year compulsory course. DES comprises theory (3.0 credits) and practical work in the laboratory (3.0 credits). Students taking this course have already a background on digital electronics provided by two first and second year courses (Digital Electronics I and II), and knowledge of microprocessor architecture and assembler language, provided by Computer Fundamentals I and II, as can be seen in fig. 1.

The aim of the course is to learn how to design simple embedded systems based on microcontrollers. Students learn microcontroller architecture in detail as well as A/D conversion in class lessons. Half of the course is devoted to lab work, where several microcontroller based systems of incremental complexity are implemented. A PIC16F676 from Microchip (Chandler, AZ) and the rfPICKit1 have been selected as lab tools.

A first lab assignment is a simple traffic light controller. The second assignment involves Analogue to Digital conversion from a LM35 temperature sensor. The aim of the third assignment is the connection of a LCD display to the PIC controller. Both ideas are integrated in the next assignment, in which a converted temperature is displayed in the screen. The last assignment consists in controlling a fan using a step motor through PWM according to the temperature of the room.

All lab work is carried out in assembler language, which students have already used in a previous course on microprocessor architecture. Although higher level languages are now commonly used for microcontroller programming, we think working directly with assembler is the best way to learn the architecture in detail.

Students are evaluated in situ in the laboratory and, in addition, they will hand in a final report of the laboratory work. Those with a good laboratory work can raise the exam mark up to one point. Thus, the final grade is given by the exam mark on top of which the laboratory mark is added (ranging from 0 to 1).

F. Electronic Systems and Circuis Design (ESCD)

The ESCD course [1] is a fourth year 6 credit compulsory course. The main objective of the course is to make students face the challenge of designing real digital electronic systems, showing the different design alternatives and their tradeoffs. As it can be observed in fig. 1, students taking this course have demonstrated their fundamental theoretical knowledge in digital design, computer architecture and analogue electronics. Thus, in this course we want students to learn the design methodology in a practical way, assimilating the acquired knowledge in those courses and above all, that they face the real problems of digital electronic design and that they are able to solve them.

The contents of the course cover issues related to design methodology of complex circuits (modular design, reuse, testability, optimization), circuit interfacing and specific circuits, such as arithmetic circuits.

The course follows a PBL methodology. Rather than following a course based on the contents, we have decided to propose projects that introduce the students to those contents. Hence, during circuit design students face new challenges, and find the need to solve these problems. This raises their interest in the different solution methods.

The course has been structured in three kinds of classes: Seminars, guided laboratories and final project

Seminars are theoretical classes given throughout the semester. These seminars introduce the initial subjects and present each guided laboratory and the final project. These seminars summarize the problems that the students will face and the different approaches to tackle them. References are also included for further research.

The **guided laboratories** are the main learning method of the course. Students are faced with design projects of incremental complexity. The implementation of these projects leads the students to acquire the necessary experience to deal with the final project. Examples of these projects are the design of an UART, VGA controller, or a tennis videogame.

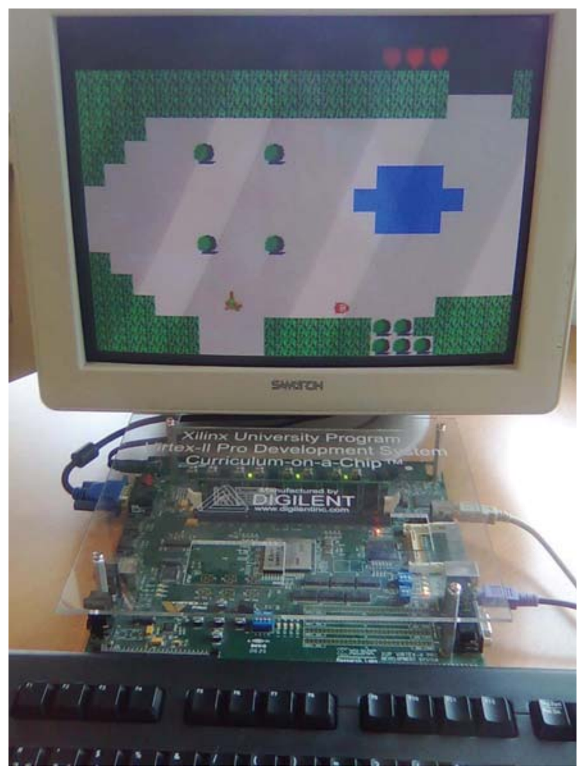

Figure 2: Snapshot of a videogame final DCSE project

Figure 3: Snapshot of a digital video final project

There is a continuous and formative assessment throughout the semester, in which alumni are provided with information on the adequacy and evolution of their work. Students are evaluated by their final project (70%) and theoretical exams (30%).

G. *Electronic Instrucmentation (EI)*

The EI course is a fourth year 6 credit compulsory course. The fundamental concepts and methodologies of electronic instrumentation are covered in this course. The course has been structured in theoretical lectures, laboratories (1.5 credits), and two design projects.

The contents of the course cover issues that have not yet been studied, i.e., sensors, the design of signal conditioning circuits, an elementary introduction to signal transmission, several lectures on noise and interference and LabView (NI, Austin, TX) virtual instrumentation and data acquisition software.

The students carry out two types of lab work. In the first sessions, they use discrete components and two different experimental setups are proposed:

- Analysis and measurement of real operational amplifier parameters
- Design of the RTD sensor conditioning circuit.

During the final lab sessions, students learn about NI LabView environment and the basics of data acquisition. Finally, they will develop an analogue input tool based on the RTD conditioning circuit designed in former sessions and on the NI USB-6009 Data Acquisition board.

On the other hand, students must hand in two design projects. The aim of these projects is to design a basic measurement system. Students should be able to understand the main specifications of a measuring system, select a specific sensor for an application, design conditioning circuits, connect sensors and actuators and integrate the measuring system to microcontroller-based systems. The design of a basic weather station capable of measuring the main meteorological variables: temperature, pressure, humidity, and wind speed is an example of a final project.

The final grade is given by the exam mark weighted by 0.8 plus the design project weighted by 0.2. A minimum of 4 over 10 points are needed in the exam mark to pass the course.

III. Project Based Learning Among different Courses

We are currently carrying out voluntary lab works involving knowledge of different courses. In these labs, students of different courses jointly develop an electronic design. These labs follow a PBL methodology, in which the circuit specifications are given at the beginning and students have to find their own solution and build the circuit design. The projects have minimum goals, but proposals to enhance the project goals are provided, in case the students wish to continue developing it.

These labs are carried out during the first half of the course; therefore, the students perform them as they start with the contents given in their respective courses. This approach has the following “benefits” for the student:

- Students have the need to acquire the knowledge of the course prior to the exam and the compulsory labs.
- Students have investigated different solutions and have implemented the solution they think is more adequate.
- When the course contents are given during the compulsory classes and labs, students can compare their solution with other solutions.
- Students reinforce their knowledge when the contents are given during the classes and compulsory labs.

We have developed two kinds of projects:

- Horizontal projects
- Vertical projects

The horizontal projects involve students of the same year. For this kind of projects, the participants are students of Digital Electronics II (DE2) and Analogue Electronics (AE), both belonging to the first semester of the second year. These projects can be considered as horizontal in the sense that all students have the same level.

The vertical projects involve students of different years; therefore, the participants have different knowledge in electronics. These projects are considered as vertical since students of upper courses guide the other students. As a result, some students have to coordinate the project and guide the others. As a consequence, the competences learned are wider than those learned in a same-year project.

Following, two of these projects will be described.

A. *Electronic Piano Project*

The electronic piano is a horizontal project carried out by students of Digital Electronics II (DE2) and Analogue Electronics (AE), both courses given during the second year.

The basic project consists in a digital square wave generator whose output is amplified to be heard through a small speaker. Fig. 4 shows the scheme of the basic electronic piano project. The digital part of the project is developed in a FPGA using VHDL and the output is amplified using analogue components.

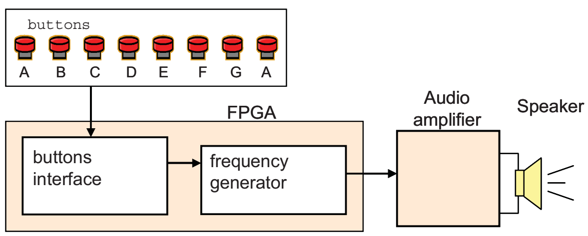

Figure 4: Basic electronic piano project

A minimum of eight frequencies have to be generated using one of the octaves. Table 1 shows some of the frequencies that could be used to generate the notes of an octave.

TABLE 1: FREQUENCIES OF THREE OCTAVES

Note / Hz	A	B	C	D	E	F	G	A
	220.00	246.94	261.63	293.67	329.63	349.23	392.00	440.00
	440.00	493.88	523.25	587.33	659.26	698.46	783.99	880.00
	880.00	987.77	1046.5	1174.7	1318.5	1396.9	1568.0	1760.0

The audio amplifier has to be built considering the working frequencies. Fig. 5 shows the general scheme on an amplifier.

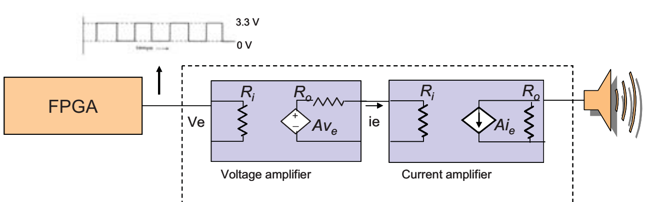

Figure 5: General scheme of an amplifier

Several considerations must be taken into account in order to design the audio amplifier. The output of the FPGA is a square signal with amplitude varying from 0 to 3.3 V; therefore, the output level is high enough to consider that the voltage amplifier stage of fig. 3 is not that critical. Loudspeakers introduce an 8 ohms load resistance and consume a power of 0.5 watts.

Finally, the amplifier bandwidth must be designed considering the frequency notes. In order to amplify the three octaves of table 1, low frequency should be one decade below 220 Hz. In this sense, external coupling capacitors should be carefully chosen. In the working frequency range, high frequencies pose no problems, since internal transistor capacitors introduce a cut off frequency well above 1760 Hz.

1) *Electronic Piano Enhancements*

The electronic piano can be enhanced in many ways. Some proposals are given to the students; nevertheless, they are free to propose any idea the like. The proposed enhancements are:

- Display the frequency or the note name through four seven-segment displays
- Instead of using the buttons or switches of the FPGA board, build a digital interface for a PS/2 keyboard.
- Build an analogue filter to modify the shape of the square wave
- Instead of generating a binary signal, generate an 8 bit digital signal with different shapes. Therefore, this signal has to be converted to analogue.
- Performing any other digital processing to the audio.

A scheme of the electronic piano project including some of the enhancement proposals is shown in fig. 6.

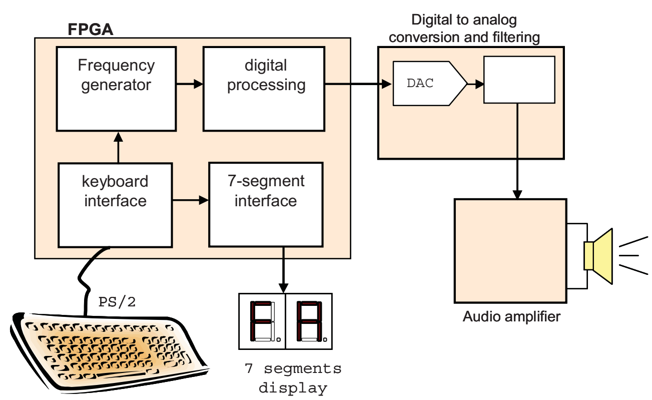

Figure 6: Proposals for the enhanced electronic piano project

B. *Electrocardiogram Project*

The electrocardiogram (ECG) project is a vertical project carried out by students of second (DE2), third (DES) and fourth years (ESCD and EI), see fig. 1. This project is more complex than the electronic piano project since it involves different technologies and requires a wider communication among the students, which, in addition, belong to different years.

As it has been stated, in these labs a basic project is first proposed to the students, but ideas are also given for possible enhancements.

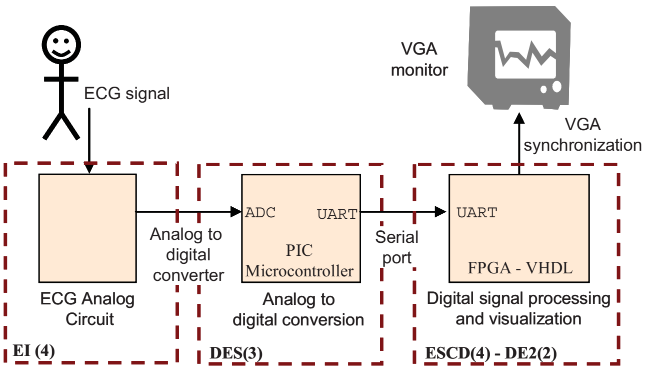

Figure 7: Basic ECG project

The basic project scheme is shown in fig. 7. In this scheme, the project has been separated in three blocks, corresponding to the different courses involved. These blocks are:

- ECG Analogue circuit: this block deals with the acquisition of the biological signal. It will be performed by students of Electronic Instrumentation (EI).
- Analogue to digital conversion: this block will convert the analogue signal into a digital signal. Students of Digital Electronic Systems will be responsible for building this block.
- Digital signal processing and visualization: this block will receive the digital signal from the PIC microcontroller and will show the ECG waveform in a VGA monitor. This block will be designed jointly by Digital Electronics II (DE2) and Electronic Systems and Circuits Design (ESCD) students.

The project has to be done in two stages because the course Electronic Instrumentation (EI) is taught during the second semester of the fourth year. Therefore, during the first stage, the students have to build the project considering that the analogue signal is already given (with an ECG emulator).

The project is coordinated by the students of ESCD. These students will assist the rest of the team helping them to define their block and the interfaces with the others. Later, in the second semester, ESCD students will finish the project building the ECG analogue circuit as part of their EI course.

As in the piano project, fig. 7 shows the basic implementation of the ECG project. Further enhancements are proposed as shown in fig. 8. These improvements include:

- Performing signal processing in the PIC microcontroller or in the FPGA.
- Showing the heart rate through a LCD or seven-segment display (using the PIC or the FPGA).
- Generate a sound every heart beat and amplify it with a analogue circuit. This enhancement would include students of AE, and would be similar to the electronic piano. The sound wave could also be generated by the PIC microcontroller.

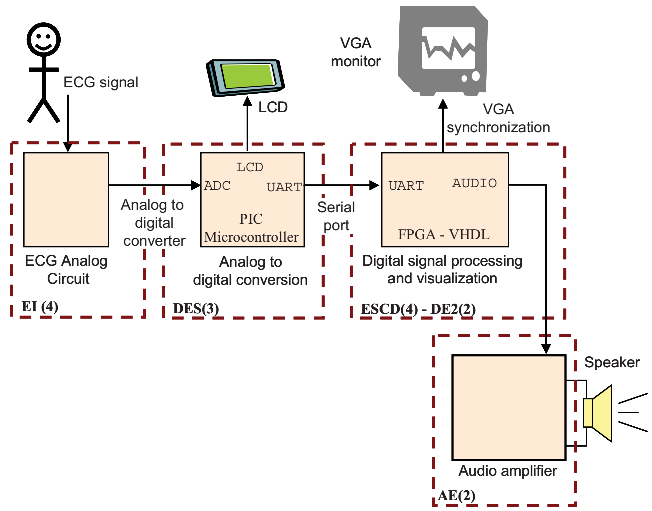

Figure 8: Enhanced ECG project

IV. RESULTS AND DISCUSSION

The proposed curriculum covers all aspects of analogue electronics (components, amplifiers, feedback, filtering, frequency analysis) with the ECM, AE and EI courses. Only some topics in communication electronics are not covered (PLLS, oscillators). Digital electronics is also thoroughly covered. Hardware description languages are covered in detail inDE1, DE2 and ESCD. Digital system design is taught through the DES and ESCD courses.

The curriculum has been evaluated taking into account the grades obtained by the students and their degree of satisfaction, as shown in official University surveys performed at the end of every course. Results show that students are highly satisfied with their training in electronics. Among the main topics pointed out in the survey we can highlight:

A. Teaching methodology

B. Course planning and organization

C. Are the contents of the course interesting?

Table 2 shows the student evaluation of the electronic related courses described in section II. Scores range from 0 (lowest) to 5 (highest). The mean of each topic is above 4 out of 5.

TABLE 2: STUDENT EVALUATION OF THE COURSES

	ECM	DE1	DE2	AE	DES	ECDS	EI
A	4.1	4.0	4.0	3.5	4.1	4.5	3.6
B	3.9	4.0	3.9	3.8	4.2	4.2	3.8
C	4.0	4.4	4.4	3.8	4.3	4.6	3.7

Regarding PBL among courses, both horizontal and vertical projects were carried out as an experimental activity.

We have observed that horizontal activities are easier to perform, as students belong to the same group and have previous experience working together. Vertical activities (integration of sub-project among student of different years) were harder to coordinate due to the different timetables, and degree of acquaintance. Around 15-20% of the students volunteered to participate in the special projects.

All horizontal activities were successfully accomplished in about four weeks, two weeks less than the time initially estimated. During that time, students worked mostly on their own, anticipating the concepts the professor explained in the regular lectures. Only in few occasions did they need the professor's advice. Additional skills inherent to the experimental work were acquired by the students, such as reading and comparing datasheet to meet project requirements and soldering in board. They even enhanced both by ideas proposed by the professors and by themselves. As an example, they proposed to store a melody in the FPGA. One of these projects is shown in fig. 9.

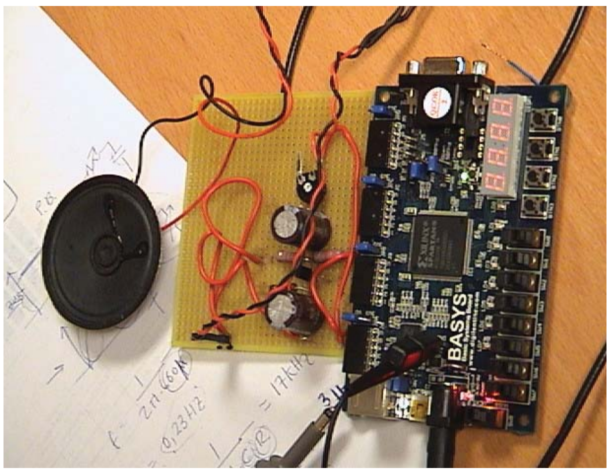

Figure 9: One of the resulting piano projects

Students that successfully completed the project, volunteered to present their work to the rest of the class. They prepared a fifteen minutes oral presentation and a live demo with the melodies stored in the FPGA. The response of the students that were not involved in the projects was of great enthusiasm, some of them expressing their will to join the project methodology next year.

In the vertical activities, two thirds of the groups completed their subproject, but they did not have enough time to integrate into the complete project. This was due to the difficulties in coordination among groups. However, all students intend to complete the integration along the next semester.

V. CONCLUSIONS

We have presented a project-oriented curriculum on Electronics for Telecommunication Engineers. These courses have been evaluated very positively by students. The consistent approach of this curriculum has allowed us to design project activities among different courses. This fact, together with the project orientation of each course, makes the transit to the Bologna Process easier.

The developed PBL activities among different courses have been received positively by the students. These projects provide students with skills and competences promoted by the Bologna Process, such as team work, initiative, responsibility and leadership. Participants have shown a high degree of motivation since many of the groups have finished before the assigned time and have performed many of the proposed enhancements.

Abstract—**The paper presents the ongoing activities within an European project for development of eLearning courses in microsystem technologies. It is a two-year project within the Leonardo da Vinci programme and the partners are from small and medium enterprises in microelectronics, training organizations and universities from four European countries – Romania, Bulgaria, France and Germany. The project is aimed at implementation of innovative approaches for performance–centred learning and development of new instruments in instructional design of task-performance-centred courses for education in Microsystems design and technology.**

Keywords-Microsystems technology education, performance-centred approach; e-learning, European project

I. Introduction

Scientific research, technological development and innovation are at the heart of the knowledge-based economy, a key factor in growth, the competitiveness of companies and employment [1]. "The shift to a knowledge based economy is of crucial importance to competitiveness and growth. Business and citizens in the EU have been slower in embracing this new economy than in the United States. The Lisbon indicators confirm that investment in the development and introduction of new technologies is behind the United States." [2] Micro- and today nanoelectronics is the most rapidly developing science. All specialists in the field need regular re-training. In this most rapidly developing science which represents the basis of the e-economy and the e-society the continuous training is crucial.

The shortage of engineers in micro- nanosystems and the systematic decrease of students in electronics at the university can be a threat to the European economy competitiveness. The informal Meeting of Ministers of Education and Ministers of Research in Uppsala underlined the importance of increasing recruitment to scientific and technological disciplines, including a general renewal of pedagogy and closer links to working life and industry throughout the whole educational and training system [3]. In many publications at the 3rd European workshop "Microelectronics Education" it was stated that "a new breed of engineers must be created and the way we create them has to change" [4] "from the classical engineering schools to multi-disciplinary research organisation - system design centres". So, a partnership between small and medium enterprises (SME) and universities for delivering training in Microsystems technology has crucial importance for the European competitiveness on the world market for electronic systems.

Additionally, it is important to be mentioned that Europe's electronics industry is increasingly moving east. Multinational OEM (Original Equipment Manufacturer) and EMS (Electronics Manufacturing Services, contract manufacturers) companies invested great amount of capital and built up high-tech plants in Romania during the last years. The reasons why Romania is an ideal investment location in Europe include, first of all, their well-trained, creative and flexible human capital, in particular highly educated engineers and skilled workers, accompanied by high productivity/wage ratio. Based on mSysTech project, the Romanian working force involved in micro-systems and related fields will have the opportunity to be in contact with the latest developments in these very dynamic fields and to have access to practice oriented, vocational training courses destined to the knowledge level.

Bulgaria has also strong traditions in microelectronics (in 1989 the foundry in Botevgrad worked on a technology of 2 μm which was the top technology at that time) and the last 5 years a number of new SMEs in the field are created (HIC, EPIQ, Milexis, Centillion, NanoToolShop, etc.) and MSysTech project is designed to meet their needs of qualified and trained personnel.

II. Rational of the Project

In the 21st century the high level research is increasingly complex and interdisciplinary; it is increasingly costly; high level research requires a constantly increasing "critical mass". Microsystems are developing on highest level of research and the continuous training is crucial. This project is aimed at adapting the existing and developing new courses for the lifelong performance support systems in microelectronic packaging and microsystems for the needs of the Romanian and Bulgarian SMEs, vocational schools and universities.

There are very few individual research teams or laboratories or companies that can reasonably claim to be able to respond to the technological challenges. In nano-era an integrated approach is needed, and interaction of innovative SMEs, universities and research organisations in the research and training actions and it is a key factor for strengthening the European RTD potential. The Internet courses within the mSysTech project will provide new opportunities for co-operation between vocational training institutions, universities and SMEs in the sharing of knowledge and educational resources: the distributed support system in four European countries created in the IPCI project will be enlarged with two new countries within the proposed project.

III. Objectives

This project is aimed at adapting and integrating innovative performance-centred training approach into engineering education and training organisations and SMEs in microsystems technologies. The focus is on the transfer of innovation in two new countries: Romania and Bulgaria and in the multidisciplinary area of microsystems. Its objectives are:

– identifying and analysing user requirements of managers, engineers, students and technical staff in the multidisciplinary science of microsystems technologies,

– selecting ICT-based innovative content to meet these requirements and analysing the feasibility of transfer of the performance-centred approach to train this content,

– adapting and implementing the e-learning environment with training materials with simulations, demonstrations to improve skills in microsystem technology.

– training the core user groups of training providers – teachers, managers and educational policy makers in the innovative learning approaches and in the effective collaborative use of new technologies in vocational education and training.

The primary target groups concerned are: students in engineering education and vocational schools, professionals from SME in electronics and Microsystems, educated but unemployed people (e.g. engineers, physicists) looking for additional training for employment.

IV. Implementation

The mSysTech project is based on the positive results and experiences in two European pilot projects: Leonardo da Vinci project “Internet-based Performance Centred Instruction – the Link between Work and Education” (IPCI) and Socrates/Minerva “On-line Learning Mathematics and Sciences”.

Within the IPCI project a complete set of courses covering microelectronics design, technology and packaging were developed. There are not many frameworks that unify these subjects in an attractive way. The performance centred approach has been proven to be more effective than the traditional lecture-practice-test (expository inductive) in training higher order skills, for preparing learners for self-learning, improving, adapting for changing tasks, jobs.

In mSysTech the performance-centred job-linked training approach will be used also and the selected content from the courses of IPCI will be adapted and up-dated for the needs of Romanian and Bulgarian electronic sector and education. The new learning materials on the Microsystems technology and the evolution of nanosystems during the last three years (after the end of IPCI) will be developed and used by all partners in the project, as well by the partners from the IPCI project who are not in the mSysTech partnership.

The project main result will be an e-learning environment with innovative pedagogical approach and the use of state-of-the-art multimedia materials to train the newest technological achievements in the sciences representing the basis of the e-Europe. It will provide performance support to the individuals undertaking self-directed learning.

The following courses are already developed:

- *Microsystems Design and Technology* by Institut National Polytechnique Grenoble, Centre interuniversitaire de microélectronique, NanoTech.

The objective of the course is to show the physical background and the approaches that are used in the design of MEMS-based sensors and actuators. The course gives an overview of microsystem technology and its applications. The course suits especially well for students who aim for R&D tasks. Following issues are discussed using examples of different MEMS devices design:

• Modelling and simulation of MEMS devices

• Different types of transduction processes used in MEMS

• MEMS based accelerometers

• MEMS based pressure sensors.

- *Packaging Technologies* by Politehnica" University of Bucharest, Center for Technological Electronics and Interconnection Techniques (Fig. 1).

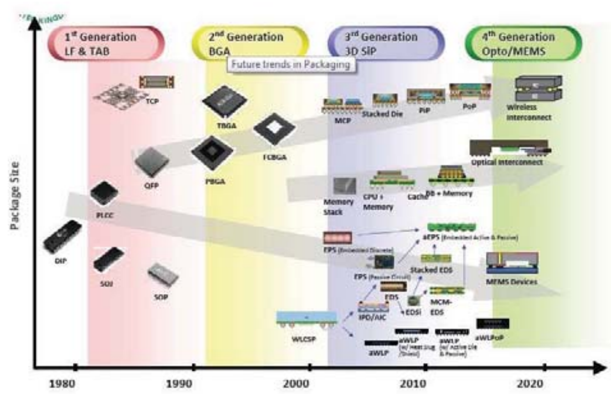

Figure 1. One image from the “Packaging Technologies” course

The objective of the course is to introduce the learners in microsystems packaging technologies, including design, analysis, fabrication, assembling, characterization and testing. In addition, this course introduces the most recent developments of micro-/nanofabrication technologies. The course covers the research and innovation in the following major topics:

• Fundamentals of microsystems packaging;

• Packaging Materials;

• Electronic design, CAE-CAD-CAM and EDA of microelectronic systems;

• Modelling and simulation of electronic/microelectronic structures;

• Assembling technologies based on RoHS & WEEE European Directives;

• Measurement, characterization and testing of microsystems.

- *Thermal Management of Microsystems* by the Technical University of Sofia, Department of Microelectronics.

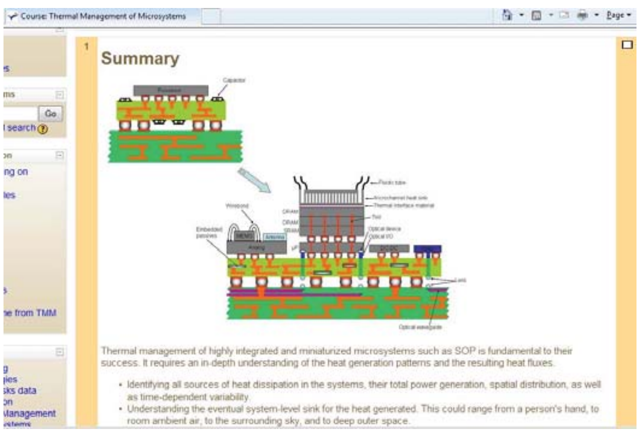

Figure 2. The “Summary” screen of the course “Thermal Management of Microsystems”

This course deals with effective thermal management of highly miniaturized system-on-package (SOP)-based systems (Fig. 2). The learners will be able to define the most appropriate method of design and packaging of different microsystems for effective heat evacuation and minimisation of the hot spot effect; to evaluate the reliability and to identify the possible defaults dues to overheating in order to insure the reliable functioning of the microsystem. The course covers the following major topics:

• fundamentals of thermal management of mycrosystems;

• thermal sources in systems on package (digital SOP, RF SOP, Optoelectronic SOP, MEMS);

• fundamental heat transfer modes;

• thermal characterisation: numerical methods for thermal characterisation; evaluation of thermal analysis software for Microsystems; experimental methods for thermal characterisation;

• thermal management technologies: passive methods of thermal management (high-conductivity package materials, thermal vias, heat spreader, extended surfaces, heat pipes [5]); active methods of thermal management (liquid loops, spray cooling, thermosyphon, thermoelectric cooling, thermionic cooling etc.);

• power minimisation technologies.

- *Photomasks Data Preparation* by Xyalis Ltd, Grenoble.

Main goal of this course is to present the techniques used in micro- and nanocomponents photomask data preparation. This course will allow to fully understand all the issues related to this critical step of chip development as well as the methods used to reduce both costs and delays. The course introduces the basics of photolithography and the various types of masks used. A detailed description of the multiple constraints and of all the patterns required on masks is provided:

• process control modules

• measurement structures

• alignment marks

• identification patterns

• chips

The different steps of mask data preparation will be explained:

• input data manipulation, validation, fracturing, OPC (optical Proximity Correction)

• assembly of various devices

• constraints and optimization

• inspection techniques

• repair techniques.

Figure 3. The module on MEMS mask data preparation

MEMS related issues are detailed (Fig. 3). The last module gives an overview of advanced research and state of the art in photomask development.

The courses available on Internet will improve the accessibility of the learning materials and the delivery of training in all contexts: at home, in the university or vocational school, and the most important - on-the-job.

V. THE APPROACH

Focusing on learning or knowledge transfer rather than performance results in people who know what to do but never do it [6]. Learning technologists must recognize that their jobs do not end with training. Learning must be turned into performance, shared with the entire organization, then cycled back into the next iteration of training. Learning technologists must take an interest in - if not responsibility for - the full cycle. They need to embed performance support and knowledge sharing into learning activities so they become second nature to the learners/performers.

So, in our project we decided not just to design an improved training but to perform a performance-centred design. The performance-centred design transforms knowledge into performance by creating an interface to the knowledge base. In the design we followed the principles, determined by Rosenberg [7].

Performer-Centred Design. A key difference between performance support systems and training systems is the locus of control. In training systems, the author takes the role of expert and sets the rules for working and the criteria for success. In a performance support system, we must recognize the performer's expertise in his/her environment and the fact that the performer may have additional information not contained within or considered by the support system. Our system, therefore, takes the role of an assistant rather than a director.

Learn by doing. Much of what we know to do in a job we learn on the job. One of the responses of the training community has been to provide just-in-time training or on-demand learning, so as to situate the training in the job environment at the time of need. This direction has great merit and no doubt will benefit development of work competencies, but I suspect that the greatest limitation of training is its abstractness. Merely changing the time and place will not make it contextually appropriate. Our learning and support systems need to increasingly model apprenticeships rather than simply serve as information distribution systems.

Apprenticeships embed the learning of skills in their social and functional context and make the "what is learned" more meaningful and valuable. A performance support system should encourage workers to try things that stretch their knowledge and skills.

Organizational Memory. Organizational memory refers to the knowledge that an organization has or could have about its business and to the process it uses to acquire and recall that knowledge. It includes what is archived in electronic and paper documents, but even more critically, what people in doing their work have learned. How often have we been in a situation where we need to know something and instead of looking it up in books or other archives—we call someone?

Our support systems should aspire to mimic the knowledge base and process for acquiring expertise that is used by practitioners. Thus, the process needs to be on-going, rooted in practice and experience, and constantly adjusted by new inputs. We need to find ways to capture and share expertise. So, in the reported Web-based performance support system the knowledge base is the core component.

Technology Use. The performance support system (PSS) is a natural extension of building technologies that transform the way people work and learn. The technologies of performance support help people be connected when they are mobile [8], be competent when they are inexperienced, be reflective when they are hurried, and be resourceful when they are challenged. Our system is Web-based.

VI. HOW INSTRUCTION IN PSS IS DIFFERENT FROM TRADITIONAL COMPUTER-BASED TRAINING

Computer-Based Training (CBT) systems are often set up to enforce the sequencing of sections determined by the task analysis [9]. The enforcing of the sequencing relies on the system keeping learner's records. The system checks the learner's record to determine if the learner has completed the required prerequisite sections satisfactorily before allowing the learner to enter a new section of the lesson.

In PSS enforcing the viewing of prerequisite is not present. It is up to the learners to determine if they need to review the prerequisites. Links to the prerequisites are provided, but viewing them is not mandatory.

Learner's records should not be kept, if at all possible. One of the main purposes for keeping learner's records is to enforce the sequencing of instruction. Because the learners choose their own sequence in PSS, there is no need to keep learner's records for sequencing purposes.

Lesson segments are as small as possible. In PSS, the learners usually enter the instructional component to learn a specific task. The lesson segment should only cover that specific task. If the lesson component covers more information, the learner takes longer to complete the original task.

Lesson segments are self contained. The instructional developer should try to limit the dependence on other lesson segments, because there is no guarantee that the learner has viewed the other lesson segments. The instructional developer should try to minimize any undefined acronyms and backward reference.

It is easy for the learner to use the instructional component. We don't make the learner sign in to the instructional component, and we allow the learner to escape from the training at any point.

The primary targets groups of mSysTech system are the students in engineering education and colleges, who need education related to their further work, learning competencies necessary for the workers in an 'intelligent organization'. So, the instruction in the training modules is designed following the PSS technology.

VII. Project Outcomes and Innovation

The main expected outcomes of the project are:

- System for on-line course development with a performance support system (PSS) for developers;
- Virtual Performance Centred Environment for Training in Micro- and nanoelectrinics, and Microsystems technology;
- Training materials for 3 courses in microsystem design and technology, packaging and thermal management; Internet-based tutorials;
- Database to facilitate access to training and professional realisation of women in the sector of micro- and nanoelectronics, and microsystems and to provide equal opportunities for women and men.

The innovation contributed by this project involves:

- new approaches to the use of existing methods: distributed performance support system

The project considers the concept of a performance support system from a new theoretical perspective in where distributed cognition and distributed learning are underlying concepts. Learners have opportunity to interact not only with particular content but also with peers, instructors and other experts.

- new products in response to existing problems: training courses in Microsystems technology

The courses are developed in response to the training needs described above.

- new processes: distributed learning

Distributed learning rather provides new perspective and dimensions of the classical distance learning concept. *Distributed learning* in the context of PSS does not ignore the importance of organising learning content and its sequence, but emphasises on creating a learning environment that enables an interaction with learning resources, peers, instructors, and external experts, located at different places, with no time constraints. Learners gain a greater control on constructing their learning. Distributed learning changes the role of the instructor from knowledge transmitter to coach or facilitator.

- new forms of co-operation between partner organisations: distributed curriculum.

The idea for distributed curriculum or a Virtual Technical University is not so novel. For example in USA the National Technological University is providing distance engineering education with distributed curricula, i.e. the departments from different universities which are the best in some area develop the corresponding course and it is delivered in a common curriculum in one virtual university.

In the proposed project we will apply the same approach in the development and delivery of the distributed curriculum in microsystems with the difference that we will involve not only training organisations but the main users as developers – the SMEs. The notion of distributed PSS introduces the concept of *distributed instruction* as well. It applies embedded content management facilities with tools, templates, and guidelines for designing courses from reusable learning objects in a shared repository. The *mSysTech* is an open course initiative with an attempt to build a case of good practice based on the collected experience.

VIII. Summary and Conclusion

In this manuscript we presented a work in progress within the European Community project "e-Training Microsystems Technologies". The project is aimed at implementation of innovative approaches for performance–centred learning and development of new instruments in instructional design of task-performance-centred courses for training in microsystems. At this stage in the project lifecycle we have already developed the IPCI environment with its main components, and with an integrated environment for the training materials development. Four courses are being designed and the learning materials of three courses are under development by the teachers.

As a new technology, IPCI will move the traditional teaching systems to the closely related to the job learning. In this point, these systems have a strong potential to help students mastering job-related skills. The message to the teachers, to consider the impact of teaching on results, good performance and competitiveness, is another perspective of this innovation.

As happens with most new technologies, some people will promote PSSs as the answer to all problems. But like most technologies, PSS has its limitations. If the improvement in employee's performance in corporate setting thanks to the PSS is already proved, for the students there are some doubts and we have to study the effectiveness of this approach in the university context. And we expect to learn more about the effectiveness of this approach through experiment planned for the pilot test.

ACKNOWLEDGEMENTS

This project has been funded with support from the European Commission, Leonardo da Vinci programme "e-Training Microsystems Technologies" project (mSysTech), LLP-2008-1-RO1-LEO05-00694 (2008-2010).

Abstract— **Open Educational Resources (OER) are digital content that are accessible through web repositories. They are used as support tools for education, especially for higher education, and they promote equality and social justice by providing access to, applying, and generating knowledge. Until now OER's have been developed from the pedagogic perspective, without taking advantage of the recent developments in communication technologies.**

Integration of social tools improves the active participation of both the developers and users of the OER's. This promotes the rapid creation of content that is easily accessible via search engines linked to educational platforms and social networks. It also allows *tagging*, which gives users the ability to add descriptive metadata. Authorship is recognized through the use of intellectual property licenses that promote open use of the material so that it can be used and edited. And above all collaborative learning is promoted.

In this article a new cycle of OER production is proposed that includes activities to incorporate social networks and semantic technologies. The phases of the production cycle are developed using the ADDIE instructional model. The purpose of each phase and the social and semantic components to be included are identified. And finally, application guidelines are presented that detail the strategies and expected results for each phase of the proposed cycle.

We have determined that the primary reasons for developing a production cycle for OER's using social authorship are: to allow educators and students to develop resources collaboratively; to reduce the amount of time spent in resource development; and to provide for reutilization of quality OER's. Finally, it should be recognized that the success of the model and its application depends on the institutional context where it is implemented, as well as the policies related to content generation, authorship acknowledgement and distribution of the resources.

Keywords-component; Open Educational Resource; Social Authorshi;, Semantic Web; Collaborative Learning.

I. INTRODUCTION

Open Educational Resources (OER) have been identified by the Flora Hewlett Foundation, one of their primary supporters, as a means of providing equal access to knowledge worldwide [1]. For this reason, many universities throughout the world are involved in these types of initiatives. These initiatives have also raised the interest of international organizations who are working to develop a framework that will assure accessibility, usability and quality of the content and structure and tools utilized to produce OER's.

The Web 2.0 allows users to actively participate in the development of knowledge through the use of tools such as blogs, wikis, RSS, social networks, microblogging, etc. The Semantic Web is the web of data, that is, it incorporates meaning through the use of semantic metadata and ontologies and allows users to find results more quickly and easily.

OER development would be enriched by the features offered by the Web 2.0 and the Semantic Web. These features can be integrated into the production cycle to promote collaborative learning between producers and consumers of resources during both development and implementation. Also, the use of tagging and other semantic technologies optimizes the detection, identification and dissemination of OER's. This proposal also supports the use of Creative Commons licenses for authorship recognition, which should be adapted to the individual policies of each institution.

II. TRENDS IN OER´S

The evolution from a static web to a social and participatory web, with its many manifestations that have gained great acceptance among internet users, provides an opportunity to utilize social software as an e-learning method, to develop the skills and capabilities needed in the knowledge society (the abilities to analyze, synthesize, communicate, and resolve problems, among others).

OER's – resources that provide educational content with an open license that facilitates their use, adaptation and modification – have become key elements for higher education. UNESCO refers to them "web-based materials that are freely available for use in teaching, learning and research" [1]. The Creative Commons licenses allow content and resources to be open and free, in this way favoring open access to knowledge for the benefit of society and at the same time promoting the development and use of OER's.

The William and Flora Hewlett Foundation has supported many projects in this area because of their great potential and their contribution to the development of education. Due to the fact that there is a great quantity of educational material available on the web, but that is poorly organized and therefore does not contribute to quality instruction, the OpenCourseWare (OCW) projects have been developed.

In 2001 the Massachusetts Institute of Technology (MIT) launched the first OCW initiative offering complete courses with study guides developed and utilized by their educators. The guides were freely accessible and distributed on the internet; their use, re-utilization, adaptation and distribution was permitted, with certain restrictions determined by the licenses assigned by the authors. Hundreds of universities have joined this initiative and have made their materials available to professors, students and laypersons world-wide.

The evolution of the internet includes four phases: the Web 1.0 develops an information network; the Web 2.0 creates relationships between people through social networks which promote collaborative knowledge; the Web 3.0 includes representation of meaning, connection of knowledge and improvement of the internet experience; and the Web 4.0, which is yet to be developed, that involves the connection of intelligence in an ubiquitous and universal Web. [3]

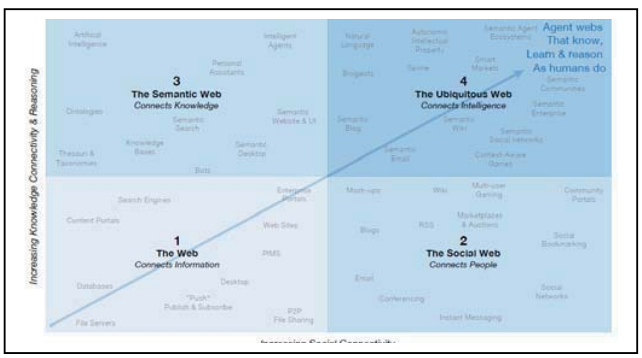

Figure 1. Internet Evolution [3].

The Social Web is driven by those applications that gain value through the actions and participation of their users; it is an attitude not just a technology. In this environment it is possible to gather, distribute and share individual actions within a social context, using tools such as wikis, blogs, microblogging, RSS, messaging, and social networks (Figure 2).

The social web allows the user to participate actively as an author in the knowledge society, and this includes the development, management and distribution of knowledge in a collaborative manner. These activities generate collective intelligence that accompanies the learning process, promoting the development of skills among the participants adapt to the process through open and free discussion opportunities that stimulate creativity, critical thinking and social and communication skills.

Figure 2. Social Tools [4]

In the production of OER's it is necessary to include semantic components to exploit the aforementioned resources.

Since OER's are found on the Web, they are becoming part of the Semantic Web (which gives meaning to all types of information available on the Web). According to [5] the Semantic Web has unique properties that facilitate the development of OER's:

- Improves discovery and storage in local and global databases, and therefore OER's should have semantic information (metadata) to simplify their discovery and re-utilization.
- Promotes the use of ontology that highlights the structure of the resources to assign pedagogic meaning, and
- Strengthens the personalization of educational content and the development of resources to assist the user with significant tasks in the Semantic Web.

The basic semantic technologies that should be used are:

Unicodes1 and URIs2 to identify web resources.

- XML 3 : To present, manipulate, and transmit structured data and documents.

---

1 UNICODE: http://www.unicode.org/

2 Naming and Addressing: URIs, URLS. (http://www.w3.org/Addressing/).

3 eXtensible Markup Languague (XML). (http://www.w3.org/XML/

- RDF4: Provides a model of common data, based in XML NameSpaces, which is used to formalize metadata.
- Educational Ontologies: Used in web-based teaching. [6]
- Ontologies related to the physical structure of the object: So that the OA can be interpreted and utilized in different teaching systems. DAMP5 and OIL6 are used for the development of ontologies.

Social repositories facilitate the storage of resources that are available for users to share on platforms that permit them to download, tag, vote and comment on these materials.

III. OER Production Cycle

An OER is the result of a production cycle with many intertwined phases. Each phase has its own specific purpose and is carried out in a generally sequential manner. Throughout the process the needs of the education community are considered and active participation is promoted.

Normally the development of these materials involves the use and reuse of digital resources such as videos, text, and images, which are considered by many authors to be digital content and information objects. This process also involves the development of metadata associated with these objects, which allow them to be stored, catalogued and searched in data repositories, as well as provide information about copyrights that can be used to determine if the content may be consulted, utilized or edited.

An analysis of several OER production cycles was conducted and the common denominator found was the use of standards for packaging and for metadata. These standards are shown in the following table:

TABLE I. Comparision Of University OER Producion Cycles

University	Methodology	Packaging	Metadata	Storage or Implementation
Universidad Técnica Particular de Loja (Ecuador)	Based on the principals of LOSADA	SCORM	LOM	DSpace
Universidad de Aguas Calientes (Mexico)	AODDI, based on the instructional model ADDEI	SCORM	LOM	MOODLE
Politecnica de Valencia (Spain)	Via the use of models	SCORM	LOM	Agrega Ruinet
Universidad de Burbula de Venezuela	ADDIE	SCORM	LOM	MOODLE
Politécnica de Madrid (Spain)	TAEE	SCORM	IMS Metadata 1.2.2	MOODLE
Universidad de la Sabana (Colombia)	(Instructional model in learning objects)	SCORM	LOM	MERLOT

4 Resource Description Framework (RDF).(http://www.w3.org/RDF/

5 DARP Agent Markup Language (DAML). (http://www.daml.org/)

6 Ontology Inference Language (OIL). (http://www.ontoknowledge.org/oil/)

This comparison of the OER cycles employed by the previously mentioned universities shows that the majority of these institutions use the ADDIE instructional model. This model is favored because it includes characteristics such as feedback and continuous review, and because it is the most widely-used model in educational contexts.

Instructional Design is a method that defines the steps to take in the process of evaluating student needs, designing the project, developing the educational materials, and evaluating the effectiveness of the OER's in the learning process.

There are more than 100 different Instructional Design models but they are all based on the Analysis, Design, Development, Implementation, and Evaluation (ADDIE) model. Each phase of the model produces a result that provides information for the following phase. When the "Revision" phase is added to the process the model is called ADDIER.

The activities performed in each one of the phases of the ADDIE instructional model are described below:

- **Analysis:** The instructional needs (lack of knowledge), the audience, the learning environment and the technical infrastructure are analyzed.
- **Design:** The content and structure of the OER's are defined and categorized.
- **Development:** The development of the OER's, which includes quality control and storage.
- **Implementation:** A strategy is selected to integrate the OER's into a product, and a management and follow-up plan is created.
- **Evaluation:** A comprehensive evaluation is conducted to determine the impact that the OER's have had on the teaching process.

Most Instructional Design models are based on the ADDIE model, which is why the OER production cycle with social and semantic components proposed in this article is based on the ADDIE model.

Furthermore, there currently exist many data repositories that include semantic metadata, such as:

TABLE II. Open Educational Repositories

Project	Number of resources
CAREO	4 137
MERLOT	14 376

Project	Number of resources
EdNA	28 471
DLESE	11 864

IV. OER Production Cycle With Social Authorship

For OER's to be created with social authorship it is necessary to develop them in a collaborative manner, using collaborative learning techniques. This process is becoming a common practice within different disciplines.

Johnson and Johnson, in 1998, defined collaborative learning as "a system of interactions carefully designed to organize and promote reciprocity between group members." Collaborative learning is achieved by implementing methods to promote working as a group, which are characterized by the interaction and support between the members of the group for the development of knowledge.

Longmire [7] mentions that "the challenge faced by those that develop educational objects and the repositories to store them is not only to provide the possibility of finding educational content, but also to provide relevant and significant contexts for the students that locate the content." This thought is, without a doubt, applicable to OER's because of the need to incorporate semantic components that provide significant context to the resources and allow them to be located and utilized within the growing supply and demand for web resources.

There are several key characteristics that OER's must possess, and their existence must be guaranteed in the production cycle, as shown in Table 1. Tools exist to evaluate these characteristics, such as the Learning Object Review Instrument (LORI), whose results promote the proactive development of learning objects and support those who actively participate in their development [2]. It is thought that LORI can be a valuable support for the evaluation of OER's.

TABLE III. BASIC CHARACTERISTIC OF OER'S

Characteristics	Brief Description
Quality Content	Precision, veracity, adequate level of detail, balanced presentation of ideas
Alignmen t with objectives	Alignment with the objectives for which they were conceived
User interaz	Visual design that facilitates learning and mental efficiency
Reusability	Educational resources that are usable in various contexts
Accessibility	Design of elements in formats that permit access from other media
Interoperability	Guarantees the exchange of content

In order to produce OER's with the abovementioned characteristics, the proposed production cycle is focused on providing flexible and usable resources. If an opportunity is identified during any one of the phases, ideally during the evaluation phase, the analysis phase should start again and the process should be repeated with the objective of developing a new version or a new meaning for the resource.

For the proposed social OER production cycle the five phases of the ADDIE model have been modified to include specific tasks. For each one of the phases a social and semantic component is proposed depending on its specific purpose.

1. Analysis:

- ***Purpose:*** Identify the needs to be addressed by the OER. What needs to be produced?
- ***Social component:***
    - o Use existing social tools such as blogs, wikis, social networks, and microblogging as a source of information by which the users communicate their needs and expectations regarding their education and training.
    - o Document the analysis using tools such as wikis, blogs and Google Docs.
- ***Semantic Component:*** Identify terms to associate the OER with metadata.
- ***Application Guidelines:***
    - o Utilize social tools (blogs, wikis, social networks) within specific courses or subjects.
    - o Allow students to fulfill course requirements by means of social tools.
    - o Tabulate suggestions for improving the course using collaborative tools such as Google Docs and the subject blog.
    - o Identify the primary metadata.

2. Design:

- ***Purpose:*** What? Who? How? Define objectives, content, structure, categories, metadata, policies and licenses
- ***Social component:***
    - o Use social tools such as wikis, blogs, and Google Docs which provide an opportunity for designers, experts, educators, academics, students and technical personnel to effectively participate in the process of defining the objectives, base content, structure, categories, metadata and policies of the OER.
    - o Provide opportunities for feedback on proposed definitions.
- ***Semantic Component:*** Define metadata for the resources.

- ***Application Guidelines:***
    - Redefine objectives, basic content, structure, categorization systems, metadata and policies taking into consideration the issues raised during the Analysis phase, as well as the possibilities offered by the Web 2.0 and the Semantic Web.

3. **Development:**

- ***Purpose:*** Implement the design, search for content resources, storage and quality control elements.
- ***Social Component:***
    - Search and locate resources using social tools, considering the value associated with each resource, comments, and number of visits.
    - Use social defined metadata (folksonomies) to locate available resources.
    - Find and develop resources in accordance with the characteristics defined in the design phase such as interoperability, re-utilization, and re-mixing.
    - Use functionality the Sharable Content Object Reference Model (SCORM) [7] ; metadata definition, metadata specification in XML and packaging.
    - Reload Editor
- ***Semantic Component:*** Linking metadata utilizing folksonomies and ontologies.
- ***Application Guidelines:***
    - Inventory social tools within the university.
    - Select appropriate resources in regards to subject matter, visual quality
    - Adapt or create specific resources for the course.

4. **Implementation**

- ***Purpose:*** Integration and management of the resources.
- ***Social Component:***
    - Use social recommender systems to link and integrate the resources with other related resources and repositories.
    - Distribute resources using social tools such as microblogging and social networks, and make the resources more accessible by including RSS and other technologies related to this purpose.
    - Apply the SCORM runtime environment guidelines, sequencing and navigation.
    - Associate the resources with reputation systems, version control, and feedback and monitoring systems that improve management activities.
- ***Semantic Component:*** Link the folsonomy or ontology to the network.
- ***Application Guidelines:***
    - Use RSS feeds to link other related educational resources with the institution's OCW.
    - Use social tools to distribute new resources.
    - Use reporting tools to track the number of visits to course resources.

5. **Evaluation:**

- ***Purpose:*** Monitoring, control, improvement of the resources.
- ***Social Component:***
    - As with the creation and distribution of the resources, evaluation and feedback will also be conducted by the users using social tools. The users will be given the opportunity to communicate whether the resources fulfilled their expectations and to provide suggestions for improvement through their comments.
    - Rubrics will be used to determine the quality of the resource using a scale based on parameters that the user considers pertinent.
- ***Semantic Component:*** Effective access to the resources in relation to their significance and context.
- ***Application Guidelines:***
    - Use the course blog to solicit feedback from students about new resources posted on the institution's OCW site.
    - Evaluate materials from the Information Fundamentals course.
    - Implement version control through a shared Google Docs document accessed by educators and the team responsible for the current cycle's proposal.
    - Utilize reporting tools to track the number of visits to course resources.

The figure 3 is a representation of the phases of the model, with the social and semantic components included.

---

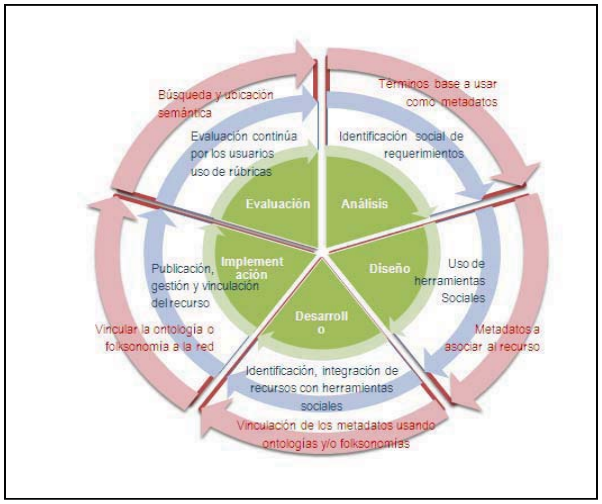

Figure 3. OER'S Production Cycle considering social and semantic components

The production cycle should adhere to the fundamental principles of Open Educational Resources – the resources should maintain an educational focus on developing the knowledge, skills and abilities of the users and they should be publicized using the appropriate legal framework within the Creative Commons licenses and its principal variations: Commercial/NonCommercial, ShareAlike, and NoDerivs:

Attribution or Recognition

Recognition and Share Alike

Recognition and no derivative works

Recognition and Noncomercial

Recognition Noncomercial and Share Alike

Recognition Noncomercial and no derivative works.

V. Application Of The OER Production Cycle Using Social Authorship AndThe Semantic Web

To complement the proposed OER production cycle using social authorship and semantic tools the following is a discussion of the expected results from each phase of the proposal, followed by a brief case study:

1) **Analysis Phase:**

- ***Purpose:*** Identify the need to be addressed by the OER. What needs to be produced?
- ***Expected Results:***
  - Social tools (blogs, wikis, social networks, among others) implemented.
  - Student requirements tabulated and organized.
  - Suggestions to improve the course gathered.
  - Metadata defined.

2) **Design Phase:**

- ***Purpose:*** Why? For whom? How? Define objectives, content, structure, categorization system, metadata, policies and licenses.
- ***Expected results:***[8]
  - Course structure and components reviewed.
  - Objectives and course structure redefined.
  - Resource types to be included identified and categorized.
  - General, specific and social metadata taxonomy established.
  - Metadata management strategy developed.

3) **Development Phase:**

- ***Purpose:*** Find resources for content, storage and quality control
- ***Expected results:***
  - Resources are identified.
  - Measurement tools for resource evaluation (criteria, values) are identified.
  - Resources are selected.
  - Necessary resources are created or adapted.

4) **Implementation Phase:**

- ***Purpose:*** Implementation and management of the resources
- ***Expected results:***
  - New structure and components established, resources designed and implemented.
  - RSS established linking other open educational resources related to the course within the platform in which it is implemented.

8 Not all results are required in this phase will depend on the identification made

- New resources are distributed using the social tools of the course.
- Tracking tools for the course and resources are implemented.

5) **Evaluation Phase:**

- ***Purpose:*** Assess and improve resources
- ***Expected Results:***
  - Feedback from users on the course and its resources obtained.
  - Results from the course evaluation system obtained.
  - Versioning of the Google Docs documents shared between educators and the work team completed.
  - Reports from course tracking tools obtained.

The OER production cycle using social and semantic tools was implemented in a course that is posted on the UTPL's OCW site. The process made use of the application guides previously described. Below is a summary of the process:

The course entitled "Information Fundamentals" was selected because it is one of the first courses available through the UTPL's OCW project and because the course instructors were available to implement the production cycle. In the analysis phase a blog was created (http://blogs.utpl.edu.ec/fundamentosinformaticos/); and subsequently the course requirements were obtained via the blog and the UTPL's Virtual Learning Environment (EVA). During the process of information collection the students suggested in increase in the utilization of social tools and other resources (videos, presentations, and additional documents) in order to improve their active participation and to support the theoretical portion of the course. In response, the instructors were asked to revise the course outline and redesign the course structure so that social tools could be utilized more readily, and to allow linkages to resources other OCW sites that could be reused and/or revised and adapted to the course. Also the first metadata were identified.

In the design phase the objectives and content of each section of the course were redefined by the instructors, taking into account the information obtained during the analysis phase as well as the suggestions from the work team responsible for the OER social production cycle. Thereafter, the resources were categorized by type and subject. Three types of metadata were identified according to their role. These metadata were used to create a unique taxonomy for the Information Fundamentals course within the Schools of Science and Computation. These metadata were managed by including them in all of the course's social tools; they were classified using the system previously described. They are governed by the UTPL's institutional policies regarding academic OER production, and they must conform to these policies.

In the development phase the taxonomy defined in the previous phase was utilized to search for resources using the OCW search engines. The resources were evaluated by applying the designations "Very Good", "Good" or "Average" to different criteria. After the resources were evaluated it was suggested that only those with all criteria qualifying as "Good" or "Very Good" be utilized, and those with criteria qualifying as "Average" be discarded. The last step of this phase was to adapt and/or create resources.

In the implementation phase the resources produced in the development phase were combined. RSS feeds from Information Fundamentals courses from external OCW sites were linked via the RSS feed portlet. The new resources were distributed via the EVA social network and the subject blog.

In the evaluation phase the course blog was used to acquire new information; the resources of the Information Fundamentals were evaluated. Also, a Google Docs document was created to share ideas between instructors and the proposal team to obtain feedback from the students, and report tools were used to track visits to the course resources.

As shown in Figure 3, the proposed production cycle is circular and the evaluation phase serves as feedback for the next production cycle.

VI. Conclusions

The following points have been identified as a result of this study:

- Although ADDIE is a linear instructional model utilized for production cycles of various types of resources, in the case of OER's it is necessary to include evaluation and quality control components within an educational context.
- Including social components in the OER production cycle facilitates collaborative learning between teachers and students.
- Web 2.0 tools improve OER searches by using their semantic meaning, and improve the evaluation of the quality of the educational content by reputable systems.
- The OER production cycle with social and semantic components reduces the time needed for development of these resources since available resources are being re-utilized and are available via social tools.
- Including social and semantic components in OER production is without a doubt an opportunity to take advantage of the benefits of these new web-related trends that provide pertinence, relevance and meaning to the resources.
- The success of this Model depends on the institutional context in which it is implemented, as well as the policies of content generation, author recognition and distribution of the resources.

- The use of social tools with resources is an improvement, but it has been observed that the time needed to access the resources increases for those users with slow connections.
- With institutional support, and especially that of the instructors, the production cycle will not produce the expected results.
- In the development of OCW courses, the use of other OER's is feasible because there are many quality educational resources available that can be reused in other contexts.
- When adapting existing OER's, quality assessment is an important activity for the optimal production of resources.

ACKNOWLEDGMENT

This research project has been partially supported by the Republic of Ecuador through the National Secretary of Sciences and Technology (SENACYT).

This project was developed thanks to financing from Project AL_PID09_036 of the Universidad Politécnica de Madrid.

Abstract— **The social network analysis (SNA) is an approach that can be applied as a complement to other analysis (such as statistical) in order to obtain other valuable information. The social network analysis has been used in several initiatives showing that it is an approach that can contribute in building the semantic web. Within the project Technologies Applied to Electronics Teaching (TAEE) there are biannual conferences (it has been organized since 1996) and have accumulated a significant amount of data resulting from the conferences held. All of this information constitutes a data source that should be exploited and that can provide meaningful information. In this document we describe, how to social network analysis has been used on data sources generated by user communities, in order to obtain some semantic artifacts, like ontologies. Also describes how to was applied the social network analysis and its metrics on the information generated in the TAEE congresses to answer a set of questions (What are the relationships and the level of cohesion of the different organizations (at the level of Spain and across continents) involved in TAEE? How have evolutioned the thematics covered in the conference?, What are the new ontological additions in technology over the years?, and How have evolutioned the thematics in the research and studies related to teaching electronics?) formulated by the organizers of the congresses and that through other approaches would have been a large task and complicated. The answers to the questions can provide us important information about the behavior and characteristics of the elements present in TAEE conferences, furthermore being an element for making decisions on future initiatives with the same style of TAEE.**

***Keywords-** SNA, meta-analysis, TAEE, metrics, results, RedOBER*

I. Introduction

The social network analysis (SNA) is an approach used to find not evident information within the structures formed by the interaction between user groups or entities. The less evident information is the basis for finding patterns of behavior that provide additional and relevant information about the operation and characteristics of a network of some kind. The Social networks analysis covers areas such as: conflict of interest, criminal's networks, finding influential individuals, and study of co-author's networks, among others.

Since a few years ago the social network analysis has been used in several initiatives that have selected as data source the content generated via Web 2.0 tools and have developed networks in order to apply concepts of social network analysis and find a starting point on the road to the Semantic Web, showing that the semantics can emerge from user communities and through simple actions such as tagging. Other initiatives have proposed expanding the Query Language for the Semantic Web (SPARQL) with some concepts and metrics of social network analysis to enable the discovery other types of relationships, derived in a context, which they have called semantic associations.

The project of Technologies Applied to the Teaching of Electronics (TAEE) is an initiative involving several educational organizations and companies from Europe, North America, Central America and South America. The aim of TAEE is implement massively new technologies to the teaching of electronics. Since 1996, a biannual conference has been organized by TAEE project that talks about technologies for teaching electronics and whose aims to disseminate results of projects and initiatives in the areas of educational innovation and application of new technologies in teaching electronics.

The articles of the TAEE's conferences have been classified into large ontological families such as: Systems, Devices and Components, Instrumentation and Measurement, Automation, Robotics, Laboratories, Educative Software, Teaching and Construction Techniques, Implementation and Practical Realization. The documentation generated by each article in each conference is a data source to be exploited. To date there are; 964 documents, 1348 unique keywords, 1092 participating entities, and 1674 authors, among other data.

The aim of this paper is to show the results of the meta-analysis of the TAEE project's conferences (from 1996 to 2008) by applying social network analysis. Through some techniques, metrics and indicators of social network analysis was answered a set of questions that were asked by organizers of the congress and that are of your interest. Also was used to show some relationships such as the use of keywords in the description of the themes and the sub-structures that form between the co-authors of the documents. The metrics and indicators were used thus: to study the connections and distances between actors were used degree of a vertex and density, to determine the power and centrality of an organization were used degree centrality, closeness and betweenness, furthermore to analysis thematic and keywords, weight networks were used, Hubs, Authorities, and to study relations between co-authors k-cores was used.

The results obtained by applying social network analysis on the congresses of TAEE project unlike other analysis (such as statistical), has permitted us to: see graphically the relations between the different participants as well as the development of ontological families. Likewise, the task of finding isolated organisms and those organisms that serve as a link or bridge with others went simple, and showed the way in which they have been used keywords in different ontological families.

The paper is structured as follows: in the first section, we will discuss the social network analysis, its importance and its implementation in some projects of Semantic Web. The next section will be devoted to the TAEE Project's data source for meta-analysis. The third section will show the application of social network analysis and the metrics used to answer the questions described above. Finally, a section of conclusions and recommendations.

II. Social Network Analysis

A social network is a social structure made of individuals (or organizations) called "nodes," which are tied (connected) by one or more specific types of interdependency, such as friendship, kinship, financial exchange, dislike, sexual relationships, or relationships of beliefs, knowledge or prestige[1]. As long as, as mentioned in [5], the social network analysis offers the methodology to analyze social relations; it tells us how to conceptualize social networks and how to analyze them.

The social network analysis (SNA) is an approach used to find information not evident within the structures formed by the interaction between user groups or entities. As you can read in [5] the objective is to detect and interpret patterns, in the social ties between actors that provide additional relevant information about the operation and characteristics of a network of some kind.

Because of its inherent power to reduce a system to its individual components and their relationships (network characterization), moreover the existence of several metrics (sociometric) and indicators that characterize these structures, is an approach that has gained popularity in recent years, successfully applied in scientific and technological disciplines as diverse, mentioned in [13], some examples of projects: conflicts of interest [1], criminal networks [14], search of influential individuals [15], study of co-authors networks [3], among others.

For a few years ago the social network analysis has been used in several initiatives, such as [12], which have selected as a data source the content generated via Web 2.0 tools and have developed networks in order to apply concepts of social network analysis and find a starting point on the road to the Semantic Web, showing that the semantics can emerge from a users communities and through simple actions such as tagging. For the creation of ontologies, the social network analysis has been used on data repositories created by user's communities to find lightweight ontologies, lacking some formalities such as restrictions, but they cover a large number of entities that have been created to through simple actions, but extremely participative.

Within this issue is important to mention the model of ontologies, Actor-Concept-Instance proposed in [12] inspired by social tagging mechanisms, creates semantic-social networks represented in a tripartite graph, person, concepts and instances, expanding the traditional concept of ontology (concepts and instances) with a social dimension.

According to the model, a network of folksonomies is a hypergraph with ternary sides, where each side represents the fact that an actor (user) associated with a certain instance (resource) with certain concepts (tags). From the ternary hypergraph, is posible obtain three bipartite graphs (actors and concepts, concepts and instances, and actors and instances) of whom (actors, concepts) shows an ontology formed by the interests of communities, while (concepts, instances) reflect ontologies formed by the co-occurrence of tags in the resources, thus showing how from a folksonomy can be deduced an ontology.

In SPARQL, arises the need to incorporate, to RDF graphs, some concepts and metrics own of social network analysis, such as: length between nodes, the search for shorter paths, among others, and this way enlarge the information than a SPARQL query provides, as show [7], [1], [14], [8], [2]. With these information extensions, SPARQL will be able to find certain relationships that have been called semantic associations or complex semantic relationships. Semantic associations are meaningful and relevant complex relationships between entities, events and concepts. They lend meaning to information, making it understandable and actionable, and provide new and possibly unexpected insights [14]. Discovery of semantic associations is the process of finding paths of possibly unknown length that connect the given entities and have a specific semantics [8].

1 Taken from Wikipedia http://en.wikipedia.org/wiki/Social_network

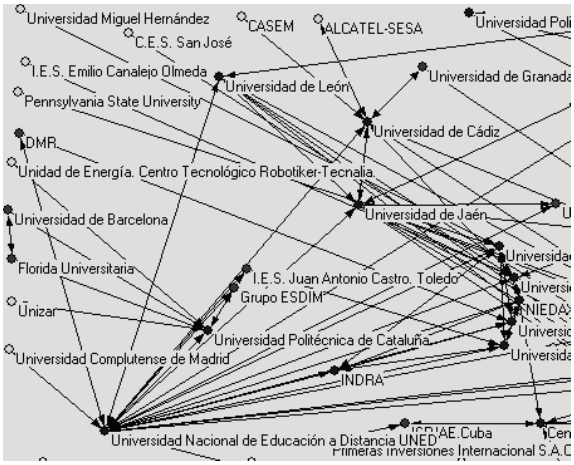

Figure 1. A section of the network constructed

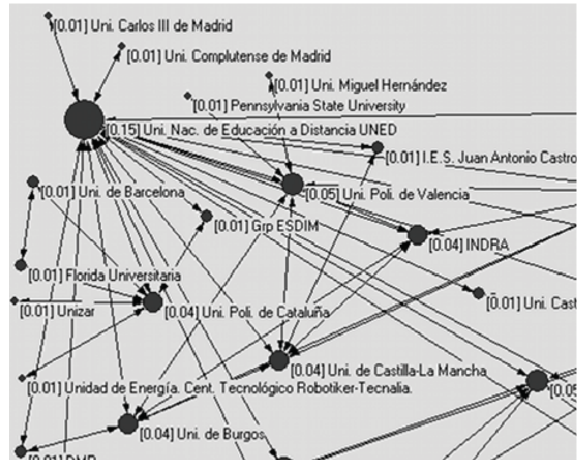

Figure 2. Vertex degree. Each vertex shows your degree

The SPARQL extensions are potentially applicable to: discovery of conflicts of interest, the study of criminal networks, for example.

Other applications of social network analysis, similar to the analysis described in this document can be found in [9], [10], [11] and [13] whom have taken as a data source code repositories of open source projects, including: Apache, GNOME and KDE; building a methodology which highlight the relevant information for a given aspect of project, as mentioned [10].

Another similar application can be found in [6] in this case the data source are communication archives, such as e-mails, blogs, with the aim of improving the understanding of organizational behavior in a company.

In [4] was used social network analysis to detect interesting structures in the resource repository called SIO (Slovenian Educational Network).

III. TAEE Project as data source for the meta-analysis

Under the project of Technologies Applied to the Teaching of Electronics[2] since 1996, a biannual conference has been organized that talks about technologies for teaching electronics and whose aims to disseminate results of projects and initiatives in the areas of educational innovation and application of new technologies in teaching electronics. The presentations prepared for each conferences are varied but have been classified into large families themes such as: Systems, Devices and Components, Instrumentation & Measurement, Automation, Robotics, Laboratories, Educative Software, Teaching and Construction Techniques, Implementation and Practical Realization. The documentation generated by each article in each conference is a source of data to exploit and seize.

2 ¿Qué es el proyecto TAEE?. Proyecto TAEE: Un entorno para desarrollar proyectos. (Disponible en: http://www3.euitt.upm.es/taee/presentacion/presentacion.htm)

For the development of this article we took as a data source, the documents generated in the congress of TAEE Project, 8 congresses executed (from 1996 to 2008) organized in 150 sessions, which has resulted, in a data group consisting of: 964 documents, 1348 unique keywords, 1092 participating agencies, 1674 authors, 9 thematic families, several levels of specialization in each of the families, 4425 learning objects extracted from each article and approximately 5000 references.

The data listed above were provided by the organization of TAEE congresses and were delivered in two formats, spreadsheet and a database of MS Access.

To perform the meta-analysis was used Pajek[3], an open source tool designed for representation of large volumes of data. There are other tools like Pajek, how can see in "Social Network Analysis: Introduction and Resources"[4]

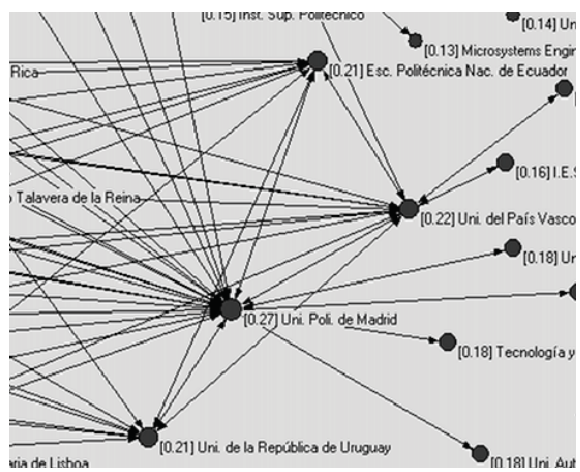

Figure 3. Closeness

3 http://vlado.fmf.uni-lj.si/pub/networks/pajek/

4http://lrs.ed.uiuc.edu/tse-portal/analysis/social-network-analysis/#software

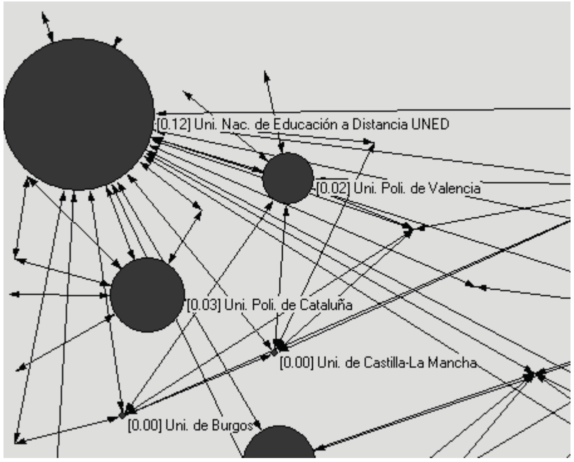

Figure 4. Betweeness

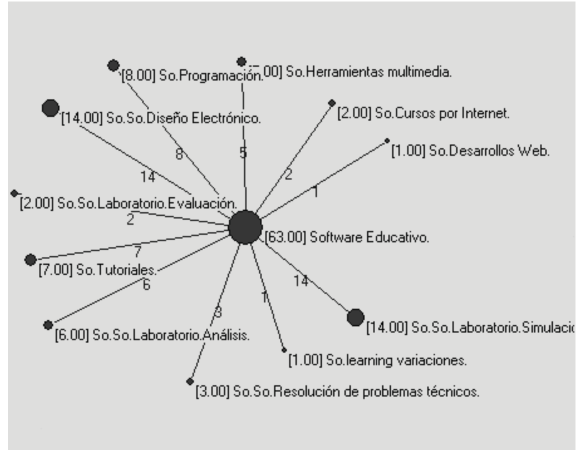

Figure 5. Thematic classification to Educative Software in 1994

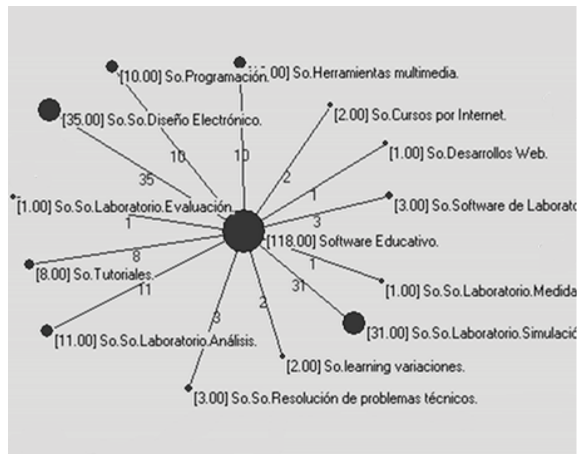

Figure 6. Thematic classification to Educative Software in 1996

Most of the data for meta-analysis were obtained through SQL queries executed against the database and the results were exported as plain text files. In some cases Java programs were developed that allowed to obtain structured data files in the format of Pajek.

IV. Application of social network analysis

Through meta-analysis, we have attempted to answer the questions: What are the relationships and the level of cohesion of the different organizations (at the level of Spain and across continents) involved in TAEE?, How have evolutioned the thematics covered in the conference?, What are the new ontological additions in technology over the years?, and How have evolutioned the thematics in the research and studies related to teaching electronics?

To answer these questions, we have used several metrics of social network analysis, such as vertex degree and density (to study connections and distances between the actors), degree centrality, closeness and betweenness (to determine those organizations with greater power and centrality). Furthermore, we have used Weighted networks, Hubs and Authorities for analysis of thematic and keywords. Lastly K-cores for the study of substructures formed by the relationships between the authors of documents. The results obtained by applying social network analysis on the Congress documents of TAEE project is a complement to statistical analysis, and has permitted: see graphically the relations between the different participants as well as the development of thematic families by facilitating the task of finding isolated organisms and those organisms that serve as a link or bridge with others, and has identified the relationship between keywords in different thematic families.

TABLE I. Summary of the vertex degrees

Degree	Frequency	Representative
0	51	SELCO. SA
2	36	ALCATEL-SESA
4	13	DMR

A. *What are the relationships and the level of cohesion of the different organizations (at the level of Spain and across continents) involved in TAEE?*

To answer this question was built a network composed as follows: the nodes or actors representing the organizations participating in any edition of the congress. The arcs of the graph are formed between organizations that cooperated in the creation of any presentation, at least once; due to lack of hierarchies, the arcs are bidirectional. See Fig. 1.

The indicators and metrics used to answer the question were: cohesion, density, centrality, vertex degree, closeness, and betweenness. Before to continue is necessary some definitions.

Cohesion is the degree to which actors are connected directly to each other, forming groups, and intuitively means that a social network contains many arcs [5]. To determine the degree of cohesion there are some metrics that are described briefly below:

TABLE II. TABLE SUMMARIZES FOR THE INFORMATION OF THE THEMATIC TEACHING

Teaching	1994	1996	1998	2000	2002	2004	2006	2008	Año

Mode									1994
Frequency and median	9	9	8	9	10	11	11	11	M_e = 9.5

- Density: is the proportion of existing ties or arcs in a network with relative to the total number of possible arcs. The density calculated for the network of all organizations that participated in a conference is 0.0191 which means that only 1.91% of all possible arcs are present, although as noted in [5] the density is not a useful measure of their dependence on network size. See Fig. 2.
- Centrality: This measure provides an approximation of the social power of a node on the basis of how well "connected" found on the network. For the calculation of centrality, the following indicators: degree, closeness and betweeness have been used.
    - Degree: The vertex degree is a count of the number of ties or arcs (incoming, outgoing or both) with other actors or nodes in the network, for summary sees Table 1.
    - Closeness: It is the measure that has a node and shows how close is (directly or indirectly) to all other nodes in a network. It reflects the ability to access information through the group of network members. It is inversely proportional to the sum of the shortest distance between all nodes in the network. See Fig. 3.
    - Betweeness: This measure shows how a node is, compared to other network nodes. This measure looks at the connectivity of the neighboring node, assigning a higher value for the nodes that serve as bridges between clusters. The measure reflects the number of nodes that a node connects indirectly through their direct links. See Fig. 4.

TABLE III. THE MOST IMPORTANT ARCS BOTH BY THE WEIGHTED ARCS, AND BY THE AUTHORITIES ANALYSIS

Weighted arcs			Hubs y Authorities

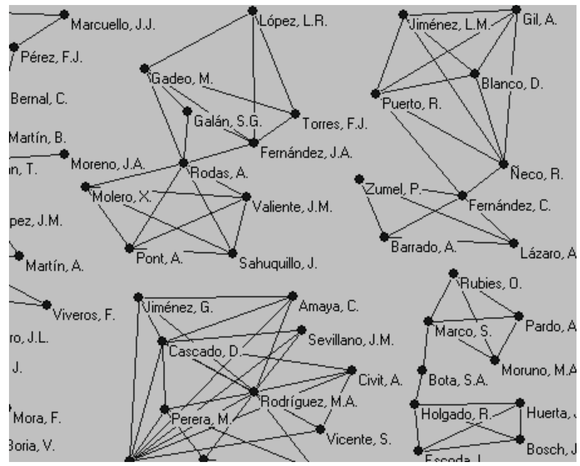

Figure 7. Part of k-cores in the authors network

B. How have evolutioned the thematics covered in the conference?

To answer the question several networks were formed, one by year of publication of the congress, whose nodes are the thematic (which remained fixed in all the years) and their sub-thematic (which appear and disappear depending on the existence of documents classified under this sub-thematic). Giving as result 9 groups, one for each thematic, around which are shown, according to existence of documents, the sub-thematic.

For the arcs, we used weighted arcs, the weight representing the number of documents belonging to a sub-thematic. The diameter of the nodes varies proportionally to the number of documents that were published, it should be noted that the nodes that represent the thematic, show the total amount of documents.

As mentioned above the metric used was the weighted arcs, which is a value assigned to an arc to represent a certain characteristic and the weights can be classified into input, output or both.

In the following figures (Fig. 5. and Fig. 6.) you can see part of the evolution of the Educative Software thematic in the events of the years 1994 and 1996. To the generation of images we used an option of Pajek called "Generate in Time" [16] option that generates a series of images from a single data file.

Through the series of generated images, was possible: classify into groups according to the level of specialization; get the years in which different thematic achieved its minimum and maximum levels of specialization, and find the families whose thematic had a lower index changes.

C. What are the new ontological additions in technology over the years?

To answer this question were selected the following thematic: Systems, Educative Software, Devices and Components, Automation and Robotics, considering them, that are the families more related to the area of technology. In addition, use the metric called the weighted arcs and the statistical measures: mode and median. The mode, allow get the common year in which they appeared each sub-thematic, while the median is used to determine the number of sub-thematic.

The above has helped focus attention on a specific subset and provides numerical arguments that describe the group's situation. Demonstrating that social network analysis needs to be complemented with statistics metrics and vice versa.

D. How have evolutioned the thematics in the research and studies related to teaching electronics?

Like the previous question was used: the weighted arcs, mode and median to answer this question, but the thematic family selected was Teaching. The following table, Table 2 shows a summary of the data source to calculate the mode and median.

E. Another analysis

The following analysis not responds to a specific question, but we use it is to show relevant information about the network behavior of thematic families and keywords, and the network of authors and co-authors of articles.

- Thematic families and keywords. This analysis tries to show the use of keywords in the description of the documents that belong to a thematic family. It formed a network of nodes representing the thematic families and keywords, there is a tie between thematic family and keyword if there are one or more documents that belongs to a thematic family and was described with that keyword. To perform the analysis, the following metrics were used: arcs weighted, Hubs and Authorities, this metrics try to show that a keyword is important not only for the number of times it is used, but instead it is important for the way in which used. Hubs and Authorities are useful metrics for finding important vertices inside a network structure. A node is a good Hub if it points to a number of vertices that are good Authorities, and a node is a good Authority, if it is tied to several vertices, that are good Hubs. The most important arcs both by the weighted arcs, and by the Authorities analysis are: Teaching, Educative Software and Systems, while keywords (Hubs) are summarized in the following table, see Table 3.

In the analysis of Hubs and Authorities, and as shown in Table III, only 9 keywords are showed, because the Pajek did not generate the tenth, possibly due to the lack of a keyword that is used to describe the 3 Authorities. We can see how the ranking of keywords varies depending on the type of analysis, even; we can see the omission or addition of other.

- Authors and co-authors. The objective of this analysis was to show the groups constructed by the authors of published documents, and beyond the simple groups, we can see how simple groups interact to form larger groups. To do this analysis, we formed a network whose nodes are authors and there is an arc between two nodes, if two authors have collaborated to write an article. The metric used was K-cores. A k-core is a maximal sub-network[5] in which each vertex has at least degree k within the sub-network [5]. It uses the degree of a vertex to identify groups (clusters) of vertices that are strongly connected because each vertex has the same level within the group. The value of index k was selected to display as many authors as was possible. Fig. 7. show part of the graph. In the case of the Fig.7. we set the value of k to 4, which means that groups are formed by nodes that are related to 4 nodes, ie the degree of each node is equal to 4.

V. Conclusion

Through the development of this work, we can draw the following conclusions:

- The answers to the questions raised were developed using techniques of social network analysis. Demonstrating that most activities that involve a group of people can be represented through a graph and can apply techniques of social network analysis to characterize them.
- The social network analysis is a type of analysis that allows to obtain other relevant information, complementary to other analysis like statistical and, through the metrics and indicators that it has, is possible to show with numerical data, the different characteristics that a social networking has.
- Through analysis of the relationships between thematic families and keywords, we can see how social network analysis provides a different approach that shows other information in a simple, fast and graphically.
- The meta-analysis just presented in this document has served to provide insight from massive data analysis and statistics. From this point of view has been included joint variables parameterization based social networks and graph theory by using the Pajek tool.
- TAEE congresses have followed a positive development reflecting the electronics world in terms

---

5

A maximal subnertwork is a network with maximum density of thematic diversity and their adaptation to new techniques and products.

- However, the partnership between organizations and between authors from different organizations is a topic that could be improved, in addition to achieving a better balance between organizations from different continents. From this paper, the authors support the dedication of all the organizing committees of various conferences and summons them to encourage to new organizations to participate and strengthen partnerships between organizations.

In order to generalize this type of analysis for any repository generated through user communities, we make the following recommendations, attempting to mitigate some risks described in [12]:

- The ternary hypergraph, could be formed by authors (actors) who write documents (resources) that are described by keywords (tags).
- To achieve the volume of information necessary to ensure the accuracy of the generated ontologies, is necessary the publication of documents on a public website, accessible through the use of Web 2.0 tools that allow the enrichment level of tags, for the resource description.
- To avoid some of the problems in creating the folksonomy, especially to avoid the use of nonstandard acronyms and errors in writing, we propose the use a suggestion service (but not with the intention to limit, restrict or impose criteria to users) without losing the social participation and freedom to choice.

ACKNOWLEDGMENT

The authors wish to thank to: Ministry of Science and Innovation in Spain, the Spanish National Plan I+D+I 2008-2011, and Technical University of Loja, UTPL. Abstract—**Social media services have recently become well known especially among young people [1]. In social networking sites a user can participate intensively in activities in the service. To support collaborative study at Tampere University of Technology (*TUT*) and also to provide social networking tools for students especially at the beginning their studies, the development TUT's own social network site was begun in spring 2008. To make the system popular among students, developers and researchers at the Department of Mathematics and Hypermedia Laboratory at TUT designed interventions for fall 2009 when the semester began and new students started their studies. The earlier research [2] revealed numerous motivating aspects that should be somehow included in a study oriented social networking site. This paper will describe the research results of interventions to motivate students to use a social networking site in the context of studies. The results will show that such an environment with social aspects connected to studying and study life on various levels is a means of enhancing studies and basically a necessary tool, especially for students in the early phase of their studies in a new university. The motivation should be further encouraged by the system itself when it relies on students' own voluntary activity. Moreover, the intensive actions of developers, researchers and administrators can be used as tools in directing network activity development.**

Keywords; social media, social networking, study support, motivations, interventions, mathematics

I. Backgrounds

Web 2.0 based social media services (e.g., *Facebook*®[1], *LinkedIn*®[2], *Last.fm*®[3], etc.) have recently become well known especially among young people. There is clearly something appealing in web-based social services [1]. In social networking sites a user can participate intensively in activities in the service, share contents, debate and share opinions and create different kinds of groups for different needs. Why use social networking sites in the study context? Kärkkäinen [3] observed that one of the crucial problems in (Finnish) university level studies is that the very early steps at the beginning of studies are the most difficult for many students. One reason for this is that only a few new students know any of their peers at the beginning of studies in their new university.

To support collaborative study at Tampere University of Technology (*TUT*) and also to provide social networking tools for students especially at the beginning their studies, the development TUT's own social network site was begun in spring 2008. The development project is still running and the site has been improved.

Social network sites are defined as web-based services that allow individuals to (1) construct a public or semi-public profile within a bounded system, (2) articulate a list of other users with whom they share a connection, and (3) view and traverse their list of connections and those made by others within the system [1].

II. TUT Circle

The social networking site *TUT Circle* is a web based environment for students offering customized tools for enhancing social aspects of student life at TUT. The primary target is to provide an efficient and compact system to help new students at TUT to create new social contacts with each other and with students already studying at TUT, e.g., peer tutors etc. The secondary target is to help students form studying groups and circles for their own needs considering their motivations, attitudes, learning methods and orientations [4]. Supporting studies is one part of the whole.

The passivity in the use of the first version of TUT Circle, which was mainly designed to be a tool for collaborative studying at TUT, and the results of the study regarding students' motivation for social media enhanced studying and learning led the developers and researchers to include the context of studying and especially first year mathematics studies at TUT as a different kind of widgets offered to users through specific interventions. The research on students' motivations to use social networking sites in the context of studying showed that systems of this type should not be too complex to use and that the added value for the student should be something unique. A networking site in the context of a student's own university could suffice to motivate students to use the system if it works properly and provides only the tools needed for basic interaction and social activity [5]. Developing a new Facebook was deemed totally worthless [2].

1 http://www.facebook.com/
2 http://www.linkedin.com/
3 http://www.last.fm/

TUT Circle uses an open source CMF (*Content Management Framework*) *Drupal*®[4] that provides basic tools for content management and editing. With specific modules the system can be tailored to various needs. Therefore building up a social networking site on CMF is not a problem in Drupal. Technically development focused on improving the dynamics of the network. In TUT-Circle there is a personal dashboard for every user. The dashboard collects all activity of the user and the user's neighborhood into one page in a systematically ordered way and in real time. Even the activity of users outside the user neighborhood is shown on the dashboard, which enables the user to widen his/her network [2].

TUT Circle is in general a social network site with separate features offering support for studying at TUT at crucial points during the semester. These features are brought into the system through well-planned interventions. The priority is to support new students' social networking process in real life at TUT. Student life at TUT includes a variety of aspects of everyday life. TUT Circle provides a channel for individuals and groups to join together and share the same interests etc.

To make it much clearer that TUT Circle is not primarily a learning environment at all, new students that started their studies at TUT in fall 2009 received information about the system already in summer 2009 before arriving at TUT. This way the new students could familiarize themselves with TUT in general and got to know each other beforehand. This was thought to facilitate the start of studies at university level [2].

As a social network site TUT Circle provides all the common tools for interaction between individual users. Every user has his/her own profile where a wide range of information about user him/her can be shared with others. Typical profile information is e.g., name, gender, date of birth, year of starting studies at TUT and degree program. A user can also add something about his/her hobbies, interests, skills and life in general (e.g., biography, place of birth and current place of residence) [2].

Among basic user actions like status updates and private messaging between users every user can request some other user to be his/her friend in TUT Circle. The friend requests must be accepted before the relationship is formed. Through these friend requests and by accepting others' requests a user's neighborhood in the environment widens and more options for social activity become available. For example, in a user dashboard friends' activity is shown with higher priority. Furthermore, the system can more precisely suggest other users of network as potential friends for a particular user. These suggestions are based on social network theories concerning friend's friends etc. Simple SNA (*Social Network Analysis*) [6, 7, 8] methods and algorithms are used to find potential users.

To enhance the dynamics of activity all content in TUT Circle can be tagged with keywords. These tags help users to find contents on particular topics dynamically without using complex searches etc. Tags also support social networking when users can easily list all users e.g., according to some specific interest or hobby. Tags describing geographical information such as place of residence and place of birth can be shown for all users or restricted to user's neighborhood using *Google Maps*™[5] based map widget [2].

Groups in TUT Circle provide more efficient tools for collaborative activity in the environment. Every user can create his/hers own group. The purpose of the group is not restricted and topic can be anything that is relevant. Every group has member management tools and the visibility of a group in TUT Circle can also be modified by a group administrator (the creator of the group). A group has tools to help collaborative activity and even group studying and learning in web environments. In a group members can chat, write news, manage events, write blog posts and edit wiki pages collaboratively. Sharing resources (e.g., files, images, etc.) is also an option [2].

The discussion board has a static structure that helps users to find the correct forum for their posts more easily than in discussion boards with user modifiable tree structure of discussion topics. Under every default topic users can initiate new discussions about subtopics related to the primary topic and these subtopic trees are user modified. The default topics consider many aspects of student life at TUT. One topic is discussion about first-year studies; another is student life in general. Topics related to leisure time and living in Tampere are also included, likewise a flea market where students can easily sell and buy items (e.g., course books, furniture, etc.) from each other [2].

The questions feature enables every user to ask a question anonymously. This feature was developed because according to the research students found it easier to ask even a stupid question out loud if it was possible to do so anonymously. Every user can answer these questions and the answers are given with a name. This gives active respondents social credit when they help others with their responses. It also gives visibility for a respondent when his/her answer to a question is shown on dashboards [2].

Furthermore, the questions feature is used to support studies in Basic Engineering Mathematics. Through an intervention special groups in the context of mathematics are brought into the system and users are directed to join them. In these groups users studying mathematics at TUT can ask questions about mathematics anonymously and an online tutor answers those questions. Clearly every user can also answer any question. This way lecturers teaching Basic Engineering Mathematics can recommend the TUT Circle for students as a system for supporting studies and truly rely on the fact that support really can be obtained [2].

Other features designed to support study are mainly special widgets available to users through interventions. These widgets are surveys etc. One example is a *Mathematics Horoscope* which through a 15-question survey tells the user how he/she is oriented to study mathematics, his/her mathematical skill level and how he/she could study mathematics at TUT to learn certain topics better. Students also get some tips on how to improve their study methods [9]. The analysis of the survey is based on a study conducted at TUT on students' skills, orientations and methods in learning mathematics [4].

III. MOTIVATIONS TO USE WEB COMMUNITIES IN STYDYING

According to McMillan and Chavis [10], there are a four features of sense of community; (1) feelings of membership

[4] http://drupal.org/
[5] http://maps.google.com/

(i.e., a member has a feeling of belonging to, and identifying with the group), (2) feelings of influence (i.e., a member has feelings of having influence on and being influenced by the community that emerge from enforcing and challenging norms within the group), (3) feelings of reinforcement of needs (i.e., a member feels support from others, has status in the group, and meets other people's needs while having his/her own needs met) and (4) feelings of shared emotional connection (i.e., members feel having a relationship and a shared connection with others due to frequent and high quality interaction) [10].

In the earlier research [2] it was noticed that the nature and purposes of a social networking site affect users' motivations to use the systems. Simple and easy might even be considered lame, but on the other hand an excessively complex service might overload users' capabilities in system usage [11]. Furthermore, it has been observed that in addition to exemplifying principles of usability and accessibility, the system should be visually fascinating and technically modern and workable (see Table I) [2]. The connection between the service and the context should be obvious, i.e. student life related activities and topics should be easy to bring into the service. "Using the service it's easy to find other students in the same phase of studies. This will help a student to take studies more personally, when the networking service gives a user a sense of belonging", one student earlier encapsulated the general mood in his answer. Another student claimed: "When users' first experiences of system usage were positive the information about the system started to spread to other students, for example, in coffee table discussions." After all, the quality of a social networking site depends on the quality of the community within it [2].

Students are not so interested in joining a networking service that lacks users to be connected with, but it was noticed during TUT Circle first version usage that an empty networking service does not gain any content. For example, according to Nielsen, [12] most users (90 %) are lurkers who just read messages and only 9 % produce contents once in a while. Only 1 % of users can be considered to produce contents constantly. Despite these limitations the sense of belonging to the student web community is deemed important: "For many youngsters starting their studies at university might be somewhat difficult, because older peers often start their studies somewhere else or stay in their home town. Especially if the high school and the university are in different towns it is inevitable that old friendships get weaker and new friendships are formed with other university students. Sometimes it is hard to get to know new friends out of the blue. It usually takes days, often weeks. Studying generally feels better, when one does not have to study alone… In the web it is easy and comfortable to meet new people and discuss with them. Starting a discussion and joining one is often easier in the web than face to face. In a social networking site in the context of university studies one can seek and find new and old students from a specific study program and get to know them already before actual start of studies as well as during the studies. This could be a convenient ice breaker for many students. Discussion face to face could be easier at the first meeting, when both could recognize one another."[6]

[6] A quote from a student's answer in the research data

TABLE I. ASPECTS INCREASING AND DECREASING STUDENTS' MOTIVATION FOR STUDY ORIENTATED SOCIAL NETWORK SITE USAGE [2].

	Motivating	Non-motivating
Background and reputation of system	Voluntariness Free of charge Positive usage experiences General popularity Trendy Fashion craze	Narrow focus Bad or dubious reputation Unknown system Uninspiring
Basic idea and targets	Centralization of information Collaboration Social networking Improvement of communication Connecting studying and leisure	Nothing new Everything about anything in one place Similarity to other services available
Usage needs	Networking Social interaction Enriched user profile University related information sharing Study support Connecting users with similar interests etc.	Irrelevant features The system is not supported to be adjusted to individual user behavior Lack of interactivity
Functionalities	User-to-user relations Messaging Groups Discussions Resource sharing Managing events (incl. calendar) Collaborative content production	Complex widgets Irrelevant games
Content	Information about student life University related content General discussion board with clear structure and relevant topics (e.g., living, studying, jobs, buy or sell, …) Study schedules	Lack of content Too much information Irrelevant or too specific discussion topics (e.g., discussion about one single course etc.) Spam messages
Usability	Easy to use Clear and simplified user interface	Too complex structure Content cannot be found easily Long chains of navigation
Layout	Eye-catching layout Trendy theme	Machine-like Lack of pictures and images
Technical sustainability and flexibility	Fast and stable system Fault tolerance Fully functional Open interfaces User agent independence	User feels like a test user Unstable system Parallel systems cannot be synchronized Lack of mobile version
Moderation	Continuous surveillance and development Bug fixing Responses to feedback Short service breaks (prior notice sent to users)	Slow and/or inaccessible administrator Lack of surveillance No control Long service breaks Feedback is ignored

IV. Research Data and Data Analysis

To make TUT Circle popular among students, developers and researchers at the Department of Mathematics and Hypermedia Laboratory at TUT designed interventions for fall 2009 when the semester began and new students started their studies. During summer 2009 the focus was on encouraging the activity of new students so that in fall the study supportive widgets would have been easily-obtained and used by students. Furthermore, the activity was monitored and the development of networks in TUT Circle studied using social network analysis methods and applications.

In autumn 2009 data was also collected from 38 hypermedia students regarded as early adopters. They were asked to sign up for TUT Circle and analyze aspects, functions, or features motivating users to use the service. In this evaluation students used a specific *WeSQu* tool and its User Motivation section. WeSQu is a web-based tool for evaluating web service quality, e.g., in terms of reliability, accessibility, visual design and community properties [13, 14, 15].

WeSQu's theory is based on research in HCI (human-computer interaction), psychology, and pedagogy as well as on evaluation research, which has its roots in the theory of usefulness of computer systems. The usefulness of web-based services includes usability and utility sections. The framework is needed to define the factors crucial to the implementation of web services for a varied group of users. The main issues within this evaluation framework are usability, added value as well as accessibility and informational quality of web services [16, 14, 17, 18].

Usability means that the user interface of a web-based application must be easy and effective to use so that the user can concentrate on the information content instead of the interface. When software is usable it is easy and efficient to use, easy to remember, has few errors and it is subjectively pleasing [18].The added value of web services can be evaluated as in conventional services. Is there something special or something new for users? An essential part of quality is also accessibility, because web design today is designed for individuals in various contexts with different devices [19, 20]. The fourth part of quality is the informational quality of any web service. To be of high quality the informational content of a web service should meet the five main criteria: accuracy, authority, objectivity, currency and coverage [21, 22, 23].

In addition the foregoing quality experiences of web services are also subjective and depend on the user's personality, expertise, needs and use situation and context [24, 25]. WeSQu's User Motivation section concentrates on means of awarding the user for using the system, how different user groups are considered, how the system can be personalized and how easily service content can be followed. In addition, the students were asked to analyze the extent of evaluation.

The total amount of text data collected was 160 pages. The data was analyzed using theme analysis, which is suitable for research pursuing more profound knowledge about a phenomenon and having theory based data collected. In practice theme analysis is data slicing and rearrangement in different categories. The purpose is to find themes explaining the research problem, i.e. relevant topics are identified and separated from text data. A strict connection between data and theory is crucial in theme analysis [26].

V. Results

In the evaluations the same topics from the earlier research (see Table I) were emphasized. In addition, the following was highlighted in students' answers:

- New features should be added into the networking service a bit by bit. It was considered that beginning system usage is easier if a platform is fairly simple at first. To maintain interest there was appreciation for new functionalities introduced in the platform, when the network was organized and properly formed.
- A networking site is a suitable tool for promoting different events for students. The option to add geographic information [27] into the Google Maps widget [2] was deemed very motivating: "…Profile section is fairly versatile and it is very easy to add information, e.g. a map with a tag representing one's own home or home town."[9]
- A profile level indicator was considered a good feature. It was also appreciated that a user can give only the personal information he/she wants to share: "Different kind of interests are also clearly visible if wanted. This helps to find similar or certain new friends and can also enhance the motivation to use the service when one can show what kind of music and movies he/she likes. It is also convenient that titles of songs listened in Last.fm (see Fig. 1) can be imported to TUT Circle."[10]
- It was motivating to follow friends' events, content and profile information.

[8] http://twitter.com/

[9-10] A quote from a student's answer in the research data

- E-mail messages about new features and content feeds are increasing the participation in content producing in the social networking site. In addition, content feeds in a user dashboard were considered to be motivating: "The dashboard gives a great overview of all new content and activities."[11]
- A function to register like or dislike of content and features was desired, likewise listings of the most popular content, users, actions, etc.: "…The 'like' function gives a user an opportunity to give positive feedback on content produced by another user."[12]
- RSS feeds were considered convenient functionalities: "A chance to export an RSS feed from a discussion board also motivates users, likewise the option to produce one's own content."[13]
- Some students emphasized the importance of anonymity in web community activity.

After all, TUT Circle was seen to increase a sense of belonging, because in the system it is "easy to discuss local issues and get to know the people at TUT" [14]. Wellman [28] refers to this phenomenon as "glocalization"; the ability of the Internet to both expand user's social contacts and bind them more closely to the place where they live.

For basic usage monitoring in TUT Circle *Google Analytics*™[15] is also used. Using this data the network activity can be analyzed from the perspective of interventions executed. The results of this analysis support the results of motivation research. It is obvious that a social networking site in the context of studying requires constant steering when system usage is not mandatory at any level. Proper interventions can be seen as means to accomplish such network steering, but even successful interventions are not enough alone to maintain system usage at a satisfactory level.

As can be seen in Fig. 2 the usage level can be enhanced by interventions. Obviously, an intervention should be appropriate to users and to the system itself to be successful. It is fairly easy to implement successful interventions of any kind to increase activity in the system for a short period of time,

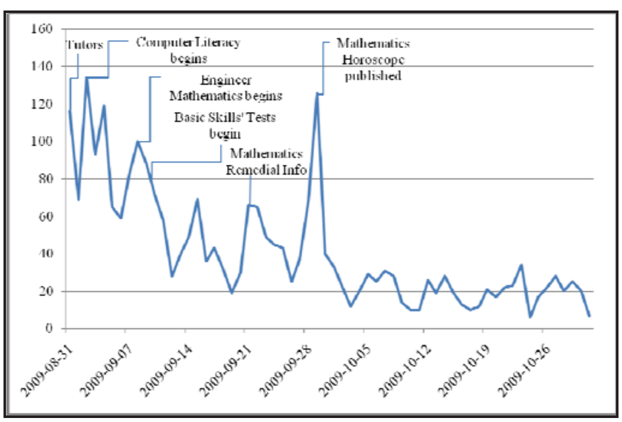

Figure 2. Daily visitors in TUT Circle. The most of the peaks can be explained by interventions executed.

Figure 3. SNA graphs and figures of the evolution of a social network in TUT Circle. It can be seen that the most intensive network evolution occurred in September 2009. However, while the network gained more users its density was declined as well as its group degree centralization. This is explained by several network cliques. There is only few users interacting with many other users in the web based student community.

but successful interventions steering system usage to be more self-oriented are much more difficult to design and execute.

At the beginning of the semester the peer tutors gave the first information and true examples of TUT Circle usage as well as demonstrations on Computer Literacy and Engineer Mathematics courses. Due to this promotion most of the new users were registered in the system and actually more or less started to use the service. However, the sustainability of system usage level was rather sensitive to changes. For example, when new contents did not appear usage was slight. On the other hand, when a new intervention was executed, the usage level soared, for instance, with Mathematics Horoscope by over 150 percent compared to the average usage level of the preceding usage period. However, the interventions did not ensure long-term system usage.

In TUT Circle there is a tool that is used to collect log data in XML (*Extensible Markup Language*) format about different network actions. The data can be used for SNA that enables enriched network information production. Based on log data and together with SNA methods different visualizations can be produced. Visualizations can be used to support the analysis of social networks e.g. to detect changes and weak signals, to gain an overall view of the social network as a whole, and to concretize development of the network [29].

10-02	14.8 %	3.8 %	3.3 %	1.1 %	1.6 %	1.1 %	0.5 %

SNA was used to analyze network evolution during the intervention process. Analysis was concentrated on friendships formed in TUT Circle. Basically, a friendship between two users is formed through a request-acceptance process. These connections are considered undirected. Moreover, connections are considered dichotomous so that no value was added to describe a connection as intense etc., because analyzed log data included only information about friend requests and accepted or ignored requests.

Through SNA analysis it was possible to create a time series of visualizations representing a network of active users in TUT Circle. The graphs were created using *Pajek*[16] software and its *Kamada-Kawai graph layout algorithm*. Furthermore, detailed information about network was evaluated through SNA analysis using *Matlab*®[17] software.

In SNA graphs network actors are represented as nodes and connections between actors as edges. Characteristic network figures like density and group degree centralization give more detailed information about a network under study.

Network density simply describes how many connections (edges) there are in the network. It gets its maximum value 1 when every possible edge exists in the network. When there are no edges in the network the density is 0. Degree centrality is a proportion of an actor's existing connections of all connections which can be formed with other network actors and thus gets its maximum value 1 when a given actor is connected to every other actor and minimum 0 when the actor has no connections. Network degree centralization describes the rate of a single actor's effect on other actors' interactions on the general level of the network under study. This indicator is assigned a value from 0 to 1 and the higher the centralization index the more interactions there are in the network [6, 7, 8].

A closer view of Fig. 2 connected to SNA visualizations (see Fig. 3) shows that the interventions done did indeed accelerate TUT Circle usage but did not significantly increase the level of social networking in the system. Moreover, it can be seen that the effect of the interventions on general activity in terms of content production and interaction between users was not significant, even though users did return to the system due some certain intervention. In fact, SNA figures such as network density and group centralization indices show that new registered users behaved in the community like all the other users. The network did not become more connected when new users were introduced into the system. Most of the users were connected with their friends, but the interventions did not significantly influence new friendship creation. Basically users only participated in activity related to the intervention and ignored other features offered by the system.

An example of this kind of behavior is an intervention considering the publication of a new feature in TUT Circle. Fig. 2 presents the frequency of daily visitors and the frequency of Mathematics Horoscopes, created daily. The Mathematics Horoscope is a questionnaire that profiles a user's mathematical competencies, study methods and targets with 15 questions. Clearly this new widget motivated users to return to the environment and use the new feature. An e-mail announcement on Tuesday 29th September 2009 activated the TUT Circle users instantly and the effect on system usage level was truly significant. But users were not active regarding anything else in the environment. This can be seen in Table II. Usage of any other function did not increase. Moreover, when the users had once created their Mathematics Horoscope this feature was simply forgotten.

VI. CONCLUSIONS

Crucial properties of web communities are functionalities supporting networking, community evolution and activity [1]. Services are offering various means supporting community members to connect each other and communicate, for example, private and public messaging, commenting, updating statuses, feeds of new contents, popularity listings and different user search options. A challenge for a new web community is still motivating to content provision and production. Although there is a need for a community, only a part of registered users really start to use the networking service. Creating friendships, friend lists and filling in one's own profile interest most users, but actual discussion is still at a low level. Is it actually enough for students to have this kind of tool only to get to know each other, or are there still some other expectations for network activity? In addition, in designing web community functionalities consensus between user privacy and showing interesting content should be found.

Different actors feel their identity in a web community in different ways. It is essential in interactions between individuals that enough personal information can be received so that identification is possible in the community. In contrast to face to face situations, where people are physically present, user identification in web communities is based on information profile information provided by the user him/herself. In profile information a user describes him/herself and on the basis of this information other users are able to identify the user and imagine what is he/she like. There are still some users preferring to act anonymously so that their physical identity is not revealed [1, 30].

Clearly interventions can be used to enhance network activity. A well-designed intervention can increase the usage level significantly, but the long-term effects to motivate students to use a social networking system in the context of studying requires obvious added values for users to be reached through the intervention process. This means that the intervention itself does not feed motivation, but it certainly can activate users.

[16] Pajek is a Microsoft® Windows® based SNA software that is free for non-commercial use, http://pajek.imfm.si/doku.php

[17] Matlab® is a high-level language and interactive environment that enables performing computationally intensive tasks, The MathWorks™ Inc., http://www.mathworks.com/products/matlab/

Connecting the activity in real life and the activity in the social networking site should be seen as adjacent. When something crucial and relevant happens in the real world, some aspects of it could also be processed in the web community. This is still an automated process in only few areas of student life and studying in general. Therefore, an intervention can be used as a steering method that directs students to take advantage of the opportunities provided by a social networking site.

Abstract - **Students at MIT have traditionally executed certain experiments in the containment building of the MIT nuclear reactor as part of courses in Nuclear Engineering and the third year laboratory course for Physics majors. A joint team of faculty and research staff from the MIT Nuclear Reactor Laboratory (MIT-NRL) and MIT's Center for Educational Computing Initiatives have implemented online versions of three classic experiments; (a) a determination of MIT reactor coolant temperature through measurement of thermal neutron velocity, (b) a demonstration of the DeBroglie relationship of the kinetic energy and momentum of thermal neutrons and study of Bragg diffraction through a single copper crystal at various orientations, and (c) a measurement of beam depletion using a variety of shielding filters. These online experiments were implemented using the LabVIEW® virtual instrumentation package and the interactive version of the iLab Shared Architecture (ISA). Initial assessment of the online experiments indicates that they achieve comparable educational outcomes to traditional versions of the labs executed in the reactor containment building.**

Keywords - remote Labs, online labs, iLab architecture, web services, engineering education, nuclear physics.

I. BACKGROUND

Online laboratories (iLabs) are experimental facilities that can be accessed through the Internet, allowing students and researchers to carry out experiments from anywhere at any time. They harness the Internet and enable students to access and utilize real instruments remotely. These types of remote labs enrich science and engineering education by vastly increasing the scope and variety of experiments that students are able to access. Experiments allow a student to compare reality with simulations, collaborate with each other, and follow their curiosity. Conducting experiments motivates students and causes them to learn more effectively.

However, many science and engineering classes do not include a traditional lab component due to the prohibitive expense involved in staffing and operating labs, space and logistical requirements and safety considerations. By providing online access to remote laboratories, iLabs are delivering the educational benefits of hands-on experimentation over the Internet to our own students and to students around the world. Remote laboratories allow for the more efficient use of laboratory equipment and can give students access to exciting and unique resources. In this case, the Spectrometer iLab project's goal is to provide educational opportunities to students at various educational levels nationwide and internationally that do not have the benefit of an on-site nuclear reactor or other neutron source.

II. THE ILAB SHARED ARCHITECTURE

The iLab Project at MIT has focused on the design of a common architecture for the development and deployment of online laboratories called the iLab Shared Architecture (ISA) [1]. ISA is a robust, scalable, open-source infrastructure built on web services that provide a unifying software framework to support access to a wide variety of online laboratories. The ISA provides a set of generic lab services, such as user account management, scheduling and data storage, in a middleware system that can be accessed using web services. Students and the online laboratories can be globally distributed across an arbitrary number of locations linked only by the Internet. Users access these remote laboratories through single sign-on and a simple standard administrative interface.

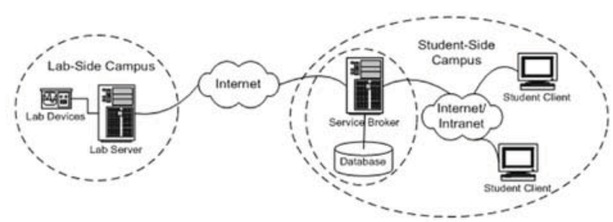

Figure 1. ISA components: Service Broker, Lab Server and Lab Client

A founding principle on which iLabs is built is the separation of responsibility. iLabs separate the responsibility for lab development from that of managing information about the students using the lab. Not only do the services provided by the iLab Service Broker (authentication, authorization, experiment storage, user management) simplify the task of implementing a particular experiment, but the location of the iLab services on a separate server divorces management of students on the Service Broker from management of the lab experiment on the lab server. In a typical configuration, as shown in Figure 1, a campus using iLab-based experiments will run a Service Broker administered by IT staff responsive to their own faculty and students. This Service Broker can access multiple lab servers potentially located at multiple remote campuses anywhere on the Internet. The students' accounts and their experiment storage reside on their local campus Service Broker regardless of where the experiment itself is executed. The lab server team need not be aware of which student is using their equipment at any given time, but they are assured that the student comes from an approved campus. The separation of responsibilities gives iLabs unique scaling properties and potentially enormous economic advantages with revolutionary impact in science and engineering education at all levels.

The iLab Shared Architecture is divided into three major components; Service Broker and related service, Lab Server and Lab Client [2].

The Service Broker serves as the heart of the ISA. It provides generic administrative services, such as authentication, authorization, user management, scheduling and data storage. The design of the Service Broker strictly separates the task of publishing an iLab from that of managing the students using it. This separation encourages the sharing of such experiments between institutions. The Service Broker also serves as the gateway in inter-institutional relationships. Once two institutions have mutually registered their Service Brokers with each other it becomes much easier to share iLabs.

The Lab Server is the component connected directly to the lab equipment and deals with the actual operation of the experiment hardware. It is the administrative interface to the lab equipment and enables labratory administrators to setup and configure each experiment independently. Each lab server is specific to its experiment hardware, and as such, a different lab server must be used for each set of lab instrumentation.

The generic components of the iLab Shared Architecture require communication to be via web services. But the architecture leaves decisions regarding the construction of the experiment to the domain expert and lab developer. This allows developers to use custom, even proprietary, technology both for constructing their lab client and lab server and for managing the experiment based communication between them. Not only does this provide support for specific, potentially high-bandwidth lab experiments, but it also enables support for pre-existing lab control software. In the case of the Spectrometer iLab, we use the National Instruments LabVIEW® platform for both the lab hardware control and the lab client interface.

The Spectrometer experiment utilizes the MIT iLab project's open source reference implementation of the Lab Server called the LabVIEW® Integrated Interactive Lab Server (LVILS). The LVILS provides a standard way for interactive lab developers to interface the generic ISA services to LabVIEW® instrument control software. In the LVILS, as in the interactive model generally, the lab client is developed in close relation with the lab server and corresponding instrumentation. The LVILS furnishes support for accessing the ISA services such as experiment storage and scheduling, as well as interfacing to LabVIEW® Virtual Instruments.

The Lab Client is the interface through which students access the iLab. It provides an intuitive representation of the iLab being run, allowing users to specify parameters and interact with the lab hardware. The ISA supports many client technologies including Java applets, Java Server pages, Windows Forms clients, and LabVIEW® remote front panels.

The ISA supports multiple Lab Clients that utilize the same backend Lab Server and experiment hardware. Building educationally valuable online labs is expensive and it is necessary to leverage, where ever possible, this investment by encouraging the sharing of lab resources. One way to share labs is to develop new educationally appropriate interfaces targeted to specific audiences. The ISA offers a scalable solution to improving STEM education by growing the use of online labs to increase inquiry-based learning and encouraging student interest in science through experimentation. We hope to bridge the traditional gap between the university, secondary school and other communities while recognizing differences in educational context and goals.

Consider, for example, the manipulations required to perform a basic time-of-flight (TOF) spectroscopy experiment. With the chopper wheel motor running, the low efficiency BF3 detector is positioned close to the chopper wheel and data is accumulated using a multi-channel scaler (MSC) card. The detector must then be re-positioned much further from the chopper and the data acquisition process repeated. For this experiment, we plan to develop at least three different interfaces each targeted at a different educational audience.

We envision a variety of client implementations to accommodate the needs of different educational audiences. For high school students, we need a simpler client that is focused on a single experiment which includes a set of predefined detector positions and some initial setting of the counting parameters. This will allow high school students to step through the experiment and observe accumulation of real data with little possibility of experimental errors that might interfere with basic data analysis and understanding.

For advanced undergraduate or graduate students, there is our current client, where students have access to all three experiments and they select the experiment at run time. In this interface users are allowed to determine detector positions for themselves, check and adjust alignment of the detector with the beam and set various MCS parameters.

One could also imagine additional hardware being added to the experiment implementation for research purposes and new clients being developed specifically for research staff. Each of the clients described would use some if not all of the hardware features currently implemented in the Spectrometer iLab but would be geared towards a specific group or classes need.

The iLab team is currently developing a simpler version of the beam depletion or neutron absorption experiment for use in advanced secondary school courses in cooperation with the University of Queensland, Australia and the Queensland Academy for Science, Math, and Technology (QUASMT). We plan to begin beta testing this summer.

III. THE SPECTROMETER EXPERIMENTS

In the early 1980s, Nobel Prize winning physicist Clifford Shull collaborated with the MIT Nuclear Reactor Laboratory (MIT-NRL) to build the neutron spectrometer facility so that MIT undergraduates could replicate basic neutron science and physics experiments. These experiments utilize a beam port which provides a continuous beam of well-thermalized neutrons from the heavy water reflector region of MIT's 5MW research reactor. The experiments are part of courses in Nuclear Engineering and the third year laboratory course for Physics majors [3]. The experiments developed include:

- Measurement of the Maxwell Boltzmann Distribution of Thermal Neutrons. The objective of this experiment (also called the Time-of-Flight Neutron Physics experiment) is to measure the energy spectrum of the beam neutrons using time-of-flight techniques, and then to compare the results with the expected Maxwell Boltzmann distribution that is predicted. Students are asked to perform measurements at two points in the beam guide tube using neutron detectors, multichannel scalers, and oscilloscopes. Students plot the data they gather and attempt to calculate thermal neutron velocity and flux density.
- Demonstration of the DeBroglie relationship of the kinetic energy and momentum of thermal neutrons and demonstration of Bragg Diffraction. The objective of this experiment is to demonstrate neutron diffraction using a copper single crystal. Students are asked to measure the Bragg-diffracted beam that results when the neutron beam interacts with the crystal. They perform several measurements at various angles of incidence, and are asked to plot their data to demonstrate the DeBroglie relation.
- Demonstration of Beam Depletion or Shielding Effectiveness in a Neutron Beam. The objective of this experiment is to demonstrate thermal neutron behavior in the presence of various absorption materials. After characterizing the "open" beam in the TOF experiment, the students place samples of materials such as lead, cadmium, water and borated polyethylene in the beam and repeat their energy spectrum measurement. Based on the data collected, students are asked to calculate cross-section or attenuation coefficient of the materials and qualitatively evaluate how these parameters depend on neutron energy.

The neutron spectrometer was initially designed as a non-automated facility installed in the Massachusetts Institute of Technology Research Reactor (MITR) which utilized the 4DH1 beam port. Students entering the reactor containment building to utilize one of the experiments are required to complete General Employee Radiological Training (GERT) and become radiation workers by federal law. These requirements and other security issues have limited the number of students able to utilize the spectrometer experiments. In 2007, with funding from the Department of Energy's Innovations in Nuclear Infrastructure Education grant for the New England Consortium and funds from the MIT iCampus project, a joint team of faculty and research staff from the MIT Nuclear Reactor Laboratory (MITNRL) [4] and MIT's Center for Educational Computing Initiatives [5] was created to enable online access and usage of these experiments based on the iLab Shared Architecture. Figure 2 shows a rendering of the principal components involved with these experiments. They include a mechanical chopper, a low efficiency detector, a crystal, a high efficiency detector and a materials attenuation slide.

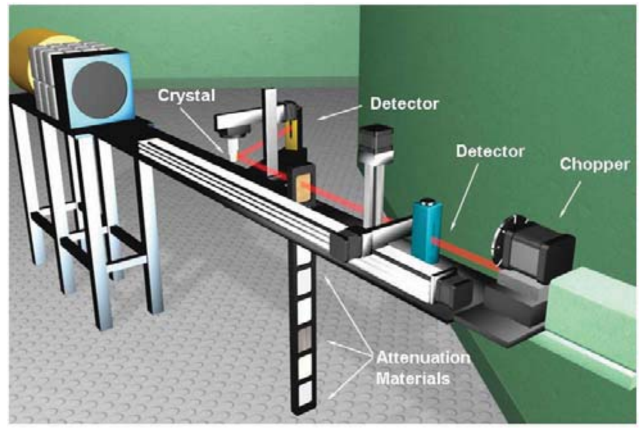

Figure 2. Rendering of the principal components of the spectrometer experiments by R. Mark Bessette (MIT).

IV. IMPLEMENTATION

The student spectrometer hardware implementation can be described in terms of three major subsystems. The first of these consists of the equipment required to manipulate and detect a low energy neutron beam from the MITR research reactor and is essentially unchanged from the established version of the experiment that has been run locally by MIT undergraduate and graduate students for several decades. The main components are a collimator and chopper wheel that produce a narrow, pulsed, beam of neutrons, a low-efficiency BF3 detector (LND Model 201) that is used to count the neutrons in the direct beam, a copper single crystal to diffract the neutrons and a high efficiency 3He detector (LND Model 251) that is used to count the neutrons in the diffracted beam. The detectors are powered by a dual high voltage power supply (Canberra Model 3125) and the signal from each detector is processed by a preamplifier and amplifier/timing single channel analyzer (TSCA) (Canberra Model 2006 and Ortec 590, respectively). These components are mounted in a standard nuclear instrumentation module (NIM) bin. The TSCA produces a sharp voltage pulse corresponding to each detected neutron that is processed by a multi-channel scaler (MCS) board (Ortec MCS-pci™) installed in the local PC. The MCS is gated by a signal produced by a light sensor that detects the passing chopper wheel slits. Accumulating data in the MCS produces a time of flight (TOF) spectrum of the neutrons in the beam that can be converted to an energy spectrum for analysis of the neutron energy distribution.

The second subsystem consists of components used to position the detectors and other elements of the experimental apparatus such as the single crystal and a set of materials that can be positioned in the beam to measure their neutron attenuation properties. Most of the detector motions are accomplished using stepper motors (Automation Direct, various models) with linear slides or rotary tables (Velmex, Inc., various models).

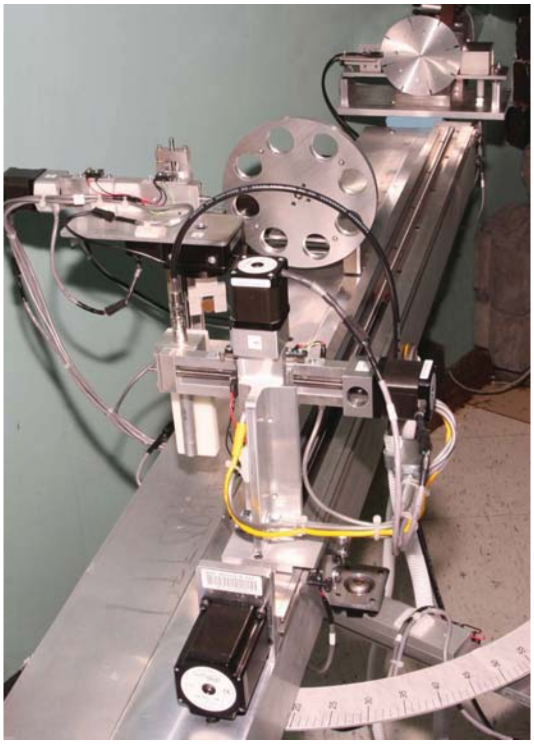

Figure 3. Spectrometer Experiment Hardware

The low efficiency detector has three linear axes of motion: two orthogonal axes perpendicular to the beam and one axis in the beam direction to allow spectra to be generated at varying distances from the chopper wheel. The single crystal has two linear axes of motion for positioning in the beam and one rotational axis to align the crystal planes at varying angles to the neutron beam. The high efficiency detector has one axis of motion driven by a linear slide but producing a rotation centered on the crystal position in the beam. This motion is used to find diffracted neutron beams. A stepper-motor-driven rotary table is also used to select different materials for attenuation experiments. In addition to the stepper motor systems, there are relay-controlled pneumatic actuators to move the attenuation material setup in and out of the beam and to raise and lower the chopper wheel to allow a "white" (unchopped) beam to be produced. A relay is also provided to start and stop the chopper wheel motor. Figure 3 shows the finished experiment implementation of the main components.

The third subsystem is a National Instruments PXI-based data acquisition and control system that provides the interface between the first two subsystems and the LabVIEW™ Virtual Instrument (VI) client that is used to perform the experiment in either local or remote (iLabs) mode. Components are housed in a PXI-1042Q chassis communicating with the local PC over a PXI-8360 interface card. There are 3 PXI-7330 motion control boards operating the stepper motors and associated limit switches, a PXI-6259 multi-function DAQ to receive signals from additional limit switches on the pneumatically controlled motions, a PXI-6521 8 channel relay card to drive the relays described above and a PXI-6602 timing I/O board to acquire time-independent counting data from the detectors (i.e. independent of the MCS system).

The Spectrometer client interface, called a Virtual Instrument or VI, was also implemented using LabVIEW® from National Instruments. LabVIEW is a graphical, event-driven programming package optimized for data acquisition, instrument control, and the graphical display of data. For this experiment, students need to download and install the LabVIEW® plugin for their browser.

Figure 4 shows the Spectrometer LabVIEW® client for the Maxwell Boltzmann Distribution Experiment otherwise known as the Time-of-Flight neutron physics experiment. In the client, students use the "Motion Control" area to position the Low Efficiency detector, control the choppers position and spin, and set parameters in the MultiChannelScaler (MCS) tab for the experiment. While the experiment is underway, students can watch the counts both by numbers counted in the Low Eff Detector Data field and graphically in the Waveform Graph of the Time of Flight data.

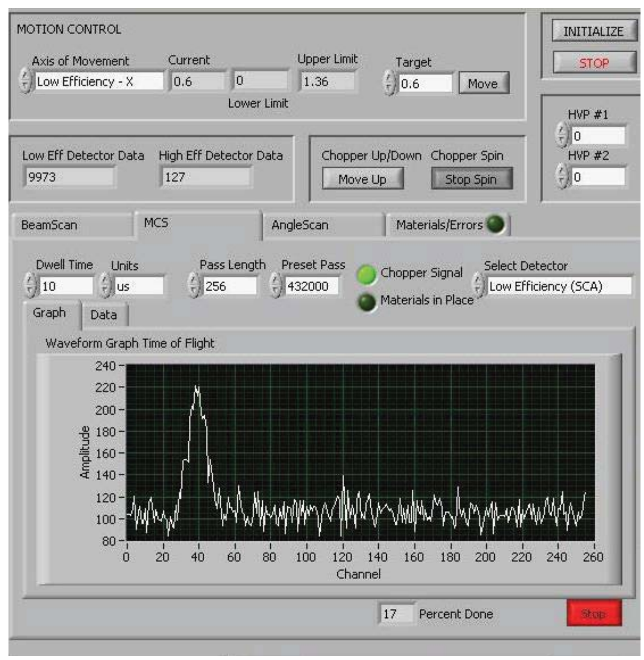

Figure 4. LabVIEW® client for the Maxwell Boltzmann Distribution Experiment otherwise known as the Time-of-Flight Neutron Physics Experiment.

V. RUNNING AN EXPERIMENT

The Spectrometer iLab is an interactive experiment that requires users to schedule experiment time in advance since typical experiment times can range from 20 minutes to 8 hours. Scheduling in advance ensures that the operators in the reactor control room can open the beam port. The beam port is only opened when an experiment is scheduled. Students typically work in teams of two or three.

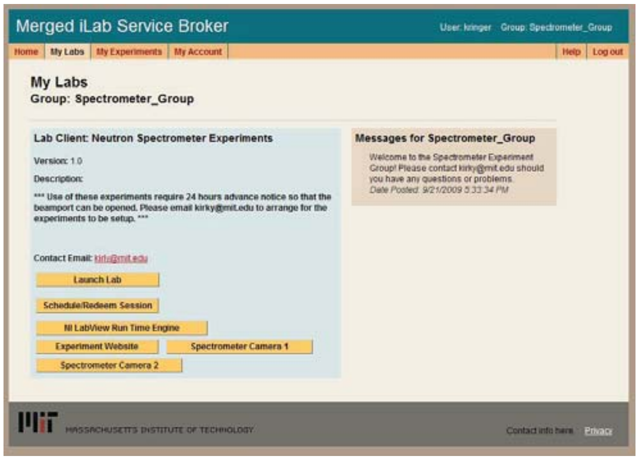

Figure 5. Student view of the Spectrometer experiment page on the Service Broker

To run an experiment, students login to the Service Broker, select the Spectrometer experiment group and redeem the reservation they scheduled in advance. The Service Broker checks to make sure that the user has a valid reservation and that he/she is authorized to use the Spectrometer experiment. The user is then presented with a "Launch Lab" button and is able to start the experiment client, as shown in Fig. 5. When the experiment is launched, the Service Broker facilitates the exchange of credentials so that the Lab Client running in the student's browser can talk directly with the Lab Server and experiment hardware. The LabVIEW™ client VI is launched from the LVILS Lab Server and displayed in the user's browser using a LabVIEW™ plugin. The client also establishes communications with the datasocket server so that experiment data can be stored in the database for later retrieval.

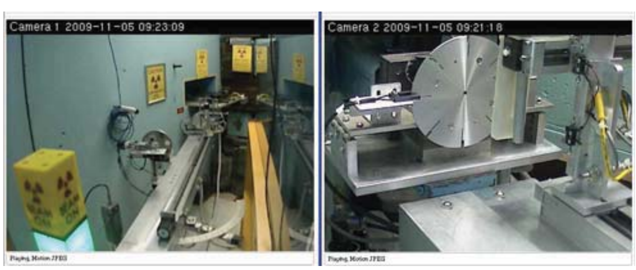

Figure 6. Spectrometer web camera views that enable the remote user to view the experiment while in progress.

The Spectrometer experiment installation has two web cameras available so users can watch the experiment while in progress. We have found that the cameras are essential to the student understanding and believing that they are working on and controlling real hardware. The first camera, Fig 6, is an overall view of the experiment and allows the user to watch the detectors and crystal as they are being moved. The second camera, Fig 6, is a close up view of the chopper wheel.

We have developed animations of each of the experiments to give the user a visual understanding of the phenomena being explored and the experiment being performed. Figure 7. Animation stills from the Spectrometer beam depletion experiment showing Aluminum and Polyethelene by R. Mark Bessette (MIT).

In this version of the Spectrometer client, shown in figure 4, the user can run any of the three experiments by selecting the correct tab. Before beginning any experiment, there are several steps that all users should take. First, the experiment hardware must be initialized. This will run an initialization sequence to make sure that all the components are in their correct starting positions. Second, students use the BeamScan tab to find the centerline of the beam, by moving the low efficiency detector across the beam port area. Users will see a peak in counts when the Low Efficiency Detector is centered in the beam. Once the user knows where the center of the beam is, they can position any of the components in the correct location.

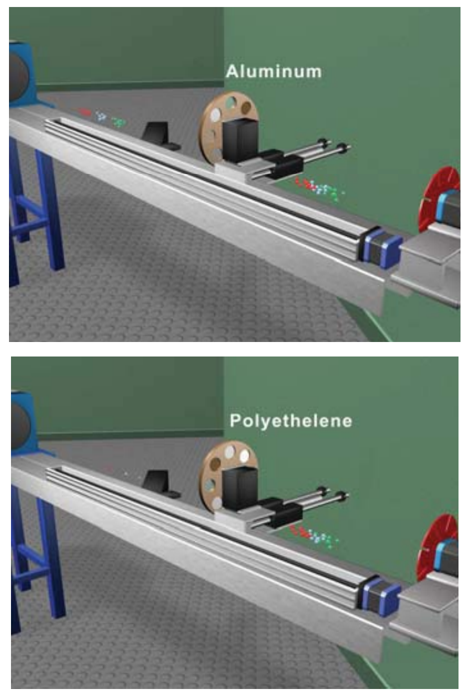

Figure 7. Animation stills from the Spectrometer beam depletion experiment showing Aluminum and Polyethelene by R. Mark Bessette (MIT).

In the time-of-flight (TOF) experiment, students use the MCS tab to perform measurements at two points (near and far) in the beam using neutron Low Efficiency Detectors and multichannel scalers. Utilizing the AngleScan tab, students can control the copper crystal's position and rotation as well as the high-efficiency detector angular position. In the Materials/Error tab, users can control the sample carousel and position various absorption materials into the beam for testing. A combination of hardware and software safety interlocks is used to avoid collisions of the movable components and to establish usable ranges for each experiment component.

VI. USAGE

Most of the usage to date has been by undergraduate students at MIT in the departments of Nuclear Science and Engineering (NSE) and Physics. These students generally have at least one "local" session at the experiment site before being offered the option to continue their work on-line. Approximately half the NSE students doing the lab as part of a required course used the on-line option, while the fraction was much higher for the Physics students. We attribute this largely to the fact that the NSE students do not perform the diffraction portion of the lab and thus require much less counting time than the Physics students. One of the clear benefits of online access is that the students accumulate counting data over much longer times and obtain better quality data sets that are more amenable to analysis. Students are also more likely to repeat experiments if data anomalies are discovered.

VII. SCHEDULING

Currently due to regulations and security issues and to avoid unnecessary activation of the beam components, the beam port is not open 24/7. The beam port is opened and closed manually by the operator on duty inside the reactor containment facility only when an experiment is scheduled. We currently add the scheduled experiments to the operator's schedule manually, that is to say, the Service Broker manager periodically looks at the scheduling calendar and tries to send an email at least 24 hours in advance to the reactor operator manager with a list of scheduled experiments and request that the beam port be opened. The Reactor operations manager then adds the beam port open and closes to the operator's schedule.

This process has several possible points where errors can occur. First, we request that students schedule their usage more than 24 hours in advance for weekday and no later than Friday midday for the weekend. We try very hard to work with the students to ensure they have access to the experiment, but this is sometimes an issue when a student makes a reservation through the Service Broker at 4:55pm on Friday afternoon for time on Sunday. There is no guarantee that the Service Broker manager will see the new reservation or that it can be added to the operator's weekend schedule. Second, the list of scheduled experiments is collated from the Service Broker by hand and sent via email. Sometimes this involves two or three email exchanges a day and sometimes emails are missed. And lastly, manual transmissions of schedules that pass daily through human hands are prone to transcription, typing or misreading errors. While we can not solve the regulatory and security issues, we hope to improve and automate part of the scheduling process in a future release of the Service Broker. We will be adding direct email notification to a mailing list (which will include the reactor operators) when an experiment is scheduled or changed. In addition, we hope to improve scheduling features to make it more user friendly and enable faculty and students to see who has the reserved time in case schedules need to be negotiated. Right now, reservations are on a first come basis.

VIII. FUTURE WORK

A variety of hardware upgrades are being planned or considered. A larger, more robust detector Z-axis motion slide with a higher power stepper motor would improve reliability of the system and reduce the required frequency of mechanical maintenance. The multi-channel scaler is fully controllable from within LabView™ and thus within the iLabs interface, but the "front end" of the nuclear counting system consisting of the high voltage power supplies and amplifier/TSCAs can neither be controlled remotely nor report their parameter settings to a computer interface. As new types of computer-based nuclear instrumentation become available, an appropriate replacement for the NIM electronics may be identified to provide this capability.

Some software improvements are also planned. Minor changes to the LabView™ interface will be made to incorporate suggestions from students and developers for improving appearance and easing navigation and operation. More substantive changes include the addition of counter/scaler and oscilloscope functionality to the interface. The counter/scaler would emulate the traditional hardware version with controls for counting time, single or repeat counts and automatic or manual count reset. This is a relatively minor programming effort because most of the functionality already exists in the Beam Scan and Angle Scan modules. An oscilloscope function that would allow on-line users to view the output pulses of the detector pre-amplifiers and amplifiers would be a significant enhancement to the on-line implementation and would be a preparatory step for putting the nuclear instrumentation under LabView™ control as discussed above. Some of the hardware required is already in place but additions would probably be necessary to allow switching the oscilloscope input between the low-efficiency and high-efficiency detectors.

ACKNOWLEDGMENT

The authors wish to thank our colleagues, Judy Maro, David Litster, Raymond Ma, Lin-wen Hu, Timothy Lucas, Meg Westlund and Maria Karatzas, whose vision, hard work and insights has guided successfully the development and deployment of the Spectrometer iLab.

Abstract— **We developed a web-based time schedule system as an important feature of the university portal along with our university's long-term ICT (Information and Communication Technologies) plan. By using the system, students and professors can get their own course timetable in collaboration with the Student Information System (SIS). Each course name on the timetable is linked to the corresponding course page on the Learning Management System (LMS) through the Single Sign-On (SSO). The system is adapted to multiple LMSs which can be selected by the course professor. In order to widely cooperate with other systems, the system is designed by using global standards (IMS Enterprise, JSR-168 Portlet, etc.) and open source software (uPortal, CAS, JSF, Hibernate, etc.) as possible as we can. This paper shows the major functions, the measured use of the portal and the time schedule system over eight months, and the implementation especially for supporting multiple LMSs, syllabus and grade books.**

Keywords-timetable; schedule; LMS; Portal; SSO; IMS; CAS

I. INTRODUCTION

In recent yeas, the university's learning environment is becoming more and more convenient, effective and efficient by various ICT(Information and Communication Technologies)-enhanced systems, for example, Student Information System (SIS), Learning Management System (LMS), portal, e-Portfolio, electric library, etc.

Our university noticed that the quality of education and the university management can be improved through the appropriate ICT adaptation, and has established a long-term and university-wide ICT strategy (called the Integrated Campus Information System Plan) in 2001. Along with the plan, our organizations, the "Center for Multimedia and Information Technologies" and the "Institute of the e-Learning Development" were established in 2004 / 2008, and we have introduced various ICT systems.

Good collaborations among the systems should be very important to build ICT-enhanced learning environments. We therefore always try to use global standards and open source software as possible as we can for data interoperability and source transparency.

Along with the ICT plan, we developed a Single Sign-On (SSO) university portal for all students and staff since 2006 [1]. Once authentication is complete at entrance of the portal, user gets personalized web pages including information for each role, direct links to the available systems without re-authentication, etc.

As an important feature of the portal, we developed a web-based time schedule system placed on the portal as a tab page, where students and professors can get their own course timetable depending on their registration of the SIS [2]. Each course name on the timetable is directly linked to the corresponding course page on the LMS through the SSO.

Our university provides WebCT (now Blackboard LS) as a university-wide LMS since 2004. For the last few years, number of online courses has been increased and some professors requested to use different LMSs e.g. Moodle or Sakai. For this reason, we improved the time schedule system to adapt to multiple LMSs.

This paper will show the status of using the time schedule system and its new features not only as the multiple LMSs support, but also as functions of syllabus and grade books.

II. THE STATUS OF THE TIME SCHEDULE SYSTEM

A. *ICT-Enhanced Learning Environment*

Our university has been advancing the ICT-enhanced learning environment [3]. Better collaborations among the systems such as SIS, LMS, portal and many related systems, should be important to enhance the learning environment. We therefore developed the university portal for all students and staff (teaching, technical and administrative) based on the open source software (uPortal [4] and CAS (Central Authentication Service) [5]) and the original tools for connecting several university-wide systems since April 2006 [1]. Once authentication is complete, each user gets personalized web pages, including information for each role, direct links to available systems, the timetable linked to the corresponding course on the LMS, etc.

The uPortal is open source software and supports the Portlet (JSR-168 standard [6]) which provides pluggable user interface components to add functions to the portal. It not only ensures high portability but also it made us easier to add convenient functions specialized for each role, position, department, and so on (10,000 students and 2,000 staff).

The CAS is also open source software and it provides SSO environments. The university-wide LDAP is used as authentic data source for the CAS, users therefore can login wireless LAN, PCs for IT classrooms (1,300 PCs over the university with exactly the same usability), emails etc. with the same user ID and password as CAS as shown in Fig. 1. The CAS has been already supported by more than twenty systems, including both campus supports (library, carrier support, registrations, address book, etc) and learning supports (LMS, SIS, timetable, etc.) as shown in Fig. 1.

The time schedule system has been added to the portal since 2008, and where students get their own course timetable depending on their SIS registration. Each course name on the timetable is directly linked to the corresponding course page on the LMS through the SSO. Professors also can use their own timetable directly linked to the LMS course page as instructor and creator modes.

In the same time, we developed an IMS-capable [7] web-based management tool for synchronizing courses [8]. The tool provides functions of various queries by HQL, some IMS-type output files (courses, persons and cross-listed courses), and timetables for the queried persons with LMS access if possible.

We improved the time schedule system to support multiple LMSs as shown in Fig. 2, which describes data flows as the time schedule system are synchronized by the CSV data from the SIS and three LMSs (WebCT (now, Blackboard LS), Moodle, and partly Sakai) are synchronized by the IMS data from the time schedule system. Details will be shown later with the other new features.

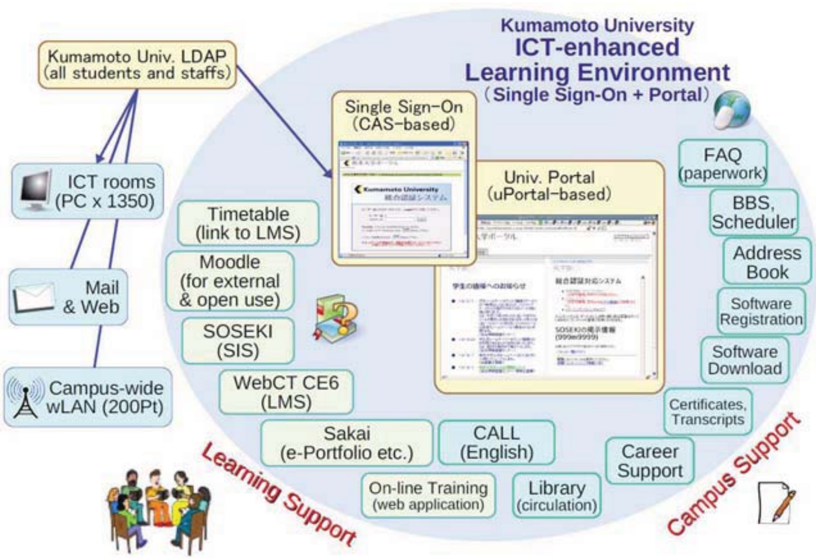

Figure 1. The Kumamoto university's ICT-enhanced learning environment with portal and the single sign-on system with web applications.

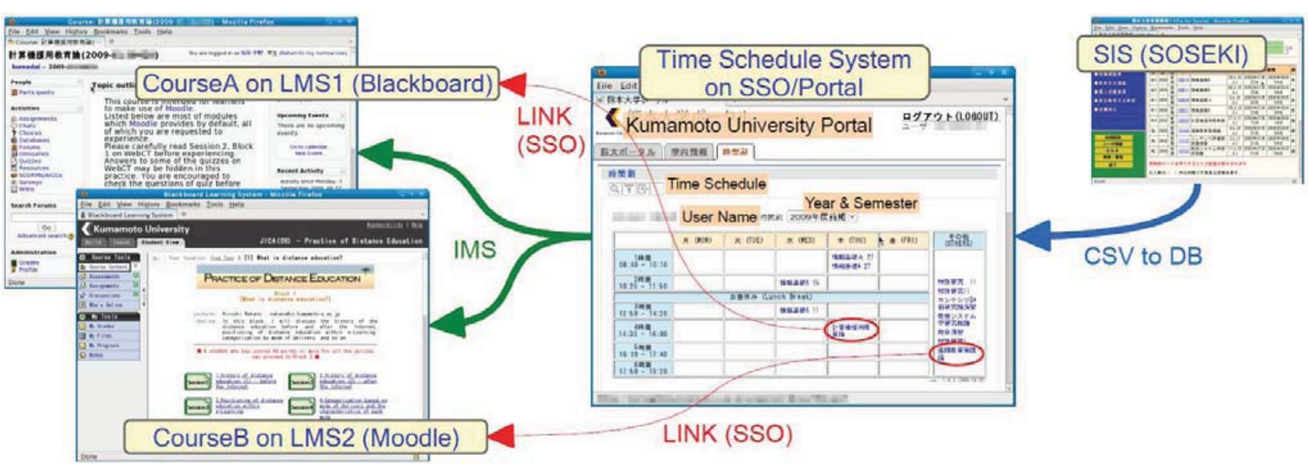

Figure 2. Data flow and SSO connections between the time schedule system on university portal, LMSs and SIS.

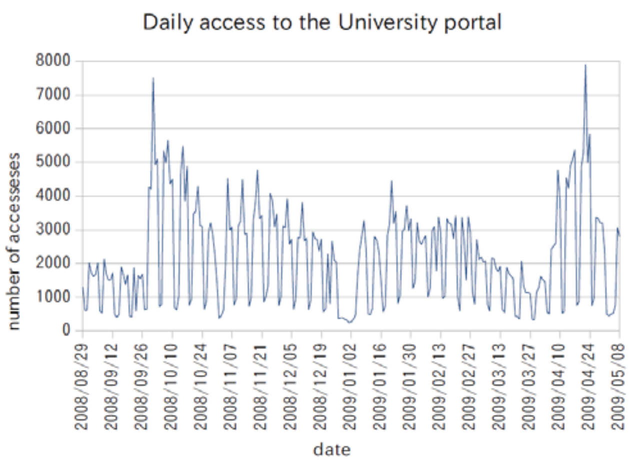
B. *Use of the University Portal*

Fig. 3 shows the use of the university portal. Left figure (a) shows the daily access number from August 29, 2008 to May 9, 2009 (for about eight months). The valleys are at the weekends and holidays as the New Year holidays. Almost all Japanese universities including us have two semesters in university year which start from April and October respectively. More than 7,000 accesses are observed at the beginning of the semesters, and a few thousands of accesses are on weekdays, and several hundreds of accesses still remain even on holidays as shown in Fig. 3(a). Because our university has about 10,000 students and 2,000 staff, we can say that the portal is used very well.

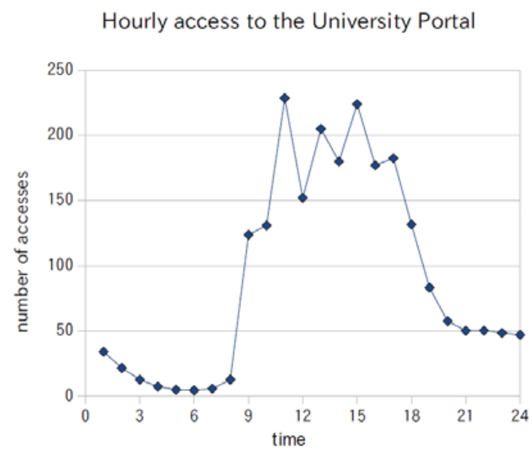
Fig. 3 (b) shows the hourly access number averaged for the same period. The curve of the daytime is not smooth, the reason is thought that many students begin to use the LMS through the portal at the beginning or break time of the courses. After 6pm, they are still using from their home and there are some accesses even in midnight.

C. *Use of the Time Schedule System*

Fig. 4 shows the use of the time schedule system. Left figure shows the daily access number from April 16, 2008 to October 31, 2009 (for about eighteen months). We can say that the time schedule system is also used well, because about 10 to 30 percents of the access of the portal are occupied by the time schedule system, in comparison between Fig. 3(a) and 4(a). The valleys are at the weekends as same as the portal. The largest difference to Fig. 3 (a) is that very low access areas can be found during spring and summer vacations. It means that users are accessing the portal even during the vacations, but they are not accessing LMS course contents through the time

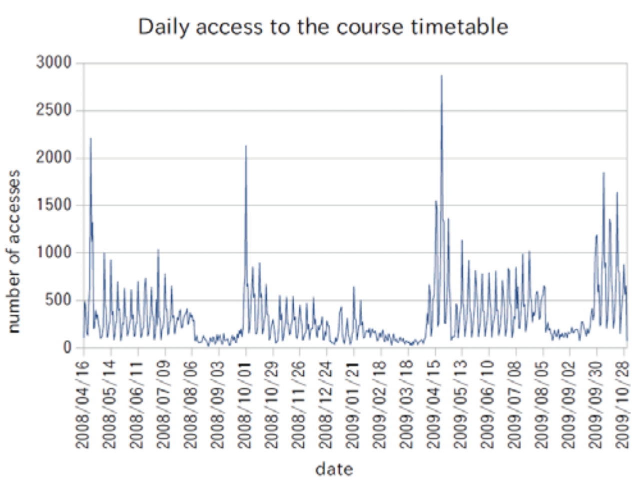


(a) daily access

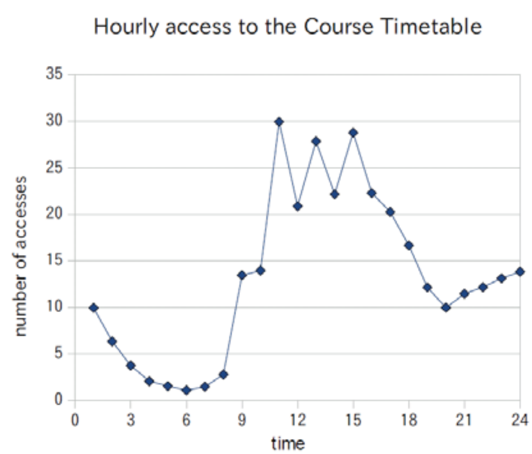


(b) hourly access

Figure 3. The use of the university portal.



(a) daily access



(b) hourly access

Figure 4. The use of the time schedule system.

scheduling system.

Fig. 4 (b) shows the hourly access number averaged for the same period. The averaged number of accesses seems to be low as the maximum is around 30, because of the very low access areas on vacations as mentioned. The curve of the daytime is also not smooth as same as the portal. After 6pm, the curve increased again, but we could not find the reason yet. In ether case, students are still using the system even at midnight from their home.

III. THE IMPLEMENTATION OF THE TIME SCHEDULE SYSTEM

A. *Developing and Running Environment*

The WebCT CE6 (Blackboard LS 6), the Moodle 1.9 and the Sakai 2.6 are targets for supporting multiple LMSs now. Our sakai support is still experimental because the courses can not be synchronized yet (only manual registration is possible).

As many users (more than 300 in the maximum case) are accessing at the same time, a relational database is used for extracting a schedule quickly for each user. User profiles and registered course information are daily synchronized from SIS to the system by CVS format, and also synchronized from the system to LMSs by IMS Enterprise format [7] as shown in Fig. 2. The WebCT and the Moodle support IMS format and all the courses are synchronized daily. WebCT does not support CAS, and we therefore developed adapters using the portlets for the Blackboard LS [9]. The system is developed by using fully open source tools; Hibernate and JSF on J2EE (Tomcat), and MySQL.

B. *The Course Timetable*

Fig. 5 shows a course timetable example on the university portal for some student. The "(e) Course timetable" shows the timetable unique for the students ID, the semester and the year. The timetable can be changed to the other one for different semester and year by using the selection box "(d) Select Year & Semester". The view of the checkboxes (f) is adjusted for the role of students / professors and on- / off-campus as shown in Fig. 6. The score icon can be shown only on campus, and the setting icon can be shown only for professors. All enabled check box can change the state (show or hide each icon) of all cells of the timetable.

Figure 5. Course timetable on the university portal.

Figure 6. Four cases of the check box (f) in Fig.5.

Figure 7. The course setting menu for professors.

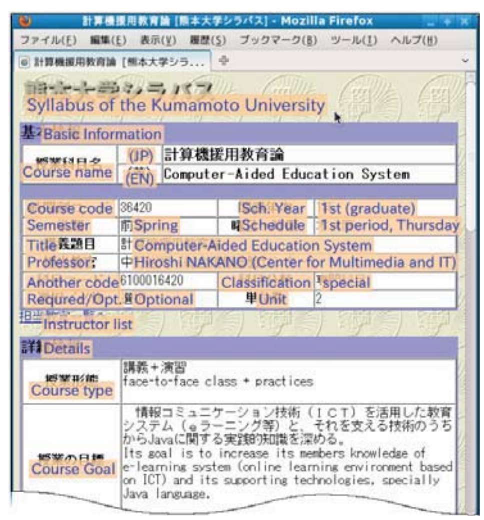


Figure 8. The syllabus for the selected course.

C. The Course Setting Menue

Fig. 7 shows the course setting menu for the professors when they click the setting icon (shown in Fig. 6 (c)) on each cell of the timetable. The professor can select one from four choices; WebCT, Moodle, Sakai and “not using”. WebCT is the current default value, and once professor select Moodle or Sakai, all students and professors will jump to the selected LMS when they click the course name in the cell of the timetable. If professors select the “not using”, the course name's color will change to black without any links. These settings can be reset or changed anytime from this menu.

D. The Syllabus Icon

When students or professors click the syllabus icon (shown in Fig. 6) on each cell of the timetable, the syllabus of the course will be shown in a new window (Fig. 8). Our university open all syllabuses over the Internet and this system simply jump to the corresponding syllabus page directly for convenience. On the syllabus, students can get whole course information as shown in Fig. 8 (translated).

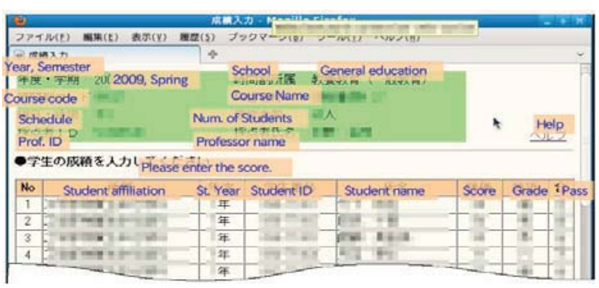
E. The Score Icon

When students or professors click the score icon (shown in Fig. 6) on each cell of the timetable, the grade-book page of the SIS system will be shown in a new window (Fig. 9, translated). For students, they will get the score list of the grade book corresponding to the semester as shown in Fig. 9 (a), where they can check their course scores for the semester. The grade book of the current semester may not have no meaning except on the end of the semester, but previous semester's ones are meaningful and it can easily shown by the selector “(d) Select Year and Semester” in Fig. 5 anytime.

For professors, they will get the students list of the corresponding course with scores as shown in Fig. 9 (b), where they can not only see but also enter or edit scores for each student.

The score function is limited to use only on campus, because of the security policy of the SIS system.

(a) for students



(b) for professors

Figure 9. The grade page from SIS.

IV. Future Plan

The time schedule system has been used university-widely more than three semesters (eighteen months) as shown in Section II, and we have already improved several points as supporting the multiple LMSs, the syllabus and the grade-book, with fixing bugs. We have several valuable comments from users, and some ideas to do.

Now we are using the university-wide course timetable, but we do not have university-wide calendar as a function of group wares. We are planning to introduce a university-wide group ware for staff and students, where the all functions of the current course timetable had better to be available on a calendar with additional information, e.g. the class subject on the date, planed examinations, cancellation, etc.

Some students asked us to use the grade-book function through the Internet (outside of the campus network), because they want to know the scores far from the campus during vacations between semesters, when they go back to their born place or stay their internship place, etc. We therefore have a plan to provide the grade-book function with limited information over the Internet, by developing a secure intermediate server which keeps only limited information synchronized to the SIS.

Some professor gave a valuable comment that he wants to use the time schedule system for leading or counseling students if he could see the course timetable of the specified student with each course scores, because he can find easily subject, time and semester dependency of the student activity. We have a plan to add a counselor mode to the system for designate persons.

V. Conclusions

We developed a web-based time schedule system as an important feature of the university portal along with our university's long-term ICT plan. By using the system, students and professors can get their own course timetable in collaboration with the SIS. Each course name on the table is linked to each course contents on the LMS through the SSO.

We developed the system based on open source software and global standards as possible as we can for data interoperability and source transparency in order to connect several systems in standard and portable ways.

The use of portal and the time schedule system were measured for about eight and eighteen months respectively. The result shows that the both systems are used well even on holidays or at midnight from homes, and reflect students' activities in weekly, daily or hourly.

The system is adapted to multiple LMSs; WebCT, Moodle, and Sakai (experimentally). The LMS can be selected by the professor for each course. The time schedule system also provides the functions of showing syllabus and scores of the course. All these functions can be selected whether visible or not.

***Abstract*—This paper describes the basis for the specification of an IT infrastructure, supported by a website, designed to manage the entire paperwork process associated with the management of Masters Dissertations. With this infrastructure it is possible to disclose the subjects offered, to allocate each subject to a candidate - "dissertations in progress", browse dissertations that are awaiting review and consult the archive of dissertations with exams already carried out. PostgreSQL technology was used to support the databases. This technology was chosen to be robust, with easy integration with PHP and its code is open source. The website is housed in a Linux server based infrastructure ready to run continuously.**

Keywords – CMS – Content Management System, Website, Backoffice, Frontoffice, PHP, Bologna Process, Dissertation

I. Introduction

The higher education systems have undergone great challenges in the last decades, initially motivated by the growing up number of students. Currently, the importance of communication technologies is found in the strong dissemination of knowledge, which has been taking place in the European systems, through the Bologna Process. The Bologna Process is named after the Bologna Declaration, which was signed in the Italian city of Bologna on June 19th of 1999 by ministers in charge of higher education from 29 European countries [1].

The Bologna Declaration leads to the adoption of a system essentially based on two main cycles, undergraduate and graduate. The access to the second cycle hall requires successful completion of first cycle studies, lasting a minimum of three years. The second cycle should lead to the writing of a master thesis.

The dissertation topics are proposed by the advisors. The students then choose one topic from the whole list of topics available. When a dissertation topic is assigned to a given student, by his supervisor, the work process starts and lasts until the dissertation report is finished. After the supervisor approval, the dissertation is submitted to an examination which will be evaluated by a jury that will award a final mark. Finally, after the exam, the dissertation document is put in an electronic archive.

In order to manage this process an information system based on a website has been created, using the PHP programming language [2]. The website is divided into two main components: the Frontoffice and the BackOffice.

A. Frontoffice

This structure enables the students and the public to browse dissertation subjects offered by supervisors, the dissertations that are in progress, the ones that are waiting review and the archive of the dissertations already carried out. A news area is also available where the site administrator can broadcast some pertinent alerts and events related with the course. In order that a visitant can easily find a particular topic, a search engine was developed since the amount of information is growing everyday.

B. Backtoffice

This is a CMS (*Content Management System*) that is supported through a database (whose relation model is showed in figure 13).

The CMS enables the creation of a hierarchical structure of users, with different types of privileges, in order to manage the introduction of different kinds of data. Its main features are:

- The administrator is the one that has privileges to create the other users (supervisors) and each user is responsible to manage data related with the dissertations for which he is responsible. All users may introduce personal data associated with a particular student, but when a student is allocated to a specific user only this user and administrator can change this record.
- A file upload system was built since it is necessary to attach some other useful information supported in files (e.g. Photos, PDFs).
- In order to produce the student invoice form it was developed a tool that collects all the information related with the student (e.g. identification, address, birth, contacts, photo), the dissertation subject (e.g. description, objectives, tasks, schedule), the supervisor and other institutional data to produce a PDF file with a layout in accordance with the administrations office.

The remaining blocks of the CMS support the introduction of contents that can be assessed through the Frontoffice.

II. FRONTOFFICE DESCRIPTION

The Frontoffice is a web based system that provides an interface to the students and supervisors in order to manage the dissertation process. The structure of the Frontoffice is composed by the following areas:

- Proposals: subjects offered by supervisors,
- Dissertations: dissertations in progress,
- Archive: dissertations already carried out,
- News: page to broadcast news,
- Documents: download area. Here are available all the files related to the registration process, assessments and some other logistics tasks,
- Search: typical search engine in order to easily find some particular topic (e.g. "find all topics proposed by a particular supervisor").

Fig. 1 shows the Frontoffice Homepage:

Figure 1. Frontoffice's Homepage.

The menu bar located at the top of the page is composed by the buttons to access all the areas mentioned above. There is also a button ("Backoffice") that opens a new window to Backoffice access.

The News area is located at the left side of the page. An event, an alert or a deadline can be announced here. The news structure has the following fields: Title, Date, Text and a Picture (optional). Only the first 25 words are displayed in the Homepage. To access to the whole news text it is necessary to press "more".

The right side of the screen is designed to show the last introduced proposals by the supervisors. When an exam is at a distance of 1 week, the right part of the screen is subdivided into two parts (fig. 2). Upper part has the reference(s) to the dissertation(s) (Title, Student Name, Exam date, Room and time). To access to all details of the dissertations (including the full text in PDF format) the user must follow the corresponding link.

The page showing dissertation details is presented in fig. 4.

The remaining lower part of the page displays the last introduced proposals by the supervisors.

Figure 2. Frontoffice's Homepage. The right side of the page is now splitted into two parts to announce the upcoming exams.

The next area that can be accessed through the menu bar is the "Dissertations Proposals", by pressing "Proposals" button. The page is shown in fig. 3.

Figure 3. Dissertations Proposals list.

The result is a list of topics disposed by scientific areas. For each topic the Supervisor Name, the Title and the Submission Date are displayed.

In order to view each proposal details, the user must press "Detail". The result is shown in fig. 4.

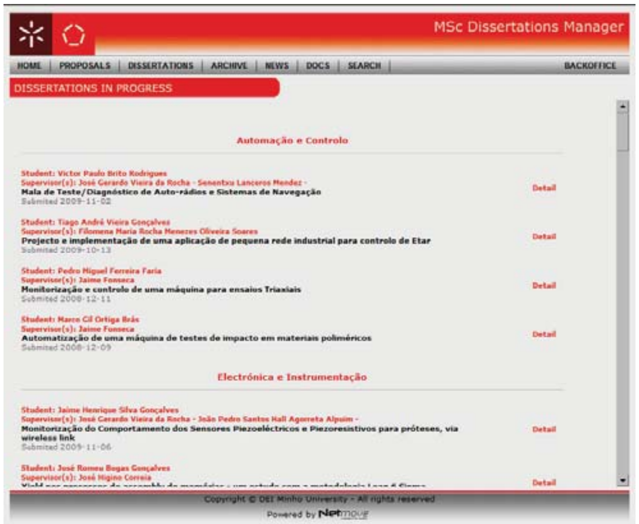

Figure 4. Dissertation Proposal details.

This page displays the full record of a chosen proposal. In fig. 4 we can see an example. The fields associated to each proposal are:

- Supervisor Name,
- Supervisor Email,
- Summary,
- Objectives,
- Keywords,
- Useful Links.

These fields must contain all the information that a student needs to select the theme that better fits to his skills and knowledge. After that, the student contacts the supervisor responsible for the chosen topic and discusses with him about the possibility (or not) of modifying the proposal in order to better fit the student profile. The result is then published in the Dissertations area.

The Dissertations area is similar to the Proposals area. The record structure contains all the fields (copied form the Proposals area) and other fields related to the allocated student:

- Student Number,
- Student Name,
- Student Email,
- Starting Date.

When the work is terminated the student writes his dissertation and a jury, recommended by the Department's Academic Board, is appointed. The Jury is usually composed by the student's supervisor, the head of department and an invited professor from another department or faculty, that will be the Reporter of the examination. At this time some more information are appended to the Dissertations area:

- Reporter Name,
- Reporter Email,
- Exam date,
- Exam location,
- Dissertation text in PDF format.

Fig. 5 shows an example of a Dissertation page in full format:

Figure 5. Dissertation page in full format.

This page is displayed in the Dissertations area until the exam date is reached. After that, this record is moved to archive. The layout and the information remain the same as previously, but the record belongs now to Archive area.

The News area consists of a page where the news, listed in reverse order of entry, are displayed in the same way as in fig.1, but now enjoying the whole space of the page.

The Documents area is a file repository that stores some useful forms, templates, tutorials and some dissertation rules and guidelines to help and support students during the whole process.

Finally, pressing "Search" at a menu bar, a page with a search engine is accessed (Fig. 6). This page is very useful since the amount of information is growing quickly.

Here it is possible to find dissertations or proposals. The search can be done by Student or Supervisor names, Scientific area or a given keyword.

Figure 6. Search engine page.

III. BACKOFFICE DESCRIPTION

The Backoffice is CMS that manage all the information that can be accessed by the Frontoffice. The login page is accessed by pressing the “Backoffice” button located in the right corner of the menu bar. The Login page is shown in fig. 7.

Figure 7. Backoffice Login page.

By entering the user’s email and password, the system goes to the Backoffice Homepage. Fig. 7 shows that homepage when a user is logged in.

Figure 8. Backoffice Homepage (user).

The Menu bar is composed by five buttons:

- Proposals,
- Dissertations,
- Students,
- Reporters,
- Personal data.

The Proposals area is a page that contains a form with the fields required to be filled with the information related with the proposed work. Fig. 9 shows the Proposals page.

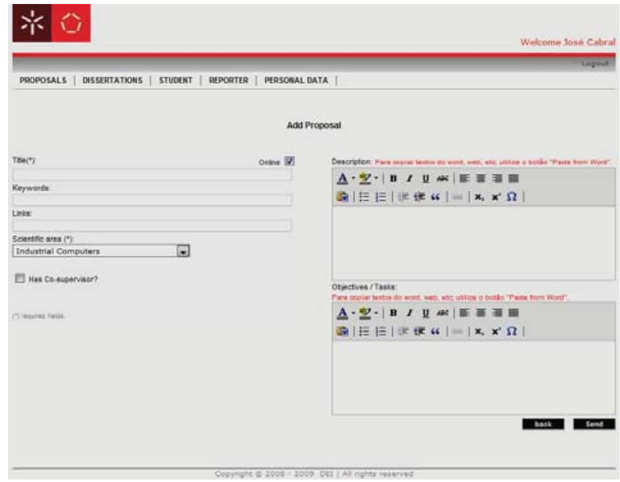

Figure 9. Proposals page.

The text inserted in fields “Description” and “Objectives” could be formatted using an editor tool visible at the right side of fig. 9. The other fields are inserted using basic text boxes. There is also a checkbox (“offline”) to show/hide the proposal in Frontoffice.

The Dissertations page structure contains all the fields of the Proposals page and other information related with the student. When a student has finished his work, the supervisor activates a checkbox to define the exam schedule. This action expands the form in order to insert other fields associated with the exam:

- Exam Date,
- Room and Time,
- Reporter name,
- Upload PDF.

Fig. 10 shows the expanded Dissertations page layout.

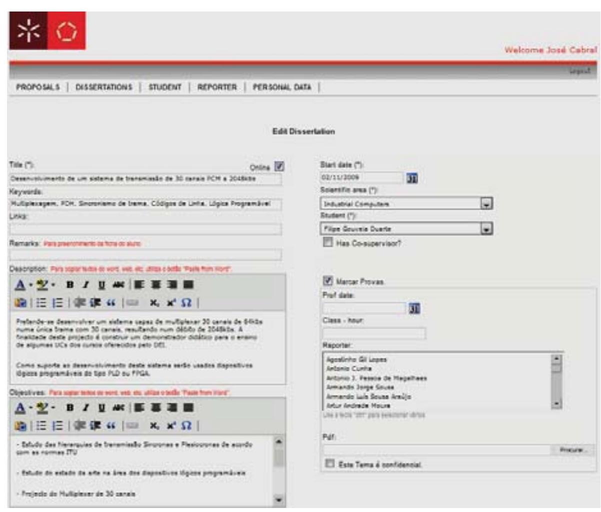

Figure 10. Dissertations page (expanded).

The next item at the Menu bar is the "Student" button. Pressing this button the system displays the page shown in fig. 11.

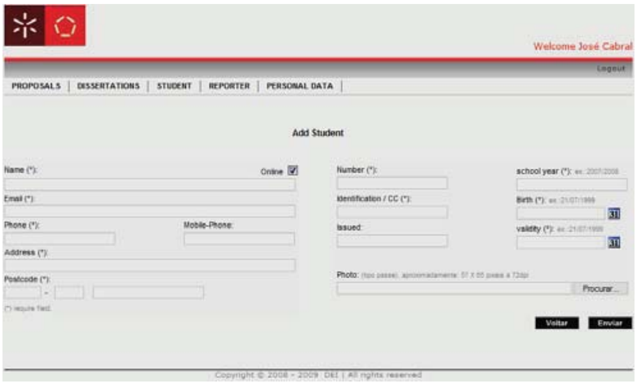

Figure 11. Student page

In this page there is a form to introduce the student data as well as an upload box to collect the student photo.

The remaining buttons of fig. 9 ("Reporter" and "Personal Data") are also forms to introduce personal information about the reporter of the exam and the user, respectively.

Since the Administrator needs additional tools in order to create, delete or change settings of regular users, create news and change a user profile, his menu bar has more buttons when compared with the one of a normal user. Moreover, a user with an administrator profile may access to the information introduced by all users. Fig. 12 shows the Backoffice´s Homepage in this case.

Figure 12. Backoffice Homepage (Administrator).

The extra buttons are:

- Personal Data,
- News.

The first button also appears when a normal user is logged in but, in this case, the Administrator has a tool that allows him to create new users with one of two profiles: "Normal user" and "Administrator". The second button produces a form that allows him to introduce the texts and the images associated to the news area of the Frontoffice.

IV. Supporting Technologies

System development was supported mainly by two technologies: PHP and PostGreSQL, described in the next two sections.

A. PHP

PHP (Hypertext Preprocessor) is a widely-used general-purpose open source scripting language that is especially suited for Web development and can be embedded into HTML (Hypertext Markup Language) [2]. PHP is mainly focused on server-side scripting and so it can do anything any other CGI (Common Gateway Interface) program can do, such as collect form data, generate dynamic page content, or send and receive cookies. There are three main areas where PHP scripts are used:

- Server-side scripting. This is the most traditional and main target field for PHP. There are three things to make this work: the PHP parser (CGI or server module), a web server and a web browser. When the web server is running, with a connected PHP installation, the PHP program output can be accessed with a web browser, viewing the PHP page through the server.
- Command line scripting. A PHP script can run without any server or browser. In this case it is only necessary the use of a PHP parser. This type of usage is ideal for scripts regularly executed using cron (on Unix or Linux) or Task Scheduler (on Windows). These scripts can also be used for simple text processing tasks.
- Writing desktop applications. PHP is probably not the very best language to create a desktop application with a graphical user interface, but for those who know PHP very well, and would like to use some advanced PHP features in client-side applications, they can also use PHP-GTK to write such programs.

One of the strongest and most significant features in PHP is its support for a wide range of databases. Writing a database-enabled web page is incredibly simple.

B. PostgreSQL

PostgreSQL is a powerful, open source object-relational database system. It has more than 15 years of active development and a proven architecture that has earned it a strong reputation for reliability, data integrity, and correctness [3]. It runs on all major operating systems, including Linux, UNIX and Windows. It is fully ACID (Atomicity, Consistency, Isolation, Durability) compliant, has full support for foreign keys, joins, views, triggers, and stored procedures (in multiple languages). It includes most SQL:2008 data types, including INTEGER, NUMERIC, BOOLEAN, CHAR, VARCHAR, DATE, INTERVAL and TIMESTAMP. It also supports storage of binary large objects, including pictures, sounds, or video. It has native programming interfaces for C/C++, Java, .Net, Perl, Python, Ruby, Tcl, ODBC, among others, and exceptional documentation.

An enterprise class database, PostgreSQL boasts sophisticated features such as Multi-Version Concurrency Control (MVCC), point in time recovery, tablespaces, asynchronous replication, nested transactions (savepoints), online/hot backups, a sophisticated query planner/optimizer, and write ahead logging for fault tolerance. It supports international character sets, multibyte character encodings, Unicode, and it is locale-aware for sorting, case-sensitivity, and formatting. It is highly scalable both in the sheer quantity of data it can manage and in the number of concurrent users it can accommodate. There are active PostgreSQL systems in production environments that manage in excess of 4 terabytes of data.

PostgreSQL's source code is available under the most liberal open source license: the BSD license.

V. SUPPORTING DATABASE

The supporting database was implemented in PostgreSQL whose relation model is shown in fig. 13.

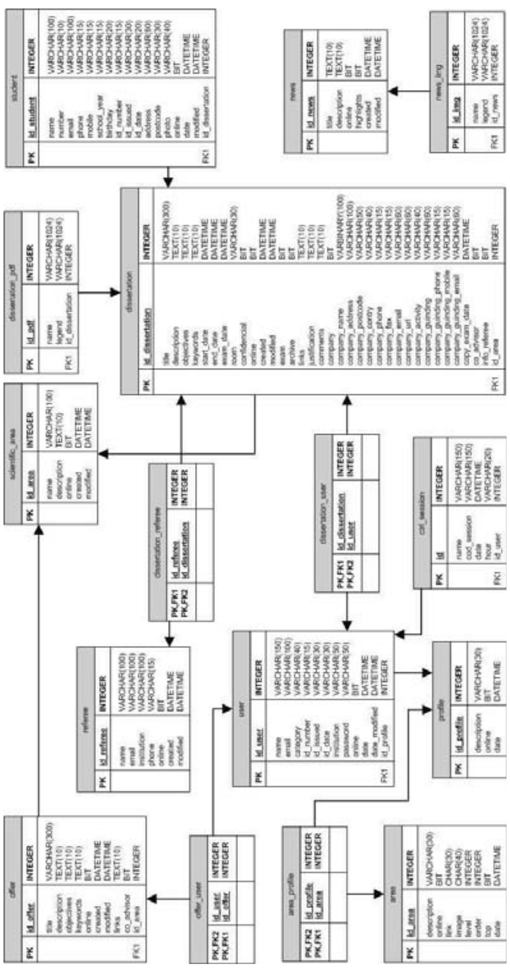

Figure 13. Database relational model.

This model is fully normalized and, thereby, ensures that the information will not be lost or duplicated. The model consists of 16 tables and could be divided in three groups.

The group, composed by tables: user, area_profile, profile, area, student and referee stores information about system users and are classified through a user profile with different privileges. Thus, it is possible to ensure that data entered by a particular user will not be corrupted by misuse.

The group, composed by tables: offer, dissertation, dissertation_pdf, scientific_area, news and news_img is responsible to store information that can be accessed in the Frontoffice such as: Proposals, Dissertations and News.

The other tables are used to troubleshoot impossible relationships in the system.

VI. CONCLUSIONS

The specification of an IT infrastructure supported by a website, designed to manage the paperwork process associated with Masters Dissertations is described in this paper [6]. The infrastructure is composed by two main areas: the Frontoffice and the Backoffice. The first one allows all the people to browse the information about the past and present master thesis, whereas the second one allows the responsible people to introduce the information. PostgreSQL database manager with integration with PHP in a Linux server were used as supporting technologies. The system is full working at the University of Minho, having at this moment 230 registered Master students and dissertations.

ACKNOWLEDGMENT

The authors would like to thank Netmove – Comunicação Global, which gave the authors the technical support in PHP and PostgreSQL, developing this system in partnership with University of Minho.

***Abstract*—Educational and training-providinginstitutions are increasingly depending on the web-based *Learning Management System* (LMS) for delivering course-contents in both on-campus and distance classes. This system offers an easily-accessible environment with various tools for managing learners and courses, and for producing rich contents. However, beside the rich contents, certain fields of study require that courses be accompanied with/followed by laboratory activities which help learners deepen their understanding of the new concepts and develop skills on applying them in close-to-real-world context. More emphasize has been put on these activities when laboratory-based courses appeared and proved to be functioning well in delivering the information. Several stand-alone laboratories have been constructed to support delivery of such activities on-line, but laboratory-tools are not available within the LMS. To address this point, our research presents an approach towards integrating one stand-alone laboratory (NVLab) into Sakai LMS to enable the use of laboratory activities within the course context. The study suggests integrating parts of the original system into Sakai, and then using the LMS's "*linktool*" to connect to the other part. So far, an initial version of the new tool has been accomplished and we are in the testing phase of the new tool on a demo version of Sakai before putting it into service within the campus-wide system.**

Keywords- K3.2 Computer and Information Science Education; K3.1.d Distance Learning; Web-based Laboratories; Learning Management Systems

I. INTRODUCTION

Dependence on web-based *Learning Management Systems* (LMS) is increasing in educational and training-delivery institutions. These systems are used not only with online-courses, but also with those delivered on-campus.

Web-based LMS is easily-accessible and incorporates tools for managing courses, learners, grades…etc, and other tools for supporting the learning process. The later are designed to assist in producing rich contents and to facilitate the interaction among learners and between them and their instructors.

In many cases, what the LMS offers is enough for building an innovating class structure; however, in certain fields of study more is required for successfully delivering the information and building the learners' capacity for real world context. This is certainly true for *Information and Communication Technologies* (ICT) courses where laboratory activities are necessary for deepening the understanding and building skills for applying the concepts being introduced [1]. Instructors put further emphasis on such activities when they successfully introduced on-campus laboratory-based courses [2].

Since current LMSs lack the capability to offer experience-building tools, and to address the need for incorporating laboratory-facilities within online courses, stand-alone web-based laboratories came to existence in a wide range of engineering fields-of-study. Examples of such systems include those which used on-campus facilities equipped with access-networks [3] [4], and others that used modern technologies for constructing the laboratory [5] [6] [7]. This arrangement worked well for classes structured in the conventional way where students get the information first and later apply what they have learnt in the laboratory.

But in contexts where carefully-designed dynamic-contents/practical-activities were combined with the course static-contents it was proven that learning-performance was better in engineering and medical sciences [8] [9]. This, in addition to the success of laboratory-based courses, indicates the importance of building a tool for either integrating practice-acquiring facilities into the online-course, or linking the stand-alone laboratory with the LMS.

- *Paper contribution*

In this paper, we demonstrate our technical approach towards integrating a stand-alone web-based laboratory (NVLab) that we already built for supporting courses concerning *Computer Networks* into Sakai LMS. We suggest:

- Integrating the tool the learners used for producing a network-design in NVLab into Sakai. and
- Using the LMS's *linktool* to enable them access the networks corresponding to their designs which the system constructs on separate servers.

The rest of the paper is organized in sections as follows: section II provides brief background about NVLab and Sakai, and section III presents technical description of the new system development process and requirements. Then in section IV we introduce the task-flow of a simple exercise that we designed for testing the new system within Sakai. Finally, we end with our conclusions in section V.

II. BACKGROUND

NVLab [10] is a web-based laboratory that we designed for supporting online courses concerning *Computer Networks*. It introduces to the learners a tool for producing a network drawing, then uses *Virtualization (Xen)* [11] technology to realize this network on a single server by instantiating *Virtual Machines* (VMs) that correspond to the devices included in the network diagram. Learners are able to remotely access the VMs' terminals via the *Virtual Network Computing (VNC)* [12] [13] module (vnc-server) running on the server.

Students are able to use NVLab for constructing networks, trying to apply what they have learned, and finding out what problems may rise with their designs. Instructors, on the other hand, use it for producing properly/improperly configured network designs and ask the learners to verify/troubleshoot the settings of the devices included in these networks.

We introduced a sample exercise on IP-addressing to a group of learners and asked them to use NVLab to complete it and provide feedback on their experiences using the system. The participants in this experiment completed the exercises successfully and commented positively on the system [10]. Figure 1 shows a screenshot for a learner's machine while connected to NVLab.

As mentioned before, our goal is to have a new laboratory-tool to be used with online courses. For this, we decided to use NVLab and Sakai LMS [14]. Sakai has been selected for some specific reasons: 1) it is an open and freely available LMS that is kept by a community on the Internet; 2) it is evolving all the time and the number of organizations implementing it is increasing; 3) Sakai is written in Java language which is the same used in NVLab and this would make our progress faster.

Courses in Sakai are created using *Sites*, and each *Site* is a workspace that has a number of tools available for all participants. Figure 2 shows one course-*Site* titled *ComNet* which uses Sakai's *web-contents* tool for introducing some information related to *Networking in Java* from Sun website [15].

Tools available in Sakai are of wide range to cover the students' and faculty staff needs. These include: general collaboration tools (like *resources*), teaching and learning tools (like *syllabus*), portfolio tools (like *reports*), and administrative tools (like *users*). The instructor has the right to include the tools he/she sees necessary for conducting the various tasks within the course from Sakai's rich tool-pool.

III. TECHNICAL DESCRIPTION

Incorporating the laboratory system as new tool in the LMS will enable us:

- Leave all administrative tasks, previously considered in NVLab, to Sakai.
- Save information necessary for tracking the learner's advancement while progressing through the course.
- Replace the VM-management solution, *virt-manager* in NVLab, which learners found difficult to use with another application that introduces a web-based interface.

- *System Description*

NVLab (Figure 3) comprises 3 main parts: 1) the *virtual network*, which the learners create, 2) tools for producing the network (*Designer* and *Builder*), and 3) tools for accessing/managing the network (*vnc-server* and *virt-manager*).

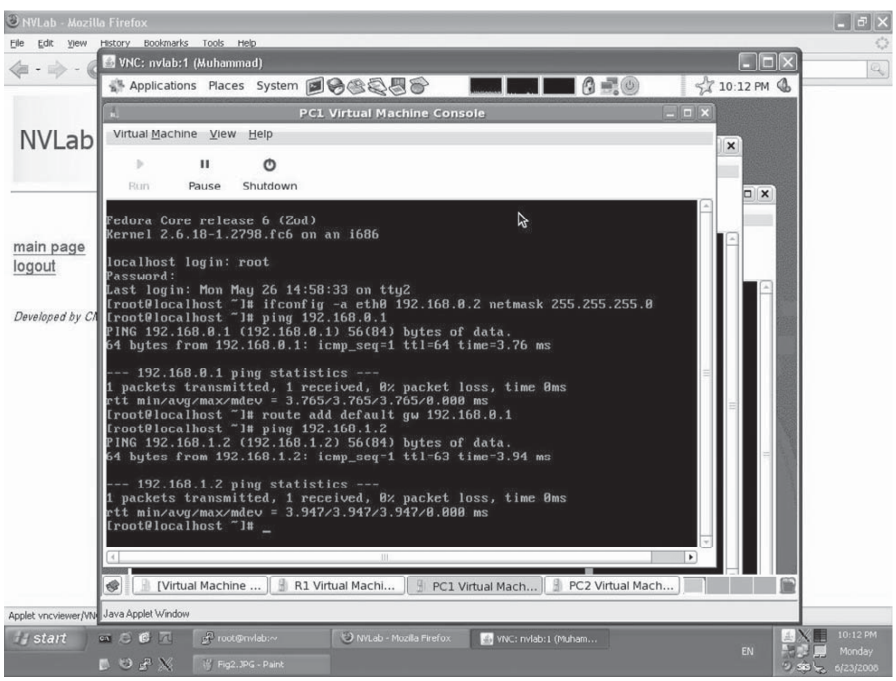

Figure 1. Learner's machine when logging into NVLab

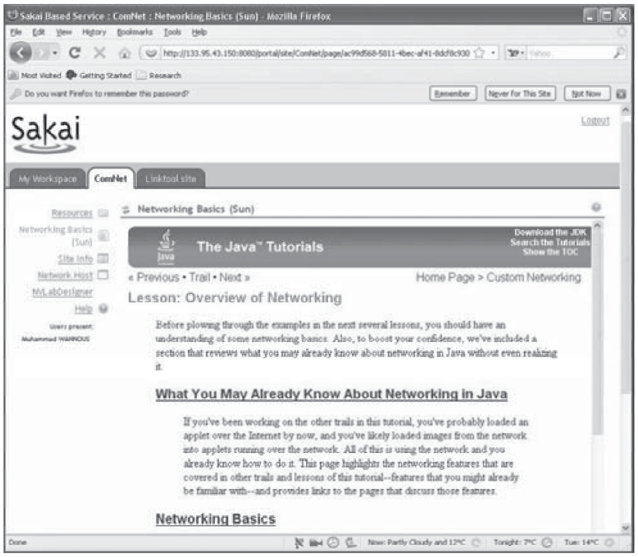

Figure 2. One course-*Site* in Sakai

We introduced two new tools within NVLab: *Designer* (Java Applet) and *Builder* (Java Servlet). A learner used the former tool to draw a network diagram and to save this diagram on the server side; then he/she invoked the later tool which used prototype VMs to create the network on the server. When the first phase is completed, a learner was able to connect to the machine hosting his/her network using the web-browser, and then used *virt-manager* to manage the VMs and start working on their configurations.

The new system has almost the same structure except that parts of it have been integrated into Sakai as shown in Figure 4. In the new arrangement, the laboratory comprises 3 main parts also: Sakai, *NVLabManager,* and a pool of *NetworkManager* servers. Network-designs are drawn in Sakai, while the system creates each of these designs on one *Networkmanager* server. *NVLabManager* works as a check point and server-pool controller /access mediator.

On Sakai side learners use *Nvlabdesigner* to draw a network diagram and save it as an xml-file in the course-site *resources*. This is a tool with GUI interface that enables producing a graphical representation of a network as shown in Figure 5. Copies of the network-diagrams generated by the students are also saved in a hidden space where only the instructor can access them for monitoring the learners' progress. When invoked from *NVLabDesigner* webpage*, createNetwork* Servlet reads the newest xml-file from the *resources* and sends it to *NVLabManager*.

NVLabManager keeps records of the users holding permission to use the laboratory and the servers available for the learners. It assigns one free *NetworkManager* server to the student when it receives a new diagram xml-file, and frees this server when the learner has finished his/her work. In this web-application, *serverManager* Servlet receives the xml-file, verify the user permissions, assign a free server to the user, and then redirect the xml-file to that server in order to create the network contained in it. *NVLabManager* also works as a gateway for accessing each *NetworkManager* through Sakai *linktool*.

Actual work is done on *NetworkManager* where the *Virtual Network* resides. The *netCreator* creates the *Virtual Network* by instantiating VMs from a VM-pool available on each server, and then starts them in preparation for incoming connection from the user side. Creating each VM involves: 1) moving a file that acts as a storage medium for the OS running inside the machine, 2) writing a configuration file that defines the resources available to it (sample is shown in Figure 6.), and 3) writing an html file that contains the definition of a VNC Applet that is used to view the VM's terminal window. The Applet takes one parameter that indicates the TCP port number to which the terminal window is bound (sample html file is shown in Figure 7).

The other Servlet called *netManager* receives the connection initiated from Sakai *linktool* included in the course *Site.* This Servlet is partially based on a web-based Xen VM management tool [16] that we previously introduced. n*etManager* provides a simple web-interface for managing the VMs in the *Virtual Network* as shown in Figure 8. In this interface, links to the html files previously created by *netCreator* are included. When accessed via these links, the learner will get a view like the one shown in Figure 9.

- *Development Environment*

Current work has been done and tested using: Sakai 2.5.4 demo version [17], the famous web-application container Tomcat Apache 5.5.25 [18], Eclipse IDE [19], and NetBeans 6.5.1 IDE [20].

Sakai developers considered that many instructors may wish to build tools that better meets achieving certain functions in the course, and therefore introduced many useful information/software pieces that simplify this task. One simple Sakai tool is considered to be a web application with special configuration file that instructs Sakai to include this application within its pool. To develop *NVLabDesigner*, we used *AppBuilder* available from Sakai developers' community [21].

IV. Task Flow in a Sample Exercise

Considering a course on *Computer Networks* where learners are supposed to gain complete understanding of IP

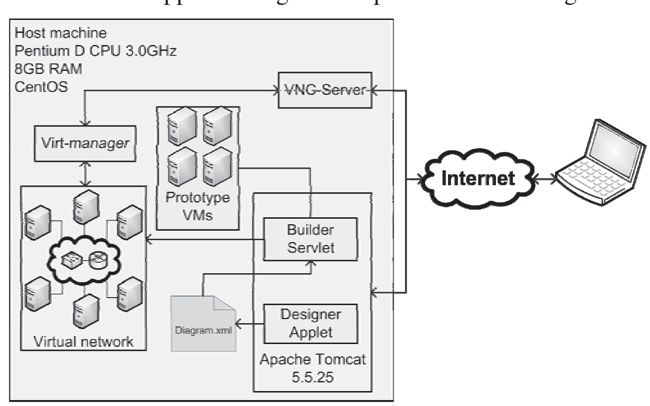

Figure 3. NVLab structure

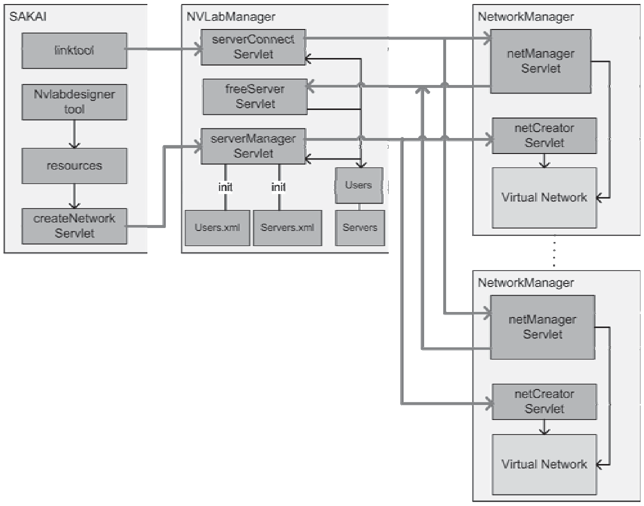

Figure 4. The new system structure

addressing concepts, the new tool has been configured and included in the course to introduce a simple exercise to the learners. The suggested exercise involves assigning the correct IP addresses to two computer machines which are connected to one switch and test the connectivity between them using the "ping" command. The original contents of the course provided the necessary background information on IP address structure and sub-net, and the student was asked to use the laboratory to apply what he/she has learnt.

The learner starts by drawing a network similar to the one shown in Figure 5 and then saves this network-diagram in the *resources* by selecting the proper option from *Nvlabdesigner* Applet's menu (save). Next, by clicking on the link *Create Network* the learner sends the diagram to *NVLabManeger* which will assign a free server to the user and redirect the diagram information to it.

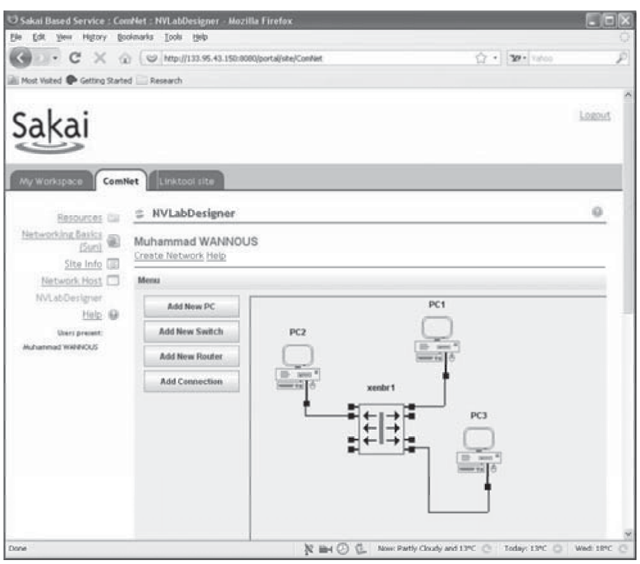

Figure 5. *NVLabDesigner* GUI

```
name = "PC1"
maxmem = 64
memory = 64
vcpus = 1
builder = "hvm"
kernel = "/usr/lib/xen/boot/hvmloader"
boot = "c"
pae = 1
acpi = 1
apic = 1
localtime = 0
on_poweroff = "restart"
on_reboot = "restart"
on_crash = "restart"
device_model = "/usr/lib/xen/bin/qemu-dm"
sdl = 0
vnc = 1
vncunused = 0
vnclisten = "xx.xx.xx.xx"
vncdisplay = "5"
vncpasswd = "********"
keymap = "en-us"

vif = [ "mac=00:16:3e:78:d9:00,bridge=xenbr1,type=ioemu" ]
serial = "pty"
```

Figure 6. Sample VM configuration file

Upon receiving this diagram, *NetworkManager* will create a *Virtual Network* that corresponds to the diagram, start the machines included in it, prepare the necessary files for accessing the VMs' terminals, and send a confirmation to the learner side indicating success. The learner is then able to use Sakai *linktool,* renamed as *Network Host* in the course *Site,* to connect to management interface residing on the server he/she has been assigned. This interface will show a list of the VMs running on the server and provide links to their terminals.

For the current exercise, we selected Fedora Core 6 to be run inside the VMs. To complete the task, any two IP addresses belonging to the same subnet will work and the learner decides to use the private network address 192.168.0.x/24, then configures eth0 interface on both machines by entering the command:

```
ifconfig eth0 192.168.0.X netmask 255.255.255.0
```

where X is 1 in the first machine and 2 in the second. Finally, to check connectivity between the two machines the learner enters the command `ping 192.168.0.2` in the terminal of first machine to get the result as shown in Figure 9.

Having completed the basic task required in the exercise, the learner may wish to move on and configure a third machine then try checking connectivity among the three machines or try to make changes to the IP plan and see what happens. And when done with the network, the learner can go back and continue navigating through the other course-contents.

V. Conclusions

In this paper, we presented a work-in-progress technical report that shows advancements in integrating a laboratory tool into the course context in Sakai LMS. The suggested system is based on NVLab which is a stand-alone web-based laboratory for *Computer Networks* online-courses. In the new system, part of the laboratory has been integrated as a new tool into Sakai, and the other part has been kept as a separate module since it requires managing a server-pool from which each learner is assigned one server to work on. New features that enable tracing the learners' progress and facilitate access to the workspace have been included.

The new system has been tested by introducing a simple exercise on basic IP addressing and connectivity check, and the learner was able to complete the exercise successfully.

***Abstract*— In this paper we will introduce the integrated projects implemented on several courses of the Electronics Engineering Bachelor and Master programs at IST with special emphasis on stimulate students' creativity and practice of implanting prototypes. The key hardware of these projects is a car model with controlled electric engine and sensors and actuators - SUBA.**

Keywords – learning experimentally; car models; component; ubiquitous learning.

I. INTRODUCTION

In 2003/2004 academic year started at IST (Instituto Superior Técnico), Technical University of Lisbon (UTL) a new studies program: a 5 years engineering graduation program on Electronics Engineering. In 2006/2007 its curricula was adapted to Bologna system: a first cycle with 3 years leading to a Bachelor degree; followed by a second cycle with 2 years leading to a Master degree. Accordingly, the first Master on Electronics Engineering had concluded their studies in summer 2008.

The program curricula [1] is 90% similar to curriculum followed by a student on Integrated Master (5 years program) on Electrical Engineering and Computers, also from IST, if he choose Electronics as the main area of specialization and Telecommunications or Computers as secondary area of specialization [2]. However, these programs are radically different on the pedagogical approach. It was introduced in the new degrees a strong experimental integrated component from the first through the last semester. Since the "numerus clausus" for Electrical Engineering and Computers is 215 and for Electronics Engineering is only 35, the available infrastructure (laboratories and teaching staff) enables the differentiation of the pedagogical approach on both programs. Also these two programs are lectured on different Campus with different physical infrastructures. The Integrated Master on Electrical Engineering and Computers is at the old Alameda Campus close to Lisbon centre and the Bachelors and Master Degrees on Electronics Engineering are at the new industry and research Campus at Tagus Park, Oeiras, a Lisbon suburb.

The Bachelor and Master Programs in Electronics Engineering are aimed to providing students with advanced training in a vast range of knowledge and stimulate their creative skills, focused on cutting-edge technologies in electronic components, equipment and systems on all its aspects and applications (telecommunications, control, informatics, energy, etc.). These professionals should be able to meet different needs ranging from engineering design to production and commercialization of electronic products with a view to speed up the technological development of the country. Since in the first years of the Bachelor program most of the courses are on mathematics and physics and few on electrical engineering are introductory, to motivate the students and illustrate basic concepts several integrated experiments on an innovative pedagogical experience were developed such as the SUBA project [3] that will be detailed on this paper.

The novelty of this project is the integrated experimental part of several courses and its key hardware. The name SUBA comes from the basic hardware used on these experiments: a Rally car model **Suba**ru Impreza WRX scale 1:10. The initials also stated in Portuguese "Be a good student" (*Seja Um Bom Aluno)*. SUBA gives to students, from the beginning of their studies, the opportunity to learn several basic courses doing design of systems with progressive and complementary complexity, in an integrated way, benefiting from knowledge acquired in successive courses: Physics, Chemical, Logical Systems, Control, Computer Architecture, etc.

Another pedagogical innovation was the creation of open integrated laboratories very well equipped with basic common equipment that is complemented every semester with specialized equipment required by the more advanced courses. . These laboratories are responsibly used, all the day, by the students in course projects and in their own projects without limitation.

II. OVERVIEW OF ELECTRONICS ENGINEERING PROGRAMS

In the Bachelor Curriculum (3 years, 180 ECTS – European Credit Transfer and Accumulation System), all courses (CU – curricular units) are given during a semester with 14 weeks of lecturers and 4 weeks of evaluation process: finalize and discuss projects and/or written examinations. The basic courses are 10: 6 courses on Mathematics, 3 on Physics and 1 on Chemistry, all located on the first two years. Additionally, on these two first years 4 courses on computers and informatics, and 4 on electrical engineering, 2 of them on electronics (devices and circuits) are lectured. In the last year 3 courses on electronics, 4 on different areas of electrical engineering and 1 on informatics are introduced and the curriculum is completed with 5 transversal courses like management and Technical Drawing and Geometrical Modelling.

In the Master Curriculum (2 years, 120 ECTS) besides the Master Thesis that is developed along the second year (12 ECTS on the first semester and 30 ECTS on the second) the students have to be approved in 4 compulsory electronics courses and 4 optional that must be at least 2 also from electronics but the 2 other can be one from any subject on electrical engineering and other from informatics or computer technology. The curriculum is completed with 3 transversal skill courses, one of them on management.

III. The SUBA Platform

The Subaru Impreza model was selected because it can be easily modified to include an aluminium chassis under the plastic cover to support added electronics for control. Figure 1 presents a photo of a model with two breadboards side by side and an ARM microprocessor development system mounted on the aluminium chassis.

Figure 1. Car model modified to include a breadboard (1) and a printed circuit (2) without the plastic cover (3).

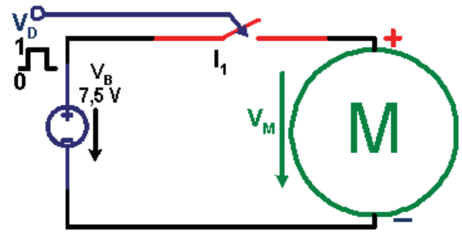
By using a reverse engineering process schematics of all the original model hardware is available for the students in the SUBA site. A special electronics board was designed with several facilities and interfaces for an ease connection of students' projects with the model electronics. SUBA has two electrical motors: one for traction and other for direction control.

The engines speeds are digitally controlled. Figure 2 presents the engine speed control basic system based on a pulse width modulation (PWM) of the engine bias. One of first student's projects is to understand and control the traction engine speed. A sequential logic machine is developed in order to simulate the operation of a mechanical gear box with several gears forward and one backward speed.

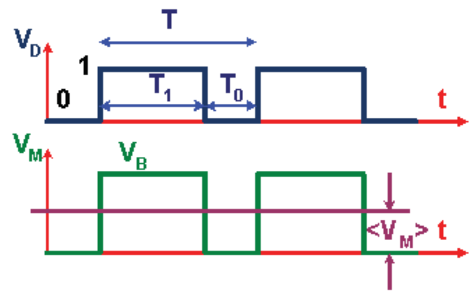
The second engine available on the model is used to control the steering movements: left and right.

In more detail are presented in figure 3 the both engines control circuits based on bipolar transistor technology DC biased by batteries (typically a 9.6 V nickel cadmium rechargeable battery).

Several sensors and actuators were added to the model namely a speed meter, a differential optical direction sensor, wheels angular speed meter and an ultra sonic obstacles sensor.



(a) DC engine power supply PWM controlled schematics



(b) Speed digital control V_D and respective supply voltage V_M

Figure 2. Car model speed control.

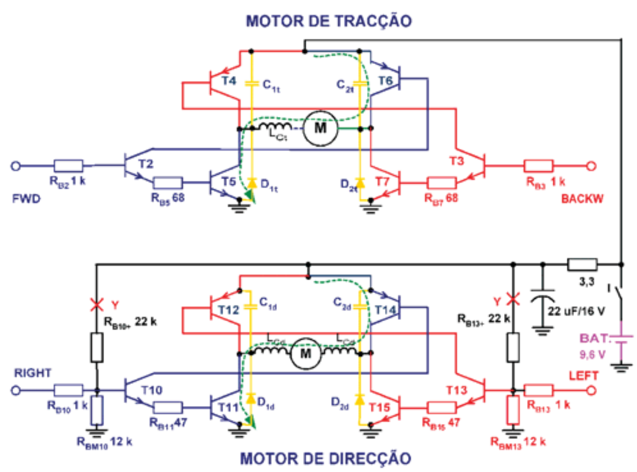


Figure 3. Car model traction and direction engines drivers.

One of the key parts of the SUBA experiments is the SUBAdrome: it is a ramp (figure 4) with 2.5 m length and 30 cm width used for several experiments (more than 20 experiments were developed for Physics course).

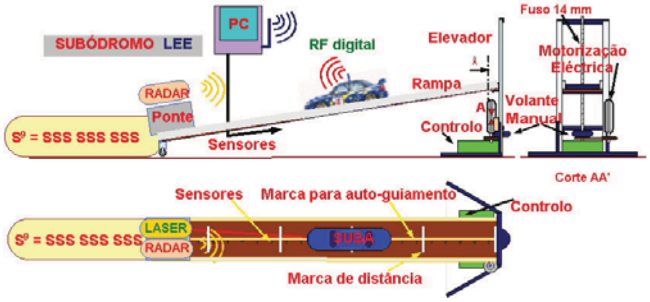

Figure 4. The SUBAdrome – ramp for experiments.

The SUBAdrome has several important features that will be following described and can be noticed on the figure 4.

The ramp slope can be changed by an electric elevator. Over a bridge is located an ultrasonic pulsed radar (30 kHz to 40 kHz signals) that allows to follow the SUBA model movements on the ramp.

The results of the telemetric system installed on board with a speed meter are transmitted via a digital radio system to a PC installed closed to the SUBAdrome. This, so called SUBAradio system has two transceivers, one connected to a PC serial port and the other is at the car model. The system is able to transmit digital data at 200 kbps on a RF carrier of 432 MHz in a range of 50 m in open space.

Also a Doppler system can be installed on the SUBAdrome: loudspeakers on the car model and an audio microphone installed on the SUBAdrome bridge allow the computer to measure the frequency shift of the sound.

Twenty five optical emission/reflection sensors are located on the ramp soil to detect the car position at any time.

All collected data is processed on a PC and allows verifying several physical kinetic laws and compare experiments with theory as it will be shown latter.

At the lower end of the SUBAdrome can be noticed the S^9 system developed to carefully hold the car and avoid any damage.

IV. Experiments

During the first semester of the first year, students have the first contact with SUBA: the SUBA Trophy. This experiment is on the mainframe of Digital Systems course.

SUBA Trophy is a creative competition among students to stimulate them on using hardware/software combination. They use simple TTL or CMOS logic components and the breadboard and/or FPGAs (Field Programmed Gate Arrays) to control the model.

Following, as an example, some of the Trophy goals are explained.

Implementation of two sequential machines: one simulating a sequential gear box with PWM signals as explained before; and a second one that controls a predefined series of movements using all gears and the right and left turn movements keeping the SUBA model always inside a predefined area of 6 m x 6 m. A seven segments display, located at the top of the car must show at any moment of the demonstration the used gear. Figure 5 presents a SUBA model totally prepared to compete on a SUBA Trophy.

Figure 5. SUBA model ready to compete on a SUBA Trophy with TTL ICs

On the first year, second semester, SUBA experiments are carried out on the mainframe of three courses: Mechanics and Waves, Computer Architecture and Data Structure and Algorithms.

On Mechanics and Waves the experiments are all processed at the above described SUBAdrome. Calculations of different rolling conditions are tested: different pavements and/or wheels materials (rubber, aluminium and Teflon), and ramp different angle. The up and down movement on the ramp for several speeds including free wheel skid is tested. The comparison with theoretical simulations is performed using the car model movement equations in different conditions. Also energy conversion potential – kinetics along the ramp and electrical-heat when the car is braking are experimentally verified. To break the car electromagnetically the engine is working as an electric generator that supplies resistive loads digitally configurable. This is the first students contact with energy recover. The car engine power supply is controlled by PWM as explained in the previous section. Its operation was already studied at Digital Systems course. The engine power is calculated for several duty cycles, i. e., power supplies or speeds. Several experiments guides are available on the SUBA website.

For basic studies on Mechanics the SUBAdrome is also used testing the movement of coaxial cylinders with different weights, dimensions and materials. Inside cylinder may be free or fixed with the external cylinder. Cylinder fall in the SUBAdrome converts potential energy in kinetic and or revolving energy. Using the 25 sensors available in the SUBAdrome the cylinders displacement can be easily followed. Figure 6 show a student using the SUBAdrome with a cylinder rolling down (a) and the generated signal on the passage of the cylinder on te SUBAdrome sensors (b). Each student prepares his own experience. All students read the SUBAdrome signal on their computers, equipped with data acquisition systems, and model the experience conditions.

(a)

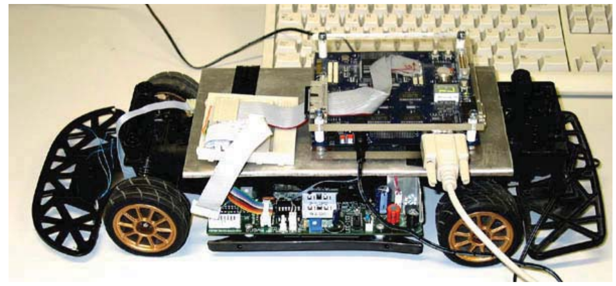
(b)

Figure 6. SUBAdrome used for basic mechanics experiments

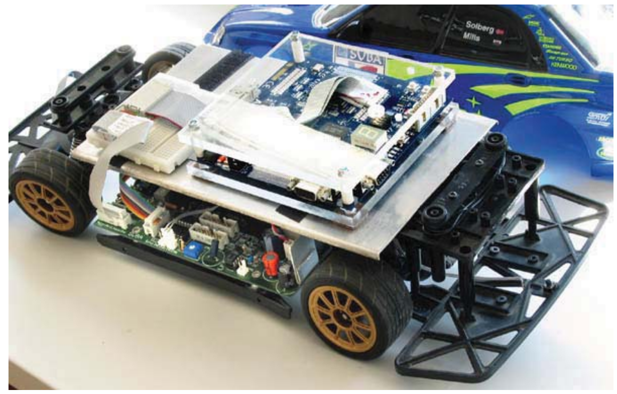
The basic Mechanics experiments can be easily implemented on secondary schools. They don't need all sophisticated and more expensive electronics associated with the study of the SUBA model movements like radio communications, 3D movements' sensors, engine PWM control and so on.

To increase the SUBA model performance, on the mainframe of the courses Computer Architecture and Data Structure and Algorithms, a 32 bit RISC microprocessor with ARM architecture was introduced.

The ARM algorithms are introduced in language C or Assembly that are studied on the courses on Basic Programming. The access to the ARM ports is implemented on the SUBA model by a connector with a flat cable that is clearly noticed on the fully armed model of Figure 7, firstly being programmed (a) and secondly ready for a more advanced SUBA Trophy (b).



(a)



(b)

Figure 7. SUBA model ready to compete on a SUBA Trophy with a RISC microprocessor

The new generation of the Subaru Impreza model direction is not only controlled by two steps L/R or straight (ahead) as in the previous ones. Accordingly, now a progressive control servo system with automatic steer alignment developed by a student on the 3rd year was implemented with a system based on a microcontroller PIC. Figure 8 presents the schematics of the SUBA model direction which has trapezoidal bars controlled by an electric engine.

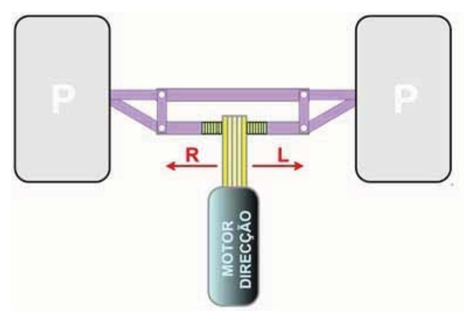


Figure 8. SUBA model trapezoidal bars direction

With this new version a SUBA Trophy where the main challenge was to program the SUBA model to follow a scaled version of the Estoril motor racing track with some short connection (figure 9) was implemented. The Estoril motor racing track is only a few kilometres from IST Tagus Park Campus.

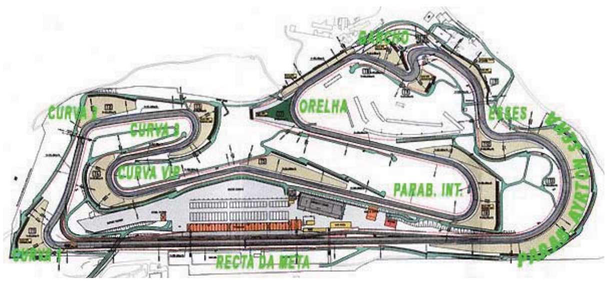

Figure 9. Racing track for advanced SUBA Trophy

V. CONCLUSIONS

Since the first year of the implementation of the new graduation program on Electronics Engineering a new integrated experimental platform has been developed. It has at least two main objectives: to allow experiments based on skills acquired in many different courses from different scientific areas to show their interdependence and the need of a 3rd century electronics engineer to have acknowledgments on a broad area of subjects; to motivate the students to develop and use electronic hardware, since the first semesters most of the courses are on mathematics and physics. The SUBA project trough their Trophies where working on a team is needed is also a good vehicle to help the engineering students loosing afraid of doing hardware, test their ideas and develop their team working skills.

Due to the SUBA experience on the first years the students are more motivated to study in detail other courses like those related to control and electronic systems to fully understand the SUBA performance on experiments of previous courses. Also the students are willing to have projects and develop prototypes on advanced Master (2nd cycle) courses.

The SUBA platform is dynamic and new features are being added. New sensors are being developed on Master courses projects. On the mainframe of one Master Thesis a SUBA car with a hydrogen cell (SUBAH) was implemented.

Also the SUBA project is used to support the Electronics Engineering program objectives presentation in secondary schools where potential future students are now studying, not only with on site demonstration but also thru the SUBA website. Two simple versions of the SUBA are being developed by students' initiative, not included in any course, to be used on the secondary schools and exhibitions, showing their own interest on the SUBA project.

AKNOWLEDGEMENTS

We must remember several colleagues and students that have been enthusiastic and involved with this project. We are Thanks to Prof. Guilherme Arroz (responsible by Digital Systems course), Prof. Rui Rocha and Prof. Rui Neves (both responsible by Compnuters Architecture), Prof. Paulo Freitas and Prof. António Ferraz (both responsible by Physics Course) for giving the opportunity to try these pedagogical concepts creating special courses for Electronics Engineering students. Thanks for all students of Electronics Engineering course for their dedication to SUBA project. A special thank to the brilliant student Luis Rosado that developed the steer servo alignment and control system that is now used on new SUBAS and is logically compatible with old SUBAS

Encouraging Interaction and Status Awareness in Undergraduate Software Engineering Projects

The Role of Social Networking Services

Terence Charlton, Marie Devlin, Lindsay Marshall
School of Computing Science
Newcastle University
Newcastle, UK

Sarah Drummond
School of Engineering and Computing Sciences
Durham University
Durham, UK

Abstract— **As part of the CETL ALiC initiative (Centre of Excellence in Teaching and Learning: Active Learning in Computing), undergraduate computing science students at Newcastle and Durham universities participate in a year long, inter-institutional group programming assignment. Teams of students act as "virtual companies" and collaborate cross-site to develop software products for real-world industrial clients. This paper investigates the emergence and autonomous adoption of social networking technologies in our students' communication strategies during the project, and explores the role that "status awareness" (knowledge of the current activities of one's team mates) had on the outcome of that collaboration. We also present and discuss the findings of a recent trial of CommonGround, an application created to harness our students' pre-existing engagement with social networking technologies such as Facebook.**

Keywords: computer science education; social factors; facebook; collaborative work; professional communication; programming; technology

I. Introduction

Active Learning in Computing is the first Centre for Excellence in Teaching and Learning (CETL) for Computing Science in England [1]. The five year initiative is funded by the Higher Education Funding Council for England (HEFCE) and is a collaborative effort between a consortium of North East UK universities: Durham University (who lead the project), Newcastle University, Leeds Metropolitan University, and the University of Leeds. Running since 2005, the CETL aims to better prepare students for the realities of working in their chosen professions by aligning their learning experiences with those sought by today's software engineering industry [2, 3]. In particular, it addresses the distributed working practices of many professional software development companies and, in turn, our need as educators to equip students with the skills required to work in this competitive environment.

As part of this project, we have extended the traditional undergraduate Software Engineering curriculum taught at both Newcastle and Durham universities to include a year long, inter-institutional team programming exercise, in emulation of modern industrial practice. Teams of students act as "virtual companies" and collaborate cross-site to develop software products for real-world corporate clients (projects differ from year to year; examples include a supply chain logistics program and a mobile GPS graphing application [4]). From a pedagogical perspective, this approach places a far greater emphasis on group collaboration and professional skill development than is usually adopted by university computing departments [5], despite research that indicates a number of significant educational benefits [6]. It also encourages greater engagement with the discipline, increases technical and transferable skill sets, and ultimately provides students with a genuine insight into the challenges faced by companies competing in a global market.

In this paper, we provide an overview of the computer-mediated communication (CMC) technologies selected by students for use on-project, and the resultant issues encountered. In particular, we discuss the adoption of the social networking site Facebook as part of our students' local and cross-site group collaboration strategies, and report on a pilot study of *CommonGround*, a Web 2.0 application developed by us to harness and monitor this engagement.

II. Team Infrastructure

In the four years since 2005 that the group programming assignment has taken place, 556 level 2 students have participated. These students are enrolled on a number of computing programmes including single honours Computing Science, Software Engineering, Information Systems, and Natural Sciences, with the Software Engineering module being common to all. During the exercise, a number of "companies" are formed, each comprising a team from Newcastle and Durham (containing on average between 6-8 and 4-6 students respectively). Membership of each team is chosen based on performance and achievement in programming classes during level 1. This is to ensure a fair distribution of programming skills throughout the teams and to give all students an equal chance of delivering a satisfactory end product.

The cross-site teams then have one full academic year to complete the project and are given a set of deadlines spanning two semesters for their major deliverables. Each team must define their own organisational structures and software design methodologies, and project-manage all stages of the development process (from encapsulating requirements through to the implementation, integration and testing of their final systems). Assessment, including the students' ability to work well as a team, takes place in a number of different ways, including group presentations, documentation delivery, live demonstrations, the completion of individual reflective reports, and observations during meetings (by members of staff who act as team-monitors).

The activity has, on the whole, been very well received by students, as the following excerpt from a team's end-of-project report demonstrates:

> *"We feel the project was very worthwhile. Our various accomplishments and failures now seem unimportant compared to the knowledge and experience gained. We have not only learned a lot of programming and technical skills but have gained some great life experiences in team working and project management which we will carry with us into any future work."*

However, despite several iterations of this cross-site collaboration, we still find that encouraging and supporting communication between students is one of the most challenging aspects of our work.

III. Communication Strategies

In the early stages of the project, to stimulate and support team collaboration, we provided students with a number of CMC technologies. These tools, representative of the techniques used in industry, ranged from fully equipped Skype-enabled video-conferencing suites to virtual learning environments, file repositories, forums and wikis. However, student feedback (gathered from questionnaires, end-of-project reports and focus groups) indicated substantial resistance to the use of these facilities, attributable mainly to the sheer variety of technologies on offer (see [7] for a full discussion). In particular, students were unaware of the relative benefits of each technology and unfamiliar with their use; as a result they tried to use them all rather than commit to any specific subset.

Feedback also showed that students found it particularly difficult to determine, even after face-to-face discussions, what their teammates were working on at any one time (see Table I). This was particularly evident cross-site, where less than a quarter of students surveyed were able to keep track of the activities of teammates. Almost inevitably, this would lead to duplication of work and increased frustration within the teams.

TABLE I. Student Status Awareness, 2008-2009

Can you tell at any one time what your teammates are working on?				
	Newcastle Uni. (N=61)		***Durham Uni. (N=22)***	
	Locally	*Cross-site*	*Locally*	*Cross-site*
Yes	41	13	16	5
No	20	48	6	17

Paradoxically, despite representing the CMC tool of choice for students, email frequently exacerbated team communication problems; it presented the longest delay in average response times. Furthermore, reports from team monitors suggest that students were reluctant – at least in the early stages of the project – to exchange personal contact information (e.g. mobile telephone numbers, instant-messenger IDs, etc.) until they had become better acquainted.

To better highlight these issues, we now include excerpts from student feedback reports discussing the communication problems encountered on-project, emphasising the difficulties experienced both locally and cross-site:

> *"We could not meet ad hoc to discuss progress. This meant we had no way of monitoring or checking the progress at the other site between formal weekly meetings, except via email – and these messages did not contain enough detail about what had been done."*

> *"The bigger the team, the more people that we needed to keep in the loop, which was a problem because each student had their own working patterns. Some did not read their email every day and some decisions needed a quick response from key members in the team. This meant that decisions were often delayed. "*

> *"Brief comments in the repositories for code and documents were not detailed enough and we were often unsure who was working on which module or document at any one time. This often led to the repetition of work."*

> *"It was often easy to misinterpret the intent and tone of an email or IM message and this led to conflict in the group. Some of us felt that being asked constantly about progress meant that our colleagues did not trust that we were working on our assigned tasks."*

Although the CMC technologies provided by us did play a role in supporting our students' collaborative efforts, when the facilities consistently failed to meet expectations, teams ultimately abandoned them in favour of more convenient, proven technologies. The social networking site Facebook is perhaps the best example of this; it was not introduced into the project by us, but was autonomously adopted by the students themselves.

IV. Creating a Common Ground

A. Social Networking

Social networking sites such as Facebook, Bebo, MySpace and LinkedIn have experienced unprecedented growth in popularity and membership in recent years [8]. Fuelled by considerable media attention, this proliferation has exposed the latent sociability of the internet – people are now accustomed to thinking of the online world as an interactive, social space [9]. Of course, social interaction and community organisation on the web is nothing new [10], but the scale at which people are adopting and actively using the technology is; today, mainstream social networking sites arguably represent one of the most important CMC mediums for individuals, organisations and researchers alike.

Since the release of SixDegrees.com in 1997, more popular (and far more successful) services have appeared that allow users to represent themselves and their social networks online. These sites are all based on the common principle of connecting and building online communities, but offer myriad variations around that shared theme. Facebook, for instance, connects people from similar educational backgrounds, MySpace connects people with similar social pursuits, and LinkedIn connects people with similar business and employment interests. Following this trend, other mainstream online services such as YouTube and Flickr (collectively referred to as social *media* sites) have also started offering integrated social networking facilities to enhance their core functionalities.

For illustrative purposes, we include in Table II questionnaire results from our investigation into student uses of CMC technologies during the 2008/2009 academic year (at the end of semester 1). 12 companies participated in the survey, represented by 61 students from Newcastle University and 22 from Durham. As can be seen, Facebook was used locally by over 70% of the students surveyed, and over 40% cross-site.

TABLE II. STUDENT CMC TECHNOLOGY USE, 2008-2009

a. NESS is a web-based Virtual Learning Environment developed by Newcastle University

B. *Facebook*

Launched in 2004, the Facebook website is based on the concept of a US-style "year book", where members create publicly-viewable, self-descriptive profiles to describe themselves and their interests [11] (accompanied by a representative, and often flattering, headshot photograph). Members are then invited to articulate their social graph by connecting to other profiles, or 'friends', and in doing so build networks of affiliations based around common interests or shared circumstances (e.g. home town, place of work, political views, recreational interests, etc.). Mutual friends (i.e. connections that have been approved by both parties) are thus able to view one another's profile information, share photos, songs, videos, discussions, and "most other forms of expression" [12]. This process of co-constructing social networks of connections on Facebook, informally referred to as "friending", represents an integral piece of an individual's online self-presentation [9].

Unique to Facebook, members tend to present their identifying information openly and truthfully (e.g. the use of real names rather than pseudonyms or aliases), seemingly undeterred by privacy issues [13]. As reasoned by Grossman [14], "identity is not a performance or a toy on Facebook; it is a fixed and orderly fact." Significantly, the ease by which this information can be accessed greatly lowers the transaction costs associated with social searching; that is, finding and connecting to one's known acquaintances [15]. Again, this act of mirroring one's offline relationships online is peculiar to the Facebook community, contradicting the longstanding assumption that CMC relationships predominantly move in an online to offline direction [16].

C. *Social Capital*

For many of our students, Facebook is an integral part of their daily routine; beyond micro-managing their social life, it offers an inherent capacity for generating social capital [17] (i.e. the resources accumulated through relationships with other people). As supporting research into the use of social networking sites in academic and professional contexts shows, Facebook can help crystallise relationships that might otherwise remain temporary or ephemeral [17]. In the business world, particularly where graduate employees are concerned, these informal connections have been shown to return strong payoffs in terms of social support and access to expertise and organisational knowledge [15, 17]. Indeed, these networks of professional affiliations allow individuals to better maintain and strengthen relationships with colleagues [18], and can often facilitate *on-task* interaction (as many productive discussions in team-working environments occur during chance, informal encounters [19]).

Perhaps more importantly, Facebook also encourages inclusion and participation from students with low self-esteem, who present difficulties forming and maintaining offline relationships with their colleagues [17]. The value of social interaction cannot be underestimated when trying to build trust and empathy between distributed team members [20]. Furthermore, as shown by Selwyn [21], the service can also act as an important site for the informal, cultural learning of being a student, with online interactions allowing roles to be learnt, values understood and identities shaped.

D. *CommonGround*

Of particular significance to this study, Facebook offers unparalleled access to the personal information and activities of one's friends and colleagues, in addition to supporting numerous synchronous and asynchronous communication affordances. To exploit these features and further enhance the user experience, Facebook opened its platform to software developers in 2007. This allowed third-party internet applications and web-based services to be seamlessly integrated into the site, taking advantage of the social connections of its users. The release of the Facebook application framework has received notable media coverage and user uptake; as of October 2009 there are more than 210 million users of 350 thousand third-party applications on the platform [23].

Endeavouring to embed Facebook's collaborative and "status awareness" features into our cross-site activity, we have developed our own *proof-of-concept* RIA (rich internet application) called CommonGround, designed to run on the Facebook platform (see Figure 1; profile images have been obscured and fictitious names used to maintain anonymity). The pedagogic motivation behind this work is to foster greater team interaction, trust [20] and self-disclosure [22] by filling the communication void that arises between students' face-to-face meetings [16]. By reducing the geographic and temporal barriers to interaction and community formation, team members will become increasingly aware of each others' skills, personalities, work rhythms and needs – both online and off – within a pre-existing, persistent, convenient infrastructure.

Figure 1. CommonGround running on Facebook

Developed in Adobe Flex, the application provides a standards-based interactive experience to the user, utilising and extending the inherent communication and social awareness affordances of the Facebook platform. Employing the new Adobe Flash Collaboration Service, the application is able to offer a number of facilities to the student: better team interaction and familiarity (via profile exploration and informal encounters), increased status awareness (via status updates), and greater project planning potential both locally and cross-site (via a simple company-wide task list).

CommonGround's status awareness features represent an area of particular interest to us. As touched upon earlier, the application allows users to publish a simple and succinct one-line textual "status" describing their daily work activities and opinions for teammates to view and comment upon. Of note, during our study it became apparent that students did not wish to have their main Facebook status altered – that is, their primary profile status that is available to their entire friend network – and so a separate, project-specific status is maintained local to the CommonGround application (and each individual company).

To stimulate informal interaction via productive chance encounters [19], and to enable basic online awareness between students, we have also created a "virtual meeting room" that displays presently connected users and their institutional affiliations. We have employed a familiar visual setting; one that is analogous to the students' real-world meeting environment (i.e. an illustrated reproduction of a traditional face-to-face meeting room). Profile images represent users and help put a face to cross-site teammates, many of whom the students may never meet in person. Basic name and team-role details can be accessed by rolling over a profile image, and then clicked upon to view that teammate's full Facebook profile (often including detailed contact information).

A simple chat facility is also available for synchronous discussion with online teammates, supplemented by the integrated and private one-to-one Facebook chat feature (discussion boards, provided by the Facebook service and set-up by us, are also available for asynchronous interaction). CommonGround also offers students a basic scheduling facility providing a team-wide overview of pending project tasks, responsibilities, due dates and progress percentages. Presented in-line, this schedule can be readily viewed and discussed, with roles and timescales collaboratively decided upon. We have also integrated our virtual learning environment NESS (Newcastle E-learning Support System) into Facebook. Accessible via CommonGround, it allows students to retrieve course timetables, share files, submit deliverables, and receive marks and feedback.

Of note, students had initial reservations with regards to using Facebook for the purposes of the project. As one would expect given the recreational use of Facebook and peoples' informal expectations of the service [24], students were particularly reluctant to be "forced" to add their teammates as friends on the service, especially with respect to their cross-site colleagues with whom they were less acquainted. However, our students' privacy is respected by CommonGround and teammates do not need to be "friends" in order to collaborate via the application. Once a company account has been created, members can simply join that group in order to participate; use of the application does not interfere with any other activity on Facebook.

V. Findings

A preliminary pilot study of the CommonGround application was performed during the 2008/2009 academic year. Four companies were invited to use the application – both locally and cross-site – during the final 8 weeks of the cross-site project (when companies typically implement their final systems). A total of 38 students from Newcastle and 24 from Durham took part. Each team reported they had already used Facebook for communication socially with their teammates, but only locally. To form a picture of the students' opinions of the CommonGround application, we interviewed participating teams and administered a second series of surveys during the final week of the project. A 100% response rate was observed.

TABLE III. Average Daily Activity on CommonGround

Companies 2, 3, 4 and 5	*Newcastle N=38*	*Durham N=24*
Impressions (i.e. application loads)	48	11
Chat Messages	33	18
Status Updates	6	3
Schedule Additions/Updates	1	1

Initial results are encouraging, supported by activity logs showing positive, heavy use of the application (see Table III). Team members, on average, accessed CommonGround more than once each day during the trial, if only to update their own status and view the activities of others. When regarded alongside the high levels of chat recorded, a considerable number of chance encounters were found (i.e. ad-hoc informal meetings with two or more team members). For example, Figure 2 demonstrates a three day single-company snapshot of student activity. Each connecting edge represents simultaneous access to the application (i.e. a chance encounter), with position (i.e. degree centrality) in the network determined by the amount of interaction which occurred during each encounter. Of note, detailed content analysis of the chat logs to determine the "on-task" nature of these interactions is currently underway and will be presented in a future work.

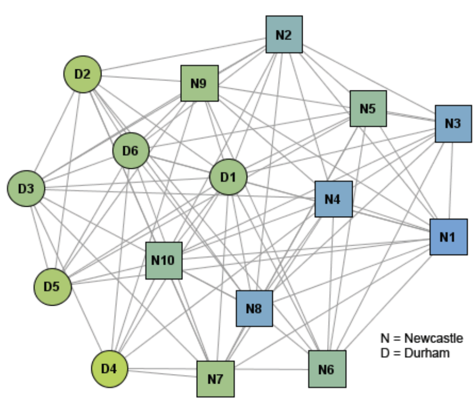

Figure 2. Network diagram of chance encounters (week 2, company 4)

Encouragingly, students in interview reported using CommonGround and Facebook as a "one-stop-shop" to contact and collaborate with teammates. As shown in Table IV, survey data also indicated that they were comfortable using Facebook on-project and integrated CommonGround into their working practices with little resistance (in stark contrast to technologies mandated by us). Indeed, these results indicate that students were significantly better able to maintain awareness of their teammates' activities when using CommonGround, with an increase in confidence of approximately 16% locally and 51% cross-site. The combined communication affordances of CommonGround and Facebook, in addition to readily accessible profile contact information, meant that students could get in touch with colleagues quickly, with standard email utilised only for less pressing matters. Of particular importance, all participants reported they felt "part of a team."

Interestingly, results from this study also show that a lot of the CMC facilities offered by CommonGround and Facebook were already provided by us in other applications (such as messaging and chat), but which the students chose not to use. The fact that this functionality was centralised on Facebook seems to have greatly influenced its adoption and use. Even email, which often tends to dominate students' local and cross-site communication strategies, appears threatened somewhat by the embedded CMC affordances of Facebook. Indeed, this finding is supported by reports of social networking message traffic overtaking that of web-based email [25]. Students feel certain that, even if teammates do not answer their mobile phone or read their email, they will eventually log on to Facebook and feel compelled to respond.

TABLE IV. Student Opinion of CommonGround

	Newcastle Uni. (N=36)		*Durham Uni. (N=24)*	
	Locally	*Cross-site*	*Locally*	*Cross-site*
Using CommonGround, were you *confident* that you could tell at any one time what your teammates were working on?				
Yes	31	25	19	19
No	2	3	0	3
Were you comfortable interacting with teammates on Facebook?				
Yes	33	28	20	17
No	2	3	2	4
Did you ever seek to learn more about a teammate via their profile?				
Yes	26	27	14	19
No	6	2	5	2
Did interacting on Facebook help your team communications?				
Yes	32	28	16	15
No	0	6	3	7

Note: 2 students left from Newcastle during the activity; "don't know" responses have been omitted

Of note, students were more inclined to formally report team communications via Facebook once they realised "it was okay to do so". Feedback shows they didn't initially perceive social networking sites as an acceptable form of professional communication, despite awareness of large corporate networks on the service. This finding is further highlighted by teams' end-of-project reports, which made only anecdotal reference to the trial use of Facebook and CommonGround for formal communication, despite the majority of participants reporting that it had helped communications.

VI. Discussion and Future Work

In the four years that we have participated in the cross-site project described in this paper, we have gained significant insights into distributed team collaboration and the areas that cause most concern to students. Some of these areas, such as assessment, have been able to improve year-on-year. However, despite our best efforts, both local and cross-site communication issues have presented much more of a challenge. As we have shown, the sheer variety of unfamiliar CMC technologies provided by us has arguably undermined our students' communication strategies, exacerbating the very problem that we were trying to solve.

More and more, however, our students are leading the way for us by autonomously incorporating freely available social networking technologies into their informal communication strategies, fulfilling their group collaboration needs and mitigating the shortcomings of the CMC facilities provided by us. Facebook in particular has emerged as one of their primary collaborative tools for both informal and on-task interaction; it was convenient, familiar, and already in frequent use.

The CommonGround tool described in this work was developed to transparently harness this pre-existing engagement with Facebook. It is a *proof-of-concept* application and, although it has received only limited use, our initial results and feedback from students have proven extremely encouraging. From a collaborative standpoint, CommonGround offers a means to foster group interaction and community-building by providing a centralised application through which students can interact and explore the personal profiles and work patterns of their team mates. By creating a persistent environment that interacts with and leverages the power of existing social networks, team members are able to better maintain their interactive cohesiveness, team awareness and project planning potential beyond face-to-face meetings. The application has helped reduce the barriers to both local and cross-site interaction and team building, and aided somewhat in the inclusion of more "peripheral" students.

It is our intention to further examine how social networks are formed and developed in this environment, and to evaluate the extent to which the added sociability, status awareness and planning facilities affect student motivation and social capital. To this end, a second, more comprehensive version of CommonGround is under development and is being trialled in the current academic year (using local and international cross-site teams, divided into experimental and control groups to allow for a more detailed comparison and exploration of the impact of CommonGround). A further trial of the software in an industrial setting is also underway, and will be reported on in a future work.

The use of agents to represent learners in role-play training

Taichi Nakamura, Akio Takashima, Akane Mikami

Abstract— **This paper proposes the use of agents to involve learners in supporting online group work for the study of project management.**

Role-play training may be an appropriate tool for universities to use as an efficient alternative to on-the-job training (OJT) for project management education. However, we have found that because of the way that role-play exercises using an on-line group work training system in the project management course have operated, students have not been able to share the required information adequately with other students.

In order to investigate the effectiveness of using an agent in role-play training, we have developed a role-play scenario so as to practice with agents. The results of analyzing the behavioral track record of each learner in a role-play exercise with agents are discussed. The results of a questionnaire survey taken among students who participated in a role-play exercise with agents indicate that the use of role-plays will enable them to learn human-related skills such as communication, leadership, and team building.

Keywords-component; Project management education; Agent; Role-play training

I. Introduction

The IT industry in Japan has required higher education institutions such as universities to provide project management education [1]. Role-play training could form an appropriate tool for universities as an efficient alternative to on-the-job training (OJT) for project management education [2].

Since 2007 we have been developing an online group work training system named PROMASTER (Project Management Skills Training Environment) to increase the learning opportunities when studying project management using role-play training and to achieve profile-based education (PBE), which takes account of the progress in study of each individual student[3]-[5].

However, we have found that because of the way that the role-play exercises using PROMASTER in the project management course operated, students have not been able to share the required information adequately with other students. In addition, a lack of understanding of the stakeholders' roles assigned to learners has meant that students have not really been able to fully appreciate the project management scenario that they have been role-playing. Accordingly some students may not be able to acquire the expected skills for project management.

In order to cope with this problem, it is desirable that a team performing a role-play exercise has at least one participant who can play the role of a mentor. This person should be an experienced project manager. However, it is not realistic to expect an experienced person to assist in leading a role-play exercise as a team member. Instead of having such a person, a software agent system, which implements the advanced professional skills of project management, may be able to act as a mentor in a role-play.

In order to realize a sophisticated agent, a Non-Player Character (NPC)-based system which can estimate the appropriate behavior of an NPC assigned to a stakeholder role to maximize its profit and generate alternative scenarios should be developed [6]-[10]. NPCs act in a role-play scenario using an outline description of a procedure for project management as stakeholders and can interact extemporarily with learners [11].

In our research, it is planned that the development of an agent system based on the general idea of an NPC will proceed on a step-by-step basis, as described by the following four stages: (1) an agent provides information which a learner needs to play a role; (2) an agent lets learners know the information needed for decision-making and encourages them to acquire information, and ensure information sharing; (3) an agent evaluates alternatives for decision-making by learners; (4) an agent proposes alternatives for decision-making [12].

This paper focuses on the first stage and discusses the results of analyzing the behavioral track record of each learner in a role-play exercise involving an agent, and the results of a questionnaire survey taken among students who participated in a role-play exercise. In section II, the expected advantages due to employing an agent in a role-play are described, along with a way of implementing such an agent. An experiment to assess and demonstrate the effectiveness of using an agent is described in section III. In section IV, we discuss the results of the experiment and future work, while section V provides a summary of our research.

This research is supported by "Open Research Center" Project for Private Universities: matching fund subsidy from MEXT (Ministry of Education, Culture, Sports, Science and Technology), 2007-2011

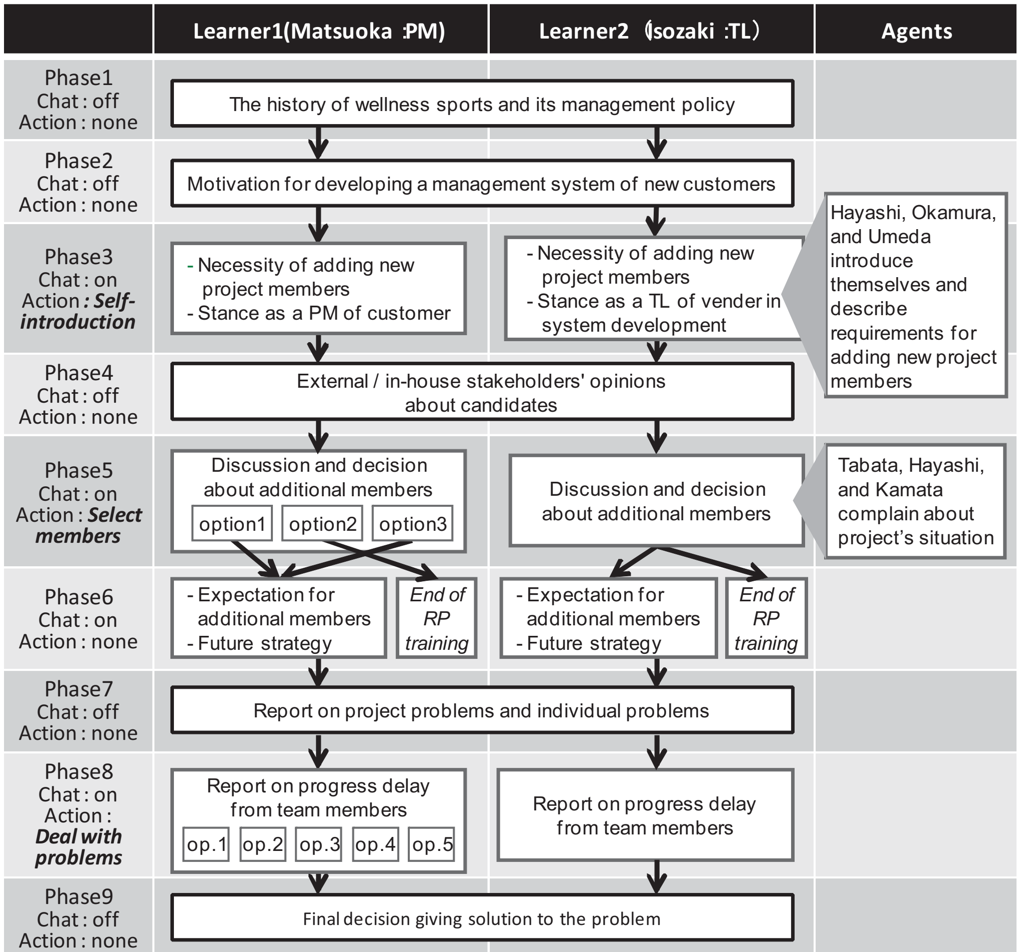

Figure 2. The structure of the team building scenario

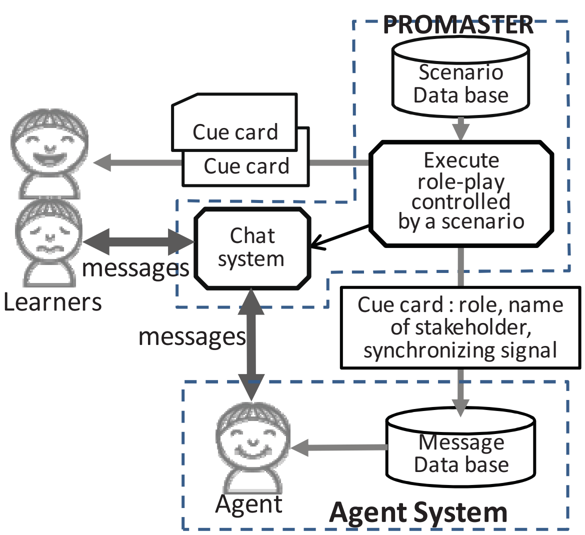

Figure 1. Role-play training environment with an agent

II. AN AGENT FOR ROLE-PLAY TRAINING

A. Role-play training environment with an agent system

Figure 1 shows the cooperation between the role-play training environment using PROMASTER and the agent system. PROMASTER provides information about a role which the agent will play and the contents of the next cue card, in accordance with the timing described in the role-play scenario for the agent. Two learners in the role-play have different priorities and exchange opinions through chat system in order to make a decision about the issue resolution in a virtual project with an agent who takes the place of one of the stakeholders, perhaps as an NPC and may be a mentor-agent advising. Two learners and the agent make effort to arrive at a win-win situation. Then the agent responds with appropriate opinions or comments to messages sent from PROMASTER to a chat system. The information retrieved from the message database in the agent system is displayed on the screen of a learner computer through a chat system.

B. A role-play training scenario using an agent

The role-play scenario used for practice with agents concerns building a team before starting a system development project. Two learners play the roles of the team leader of a system integration company and the project manager of a customer company, respectively. The task the two learners should practice is to select the appropriate members of the project in a situation where there is a conflict of interest between two stakeholders, the project manager of the customer company and the leader of the system integration company. The two learners exchange information provided by cue cards. The structure of the scenario is shown in Figure 2. In this scenario the agents take roles of other stakeholders and give different advice individually to the two learners.

The role-play exercise advances step by step with the actions of the two learners synchronized, and consists of nine steps. This scenario also has an undesirable path. If the project manager makes a decision which would result in a violation of information leak, the two learners are disqualified from further participation.

In each step the agent speaks first, before the two learners exchange opinions. The first talk by the agent in the role-play exercise seeks to make sure that the learners understand their roles and urges them to exchange the information needed to provide a solution.

The principles of designing a role-play scenario in which an agent appears are four in number, as follows.

(1) The agent must clearly present the same information to both learners through a chat session.

(2) The two learners exchange information provided by cue cards and the role-play exercise progresses.

(3) A chat medium should be used as a convenient way of exchanging information.

(4) The two learners analyze the information shared, exchange opinions, and make a decision on how to build the project team for system development. The attributes of an agent appearing in the role-ply scenario are shown in Table 1. These attributes are categorized into three types: Basic attribute of an agent; Factors influencing the agent's behavior; and Control information required by PROMASTER. If the agent takes the role of Project manager, it is acting alongside the learner.

TABLE I. Attribute Information for an Agent Appearing in a Role-play Scenario

	type	Attribute name	Content
1	Basic attributes of an agent	Name	Name of stakeholder: e.g. Mikami
2		Title	Occupation and title: e.g. Project manager and director
3		Affiliation	Name of the organization/department to which the stakeholder belongs: e.g. TUT/Planning department
4	Factors influencing the agent's behavior	Interest	Interest of a stakeholder
5		Sense of value	The most urgent and crucial thing for a stakeholder
6		Criterion for judgment	An important factor a stakeholder has to keep in mind when a decision is made
7		Character	Characteristics of a stakeholder: e.g. strong, strict, conscientious, bureaucratic
8	Control information required by PROMASTER	Action	The action expected by the agent
9		Timing	Time at which an agent should speak in a chat session
10		Phase number	Number of role-play step
11		Cue card number	Unique number of a cue card

TABLE II. ROLE-PLAY EXERCISE PARTICIPANTS AND ACTIVITY

Group No.	Learner No.	Role of a learner (Experience of role-play tarining)	No. of messages exchanged		Total no. of characters in messages		No. of times learners referred to cue cards	Duration of RP (mm:ss)
			sent	respond	sent	respond		
1	1	PM *1 (inexperienced)	6	1	427	16	10	40:24
	2	learder *2 (inexperienced)	5	2	241	23	0	
2	3	PM (experienced)	6	2	258	40	5	39:34
	4	learder (inexperienced)	6	5	309	66	6	
3	5	PM (experienced)	6	3	307	67	11	32:28
	6	learder (inexperienced)	3	3	186	56	13	
4	7	PM (experienced)	4	2	420	53	5	36:27
	8	learder (experienced)	4	2	480	58	1	
5	9*3	PM (experienced)	16	11	1116	215	26	103:49
	10	learder (inexperienced)	17	12	1880	137	11	

*1 PM, a Project Manager is working in the customer company, named Wellness Sports. The name of the PM is Matsuoka.
*2 A Leader is working in the vendor company. The name of the leader is Isozaki.
*3 This student had experienced the earlier version of the same role-play scenario without an agent.

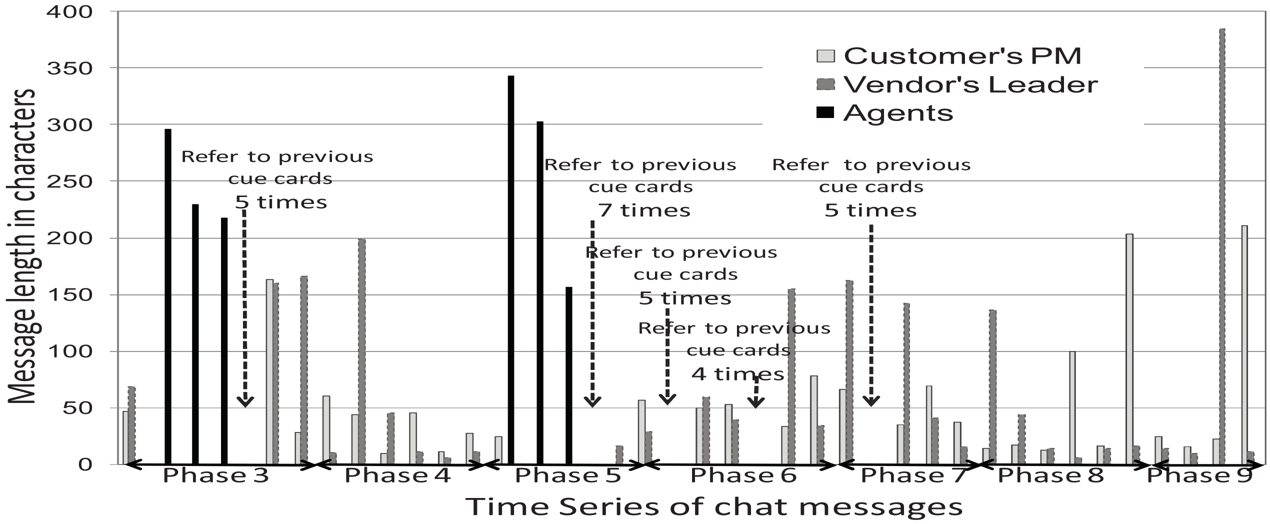

Figure 4 An example of the behavioral track record presenting the time series of chat messages of Group 5

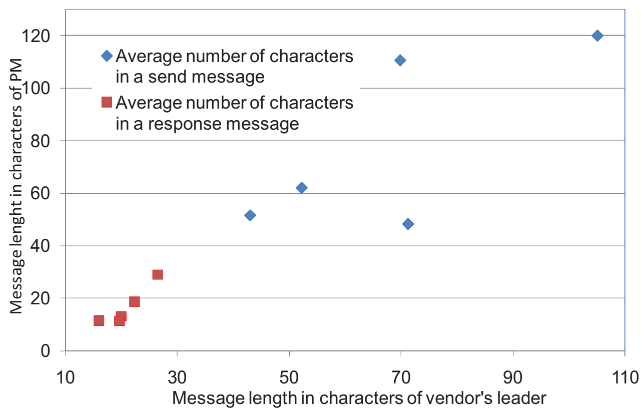

Figure 3 Relation between average length of messages (in characters) of the two participants for each group

III. EXPERIMENT USING A ROLE-PLAY EXERCISE

Ten students took part in the experiment. They were eight fourth-year undergraduate students, and a 1st-year and a 2nd-year master's degree students at the School of Computer Science, Tokyo University of Technology. Five students had previously experienced role-play exercises using PROMASTER on at least one previous occasion. Those previous exercises, which did not use an agent, had used different existing scenarios, except in the case of one of these five students, the first-year master's student, who had experienced the role-play exercise using the same scenario as we used in this experiment, although without an agent on the earlier occasion. The other five students had no prior experience of role-play training for project management education.

A. Experimental results

Table 2 shows the number of messages exchanged by each learner, the average message length in characters, the number of times previous cue cards were referred to, and the role-play execution time.

1) Role-play exercise execution time

Four groups, group 1, 2, 3, and 4 were able to finish the role-play exercise within the estimated time, which is about 60 minutes. However students in these four groups may not have exchanged enough information to make the best decision. In contrast, group 5 spent much more time on the role-play than the estimated period and exchanged five times as many messages as other groups did.

2) Number of messages exchanged

It is known that students in group 5 exchanged a large enough number of messages to practice the skill of team building because the chat log shows a change of the students' way of thinking about team member selection. Also, this group did not violate the law in handling of confidential information.

Figure 3 shows the relation between the average length of messages, measured as number of characters, which the two learners sent or responded to. One player sends more messages another player also sends more messages. The correlation coefficient of two lengths of message exchanged by the two learners is 0.92. If one player were an agent and exchanges many useful messages, other players who are students might be well trained.

3) Behavioral track records of each learner

Figure 4 presents the behavioral track record of students in group 5 from phase 3 to phase 9 in the role-play scenario. The students regularly referred to earlier cue cards after receiving many messages from agents in order to analyze the information delivered by the cue cards and gathered by chat. The agent's messages may motivate students to exchange information because Figure 3 indicates that one of players, even though the player was an agent, sent longer messages and this resulted in the other participant also sending longer messages.

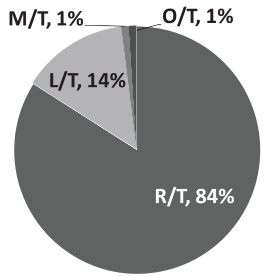

Figure 5 Message ratio of R, L, M, and O

4) Categories of messages exchanged

Chat messages were categorized into four types as follows: message as a role-player, R (Role-play); message about lesson or practice, L (Lesson); message about manipulation of role-play, M (Manipulation); other messages that do not fall in any of the above categories, O (Other) [5]. The total number of messages for all Groups, T, was 116.

The value of the message ratio R/T indicates how seriously a learner is immersed in the role of the stakeholder described in the scenario. The value of R/T is larger when a learner is more seriously immersed in the role described in the scenario. Similarly the value of (R/T plus L/T) is larger when new learners in the experiment were becoming familiar with the process; the value of R/T plus L/T was 98%, as shown in Figure 5.

B. Questionnaire survey

After the role-play students answered questions on whether they had been able to share the required information, to be conscious of their roles, and to visualize the work of project management through the role-play exercise.

1) Information-sharing

Figure 6 shows the results of the survey question about information-sharing during the role-play exercise, without an agent and with an agent, and the effectiveness of using an agent. 32 third grade students practicing the role-play without an agent answered this questionnaire and, of these, 66% felt positive about the feasibility of information-sharing while for the 10 participating students studying the role-play with an agent, 70% felt positive. Similarly, 31% of students who took part in role-play without an agent had negative feelings, but of the students participating with an agent only 20% felt negative.

In order to investigate the effectiveness of introducing agents into role-play training, we asked five learners who had experienced a role-play exercise on at least one previous occasion whether they were able to get the information required for the role-play exercise through chat, both with agent and without the agent. Two students felt that were able to obtain the information required for the role-play more effectively with the agent than without it. Another two students also recognized the advantages of adding an agent into the role-play training. Therefore we have deduced that the use of an agent may help learners share the information required to take part in a role-play exercise.

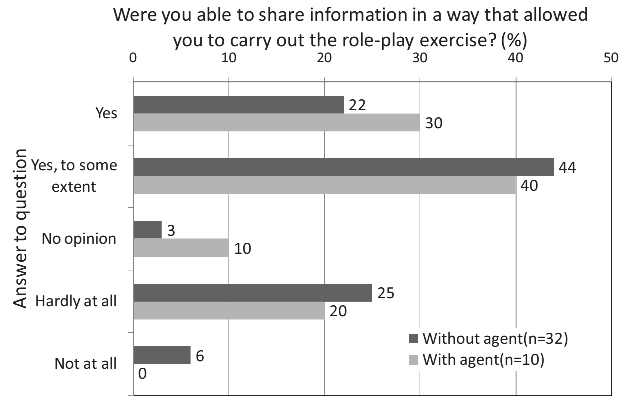

Figure 6 Information-sharing with agent / without agent

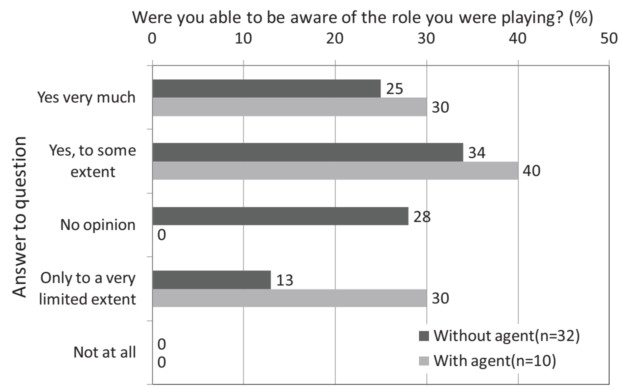

Figure 7 Awareness of role in role-play

2) Awareness of role in the role-play

Figure 7 shows the results of the survey question about the awareness of their role as a stakeholder, for students participating without an agent and those participating with an agent, to determine the effectiveness of using an agent.

Without an agent, 59% of students felt they had got into the character of a stakeholder, while for students participating with an agent, the Figure was 70%. This increase of 11% may arise from the powerful incentive of students doing the role-play exercise with an agent. Only two out of the five students said that the agent might encourage students to immerse themselves more fully in the role of a stakeholder. Some students answered an additional free response question about the effectiveness of using an agent. These answers were: they were able to get the feel of working in a real project because the information about the stakeholders whose roles were not assigned to learners was presented to students through the chat; and they were able to be immersed in a character and could understand what they should say in the chat session because a statement from the agent had provided a good example.

3) Ability to imagine a real project

Three students who had experienced previous role-play training were able to imagine a real project through participating in a role-play exercise with an agent taking the part of other stakeholders.

IV. DISCUSSION AND FUTURE WORK

A. Analysis of chat log data

From the data in Table 2, group 5 spent three times the length of time and exchanged three times the amount of information, compared with other groups, even though student 10 had no experience of role-play training.

The major reason for this significant difference is that the student 9 had experienced the earlier version of the role-play scenario, was seriously immersed in the role of the stakeholder, and so probably acted as a mentor to the others.

The two students in group 5 were both graduate students and so may have taken the role-play more seriously. If an agent were able to play the role of a mentor in the role-play, role-play training including such an agent might be a powerful tool for project management education.

According to the results of the questionnaire survey, the use of an agent may help information-sharing among learners, may help learners understand their roles as stakeholders, and may help learners imagine what it is like to participate in a real project.

B. Future work

We plan to pursue our research based on the principle of using an NPC (Non-Player Character) as follows: in the next stage, an agent will let learners know the information needed for decision-making and encourage them to acquire information, and ensure information sharing; in the following stage, an agent will evaluate alternatives for decision-making by learners; in the next stage, an agent will act as a mentor in proposing alternatives to learners making a decision; and finally an agent expressing human emotion will be provided in order to simulate practical team work in a system development project.

Scripting all of alternative scenarios which may be derived by a learner while a role-play exercise is running is typically labor-intensive. A method for automatically generating all alternative scenarios should be established. In order to generate the behavior scripts for not only a learner but also an agent, case based reasoning (CBR) may be applicable to create scenarios [11].

V. CONCLUSIONS

The aim of this research is to use an agent system to provide the function of a mentor in order to realize project management education for students who have no practical experience of project management; this will enable them to learn human-related skills such as communication, leadership, and team building.

This paper reports work which leads to the conclusion that agent can be useful in helping learners to share information, to understand their roles as stakeholders, and to visualize the job of project management. It would be very helpful to develop an agent system which can solve the problem of how to improve human-related skills. We will define an observable evaluation metric which can be used to evaluate the effectiveness of learning human-related skills by using the concept of NPC. We will also seek to implement human characteristics in an agent.

Abstract— **Management games allow students to obtain valuable first-hand experience that is of particular value in a field such as technology management, which usually involves substantial risk as well as significant time lags between a managerial decision and its effects. In drawing from more than fifteen years of experience with management games in higher education, we have developed a management simulation for teaching technology management, a field that is increasingly regarded an important area of study for engineering students. This paper outlines a blended-learning design for a course on technology management, describes the various didactical elements as well as their effects in class, and addresses the technical implementation of the management game as a service-oriented multi-tier application in Java.**

Keywords-experiential learning; management game; simulation; technology management

I. Introduction

Technological innovations are essential for the success and survival of firms in today's dynamic market place. It is therefore not surprising that managers devote large amounts of resources to research and the development of new technologies. At the same time, uncertainty regarding the success of technological endeavors is typically high. Given its strategic importance, the resources at stake, and the substantial risks involved, a systematic approach to the management of technology is considered indispensable by both the scientific community and practitioners.

Consequently, technology management has become a highly relevant area of study – not only in most business schools [1], but also in engineering management education, that deals extensively with technology management issues as means to bridge the gap between the fields of engineering and business (for examples in the US cf. [2]). This is also true for vertically-focused engineering curricula, which are however giving way to integrated programs encompassing multiple disciplines [3]. Accordingly, an increasing number of engineering programs integrate technology management in their curricula, thereby strengthening the trend towards broader scholastic experiences by offering engineering students an interdisciplinary perspective.

In practice, corresponding technology management courses more often than not are taught in a "traditional" lecture format that may be complemented by case analyses [4]. Management gaming (also commonly termed "management simulations", "management (flight) simulators" or "business gaming simulations"; for an overview on the history and a discussion of the differences in terminology cf. [5]) have been applied successfully in many areas of management education for more than 40 years [6-8]. However, they do not appear to be used prevalently in technology management education.

As means for experiential learning [9], management games allow participants to assume the role of decision-makers that compete against each other in a "safe" artificial environment. By shortening real-world decision cycles from years or decades to hours or minutes in the simulation, the learning process can be accelerated dramatically, which should help participants to gain a better understanding of the real-life situation the simulation game refers to. The main objective of using management games as tools to enhance learning is to give participants the opportunity to apply theoretical knowledge in close-to-reality situations in order to develop decision-making competence, rather than solely acquiring theoretical knowledge. In a well-designed and implemented simulation, this may lead to the synthesis of theory and practice [5]. Management simulations can thus be seen as an appropriate response to the criticisms against the "knowledge acquisition approach" (cf. [10]) in management education. They are especially useful in fields like technology management, where delays, the large amounts of resources at stake, and the high risk involved prohibit real-life experimentation.

The remainder of this paper is organized as follows: Section 2 delineates the conceptualization of the game and discusses thematic aspects covered in the simulation. Section 3 outlines how the management simulation is embedded in an overall didactic design. Section 4 provides details about the implementation as a service-oriented multi-tier application in Java. The paper concludes in Section 5 with a summary and an outlook on further research.

II. Conceptualization

In developing a management simulation for Master-level students, we could draw upon more than fifteen years of experience with management games in higher education, which allowed us to "cherry-pick" the most effective didactical means in order to tweak the learning outcomes. To account for the integral nature of decisions in the field of technology management, the simulation also comprises elements from other areas such as marketing, production, and finance, and may thus be considered a total management simulation. The main emphasis, however, is on the strategic planning of research and development (R&D) investment, the adoption of and migration to new technologies, and the management of patents and licensing. The simulation is generic in that it does not represent any specific industry, but can be tailored through parameterization using an instructor tool. The tool also allows for the creation of scenarios with varying degrees of complexity through optional features, such as stock-keeping, cooperative research or patents and licensing. Furthermore, the instructor may define all functions by setting control points and selecting linear, polynomial or cubic spline interpolation.

In each game, a single participant or a group of participants takes control of a virtual firm. At the beginning, all firms are homogeneous in that they possess the same amount of initial capital, the same amount of knowledge and an equal number as well as equal kinds of products and production facilities. Each game follows an iterative process in which participants are supplied with various reports on the performance of their firm that they may use to evaluate their strategy and possibly adapt it before submitting their decisions for the next period. As soon as all decisions for a period have been received, the results are processed automatically and financial statements and additional reports are generated before the game proceeds to the next round. This procedure is repeated until some terminating condition, such as a pre-determined time or a number of periods, is met or until the instructor ends the game manually.

Firms compete in a simulated market by developing and launching products. Before doing so, they need to conduct (basic) research to accumulate knowledge, which eventually leads to the "discovery" of advanced technologies. When such a new technology becomes available to a firm, it may be adopted and serve as a basis for subsequent product development. The resulting products are characterized by a number of attributes which are defined by the instructor, who may choose generic measures such as functionality, performance, usability, durability etc., or scenario-specific measures relevant in the simulated industry (e.g. engine performance, safety or handling in the automotive industry). Strategic decisions regarding resource allocation are a key element of the simulation. Participants need to weigh investments in research (which may lead to breakthroughs and performance leaps in the long run) against investments in the development of more sophisticated products based on current technology and/or against investments in process development (which reduces production costs). Once a technology becomes available, participants need to determine a plan for investing in the new technology and for phasing out existing technologies. Thus, participants may test various strategies, such as early adopter or fast follower strategies, and experience their respective advantages and drawbacks.

As soon as a satisfying performance increase has been achieved in a technology, firms may decide to launch new products at the market where they compete for market share with existing products that consumers are already familiar with. In our management game, we used an agent-based approach for simulating the diffusion of information about new technologies and products through the social network of consumers. To generate realistic diffusion patterns and simulate buying behavior observed in the real world, the instructor may divide the market into several heterogeneous segments with distinct characteristics regarding propensity to innovate, preferences, price sensitivity, brand loyalty, sensitivity to advertising, and communication behavior, which determines the diffusion of information about new technologies and products in the segment. Revenue generated from product sales is used to cover costs of production, stock-keeping, business intelligence and licensing, among others. Profits may be reinvested in research, development of the various performance dimensions of technologies, process development, construction of new production facilities, or advertising.

Once a game has ended, participants receive a final report that summarizes results and provides more detailed information that is not available during the game. Overall participant performance is measured by equity held at the end of the game as well as by the amount of technological progress achieved.

III. Didactic Design

In a management game, participants interact with/within a modeled system that represents a part of reality. These interactions follow a general course (see Fig. 1) where participants choose actions through decisions that are then entered – either directly (as in the online version) or via an instructor (as in the offline version) – into the simulation program. Based on these decisions and global conditions (such as market, inflation etc.) the system reacts according to the rules of the implemented model. Finally, feedback (e.g. on market development, sales etc.) is provided to the participants through various reports that, in turn, form the basis for further user action, thus restarting the loop.

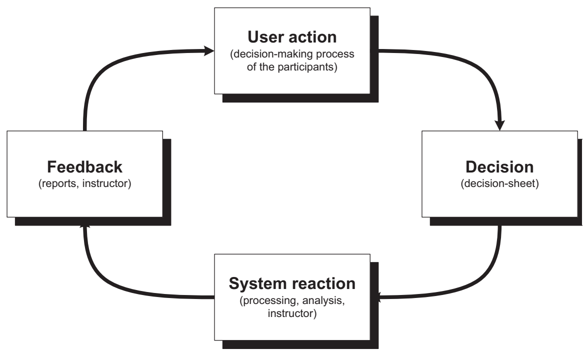

Fig. 1. General course of a management game.

Even though this general course, and therefore the management simulation itself, forms the center of the didactical frame, it has to be embedded into a broader (blended) learning concept to meet the learning objectives. To this end, the simulation game is not only played with various settings, levels of complexity and difficulty in both online and offline environments, but is also supplemented with accompanying measures and tasks. Furthermore, the management game can be embedded into a broader course design, as (engineering) students need to possess at least basic knowledge about technology management before engaging in the game. At the University of Vienna's Faculty of Computer Science, for example, the management simulation is integrated into a larger course that commences by imparting basic theory, provides students contact with business practitioners by means of excursions and invited talks, and also requires the preparation and discussion of case studies on technology management in class (see Fig. 2). Thus, participants are well prepared when they start to play the gaming simulation.

The didactic concept of the management game is illustrated in Fig. 3. Before the first game is started, participants are briefed on the overall setting as well as on technicalities concerning the decisions they need to make. However, no details about the inner workings of the game are revealed, since the participants should learn by doing. Next, a first (offline) introductory game is played in class, which bears

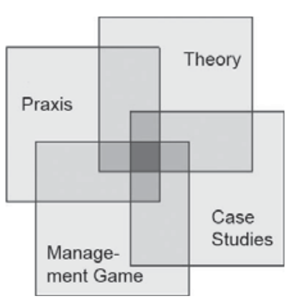

Fig. 2. Integration of the management game in a course design.

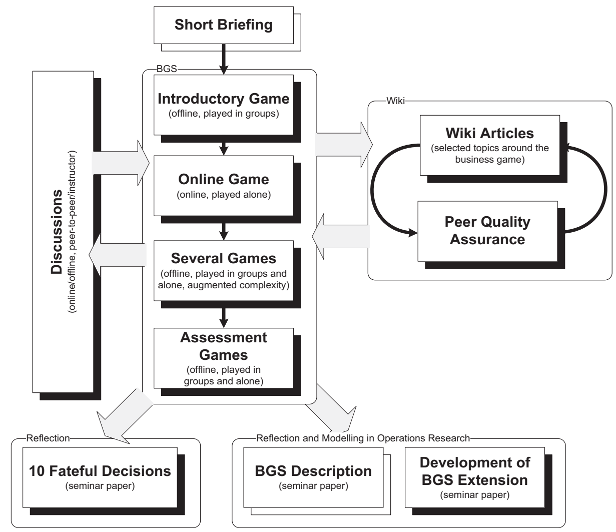

Fig. 3. Overview of the didactic concept of the management game.

several advantages. First, the instructor may directly react to questions without the typical time lag that occurs in an online setting. Second, the participants' decision-making process may be observed, which helps to spot problems or mistakes. Also the atmosphere within the group can be monitored more easily in a classroom setting, which helps to prevent frustration as a consequence of unexpected results. Even though direct assistance might be one possibility, following the learning-by-doing approach the instructor should concentrate on the stimulation and moderation of the discussion between participants. Moreover, students can, should and do help each other when performing tasks like calculating a "good" price, analyzing data, drawing graphs etc. To encourage peer-to-peer interaction during the first game, each firm is managed by two students at the beginning. As the participants should focus on the technology management aspects instead of the intricacies of a web-interface, the decisions are submitted on simple paper forms at this stage. The instructor enters the data manually and delivers the results on paper, which provides the opportunity to directly give (additional) feedback. However, these advantages of the offline version come at the cost of an increased workload so that generally more than one instructor is needed at this stage to process the data. Finally it should be noted that the complexity of the simulation is reduced during the introductory game by disabling optional aspects such as patents or licensing.

Once the initial game has ended, the web user interface is explained thoroughly to the participants in order to avoid difficulties during the subsequent online phase. During this phase, the game is played online over a time period of six weeks with two decision rounds per week. As opposed to games played in a classroom setting, participants can analyze their strategies and prepare their decisions without any time pressure. Also, in contrast to the first game, each student is fully responsible for managing their own firm in order to prevent free-rider problems. Nevertheless, both peer-to-peer and student-to-instructor communication is crucial and thus encouraged also in the online phase by providing proper channels like web forums. Experience shows that these communication channels are primarily used for questions to the instructor, while peer-to-peer interaction hardly takes place online. However, anecdotal evidence suggests that informal information exchange between students does occur offline (e.g. in the cafeteria), but is limited to selected colleagues, which indicates that students apparently regard information asymmetry as a key strategic advantage that they try to sustain. Note that the discussion forum is currently not part of the management game itself. Instead, the communication features of a learning management system (LMS) are used, which constitutes a "media disruption".

During the online phase, participants are required to prepare papers on selected topics related to the management game in order to complement the learning-by-doing approach with more theoretical reflections. The articles are co-authored in groups using a Wiki, which is integrated in the LMS. According to our experience, collaborative online writing appears to be a new concept for most of our students, which is why a basic introduction on the use of Wikis is (still) crucial. This task allows participants not only to gain experience with a new form of collaboration, but also enables them to share with other students what they have learned about the theoretical concepts embodied in the management game. This knowledge is essential for meeting the learning objectives of the course, which obviously go beyond winning the management game. A problem we frequently encountered was that students hardly ever read the articles of other participants, which may partly be attributed to the low quality of some contributions. To alleviate this problem, we decided to introduce peer quality assurance mechanisms. Upon completion of the initial Wiki writing process, every group is appointed to be responsible for an article of another group, in order to (i) improve it and (ii) write a summary. Log files show that students do not only read the article they are asked to improve, but also most other articles, possibly for comparison and inspiration purposes. A potential problem with this approach is that we frequently observe strong reservations against editing the work of others. Also, the imbalance of the workload poses a problem since some articles require more improvement than others.

The online-phase is followed by a final phase of attendance for two and a half days in class where additional games are played at a higher level of complexity. Whenever new aspects such as stock-keeping or licensing are introduced in a game, participants form teams of two students each managing a single firm to allow for reflection on and discussion of the new challenges. We also observed that information exchange typically does not only occur within each group during these games, but also between groups and thus among competitors. However, this willingness to cooperate tends to decrease as the ambition to win the game rises at a later stage. This holds true particularly for the final assessment games, where students can earn points that contribute (at a low percentage) to their grades. By including the gaming results into the grading scheme, we provide incentives that appear to be efficient in that they considerably enhance the involvement of students.

Reflection on actions and decisions plays a vital role in all management games. In addition to regular feedback during the game and in the discussions, participants therefore are required to individually reflect on their decisions and the whole management simulation at the end of the course by writing three seminar papers. In the first one, students report on their "ten most fatal" decisions and their consequences. Besides describing the circumstances and the mistake they made (e.g. failure to properly take inflation into account when determining prices), participants should also discuss possible strategies to avoid the respective problem. In order to foster understanding of the underlying model, students are required to produce a second seminar paper that describes basic elements of the management simulation and their interrelationships, both conceptually and formally. This serves as a starting point for team discussions about suggestions for extensions and improvements of the game, which result in a third seminar paper. Upon elaboration of this final paper, students concern themselves with methods of quantitative modeling. For most students, this phase serves as a "gentle" introduction to model building and simulation, which may be considered an additional benefit.

IV. Technical Implementation

A computer-based simulation that can be used in the didactic design outlined in the previous section has to meet a number of key requirements. To begin with, the application has to support multiple usage modes in order to allow for various educational settings. For instance, during the first phase of the didactic process outlined in the previous section, which takes place in a classroom, the game is run locally on a single computer; the second phase is Internet-mediated, which implies that an intuitive user interface is required to allow participants to submit decisions and analyze results easily; the third phase is again conducted in a classroom setting where each participant uses a dedicated computer connected to a local area network. Moreover, participants cannot be expected to install additional software on their computers. They should rather be able to use any standard-compliant web browser on any platform to submit their decisions and access reports. Further to this, the application core itself should be platform-independent, as it is used both locally on Windows-based computers and on dedicated application servers running

Linux. Moreover, it was decided that the implementation should rely on freely available software. Major design objectives were stability, resistance to manipulation, and extensibility of the system.

Next, a number of major functional requirements were identified. First, the application must provide an intuitive web-based user interface. Participants should be able to focus their attention entirely on the simulation rather than being distracted by usability issues. Second, the application should provide the instructor with extensive capabilities for model building in order to give her the freedom to create arbitrary scenarios. To facilitate the complex parameterization process, the system needs to provide appropriate mechanisms such as the ability to define smooth functions interactively in a graphical way. Third, it should be possible to tailor the simulation to the needs of both novice and experienced participants by limiting or extending the decision space during parameterization. Finally, the system must give ample and easily understandable feedback to provide a solid base for decisions and facilitate an effective learning process. Considering all functional and non-functional requirements, we chose Java Enterprise Edition [11] as an implementation platform and developed a distributed application consisting of four major components, as illustrated in Fig. 4.

The central component that manages user accounts and game instances and executes the simulation model is hosted on an application server. It provides a web-based interface for participants as well as remote services for an instructor client, which is used for the creation and parameterization of game instances, user account administration, assignment of participants to games, and entering decisions for participants in the second phase of the didactic process. The application server connects to a database server providing persistence.

Applying the concept of multi-tier architectures, graphical user interface, business logic, and persistence layers are strictly decoupled and the resulting services are connected through interfaces. This clear separation has significant benefits in terms of maintainability and extensibility, as it results in a modular system of independent components that can be exchanged or modified easily without affecting other parts of the system. Another key advantage of this approach is that it is relatively easy to connect multiple independent presentation layer components, such as a web interface for participants and an application client used by instructors. Finally, and possibly most importantly, a multi-tier approach is a good way to support the parameterization of management simulations for multiple educational settings, where for example the number of players, the scenario to use and the underlying simulation model may differ each time (cf. [12]).

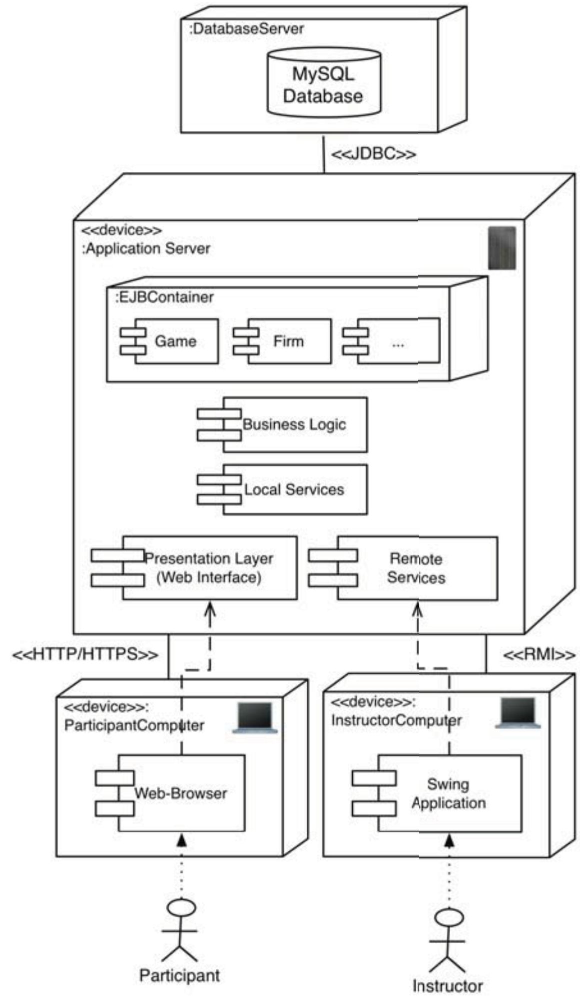

Fig. 4. Deployment diagram.

The individual components depicted in Fig. 4 can be distributed across several computers or run on a single machine. The core of the system is deployed on a JBoss J2EE application server, which is purely Java-based and can thus be run on a large number of operating systems. Container-managed persistence, a technique where the object-relational mapping is handled by the J2EE container the application runs in, is used to preserve the state of objects to a MySQL database. The web-interface relies on Java Server Faces, JSP, and Java Portlets. The instructor client is implemented in Java Swing and connects to the application server via remote method invocation (RMI). It provides a rich user interface, does not require installation, and is platform-independent. For an illustrative example of its use, see Fig. 5.

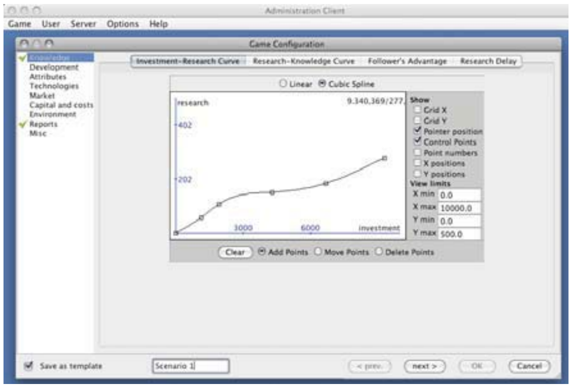

Fig. 5. Scenario creation using the instructor tool.

V. Conclusion

The management game introduced in this paper complements more "traditional" instructional methods commonly used in technology management education in a blended-learning course design and provides an excellent opportunity for students to gain relevant first-hand experience through learning-by-doing. The service-oriented architecture of the application facilitates its use in various educational settings and its adaptation to the specific needs of participants. Learning success, however, is not solely determined by the quality of the underlying simulation model or its technical realization. These factors must rather be considered necessary conditions. When it comes to achieving learning outcomes, the integration in a broader didactic design plays a key role for success. For this reason we suggest combining the game-based learning approach of the management simulation with various additional elements into a didactic design that encompasses (i) continuous peer-to-peer knowledge exchange, both on- and offline, (ii) teamwork and team play, (iii) written ex-post reflection on decisions and discovered relationships, (iv) suggestion of extensions to the simulation in a seminar paper, which encourages participants to gain a deeper understanding of the underlying model and may serve as an introduction to mathematical modeling and (v) theoretical considerations regarding various topics related to the simulation, which are prepared by participants in the form of Wiki articles. In order to assure quality of the contributions and encourage the dissemination of information among participants, these articles are subject to obligatory peer review.

Still, our management game may be complemented in several directions. First, the integration of online communication directly into the management game would eliminate the media gap caused by the use of various external communication channels and, thus, help to alleviate the lack of rich communication and information exchange during the online game. Learning blogs could be used to allow the participants to record and analyze their thoughts, strategies and decision-making processes during the game. Next, additional game options like multiple (international) markets or cross-licensing of patent portfolios with balancing royalty payments and/or the introduction of computer-controlled rivaling firms would allow for new possibilities.

Abstract— **Three studies, conducted on graduate level, show findings that students with highly proactive behavior are more likely to succeed in a Learning Management System (LMS) environment. Statistical analysis techniques were used in the studies. In the second study the concept of continuous proactivity was introduced to observe if a study-group was more likely to succeed in the lesson compared to a control-group, and in the third study, proactivity was applied to the entire class. This paper reports the results of the second and third studies and introduces the concept of "continuous proactive learning strategies" to frame the future development of proactive rules in LMS.**

Keywords: Proactive Learning, Learning Management System, Learning Techniques, Learning Methods

I. INTRODUCTION

E-Learning environments, or Learning Management Systems (LMS) are a set of methods, tools and techniques to deliver learning content through the Internet or similar networks. LMS are suitable systems to support distance learning and blended learning – used in conjunction with face-to-face teaching. Over the past ten years LMS has been adopted by educational institutions, becoming almost omnipresent in many parts of the world. These systems have been designed adapting existing interactive web based technologies – relating to a program that responds to user activity – to deliver educational content.

Although there are already a large number of functions, covering a large number of users' needs for a variety of different users acting specific roles in these LMS environments, current LMS are fundamentally limited tools. They are only reactive software, content management based, and developed like classical user-action oriented software. These tools wait for an instruction, most commonly given through a graphical user interface, and then react to the user's request, limiting the value of the LMS to the user's own action and not to the needs of the learning process.

Learning is a continuous, step-by-step effort that requires conscious undertakes in order to achieve predefined learning goals. This continuous effort is orchestrated by pedagogic approaches where step-by-step strategies for instruction are defined. Different pedagogical theories exist: constructivism, resource based learning, collaborative learning, problem based learning, narrative based teaching, situated learning, etc. One of the common denominators of these pedagogical theories is the need of a continuous effort.

Proactive systems, as defined by Tennenhouse [3] adhere to two premises: working on behalf of, or pro, the user, and acting on their own initiative, without the user's explicit command. Proactive behaviors are intended to cause changes, rather than just react to changes. This is a major change from interactive computing, in which we lock a system into operating at exactly the same frequency as humans do. Proactivity is a means of continuous effort and student's continuous LMS interaction (engagement) is an approach to proactivity. Proactive Learning Management Systems (PLMS) is a new kind of LMS, designed to improve the users' online interactions by providing programmable, automatic and continuous analyses of users (inter-) actions, augmented with appropriate actions initiated by the LMS itself.

This paper reports statistical analysis observations on three studies in Proactive LMS. The first study develops a simple proactivity test-case study to answer the research question: "Are students with high proactive behavior more likely to succeed in a LMS environment?". This study was developed in a blended learning environment for a second year bachelor class during the winter semester of 2006-2007. The second study, developed during the winter semester of 2007-2008, was designed in order to observe: "Are students with continuous

LMS proactivity more likely to succeed in a lesson?". This study utilizes a study-group and a control-group to statistically evaluate if the study-group is more likely to succeed in the lesson. Proactivity was continuously triggered to provoke students' participation and interaction via LMS. The third study, conducted during the winter semester of 2008-2009, generalized the application of the ***continuous proactivity*** to an entire class in order to observe: "does continuous proactive rule have a direct positive impact in student's results?". Thus, ***continuous proactivity*** will increase the probability of student's success in a lesson. Furthermore, this paper introduces the concept of "continuous proactive learning strategies" to frame the future development of proactive rule in LMS.

II. Observations on the First Study: Simple Proactive Study

A Simple Proactive Study [2] was implemented in a blended learning environment for a second year bachelor class during the winter semester of 2006-2007. The class itself follows the normal academic program, with the LMS as a supporting tool of the learning process.

Different activities were programmed for the students to balance the learning, and more precisely, to provoke continuous step-by-step effort in order to answer the research question: "Are students with high proactive behavior more likely to succeed in a LMS environment?". Two types of reactive activities, forums and homework were available on the LMS for the students to participate and all the students' interactions were recorded. A proactivity rule was triggered two times during the semester, one early in the semester and one in the middle. The rule was based on the students' total participation in the class activities and the rule sent an email notification to those students who had not enough participation encouraging them to participate.

Statistical analysis on this study shows a 82% correlation level between the forum and homework activities and the exam results, and a 73% correlation level for online content access of the students for whom proactivity was triggered (see table I). These first results also show by 28% and 33% respectively, that proactively triggered students were more successful than those who were not.

TABLE I. Proactively Triggered Student's Correlation Analysis

Correlation	Proactive	Entire Class
Activities vs. Final Grade	0.824	0.541
→Forum Participation vs. Final Grade	0.506	0.403
→Homework vs. Final Grade	0.742	0.665
# Online Connects vs. Final Grade	0.729	0.405

III. Observations on the Second Study: Continuous Proactivity Control Study

In the first study we observed a 82% correlation between students' LMS participation, and the final results for students were proactivity was applied compared to a 54% without proactivity. A second scenario – case study – was developed to answer the research question: "Are students with continuous LMS proactivity more likely to succeed in a lesson?".

This second study focuses on continuity as means of increasing LMS user engagement, enabling the continuous step-by-step effort required to achieve learning goals. A proactivity rule was triggered six times during the semester only to the study-group, and aimed to encourage the student's participation on online Forums. The rule was event-time based, and an email was sent to all the students in the study-group on a regular basis.

The rule is defined as:

rule description: On dates D1, D2... D6 advise the study-group about the status of the online forum by email to increase their online engagement.

data acquisition:
cc = get_course(C)
sg = get_group(
tt [...]= get_dates(D1...D6)

activation guards:
date = ***tt[...]***

conditions:
es.get_all_users(study_group(cc))

actions:
sendLMSeMail(to = es.name, subject = "*Forum Info Update*", data = "*Please be informed that the forum "WBS Level Two" has been closed and graded. The forum "WBS and Mindmaps" will be closed on 16/11. These activities represent 30% of the course evaluation.*")

The LMS recorded 12,202 student interaction events for 22 students (12 in the study group and 10 in the control group). The Figure 1 shows the integration of the students' LMS daily access and the class activities over the time. In this figure it is visible that particular events drive students to access the LMS, notably the day before a class and the day of a class connections were doubled.

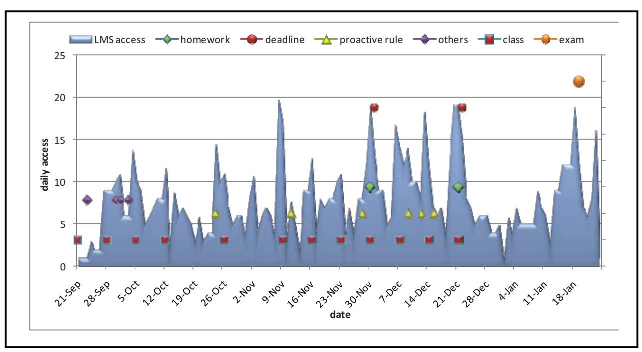

Figure 1. Interactions on the LMS

This is a logical confirmation on how the students take advantage of the LMS as source of information and knowledge.

However this is also a confirmation that students were only driven by a particular event, stimulus, in this case update their knowledge just before the class. This shows the general class trend of using the LMS intermittently and the question is: are both, study and control groups, intermittently accessing it or is there a different trend?

The study-group received six proactive rules via email notifications to create awareness of the status and availability of forum activities. Figure 2 shows the access distribution between trigger day -1 and day +3. Total traffic increased between 25% and 30% on the triggered date and up to two days after the event. This result shows that the stimulus lasts a maximum 3 days, similar to the class event where the stimulus also lasts 3 days (day -1 to day +1). The combination of these events increased continuity or student engagement in the class lessons.

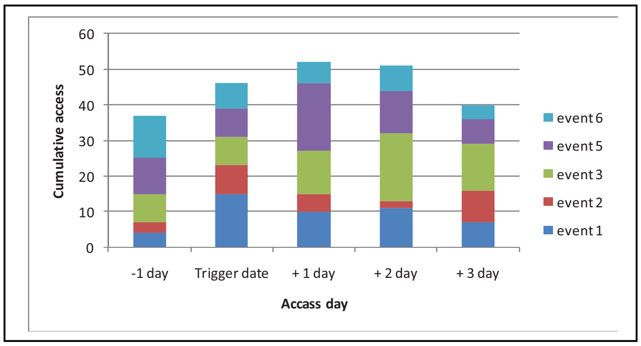

Figure 2. Study-group and control-group interactions on the LMS

To answer the research question if "students with continuous LMS proactivity are more likely to succeed in a lesson", the class assessment results were analyzed and the comparative showed 20% more success in the study-group than in the control-group. In this particular scenario the strategy was LMS engagement in order to increase the success rate. The study-group's participation in the online forums was 12% greater than that of the control-group, and assessment results were also 5% higher on the study-group compared to the control-group. Figure 3 shows the daily LMS access and events for the study-group and control-group.

Further analysis was developed to study the relation between the online forums subjects and assessment on those subjects during a final exam. Seven questions in the final exam were drawn in relation to the 13 online forums, and correlation analysis show a 7.8% direct improvement on the study-group as a result of proactivity. In summary, observations on this case show that the study-group, on which proavtivity as a mean of continuous engagement was applied, is more likely to succeed in comparison to the control-group.

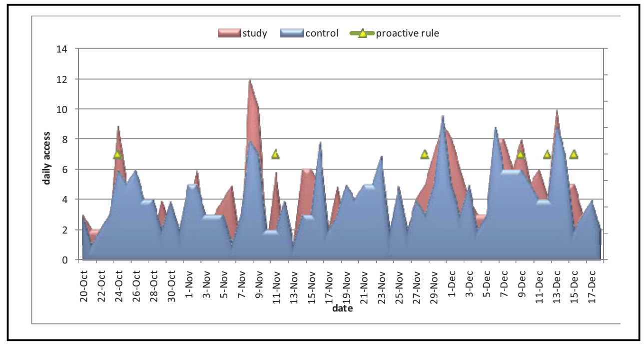

Figure 3. Study-group and control-group interactions on the LMS

IV. OBSERVATIONS ON THE THIRD STUDY: GENERALIZED CONTINUOUS PROACTIVITY STUDY

A third study, conducted during the winter semester of 2008-2009, generalized the application of the continuous proactivity to an entire class in order to observe: "does continuous proactive rule have a direct positive impact in student's results?". Consequently, continuous proactivity will increase the probability of student's success in a lesson. This third study elaborates on the observations of the second study, where a combination of events increased continuity or student engagement in the class lessons.

In this study a proactive rule, based on events, was triggered 8 times during the semester to encourage all students participation in online Forums.

The rule is defined as:

rule description: On event *New Forum* F1, F2…F8 advised students about new online forum by email to increase their online engagement.

data acquisition:
cc = get_course(C)
ee [...]= get_event(F1...F8)

activation guards:
event = ***ee[...]***

conditions:
es.get_all_users(cc)

actions:
sendLMSeMail(to = es.name, subject = "*New Forum*",
data = "*A new topic "XYZ.." has been added to your Project Management class Forum*")

The LMS recorded 5,466 student interaction events for 13 students. Figure 4 shows the access distribution between trigger day -1 and day +3 of the proactive rule. Total traffic increased 11% on trigger day and up to three days after the event, this could be seen as a decrease compared to the previous study. However, this is not the case because these events where triggered approximately +2 days after the class session to increase engagement (continuous effort) and traffic during class window increased 13%. This shows an overall 12% increase during the combined events, proactive plus scheduled class session, with a stimulation effect lasting more than 4 days in some cases.

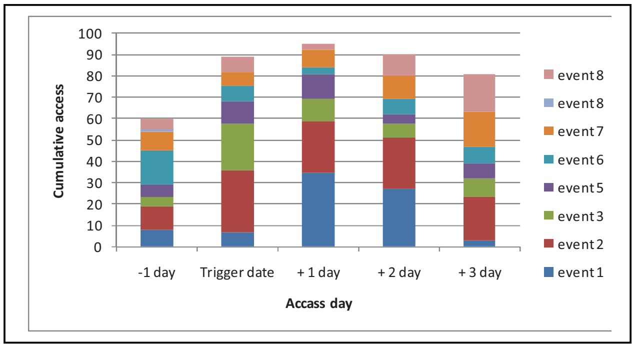

Figure 4. Third study interactions on the LMS

The Figure 5 shows the integration of the students' LMS daily access and the class activities over the time, showing a similar trend to previous studies where LMS access around an event increased.

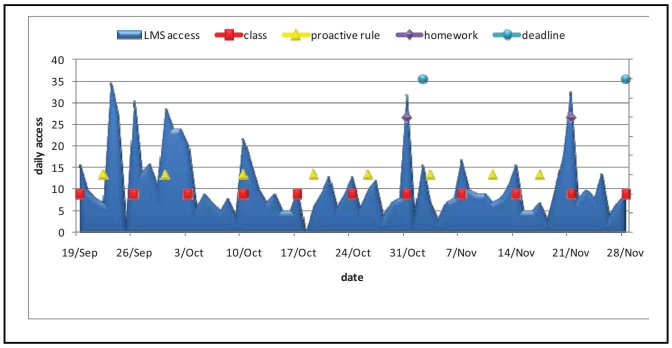

Figure 5. Third study interactions on the LMS

In this study, statistical analysis was carried out on the relation between grade results and the student's activity in the online Forums as a result of the proactive rule. Analysis on the Forums participation was done based on type of action performed by them. Three types of actions where registered; (a) create a new entry in a forum, (b) read an entry and (c) respond to an entry.

TABLE II. Correlation analysis between forum online actions and activies, exam and final grade

	Forum Online Actions		
	new	responses	read
Activities	0.50	0.32	0.60
Exam	0.54	0.41	0.56
Grade	0.61	0.42	0.68

Table II summarizes the correlation analysis. Analysis shows a 68% correlation level between students's reading the online forums and final grade, compared to 61% by new entries and 42% for responding to other students entries. This results shows that there is a direct relation between continuous proactive triggering and students success, 68% for this population. Notably reading forum entries has a 28% higher relation in the final results compared to responding to a forum entry.

V. Future work: Continuous Proactive Learning Strategies

The results of these studies cannot be considered as general conclusions, even if all three studies show a positive relation between proactivity actions and student's success. In order to further research the benefits of these observations, the creation and validation of proactive rules will be required which implies the definition of learning strategies oriented to stimulate the "continuous step-by-step effort" required in the learning process. These strategies are called Continuous Proactive Learning Strategies (CPLS).

The creation of proactive learning strategies requires the understanding of the factors involved in the learning process. Bransford [1] indentified 4 main factors in the learning process: attention, motivation, emotions, and experiences of the learner (progression).

- Focus of attention determines if a student mentally follows a class and, therefore, the degree of behavioral change. LMS requires a strategy for getting and keeping the student's attention on the learning content and activities presented.

Attention *is the cognitive process of selectively concentrating on one aspect of the environment while ignoring other things*

- Motivational states of students are of importance for stimuli given by the teacher or LMS to trigger the learning process. The willingness to learn results from different motives beginning with the intention to achieve something, competing against colleagues, helping other people, or emotional factors like anxiety. Motivational aspects for LMS may also depend on learning content, pointing out the relevance of an instruction or including interactive media elements such as online discussions, debates, games and simulations.

Motivation *is the internal condition that activates behavior and gives it direction; and energizes and directs goal-oriented behavior.*

- The emotion is an unconscious system to alert us on potential opportunities or risk, it triggers positive or negative motivation and attention responses. Triggering the student's emotional channel could improve the learning process and could be achieved in a LMS through storytelling, empathy, provocations, animations, and group works, enabling participation in the learning context.

*An **emotion** is a mental and physiological state associated with a wide variety of feelings, thoughts, and behavior*

- Knowledge transfer can be improved if students relate prior knowledge, either in the same domain or in a similar context. LMS learning strategies need to detect lack of knowledge at an early stage and more importantly, lack of progression during a learning cycle.

***Progression,** a learning principle which states that the benefits accrued from learning will continue only if knowledge is gradually learned.*

The proactive strategies need to create an adequate environment to activate these 4 main learning factors and enhance the continuous step-by-step effort. Strategies can be divided into two types: pattern recognition and event based.

- Event based strategies monitor the currents of events such as time and status of an action, and focus on increasing student LMS engagement. These strategies main objective is to enable attention, motivation and emotion.
- Pattern recognition strategies are continuous assessment of the student's LMS performance to determine the student's learning trend. These strategies main objective is to enable progression

The proactive strategies are to be activated via rules to evaluate the time/status events and patterns. The activation of a rule will generate a synchronous or asynchronous interaction back to the students. The asynchronous interaction could be achieved by the use of standard email or SMS based notification, however this mode of communication does not guarantee the reception and processing of the notification. Asynchronous interaction is still a valid mode of proactivity and the three studies have shown positive results when used in combination with a reward system. Synchronous communication modes achieve greater levels of engagement. This category groups technologies such as instant messaging, chat rooms, microblogging, traditional class and tutoring sessions, which could be used as a result of a proactive rule.

Future work will define and experiment event and pattern strategies to validate their impact in the learning outcome. The proactive strategies need to be combined with the mode of communication to cover the 4 learning factors. Different modes of communication have different levels of impact in the learning factors, e.g. emotion could be achieved in a tutor one-to-one session, but it would be very difficult to achieve it via email notification, nor to measure it automatically. Another example is the use of instant messages or microblogging to engage students in learning based reward activity, such as solving a particular problem and receiving points for it. The table III summarizes the expected impact, to be studied, for different mode of communication and the learning factors, "+++" meaning higher positive impact to "+" for lower level of positive impact.

TABLE III. Impact of communication modes

	Attention	Motivation	Emotion	Progression
email		++		+++
SMS		+	+	++
instant messaging	+	+++	++	++
chat	+		++	+
micro-blogging	+	+++		+
class session	+++	++	++	
tutoring	+++	+++	+++	

VI. Conclusions

This paper reports the statistical findings of two new studies on proactive LMS, oriented to stimulate the continuous step-by-step effort required in learning. On one study (second study) the question: "Are students with continuous LMS proactivity more likely to succeed in a lesson?" was answered with the observation that the study-group performs 20% better than the control-group. The third study answered the question: "does continuous proactive rule have a direct positive impact in student's results?", Showing that active online participation in class forums is linked (68%) with the student's grade results. The result of these studies cannot be considered as general conclusions, even if all three studies show a positive relation between proactivity actions and student's success, because the subject matter and populations were limited, a total of 75 students in three different calendar semesters have been observed.

The paper also describes the future work required to exploit the observation of this studies with the creation and validation of Continuous Proactive Learning Strategies.

Abstract— **In this paper we present an approach to increase the interest of pupils and high school students in modern science and technology. To achieve this, we developed a versatile experimentation platform for the use in schools and school projects, called VenDASys (*Versatile Control and Data Acquisition System*). VenDASys allows the interfacing of individual (micro-)sensors or complete experimental set ups while minimizing the required electronics, which are often frustrating for students and teachers alike due to limited experience in this field. Thus, students (and teachers) can directly concentrate on and successfully deal with different sensors and experiments based on these sensors. We present the concept with an example project on blood pressure monitoring. Getting involved in comprehensible MEMS (*Micro Electro Mechanical Systems*)–applications and solvable problems at a relatively early stage of their education will definitely increase the chances that high school students decide to choose a technical education later on.**

Keywords- open experimentation platform; micro-sensors

I. Introduction and Motivation

In the last years the gap between the need and the availability of qualified personnel has been increasing in many technical and scientific fields. One direct consequence is the current drastic shortage of engineers. This problematic situation has been addressed in many activities around the world in didactics and education in different ways, e.g. [1, 2]. The MEMS industry in Germany already regards this issue as a major challenge for future economic success. For this reason, in 2002, the German Federal Ministry for Research and Education (BMBF, *Bundesministerium für Bildung und Forschung*) initiated the foundation of six networks focusing on MEMS education and training [3]. One of the major goals of these networks, and especially for the network "pro-mst" [4], was to counteract this trend by increasing the interest of high school students in natural sciences and engineering.

Our learning lab SinnTec (*Sinn für Technik – Technische Sinnesorgane*) was founded as result of our experiences within the network "pro-mst". SinnTec addresses both high school students and teachers to gain hands-on experience. One of the major topics of this lab is to show where MEMS technology is used today, e.g. in a car. Secondly, students should actively work with microsensors as technical senses to gain a deeper understanding. From these activities [5] we learned that difficulties in working with sensors do not primarily arise from the basic understanding of sensor function principles or MEMS production processes but from the electronics required for sensor read out and its useful application.

Based on this experience, we developed a universal and modular experimentation platform for use in schools and school projects with an open source concept allowing exchange of experiments between schools, teachers and students [6]. The VenDASys platform offers a very comfortable and straightforward opportunity to deal with sensors by simply "bypassing" most of the electronics from a didactical point of view. Thus students and teachers in a simple way gain access to the field of MEMS in particular and science and technology in general by realizing their own ideas for experiments.

II. Technical Concept

The VenDASys consists of three main parts (Fig. 1): (a) a hardware platform providing basic functionalities like power supplies, measurement inputs and digital IOs plus dedicated sensor interfaces, (b) a multi-purpose software tool with graphical user interface (GUI) implemented in LabVIEW, NI, and (c) dedicated sensor modules for different applications. The hardware platform is connected to a PC via an USB interface; individual sensors are connected to the platform via standard lab-cables, especially during the development phase. When application specific sensor modules have been realized, they can quickly be connected via dedicated Sub-D25-interfaces with power supply, analog and digital in- and output as well as data exchange. The LabVIEW-GUI gives the user full access to a variety of hardware functions (mainly analog and digital in- and outputs) without having to address the hardware set up in detail. A more detailed description is given below.

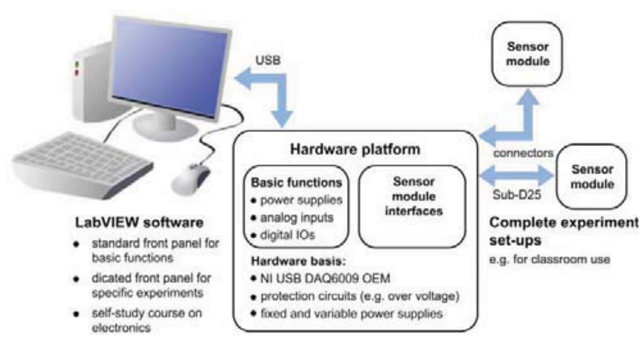

Figure 1. System overview VenDASys

This work is supported in part by the Saarland Ministry of Economics and Science. We would like to thank for the financial support.

A. Hardware platform

The electronic hardware of the system consists of several modules, with the core of the VenDASys being an USB DAQ 6009 OEM module, a commercial data acquisition system manufactured by NI. To prevent damaging the module during the course of development work by inexperienced high school students, we added additional protection circuits, i.e. against overvoltage, short circuiting or polarity reversal. The main task of the DAQ module is the acquisition of analog and digital inputs from sensors, switches etc. Furthermore, the DAQ controls the digital outputs of the system which can be used for control purposes as well as variable voltage and current sources which can again be used for control purposes or to supply external circuits. Further modules of the VenDASys are constant voltage sources (for supplying external electrical circuits), relay circuits (for switching periphery requiring higher power) and finally a separately oscilloscope with an integrated signal generator. Table I gives an overview of the integrated hardware functionalities.

TABLE I. OVERVIEW OF VENDASYS HARDWARE FEATURES

Features	Detailed properties
5 power supplies	• constant voltage source +5V/+1A • constant voltage source +11V/+1A • constant voltage source -11V/-1A • 2 variable voltage sources ±11V or 2 variable current sources [0-100] µA, [0.2-1] A
8 analog inputs	• ±10 V range, 14 bit resolution • 8 channels for absolute voltage measurement or 4 channels differential voltage measurement • overvoltage protection
oscilloscope	• 250 kHz, 2 MSamples/s • 2 channels • integrated signal generator
12 digital in- outputs	• TTL level • high impedance input • over voltage protection
2 relay circuits	• maximum voltage 250VAC/60VDC • maximum current 15A
2 sensor module interfaces	• 25-pin sub-D interface mapping all front-panel functions

By connecting sensors and other elements to the hardware platform, the need for separate power supplies, instruments etc. is obviated. The VenDASys platform therefore performs all the functions of a small electronics laboratory. For the acceptance by students and teachers alike, the proper, robust and transparent function is of utmost importance. We have therefore balanced the complexity of system, i.e. the number of in- and outputs, with the simplicity of use. For this, the module interfaces are especially important as they allow setting up complete experiments with just one connection. Fig. 2 shows the front-panel of the hardware platform with the different features.

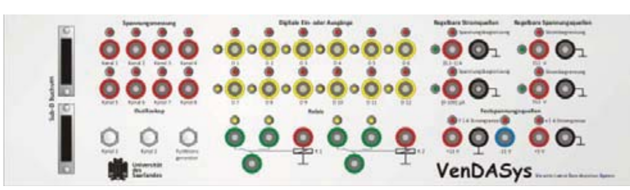

Figure 2. Front panel of the hardware platform

The DAQ module and the separately oscilloscope comes with LabVIEW software tools allowing an easy handling of the front-panel functionalities, when connected to a PC via USB.

B. Software tool

The PC software is implemented in LabVIEW because of its wide spread use in measurement applications. LabVIEW is a graphical programming language developed and optimized for the use in measurement and automation, which is divided in two basic parts: the block diagram and the front panel. The block diagram represents the programmer's working area while the front panel (example shown in Fig. 3) acts as the GUI of the completed program. The benefit for students and teachers is, that minimal experience with the programming language is required to develop programs with attractive optics for control and data display, as standard elements from the LabVIEW toolbox can be used to realize the required functions in short time.

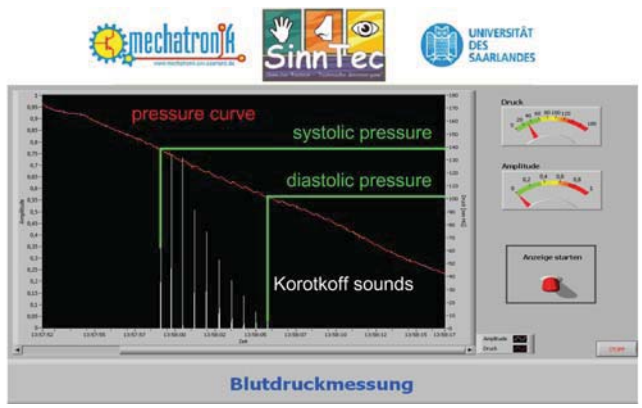

Figure 3. Example of a front-panel in LabVIEW, here showing the signals from pressure sensor and microphone for the blood pressure measurement.

To further simplify the development of programs for specific experiments a Virtual Instrument (VI) was realized, i.e. a single element or function in LabVIEW providing access to the complete functionality of the VenDASys hardware platform. By integrating this element in their own programs the complete communication and internal operation of the hardware/software combination is hidden for students. In this way, they can concentrate on the experiment itself without distraction from the electronics or the data communication.

C. Sensor modules

The system offers two options to connect the sensors with the VenDASys in order to set-up complex experiments. The first option uses standard lab-cables, which are connected individually for the different elements in the experiment. This option is used during the development phase of experiments enabling flexible connections and fast adaptation when errors are made. The second option is the connection of complete sensor modules or even experiments via Sub-D25-connectors, which is used after the development phase is complete in order to provide a fast and correct set-up of experiments. This option is especially useful for classroom experiments, when there is little time for setting up and high dependability is required.

III. BLOOD PRESSURE MONITORING: AN EXAMPLE

To illustrate the use of VenDASys for experiments with students, we will describe a new experiment that was recently realized to convey fundamental knowledge on pressure sensors as well as outlining an everyday application. After discussing the different uses of pressure sensors, e.g. for weather stations or height measurements, to monitor tire pressure etc, we chose a medical application in order to point out that VenDASys cannot only be used in physics and technology but also for other natural sciences like biology and chemistry.

The technical background of the experiment is the blood pressure (BP) measurement based on the widely used concept of Riva-Rocci as depicted in Fig. 4. A cuff is used to apply pressure on the arteries while the physician listens to the so called Korotkoff sounds in the brachial artery at the elbow using a stethoscope. In the experiment a pressure sensor is used for the BP measurement and a microphone - essentially another pressure sensor for dynamic pressure changes - to record the Korotkoff sounds. This emulates the function principle of commercial automatic blood pressure monitors for home use.

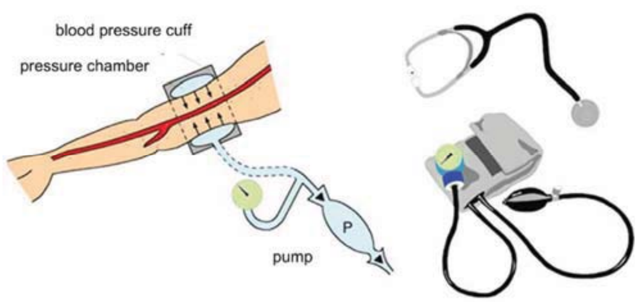

Figure 4. Blood pressure measurement according to Riva-Rocci [7]

In addition, the experiment addresses the function principle of the pressure sensor itself and the necessity to calibrate sensors before use. In order to allow a larger group of students (up to 16) to work, we divided the experiment into four sections or experimental stations as shown in Fig. 5. After explaining the overall goal of the experiments and some background on blood pressure measurement, the first two stations address necessary basic electronics and sensor concepts, i.e. a Wheatstone bridge circuit for evaluating resistive sensors and strain gauges for force, weight or pressure. The third station addresses the calibration of the pressure sensor, while in the fourth and final stage an actual blood pressure measurement is performed using the previously calibrated sensor. All stations make use of the principle of activity-based teaching, so that students have a real hands-on experience and do not only watch a teacher setting up and performing a demonstration experiment. Of course, the necessary equipment is prepared and the students are given a handbook guiding them through the experiment.

In the first three stations, basic VenDASys functions, i.e. power supply and analog measurement, are used; for the final station a dedicated program for recording and displaying the measured data and determining the blood pressure is used (Fig. 3) exemplifying the broad VenDASys spectrum.

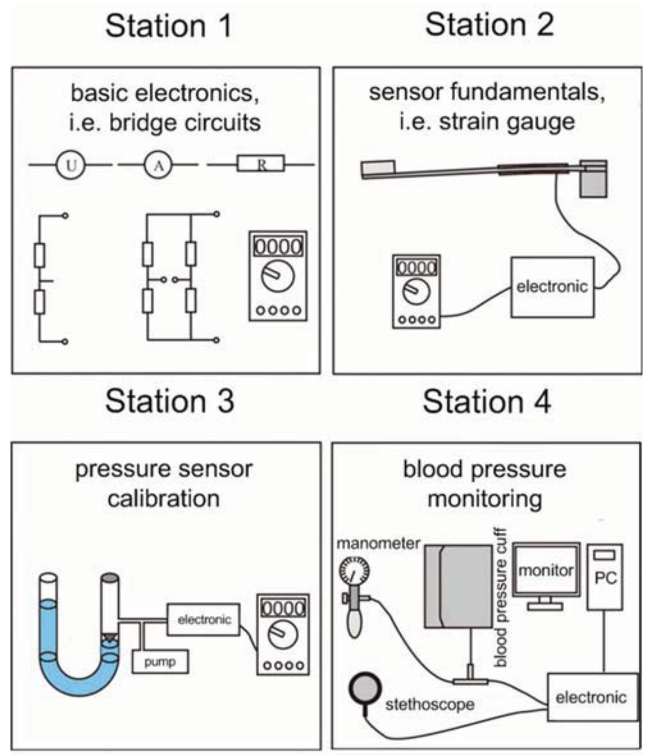

Figure 5. The four experimental stations of the BP monitoring experiment.

A. *Theoretical background*

Historically arterial pressure was measured using the height of a column of mercury to reflect the circulating pressure. Today blood pressure (BP) values are still reported in millimeters of mercury (mmHg), even though modern instruments no longer use mercury. For each heartbeat, BP varies between systolic and diastolic pressures. Systolic pressure is the peak pressure in the arteries occurring near the end of the cardiac cycle when the ventricles are contracting. Diastolic pressure is the minimum pressure in the arteries occurring near the beginning of the cardiac cycle when the ventricles are filled with blood. An example of normal measured values for a resting, healthy adult human is 115 mmHg (approx. 15.3 kPa) systolic and 75 mmHg (approx. 10 kPa) diastolic (written as 115/75 mmHg, and spoken as "one-fifteen over seventy-five") [8].

The most common method for BP monitoring is the indirect measurement according to Riva-Rocci (Fig. 5.), also called the *auscultatory* method (from the Latin for *listening*). In this method, a pressure greater than the systolic pressure is applied using a cuff which collapses the artery. Thus, the blood pressure wave cannot continue in the direction of the hand and no pulse can be felt or heard in the lower arm. The cuff pressure is then slowly reduced and the Korotkoff sounds are recorded. When the pressure falls below the systolic pressure, i.e. when blood just starts to flow in the artery, the turbulent flow creates a "whooshing" or pounding (first Korotkoff sound). The pressure at which this sound is first heard or recorded is the systolic BP. The cuff pressure is further released until the artery is open permanently, i.e. no more sound is heard (fifth Korotkoff sound), at the diastolic arterial pressure [8]. The process is depicted in Fig. 6. The Korotkoff sounds are either manually registered using a stethoscope or automatically using a microphone.

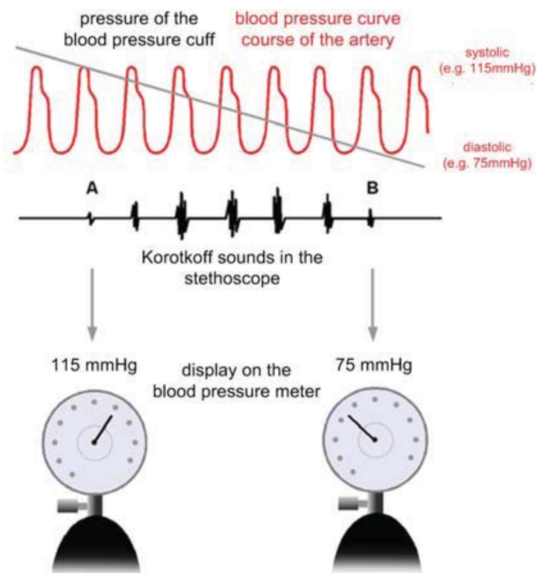

Figure 6. Blood pressure measurement based on Korotkoff sounds [9]

Thus, for BP monitoring two quantities have to be measured using appropriate sensors: the static pressure in the cuff and the Korotkoff sounds in the brachial artery at the elbow. As sound is basically a high frequency pressure fluctuation, both sensors are very similar. The experiment concentrates on the static pressure sensor which is easier to understand, but also requires higher precision. A standard microphone with audio amplifier is used for recording the Korotkoff sounds.

B. Pressure sensor function principle and calibration

Pressure sensors today are commonly manufactured using microtechnologies; they were one of the first mass applications of MEMS. The sensor basically consists of a Si chip with thin membrane and integrated piezo-resistive strain gauges in a bridge configuration (Fig. 7). A pressure difference across the membrane leads to a bending of the membrane and thus an electrical signal. With a vacuum on one side of the membrane by applying a glass cap the absolute pressure can be measured.

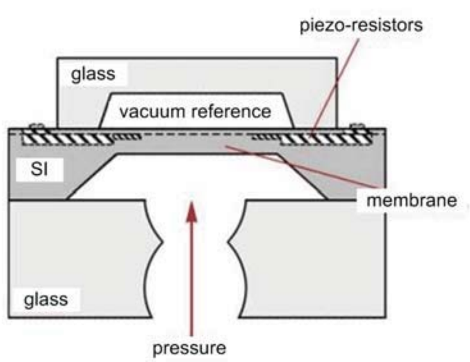

Figure 7. Schematic of a piezo-resistive absolute pressure microsensor [10]

Conversion of the mechanical quantity pressure, i.e. force per area, into an electrical quantity requires several steps. In the first step the pressure is converted into surface tension by the membrane, on which surface zones will exhibit tensile and compressive strain. Piezo resistors convert this strain into resistance changes, which is finally converted to a voltage by the bridge configuration. Since the strain and the resistance changes are small, the output voltage is also small and has to be amplified for recording. Thus, in the experiment stations the function principle of a Wheatstone bridge and strain gauges are addressed as necessary fundamentals for the pressure sensor. To make the pressure sensor, which is only a few mm square in size, more accessible to students we developed a macro model which is used to explain the sensor function principle, Fig. 8.

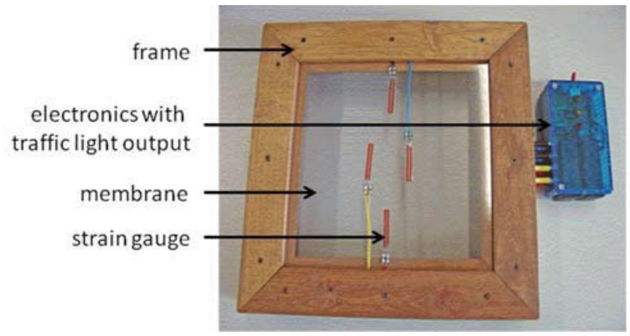

Figure 8. Macro model of a pressure sensor (size approx. 30 cm square). Applying pressure to the membrane results in a simple output (green: low, yellow medium and red high pressure, respectively).

After explaining the function principle students work with a Wheatstone bridge and strain gauges for a weight measurement in the first two experimental stations, respectively. In the third station, a pressure sensor is calibrated using a water (instead of Mercury) column, Fig. 9. The sensitivity of the sensor (in mV/mmHg) is calculated from the measurements of height vs. output voltage and the densities for water and mercury.

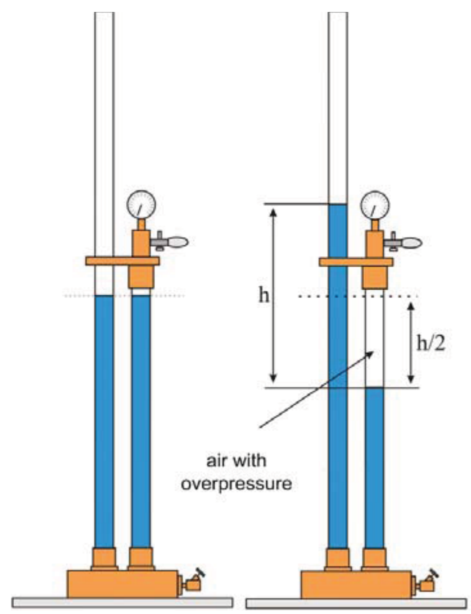

Figure 9. Calibration of the pressure sensor using a water column

C. BP monitoring with the VenDASys experiment

After addressing the scientific and technical fundamentals in the introductory talk and the first three stations students use a designated VenDASys experiment set-up for monitoring their own blood pressure in the final station. At the beginning of the experiment the necessary components are introduced and explained. Fig. 10 shows the microphone with amplifier, the blood pressure cuff with manual pump as parts of the complete experimental set-up. The experiment is set-up by the students themselves based on an instruction guide.

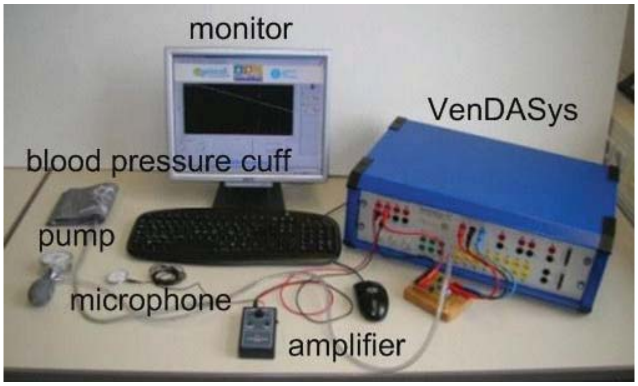

Figure 10. Complete experimental set-up for blood pressure monitoring.

Then, students can either use existing software to run the experiment or, if more time is available, realize their own program for recording and displaying sensor data and extracting the correct blood pressure values using pressure sensitivity obtained by the calibration in station 3. Finally, students take their own blood pressure using the set-up as shown in Fig. 11.

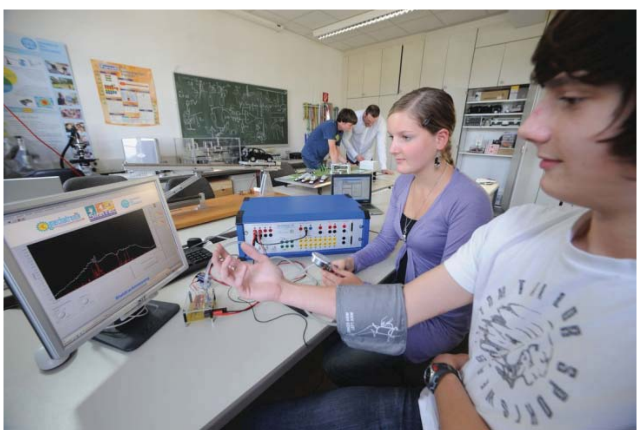

Figure 11. Students measuring their BP after setting up the experiment.

Fig. 3 shows the front panel of the standard LabVIEW software for BP measurement. In the main window, the pressure curve (red) and the signal intensity recorded by the microphone (white) are displayed; in addition analog scales (top right) show the current sensor values. After pressurizing the cuff until no noise is recorded (no reading on the appropriate scale) data recording is started with the button on the bottom right. When the pressure in the cuff is slowly reduced, the diminishing pressure and the Korotkoff sounds are recorded and displayed. From this diagram the systolic (onset of Korotkoff sounds) and diastolic (disappearance of Korotkoff sounds) pressures can be extracted as shown in Fig. 3.

With this experiment, students learn a wide range of different topics from biological fundamentals (blood pressure) to sensor basics (bridge circuits, strain gauge, pressure sensor) to automated evaluation of measurements in technical systems. Apart from function principles they also learn practical application as well as problems in using sensors, e.g. the need for correct calibration. During the experiment, VenDASys helps students with addressing the different stages, simplifying the electronics and allowing students and teachers to focus on the experiment. At the same time, they learn and understand the principles behind an everyday object like an automatic BP monitor thus taking the technology out of its “black box”. Finally, and for our purpose perhaps most important, students are shown that science and technology is fun and that they themselves can realize similar experiments with a minimum of effort, especially using VenDASys as a versatile platform.

D. Evaluation of the experiment with high school students

After the experiment, the participating students were asked to evaluate the experiment in several categories such as *the experiment was fun* using a five point grade scale ranging from *I totally agree* to *I totally disagree* and also the experiment overall on a scale from *excellent* to *awful*. Fig. 12 shows results of this survey for the first time this experiment was used in our learning lab SinnTec on March 25, 2009, by 10 students.

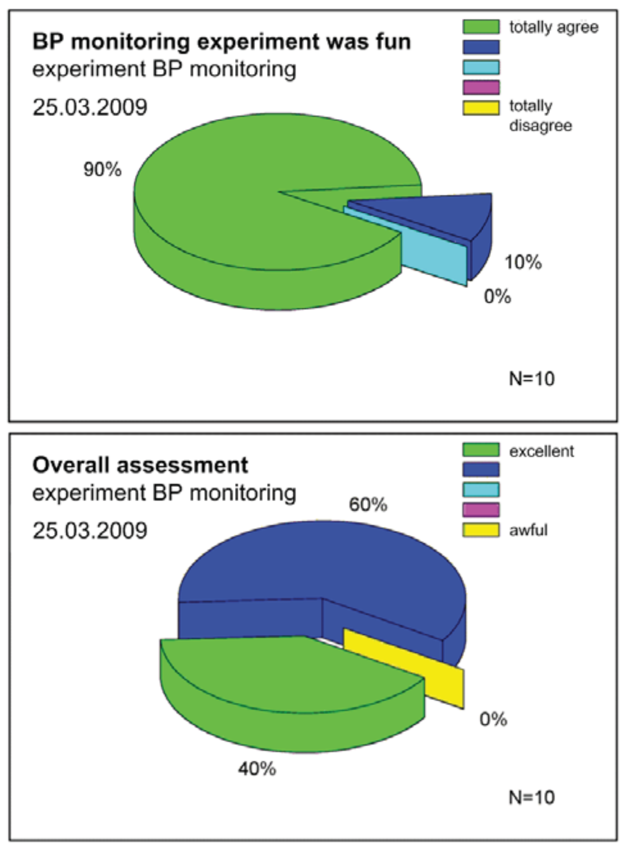

Figure 12. Exemplary evaluation results of the experiment blood pressure monitoring by participating students, 25.03.2009

While the number of students is of course too small for a sound statistical analysis the survey results and also comments by the students are encouraging. While the overall assessment is similar (slightly better) compared to other SinnTec experiments, the agreement in the category *the experiment was fun* is exceptionally high at 90%.

We attribute the higher fun factor of the experiment to two things: (1) the topic with its medical background and every day applicability was probably more attractive for students; (2) the VenDASys, which was used for the first time in a complex experimental setting, allowed students to concentrate more on the experiment and its implications than in other examples, where more effort and focus was required for the required electronics.

IV. Further Experiments

Besides the BP monitoring experiment described in detail above, we are currently developing further experiments, each of which addresses another sensor principle and an application example taken from every day experience. One experiment, implemented by a high school student in an extracurricular project, addresses the automatic identification of different solvents with a gas sensor. The experiment simulates a freight depot, where model carriages are shunted to their respective tracks. Here, VenDASys is used to automate the sequential control as well as the selection of the correct track (Fig. 13).

Figure 13. Experiment freight depot with automatic carriage identification

In addition to these experiments, we are also developing a self-study course on electronics. Using this course students and teachers will have the possibility to independently learn fundamentals of electronic components and basic circuits. In the course, VenDASys is used to replace different expensive components and instruments as well as provide step by step instructions from learning the characteristics of simple components to realizing complete circuits, e.g. for sensor read-out.

V. Conclusion and Outlook

With the approach described in detail above the following educational aspects can be addressed:

VenDASys is based on a strictly modular, open approach, i.e. all hardware interfaces as well as the software codes are fully available for every user. This enables schools and universities to interface existing and to add new experiments simply and cost efficiently - a crucial aspect for most institutions.

During the development and later in the dissemination of the course and the different experiments we are cooperating closely with different school teachers and their students to receive feedback and input. In addition, the input by teachers will be used to ensure that the VenDASys-GUIs fulfill strict didactic requirements to allow intuitive use by students and teachers alike. In the first experiments implemented jointly with teachers a didactic scheme will be designed to be used henceforth.

Synergy effects are created by exchanging experiments via our web-site [11]: mechanical designs, interface electronics and software will be made available for download allowing fast growth of the common experimental pool. Before uploading any element it is checked and, if needed, software is adapted to fit into the didactic scheme allowing intuitive use. In addition, the website will provide user support, e.g. with discussion forum and an FAQ (Frequently Asked Questions) section.

While microsensors and MEMS are our primary concern, we want to expand the application of VenDASys to other fields in engineering and science to make full use of its potential. Besides biology/medicine, as demonstrated with the BP experiment, we think that also chemistry provides high potential for VenDASys application, for example monitoring of reactions or even experiments on bio-fuel generation.

Currently, the system is extensively tested together with pilot users, the results will be continuously reviewed for further improvement. It is clearly not our goal to compete with commercial products offering highly sophisticated systems specifically for the classroom. Instead, our focus is on a system which can be used by students individually and in teams when dealing with technical and scientific subjects in general and MEMS topics or sensor applications in particular.

Acknowledgment

We thank Richard Baumbach, *Wirtschaftsgymnasium Saarbrücken*, and Benjamin Brück, *Max-Planck-Gymnasium Saarloius*, for their ideas and support in developing the VenDASys concept and in disseminating it to other schools.

Abstract—**In this paper is described the process that should be done for developing a interactive tool for supporting the musical learning specifically on how to play a flute on its basics. This device has two main stages, the first one takes over the teaching part and guidance to the student by an software interface and the second one has the responsibility of captured how is being played the flute using a pressure sensor and reflective transducers. With this example is expected to contribute in research and implementation of teaching devices around the world.**

Keywords-acoustoelectric devices; computer applications; learning systems; music; technological innovation; virtual reality

I. INTRODUCTION

Nowadays, the learning process needs a complement tool which could make it more efficient, enjoyable and accessible for every person who wanted to acquire knowledge in certain area. The virtual reality helps in making the education more contemporary it generates in young people the desire to research and learn about different stuff.

Many of the increasing challenges are arising from the emerging generation of new learners who are far more proficient with VR and other computer applications. The trend in professional society is also changing based on new learning tools and modes. Recently, virtual worlds have become an important part of teaching and training, transforming the way people work and learn. As technology allows more and more content to be virtual, so improves the possibility of better learner engagement [1].

Along with the device an educational pedagogy is integrated it ensures the success of student learning through implementing constructivist pedagogy instead of the traditional way of education giving a greater and more representative role to the student, recognizing that he/she is the main actor in the learning process.

The significant changes that today's students bring with them when they start their post-secondary education creates an urgent call to understanding the different ways they learn and therefore, to change the ways institutions educate them. But it is time not only to radically change the way teaching takes place, but also, to redesign curriculum, graduation processes, evaluation methods, infrastructure needs, and so on [1].

Making the teaching more interactive allows the student to learn on his/her own way, especially in music areas there are some difficulties for students who are subjected to inappropriate patterns of study. The skills and abilities could be different from each other.

At the same time, it is seen in our society the need to develop teaching tools and technology of interactive models more efficient and attractive, making the learning process more enjoyable. The non Immersive virtual reality offers in this case, an option where the interesting and useful interactive educational simulators are an innovative way of presenting to a student the information that is required to learn, giving the opportunity to be evaluated and followed throughout this process, leaving behind the traditional teaching, instead implemented a constructivist pedagogy.

Virtual reality is not a representation of a specific experience in the actual world, but it is a new mode of experience where various sensory and imaginary experiences are fused. This is not simply a way to understand and effectively access the actual world, but it is a driving force that carries forth the human activities and it is an independent reality that gets feedback from those activities. Users can experience virtual reality that is unrelated to the physical world [2].

Therefore it was decided to develop the "Virtual flute" in which an electronic device with software has the purpose to accompany and guide the student through the process of learning how to play a flute. The dynamic of the device has three stages a first one that gives all the instructions to the user, a second one where the hardware senses the note and finally a feedback of these data to the computer.

The following document shows the systems implemented for the realization of the device. Will present all needed to understand the functioning of the hardware, the progress made with their results and applications where the device would operate in an optimal way.

II. VIRTUAL REALITY

VR is a kind of technology that enables users to get sensory experiences on real things in a similar way to the one that they use when they interface normally with physical world. Such experience is only simulated; it does not mean a new experience has occurred. In other words, virtual reality is nothing but an artificial reality which is a substitute for natural reality that is felt in the actual world [2].

This device implements non immersive (desktop) virtual reality which offers less real sense than immersive virtual reality, but when it is accompanied by hardware it permits the possibility to the student of being in contact with the instrument that needs to play. The feeling is much more real than if they only see the information in a computer. In addition the feedback from the captured data from the sensors allow for seamless interaction between the student and this educational tool.

To stimulate creativity and productivity, the virtual experience must be credible. The "reality" must both react to the human participants in physically and perceptually appropriate ways, and conform to their personal cognitive representations of the microworld in which they are engrossed [3].

In the music field when someone wants to learn how to play an instrument is important to use a hardware which simulates the musical instrument and the student could be in contact with an object similar to the real one and be prepared for when he/she needs to play a real instrument.

New technologies related to computer music make it possible to not only create new types of music by ourselves, but also to learn conventional music more easily [4].

The principle purpose of the "Virtual Flute" is to facilitate the learning process on how to play a flute, offering a new way to practice and study the basic musical notes. Using this tool the student could practice whenever he/she wants as fast as each one decides, this allows a more enjoyable learning process.

Nijholt, thinks that technology can play two major roles in music education. Firstly, technology can supplement and support skills of parents and teachers essential to the musical development of children that are becoming rare or underdeveloped or for which time lacks. Note that such technology should not replace those skills but rather be accompanied by initiatives that encourage the development of such skills. Secondly, technology can make music education more efficient by taking time consuming, less creative, essentially 'practice' activities and offering them in a context in which students can master them individually, leaving more time for teachers to focus on the communicative/creative skills of music [5].

Therefore is seen the important mission that has the technology to develop different methods of participation in music and its processes: learning and practice.

III. METHODOLOGY

Two methodologies were implemented the first one which handled the development of theoretical research and the second which designs the interactive tool.

The research methodology was based in theories from Mendez [6], Lerma [7], Tamayo [8] and Cerda [9].

TABLE I. RESEARCH METHODOLOGY IMPLEMENTED

.Stages
Topic description
Problematic
Objectives
Justification
Similar examples
Definition of the methodology for developing the tool

During the topic description stage was determined the interactive tool scope and its limits then was seen and defined the "what for" of the learning device and clarified all the functions that should have the virtual reality tool after that was determined the motivations for the development of the device and was made a research about existing research and development about similar projects, finally was determined how would be developed the interactive tool

TABLE II. METHODOLOGY DESIGN FOR THE ELECTRONIC DEVICE

Stages
Planning
Requirements
Analysis
Devices design
Construction
Tests

During the planning stage was defined what will be done, the list of activities, team work, materials that constitute the device and the required tools then was set out the different characteristics that the device must have. After that was analyzed the requirements and the possible ways to develop the interactive tool, building a model to determine the physical structure and technology used and were made the sketches, proposals for structural design and performance. Then was made the flute's implementation with the sensors, signal conditioning and data transmission finally were made some tests of the flute's performance including the software.

IV. VIRTUAL FLUTE

A. Materials

Virtual reality's central objective is to place the participant in a virtual environment that gives the participant a feeling of "being there." This requires linking the human perceptual and muscle systems with the "virtual environment." A VR system consists of three types of hardware: 1) sensors, 2) effectors and 3) the reality simulators. [10]

The following are the most important electronic components that have the interactive tool:

The sensor Mpxv 4006 Freescale is used to measure the flow of air from the blow that leads the user when he or she play a music note on the electronic instrument. It works from 0 to 6 kPa, and is responsible for allocating a voltage value to the air pressure with a reference value of 4.8V for the maximum pressure to 0.17V for the minimum.

To identify the parameter of average pressure when the flute is played the right way were taken different samples of people with knowledge about how to play the flute correctly, noting that the results were close to a range of values specified in the driver program to analyze and compare each moment of execution.

The operating characteristics of this pressure sensor are: the pressure range is between 0 and 6kPa or what is the same 0 to 0.87 psi. The current supply could be from 7mA to 10mA. The operating temperature is between -40°C and 125 °C and the response time is 1mS.

The above characteristics determine the ease of using a device like this, its maneuverability in the prototype and its operating qualities that make it an excellent mechanism for implementing within the device.

For sensing the position of the fingers on the virtual flute are used eight reflective sensors. The Reflective Optical Sensor, CNY70 has a compact construction where the emitting light source and the detector are arranged in the same direction to sense the presence of an object by using the reflective IR beam from the object. The operating wavelength is 950 nm. The detector consists of a phototransistor [11].

Fig. 1 shows the construction of the sensor and its operation, this sensor is implemented in each hole of the flute to identify when it is being covered by a finger or not.

At the moment the finger is positioned over the hole, there is a reflective surface that makes the role of the medium of reflection for the infrared beam emitted by the diode, making driving transistor receiver.

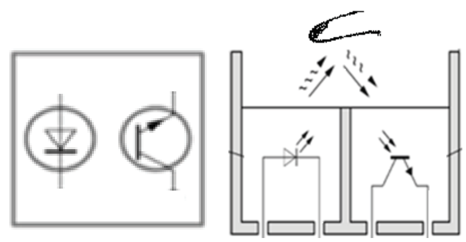

Figure 1. CNY 70 diagram

B. Flute Design

Fig. 2 shows one of the implemented prototypes of housing, which allows opening the main tube, to give the possibility to put the electronics needed to operate. It was made of wood with an original design made particularly for this application.

Figure 2. First designed flute

Fig. 3 shows another implemented prototype of housing, which is a typical flute with a little box which has the electronic components; this model permits an easier and more real way to play the flute.

Figure 3. Last designed flute

The following table shows the values of voltage measured at the output of the pressure sensor, captured in several tests to persons who knows the art of playing the flute, these data are the parameters used to design an algorithm that discriminates between a note that is played the right way and other that is not.

TABLE III. | VOLTAGE AT THE OUTPUT OF THE SENSOR

Student	Voltage at the output of the sensor
1	2.01
2	2.23
3	2.16
4	2.34
5	2.37
6	2.26
7	2.27
8	2.31
9	2.13
10	2.11
11	2.13
12	2.46
13	2.54
14	2.27

The analysis of the results, generates a voltage range in which the note is being well executed, which corresponds to approximately 0.326 psi or 22.2x10 ^ -3 Atm or 2.25 KPa.

V. Results

The main result was the successful implementation of hardware device that captures the basic musical notes which are being played on a flute and transmitted to the computer, where the interaction is consistent and efficient.

The combination of music instruction, the sensors and the communication with the computer, generated a electronic device in which has an application of software that was developed in Java, Netbeans, and it provides the necessary information to the student to learn how to play the basic notes on a flute and gives the opportunity to practice and be evaluated, according to this the computer sends data to an electronic circuit for identifying what note should be captured by a PIC microcontroller, the data are captured from the sensors of the hardware part (air pressure and fingers position) are analyzed and returned data to the software which provides a correction or an acceptance of performance, thus completing a cycle of information and feedback aimed at the understanding and successful learning.

The software makes the instruction to the user, displaying the correct way to play a flute, when the user has reviewed this information with the speed that he/ she wants and how often he/she desired necessary then they could choose the appropriate type of test to perform, creating a kind of constructivist pedagogy which offers to the student the necessary tools for the learning process.

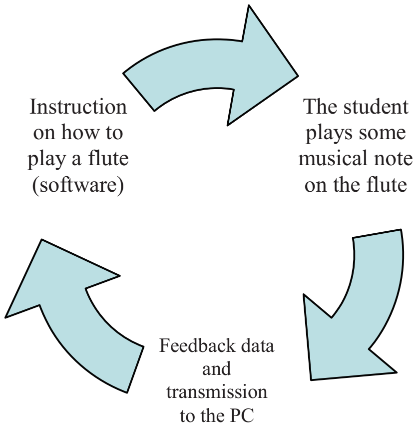

Figure 4. System Dynamic

When the activity is chosen, data are sent to a PIC microcontroller, which identifies the note that must be play by the user in the following seconds, then analyzes the input of the position of the fingers by the digital inputs of microcontroller and the air pressure exerted by the blow of the user, using analogue digital converter from the same integrated circuit to be compared with the expected feedback and response to a computer (USB communication), specifically to the software in Netbeans, indicating the student qualities or their shortcomings in implementation.

Thus, it generates a dynamic conducive to the goal of teaching the correct way to play a flute.

The following figures (*Fig. 5 and Fig. 6)* are samples of the graphical environment of the software application developed for this interactive tool, because the device is primarily designed for children, the graphics are very colorful and animated in order to attract attention.

Figure 5. Software designed

Figure 6. Software designed

VI. DISCUSSION

The learning and / or musical training are complex for many students because they do not have enough tools, for example they do not have someone or something that continually motivate and guide them for training in musical performance as a contemporary art. Also there are people who are subjected to inappropriate patterns of study for their skills and abilities in the learning process in this area. These factors cause dissatisfaction in a specific group that wants to work on their artistic abilities.

this paper presents a device able to sense the musical notes that are played by a user, with software that guides a user interested in learning the art of playing a flute, it noted the importance of implementing educational tools, which makes more efficient and effective the learning process, demonstrating the importance of electronic applications in low and high impact exploration in different aspects, as in this case in the arts and music pedagogy.

An academic impact was generated; this project brings improvements in the research and implementation of such devices and at the same time with these devices provides an innovative way of teaching that makes an easier and more interesting learning process.

Abstract— **This paper proposes an agent-based adaptive Architecture to extend *Moodle* in order to support instructional decisions and adaptive behaviour in engineering education. The paper describes the characteristics, functions, and interactions of the agents which take part in each module of the adaptive architecture. In addition, we describe the origin and function of ToDei, the proposed intelligent agent for Instructional Decisions Making. This agent is in charge of collecting information generated by the rest of agents and deciding what is best for the final users, tutors and students, taking into account their attitudes towards the learning environment.**

Keywords: *Intelligent agents; adaptive educational systems; ntelligent systems; user modelling; tutor modelling*

I. Introduction

One of the challenges of engineering education is to tackle with complex learning experiences which in many cases include the use of a diversity of tools and environments, drill and practice processes, virtual laboratories, etc. In this context, the use of adaptive content has been proven to be an important contribution to facilitate learning [1][9][10], provided as an extension of a given learning architecture. From all the VLE open sources available in the web, Moodle is the most widespread and used around the world. Currently, there are 56357 sites from 210 countries registered as Moddle[1] sites. They are supported by a development community that provides current updates and support. Due to the previously mentioned services and to the portability and modularity that characterizes this community, it has been easy to present a proposal with an adaptive focus that contributes to the growth and exponential development of the VLE open source with tendency to an Adaptative Educational System (AES).

The Moodle approach is based on three main components: the professor, the classroom in which the educational process is given, and the students. They work together in the following way:

The professor looks for and produces all the information necessary for the course development. He/she organizes it in weekly blocks or in thematic blocks and enters the topic orientation, the supporting resources and tools (files, documents, videos, audio, etc.), and the activities that must be developed by the student.

The student is in charge of developing the proposed activities, downloading or checking the resources and interacting with his/her partners according to the orientations received by the professor. The teaching-learning process is developed in the classroom, and the information generated here is stored in a relational data base that is fed and accessed through the user interface. The Moodle's structure allows providing facilities in order to give each one of the student's different resources and activities, to give advice to students, and to facilitate the interaction between students to students, students to professors and vice - versa. If there is not information related to the user preferences, the navigation sequence, the document evaluation, and the knowledge level, the teaching-learning process will be developed in a general way for all the members of a course. And a personalized service will not be offered to each student.

One alternative to such problems is to focus Moodle on students' needs, trying to adapt this system to each one of the students and training them according to their learning styles as well as adjusting the system to the students' needs. For this reason, a structure that allows Moodle to be adaptive is necessary.

The proposed architecture is based on the main areas of adaptation defined in [2], providing presentation and navigation adaptation using intelligent agents associated to different modules in Moodle. This multi-agent methodology has recently appeared as a good companion of adaptive distributed educational systems. User adaptation using intelligent agents has been developed using several approaches. For instance as users' self test, like in [3] that provides an adaptive testing tool to fit the student's level of

[1] Moodle.org. http://moodle.org/sites

knowledge, where questions are generated automatically; or integrating agents in VLE as in [10] where educational content is made available by means of a process of re-categorization carried out using intelligent agents within the VLE.

Furthermore, it is considered a multi-agent structure that needs to be easily applied to the modular architecture of Moodle and offers a dynamic adaptation through learning. This learning is developed by each one of the agents that intervene in each component .

II. Adaptative Logical Architecture Proposed for Moodle

The proposed architecture of AES for *Moodle*, has four principal modules: tutor module, student module, user interface module, and knowledge base.

Each of the first three has an intelligent agent that performs tasks for each module. For communication and interaction among agents of each component, the agent called ToDei has been defined. Its goal is to take the information of each module and decide the best method of instruction for the final user. In the knowledge base module, the development of one or more agents can be considered, depending on the way the information is structured (taxonomy or ontology, for example). For the present case, no agent has been defined in this module since its basic functions will be performed by the ToDei agent.

For each agent, the principal functions are defined. Therefore, the one who works on the tutor module has didactic-pedagogical functions and tutor modelling, and the student module carries out the creation of student models and information updating. The user interface module (student-tutor) determines the most appropriate interface for each user based on the hardware and software used for the connection. The ToDei agent communicates and determines the best instruction for the user.

The components of the different modules proposed for AES are based on research based on an analysis of available information on the Moodle virtual platform, which permits definition of the necessary task adaptation to acquire an adaptive approach. As stated clearly before, the components and intelligent agents that will intervene in an adaptive architecture, using the Moodle virtual platform as a base, are shown.

A. Tutor Model

The instructor, who is an actor in (traditional) Moodle, becomes a component in this type of architecture, in which the best way to make information available to students is identified. This function is performed by an intelligent agent, which will make decisions according to various variables that could be considered to provide knowledge to students.

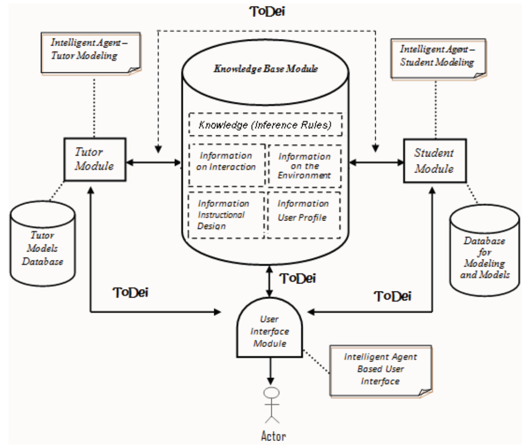

Figure 1. Moodle’s Adaptative Logical Arquitecture

This activity is supported by the instructional design and the different versions of the material made by instructors [8]. The different tutor models generated by the agent are stored in this module. At the same time, this agent is in contact with the knowledge base module in order to retrieve and store information. The intelligent agent, which is associated with this module, is the intelligent agent for tutor modeling that must perform the following functions:

- Pedagogical-didactical (teaching style)
- Tutor modeling (implementation of contents)

Intelligent Agent for Tutor Modeling

The tutor modeling agent has been designed to perform the following functions:

- *Didactical-Pedagogical*. Each instructor has his/her own style to encourage learning among students, which is perceived differently by each student. This situation is what the intelligent agent attempts to simulate and learn in order to guide students in what and how to learn.
  According to students’ acceptance and response to a particular style, the agent will be able to classify what teaching form is the most accepted by a particular student profile. Thus, once the agent has learned, it can choose the most appropriate style for each user based on his or her profile.
- *Tutor Modeling.* The main feature of this function is the analysis of the organization and implementation of contents according to the experience that the agent has acquired. This process will begin with a modeling that gathers information on activities and resources proposed to students and on their success rate. Based on this experience, the agent will learn the best way to implement contents.

After analyzing this information, some tutor models, which can be applied to determined student models, can be defined. Tutor models may vary depending on the level of learning and experience acquired by the agent. This will permit the definition of more concrete models that can be best adjusted to a particular type of student.

Considering the classification made by [4] and [5] regarding the structure of an agent, the tutor modelling agent can be categorized within the *informed agents that maintain a design of the world* due to a) the constant updating of the environment in which this agent operates, b) the updating that must be done in the tutor modelling, and c) the decisions about what content should be offered to the student.

The use case according to the task that this agent must complete is shown in Figure 2:

B. Knowledge Base Module

This module has the initial knowledge of the system, expressed in statements of general validity as like as inference rules or probability distributions [7], these are used by the agent to infer a conclusion or new knowledge, used various information sources such as a) student's personal data, b) interaction data, c) environment data, and d) information on

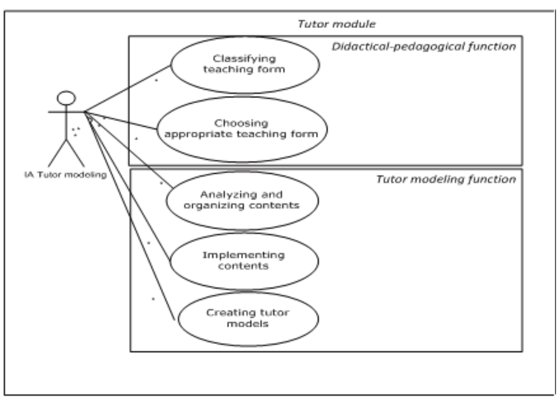

Figure 2. Use Case of Tutor Model

instructional design. This Knowledge can be organized into different structures such as taxonomies, conceptual maps, thesaurus, and even ontologies.

C. Student Module

Regarding AESs, students generate the underlying information for adaptation. For this reason, in an adaptive architecture, this actor turns into an independent module in which, based on the students' characteristics, needs and preferences [6], different models are generated.

For this module, the following use cases can be identified:

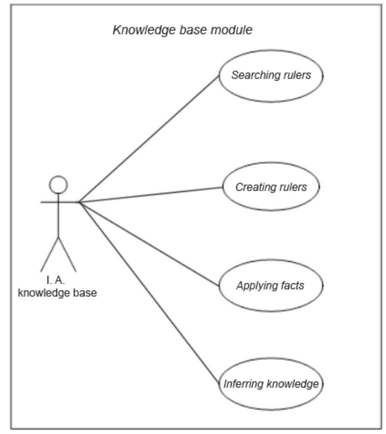

Figure 3. Use Case Knowledge Base Module

Intelligent Agent for Student Modeling

The agent for student modeling performs some functions in this module. These functions include:

- Creation of Student Models. Creation of student models based on a previous model, in which explicit and implicit variables are defined and include navigation environments, learning styles, learning levels, cooperation levels and interaction levels. Once models have been created, the agent will be able to categorize the different student profiles according to the model with which they share similarities. This will favor a more significant learning experience.
- Information Update. This function collects information about the student from the moment the student accesses the system. This information is updated by the agent, which is in charge of monitoring various activities, routes, and actions of the student in the system. After comparing some characteristics that students accumulate in their profiles, and if necessary, the agent will be able to change the model to which the user was assigned and determine the progress of the user in the system.

This agent interacts with the knowledge base through the instructional decision making agent (ToDei), from which data of each profile are retrieved and saved once the student has been identified in the system or when the student exits the system.

Returning to the classification made by [4], the agent for tutor modelling can be classified within the *informed agents that maintain a design of the world* due to a) the constant updating of the environment in which this agent operates, b) the updating that must be made in the student modelling, and c) the categorization of student profiles regarding the models that were created.

The use case diagram for this agent is shown below:

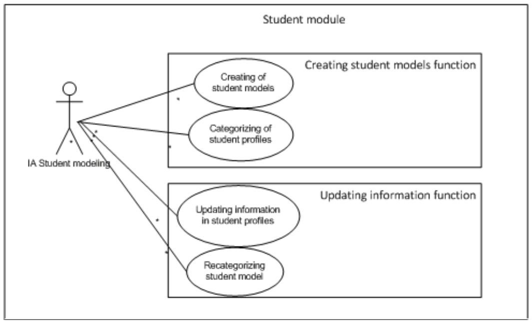

Figure 4. Use Case Studen Module

D. Interface Module for Users

This is the component that shows all the information to the students, trying to capture their attention and keeping them motivated, through redaction of messages type "Inverted Pyramids" [11]. In this module, we identify characteristics such as the type of browser used, type of device used for access, and the available connections.

Intelligent agent for user interface

The objective of this agent is to determine the best interface to be offered to each user based on the hardware and software used for the connection.

The means of connection, the software, and the equipment used are different for each user and for this reason each has different presentation needs. For example, if a student accesses the system from a cell phone, he would only need the most necessary files, but if a student accesses from a carry-on computer with a good bandwidth, he would be able to watch videos and animated films and listen to audio files.

The intelligent agent for user interface should learn these conditions and determine the most appropriate type of system interface for each one. This learning can be acquired when students can interact with the offered interface and when the identification is accepted or denied. This will help classify it as appropriate or inappropriate.

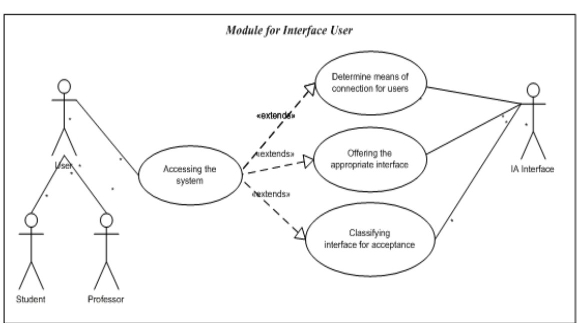

Figure 5. Use Case User Interface Module

Continuing with what [4] stated, this agent has been categorized inside the *informed agents that maintain a design of the world*, since the constant updates from the environment that surrounds it demand different answers depending on each case. For example, it must be able to recognize if a user accesses from a PALM and then accesses from a PC the same day.

The use case diagram that corresponds to this agent is presented below.

E. Intelligent Agent for making instructional decisions (ToDei)

The adaptive architecture that has been proposed is a dynamic structure and multi-agent that allows learning, communication, and independence of each component of the system. In all the components there are agents that facilitate the execution of the process and a particular defined process, but in order to fulfil the requirement of offering the use of the adaptive effect, the communication and interaction of all the components of the architecture are necessary. Consequently, the intelligent agent ToDei is used.

The objective of this intelligent agent is to fulfil these functions as well as to transmit the content to the user. Furthermore, considering the characteristics and greatest needs, it decides the best way to offer information generated in this process.

ToDei receives information through the module for user interface, specifically the one generated by the agent for interface. It is the first to have contact with the user because it communicates with the module for students where the information regarding the profile (stored in the knowledge basis) and the model student (stored in the module for students) are restored. They are then sent to the module for the tutor where, according to the tutor model assigned for the model student, the most appropriate instructional design is offered. Finally, ToDei displays the results of this process to the user. At this stage, the intelligent agent chooses how to show through the interface the content generated based on the style best suited to the learning process of the student.

As observed, ToDei is the only agent present in this architecture which has the function of restoring, transmitting, and sending information through the different modules of the system. Consequently, according to [4] and [5], it has been categorized as an *informed agent that maintains a design of the world* since its function of interacting with all the components of the system forces it to update its internal state based on constant changes of the environment.

Structurally, the intelligent agents are formed by sensors, effectors, states, and the environment [5]. The elements regarding the ToDei agent are described in the following paragraphs.

- ***Sensors:*** These are the parts of the agent in charge of detecting changes, requests, and requirements needed by the environment. Furthermore, they become the source of information and the means of updating the states stored by the agent. For example, if the environment of the agent shows that the user has accessed the system, the sensor will detect this change and send it to a state where the action-reaction rules will be applied. This will determine the student model to which the user belongs and will show through the effectors the appropriate content for this model.
- ***Effectors:*** Their function is to take the final actions to be applied to the agent environment, which were perceived by the sensors, allocated in a state, and responded to by the action-reaction rules.
- ***States:*** They are the changes that have been detected by sensors and the answers shown through the effectors of the agent according to its corresponding environment. These are stored in such a way that they allow learning from the agent, keeping for example all the actions taken according to certain perceptions and their effect on the environment. The states are part of the memory of the agent.
- ***Environment:*** It is the environment designed for the agent in which the agent acts and operates. Regarding ToDei, the environment corresponds to the interconnections of the system components.

In this proposal, ToDei has different inputs which are derived from the modules: user interface, students, knowledge basis, and tutor. They generate communication and reception of information through the agents that interact inside each module. The changes generated by such agents are received through the sensors of the ToDei agent; they are processed in the different action-reaction rules (rules of inference) of the agent. Finally, the resulting actions are sent through the effectors to the components that have generated the environment inputs of ToDei and in the same way are stored in the agent memory (states) for its self-learning.

The structure and the process carried out in ToDei are illustrated in the following chart

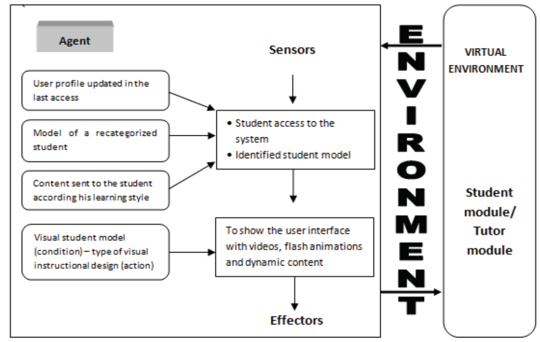

Figure 6. Example of the Structure of ToDei Intelligent Agent

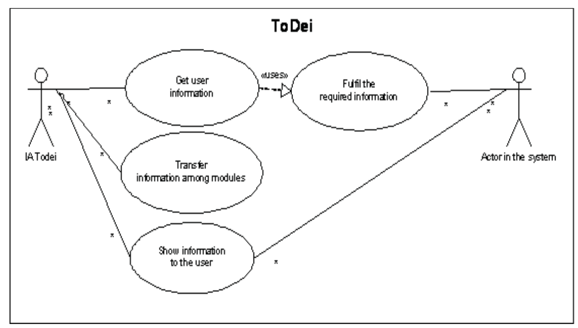
The following use case diagram shows the ToDei process in the system that has been determined for this agent:

Figure 7. Use Case Diagram for ToDei Intelligent Agent

III. CONCLUSIONS



Moodle contain basic information from tutors, students and contents; but no store the interactions path from the different actors. This aspect can be improved by including intelligent components, thus providing a personalized teaching-learning process.

The definition and implementation of intelligent agents in the components of a platform for a Moodle virtual platform do not imply the disappearance of the main actors: professor and student. On the contrary, this platform is a support that helps to reduce the teachers` workload and permits them to focus their efforts on creating good relationships with students to achieve success in learning.

Although they have the same structures, each one of the proposed agents is functionally different but depends on the module on which it is operating. The ToDei agent constitutes the main component inside this architecture since it allows visualization of the adaptive effect generated by the interaction of the components.

IV. FUTURE PROJECTS

Currently, the user model and part of the *ToDei* agent are being developed:

1. The agent which belongs to the student module performs the following functions:
   - Creates student models based on a previous model.
   - Categorizes student profiles.
   - Monitors students while they interact with the platform.
   - Updates student information.
2. The *Todei* agent will present the information according to the categorization of the student profile

Once these components are developed, the construction of any modules that involves the definition of intelligent agents can be achieved. To carry out this, it is necessary to determine the learning type best suited to the available information and to each of the works to be developed. Also is important to consider in the development of each of the modules, the application of usability standards.

In the tutor model when instructional design is defined some mechanisms have to be found to maintain the student investigative spirit, in order to not create any dependency with resources shown by the SAE

***Abstract*- Engineering students begin their first year with fundamental science and pre-technology courses which give little knowledge about engineering. As a consequence, some of the freshmen have no idea about engineering, and are lack of objective and interest in engineering. This paper presents how to help the freshmen have a general idea of engineering and an overall understanding of what they are going to study. One project activity outside curriculum in a LEGO lab and two outside-classroom DIY activity cases are presented. After three years practice, students had more interest and passion in engineering and showed their talents.**

Keywords-freshmen training, research-orientated education, engineering DIY activity

The work of this paper is sponsored by the Educational Quality Program from Shanghai Education Committee.

I. INTRODUCTION

Sino European School of Technology at Shanghai University (UTSEUS) was established in 2006, cooperating by Shanghai University (SHU) and University of Technology (UT) network in France. There are three programs in UTSEUS, for Bachelor, Master and Engineer Diploma, as shown in Fig. 1[1].

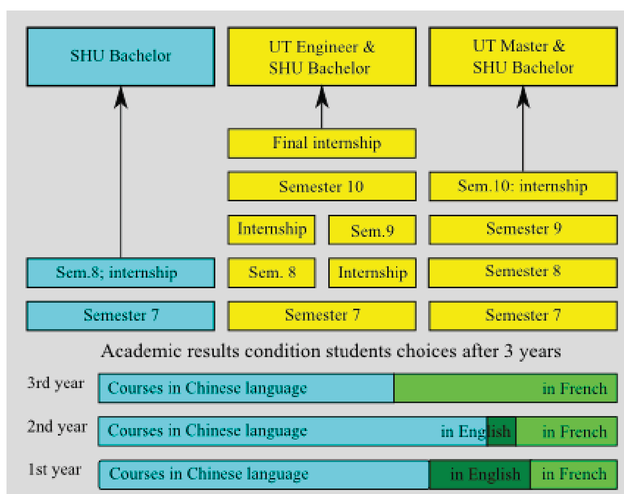

Figure 1. Three degree and diploma programs in UTSEUS

In the program of engineer, students enrolled to Shanghai University first study three years in China, and then they takes other two and half years study in France. After totally five and half years, students get both bachelor degree and engineer diploma if they are qualified to all requirements.

Usually， students begin their first year with fundamental science and pre-technology courses which give little knowledge about engineering. As a consequence of this arrangement, some of the freshmen have no general idea with what engineering is at the beginning of the university study. This leads to the engineering freshmen lack of objective and interest when they are taking fundamental science and pre-technology courses [2].

In term of this, authors of this paper did some work to help freshmen have a general idea of engineering, and make them easier to have an overall understanding of what they are going to study in university, which technology courses they need to master and how those courses are applied to their study.

To achieve this object and get freshmen understood the implicit objectives of further learning, introducing preliminary engineering courses inside or outside classroom is of vital importance. Besides, it contributes to the success of some freshmen and brings them more interest in engineering major.

In this paper one project activity outside curriculum in a LEGO lab and two outside-classroom DIY activity cases are presented. Many students showed their talents on engineering.

II. Project Activity Outside Curriculum in the LEGO Lab

This activity is a kind of project based training with LEGO robot bricks. Freshmen are encouraged to join this activity after class. The LEGO robot lab we have has more than 20 sets of LEGO NXT bricks. Usually every semester 30 students of 10 groups take part in this activity.

The idea of this outside classroom activity is described in detail in Fig. 2.

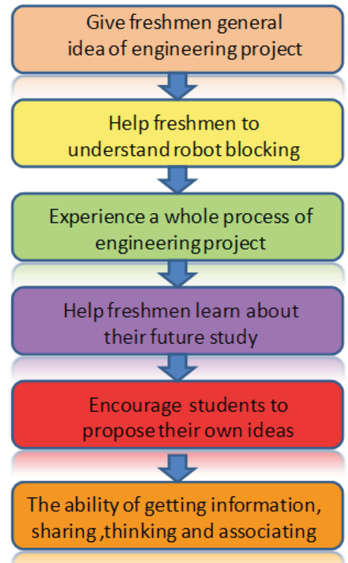

Figure 2. Idea of LEGO Robot Bricks Activity

A. *Give the general idea of engineering project*

To give freshmen the general idea of engineering, teachers usually show a whole process of engineering projects design to students, explaining every step of design. Taking the process of designing a robot vehicle for example:

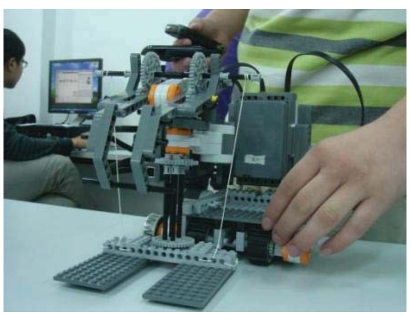
- The first step is to understand and investigate the project you are going to do, then propose several ideas and analysis using Mind Storm and Value Analysis methods, etc.
- The second step is to design the structure of the vehicle using the theory of mechanic, material science, sensor technology and so on.
- The third step is to control the robot vehicle. In order to do this, automatic control Principle, C++ language, algorithm, circuit principle and electrics are probably involved in the design.
- The fourth step is to test and adjust, using testing and measuring technology.
- The last step is to present their work, communicate with each other and make some improvements.

By this activity, freshmen have had a general idea of engineering project and which courses they will learn in their following semesters. The most important is that they know which kinds of technologies are widely used in engineering. Compared with the students who have no idea with technology courses, they are of more objective and positive to engineering major, and are tend to combine theory and practice together.

B. Help freshmen to understand robot blocking

LEGO robot is a modularize robot produced by LEGO company from Denmark. This kind of robot is composed by several modules, such as microcontroller modules with three input ports and four output ports, motor modules with ports can be connected with microcontroller by cables and sensor modules like sound sensors, vision sensors, compasses and various mechanical parts. Regarding to the mechanical part, there are gears, wheels, shafts and pins in different sizes as well as gimbals (Fig 3.).

Besides, there are several expanded interfaces, which allow LEGO robot to be connected with the sensors from other companies, for example, Hitechnic, Mindsensors.



(a)

(b)

Figure 3. Build Robots with LEGO Robot Modules

The advantage of this kind of robot is modularized, and the students could experience that by using LEGO robots with fun. If the freshmen have some ideas, they can build the robot and try their new ideas with modularized LEGO robots immediately, without spending a long time to manufacture the mechanical parts. And a useful mechanism structure can be reused, from project A to project B.

The software used for LEGO robots are also modularized, such as ROBOLAB released by American National Instrument. It is a kind of software which is a simple version of Labview. It is easy for students to begin programming, and to enjoy the convenience which modularization brings to them.

C. Experience a whole process of engineering project by designing a robot using LEGO NXT bricks

It is a necessary activity to guide freshmen to experience a whole process of engineering project. A Chinese proverb say: Tell me and I forget. Show me and I remember. Involve me and I understand [3]. In order to do this, in LEGO lab, teachers assign a target that freshmen should achieve by LEGO robots. Freshmen are divided into groups by three or four persons. They'll carry out the completely procedure of an engineering project.

D. Help freshmen learn about what they are going to study in technology courses

In the steps of structure design and control system design, the freshmen need plenty of knowledge about Mechanics, Material Science, and sensor technology and so on. However, the freshmen may know little knowledge of these domains, as they have no experience of engineering projects previously.

With the activity in LEGO lab, students could use mechanical parts, sensors even before they understand and have the skill to take full advantages of them. But the important thing is that the freshmen now have general conception of mechanical parts and different kinds of sensors. As the result of this, students know what they are going to learn in the following years, and when students are taking courses in the future, they may have more interest and better comprehension.

E. Encourage students to propose their own ideas

The activity in LEGO lab has no detailed instruction for students, and the teacher's responsibility is to bridge the knowledge and students. Students have to work out proposals and solutions by themselves. Without detailed instructions, the minds of students are not constrained at all. They are encouraged to bring out any idea, since the spirit of this activity is no stupid idea [4] [5].

F. Develop the ability of getting information, sharing, thinking and associating

As the development of information technology, the methods for students to get information are more and more [6]. They can obtain information not only from teachers or libraries as before but also from database online, Blogs, E-learning courses, BBS, and so on[7]. The activity in LEGO lab encourages students to get information and find solutions by themselves, and provide opportunities to share their information and solutions with the classmates by presentations.

In addition to working on engineering projects, some students are good at thinking and associating. For example, they know the history of LEGO bricks, the development of LEGO bricks, and why it is so popular in the world to different age people, even have some ideas about the advantages and disadvantages. Excellent students show up though the activities.

III. OUTSIDE OF CLASSROOM DIY ACTIVITY

The purpose of this activity is to manufacture mechanical products by students. This activity requires students spend more time on it. The students are required to propose, design and draw, purchase material and parts from market, manufacture and improve in workshop [8]. Here are two cases.

a). a skateboard bicycle

Figure 4. A skateboard bicycle manufactured by students

This is a bicycle driven by trampling which is different from common bicycle. It was designed and made by two students who majored in mechanics manufacture. They spent spare time doing this at their second year in university, proposing ideas, designing, manufacturing and testing by themselves with some support from supervisors.

b). a chair keeping health with traction system

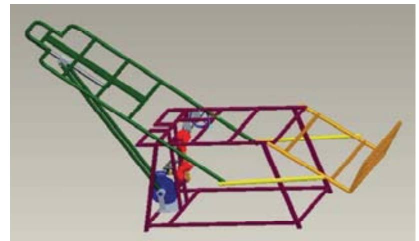


Figure 5. The 3D Assembly drawing of the Chair

Figure 6. Students are Welding the chairs in workshop

Same as the last example, the two students in the picture designed a chair with which people could keep health by dragging neck. Fig. 6 shows two students were welding the chair in the workshop.

CONCLUSION

This paper proposed the activity in LEGO lab based on projects and the outside classroom DIY activities. Those trainings help freshmen understand the whole processes of engineering projects, learn the technology courses they will take with their former experience of LEGO projects and DIY activity. It's vital to freshmen who will get involved in international engineering work in future.

The trainings also increased the passion for engineering of students. A student, Hu Zejun, who joined LEGO project said: *We proposed our own idea to the project. We spent much time, challenged a lot, but at last we know how to find solution by ourselves.* Besides, three students who ever experienced the projects as a group, have proposed an innovation project based on LEGO and gotten support by National University Students Innovation Experiment Program.

To improve the work on freshmen training in the near future, more surveys are necessary for authors to do.

ACKNOWLEDGMENT

This work is supported by UTSEUS and also sponsored by the Educational Quality Program from Shanghai Education Commission. The authors would also like to thank Prof. Hu Qingxi, Yao Qin, Zhang Haiguang, Wu Di, You Fei from Engineering Training Center of Shanghai University, and students, Li Yaozheng, Zhangxuan Fengchen, Ouyang Jingxian, Xu Dailin and all students in the projects groups from UTSEUS.

Abstract— **Mathematics is an important core of the syllabus of any Computer Science degree. We have studied the relation between the learning competence of Mathematics for first-years at the Universidad Politécnica de Valencia, and their success in the subjects of mathematics in the degree. Its relevance for their success in the whole first academic year is also reported.**

Keywords-component; Bologna Process, Competences, Computer science education, Management education.

I. Introduction

Before 2010, all higher education institutions of the European Higher Education Area (EHEA) would have had adapted their degrees to the Bologna Process. This process has the purposes of promoting lifelong learning, widening access to higher education, and stimulating the mobility across the EHEA [1]. This change does not only consist on a new measurement of the credits of the subjects in terms of the student workload instead of the teaching hours. All contents of the new syllabus should be addressed to the achievement of certain prescribed learning outcomes and competencies associated to the degree [2]. These could be related to general skills or to specific requirements of the professions corresponding to the degree. In both cases, the initial level, if exists, must be known and the desired level should be realistic and achievable. Therefore, an assessment of the initial situation is required.

A project supported by the Spanish Government has been conducted on several Schools and Faculties of Computer Science in Spain [3] in order to state the initial level of competencies of first-years. Reading comprehension, English, and Mathematics were evaluated by analytic rubrics, as a quality label for competences acquisition. The results can be compared with the PISA reports of 2003 and 2006 [4]. Such studies usually cover the period of compulsory education, until 16 years old. However, at least in Spain, nothing can be said about the competence level of the students after the High School period, before enrolling in the University. This is quite surprising since the degrees designed in the frame European Higher Education Area should be designed thinking on learning outcomes and competences that graduate students must have achieved at the end of the degree.

At the Escuela Técnica Superior de Ingeniería Informática (ETSINF) of the Universidad Politécnica de Valencia (UPV) in Spain, we have compared the results on the mathematics competence of our freshmen with their success in mathematical subjects included in the first academic course of the degree. We have also analyzed the level of the students on this competence with their success in all the subjects of the first year. These results can also be compared with other analysis conducted at this institution for first-years [5][6]. Besides, we also try to relate students who drop out of the institution after the first year with their initial level of competence in Mathematics. See also [7][8].

In Spain, children have to take compulsory education until 16 years old. After this period, a Baccalaureate period of two years should be taken in order to apply for a university. We should point out that freshmen of Computer Science have shared Mathematics in the Baccalaureate with students that have finally enrolled in other studies of engineering or science. So that these contents are dedicated to these kind of studies. However, contents of Mathematics in this last year of Baccalaureate are mainly focused on helping the students to pass the university entrance examination (*Selectividad*) that students ought to take in order to access to the University. Therefore, a general improvement of the competence in Mathematics is not the main goal of this course.

II. Computer science degree at the ETSINF

Until 2009/2010 the syllabus of the Computer Science degree at the ETSINF has been made up of 10 semesters (5 years). The number of Spanish credits for the whole syllabus is 375 (1 Spanish credit is equivalent to 10 teaching hours), divided into two stages. The first one takes 6 semesters and the second one takes 4. One academic year comprises two semesters and every semester lasts 14 weeks of teaching, with around 37'5 credits (375 teaching hours), and a period of 3 weeks for examinations.

From 2010/2011 the new degree, according to the new EHEA, will consist on 240 ECTS split in 8 semesters (4 years). Later, there will be a Master degree which will have between 90 and 120 ECTS. Some facts about the adaptation procedure were reported in [9].

Nowadays, Mathematics in the first year of the Computer Science degree at our institution mainly appear in the syllabus of these two subjects:

- **Mathematical Analysis** (Análisis Matemático - AM), 12 credits. It deals with calculus of one and several variables, complex numbers, numerical sequences and series, Fourier series, and ordinary differential equations.
- **Mathematical Structures for Computer Science I** (Estructuras Matemáticas para la Informática I - EMI1), 9 credits. It includes contents of linear algebra (such as systems of linear equations, vector spaces, eigenvalues and eigenvectors), logic (propositional logic and predicate logic), and discrete math (mathematical relations and graph theory).

In the future degree of Computer Science, that will start in the course 2010/2011, the contents of these subjects will be redistributed as follows: **Mathematical Analysis** (6 ECTS), **Discrete Mathematics** (6 ECTS), and **Linear Algebra** (6 ECTS). This distribution will imply a new revision of the syllabus of each subject.

III. The competence level test

In the flavor of the tasks used in the examinations proposed in the frame of the PISA Project, some tests were proposed in order to measure the following competences for the Computer Science freshmen: *Reading comprehension*, *English*, and *Mathematics*. The following Spanish universities were involved in this project: Universidad de Almería, Universidad de Castilla La Mancha, Universitat Politècnica de Catalunya, Universidad Politécnica de Madrid, and Universidad Politécnica de Valencia. A number of 425 students conducted these tests, 107 of them where from the Universidad Politécnica de Valencia.

Depending on the results of the activities related to each competence, rubric procedures were developed in order to classify the level of each student on each competence as *Low*, *Medium*, or *High*. A complete description of this study and its outcomes can be found in [3], see also [11].

All tests and tasks were expected to be done in 2 hours. The Mathematics part was prepared to be done in 20 minutes. Nearly all questions where proposed in a True or False way.

At the ETSINF in the Universidad Politécnica de Valencia, we have deeply analyzed the particular results of our students in the Mathematics competence. For this purpose the questions in the test of the mathematical competence were divided up in two parts: *Calculus* and *Algebra*.

The evaluated Calculus contents are basically included in the subject *Mathematical Analysis*. On the other hand, Algebra is related with *Mathematical Structures for Computer Science I*, since half of its contents are of linear algebra.

The items treated in the Calculus test were graphic representation and elemental properties of functions, derivatives, and primitives. On the other hand, in Algebra we considered algebraic computations, solution of inequalities, lines on the plane, and the solution of systems of linear equations.

IV. Results and discussion

The results in the test of Mathematics' competences, measured using rubrics, have been compared with the marks obtained by this same cohort at the end of the academic year. In Spain the students who fail the final exam after the teaching period can sit for an additional examination during the same course. For these students, we have considered the higher mark obtained in both exams.

In Figure 1 we show the percentages of students obtaining the low, medium, or high level on each of the rubrics (100 % are 107 students from the Universidad Politécnica de Valencia). In both rubrics more than half of the students show a low level of competence (52% in Algebra and 55% in Calculus). These results show us that the level of the questions was quite similar in both cases.

The number of students with a medium level of competence is higher in Algebra than in Calculus (45% and 30% resp.) However, only a 3% of students in Algebra, and a 14% in Calculus got the high level. This could depend on the fact that the text contained some questions on geometry of the plane that are treated in the first year of the baccalaureate period, and they are not considered neither in the university entrance examination nor in the university courses.

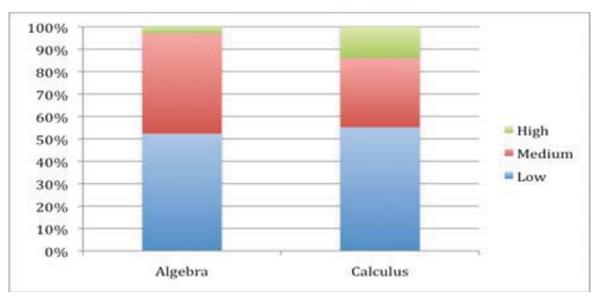

Figure 1. Percentage of students in each level of the rubric.

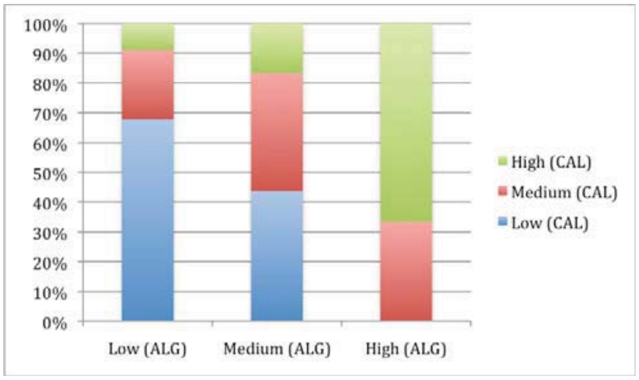

Figure 2. Percentages of students in each level of the Calculus and Algebra rubrics.

Secondly, we have studied the relation between the level on Calculus and Algebra of each student. (See Figure 2). Almost 70% of the students with a low level in Algebra have also a low level in Calculus. The medium level in Algebra corresponds with the medium level in Calculus for the 40% of the students. Finally, almost 70% of the students with a high level in Algebra have also a high level in Calculus. This also Confirms the level of the questions was quite similar in both rubrics.

The levels obtained in each rubric by the students can be compared with the marks that they have obtained in the subjects of EMI 1 (for the rubric of Algebra) and AM (for the rubric of Calculus) at the end of the academic year. This relation can be seen in Figure 3. It is important to recall that in Spain the marks obtained in a subject are from 0 to 10. A mark of 5 is required to pass a subject.

We should point out that in order to compute this average, students who did not sit for examination but did the test were also considered. A mark of 0 was assigned to these students. This fact makes the average of the marks lower than the corresponding average of the students who sit for examination in these subjects. However, we consider that exclude the results of these students will distort our study.

In Figure 3, we have represented, for each level, the mean plus/minus the standard deviation of the marks. For EMI 1 the standard deviation of the marks corresponding to each level of the rubric was (2.7 for low, 2.92 for medium, and 0.45 for high).

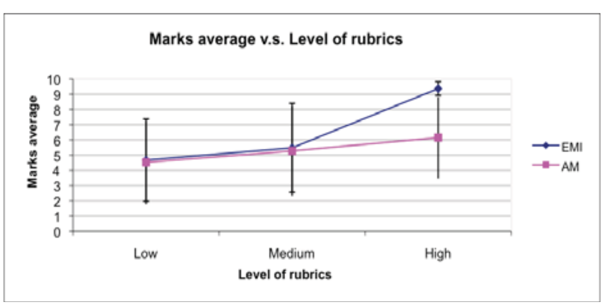

Figure 3. Marks average on EMI 1 and AM vs. level on each rubric.

In AM the corresponding standard deviations were quite similar for students with a low or medium level (2.74 for low, 2.95 for medium), and much more bigger for students with a high level (2.67).

The fact that some students who did not sit for the examination were considered makes that the deviations were quite significant for the low and medium levels, where these students were supposed to be classified.

We also see that the small number of students having a high level in the Algebra rubric show a mark very high in EMI 1 (about 9.5). This fact is different from the rest of groups where a linear relation has been established between the level on the rubric and the average of the marks in the corresponding subjects.

At this point one can wonder if the differences observed in the results of rubrics and the corresponding marks on AM and EMI 1 would imply, really, different populations. In order to measure if the means of the marks obtained in each of the cases correspond to different groups, we have used the t-statistic test, by computing the probability that the different means of the marks were significative. In the next table we show the probability (percentage) that the differences in marks between different pairs of groups are significative. The study has been carried out between the different groups of Algebra, and on the other hand, the different groups of Calculus:

TABLE I. PROBABILITY (EQUAL OR HIGHER) THAT THE DIFFERENT MEANS OF THE OBTAINED MARKS ARE SIGNIFICATIVE. GROUPS COMPARED ARE H (HIGH) VS. M (MEDIUM) LEVEL, H VS. L (LOW), AND M VS. L, BOTH IN ALGEBRA AND CALCULUS.

	Algebra	**Calculus**
High-Medium	95%	60%
High-Low	99%	95%
Medium-Low	80%	70%

These data shows that the groups established by each rubric have in fact different means with a probability, at least, of 60%. In the case of the comparison between the high and low level, the probability is higher than 90% (95% for the Algebra rubric).

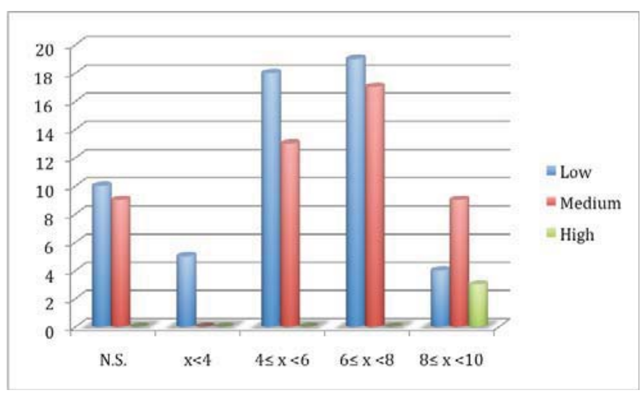

Figure 4. Distribution of the marks in EMI 1 depending on the level of competence in Algebra.

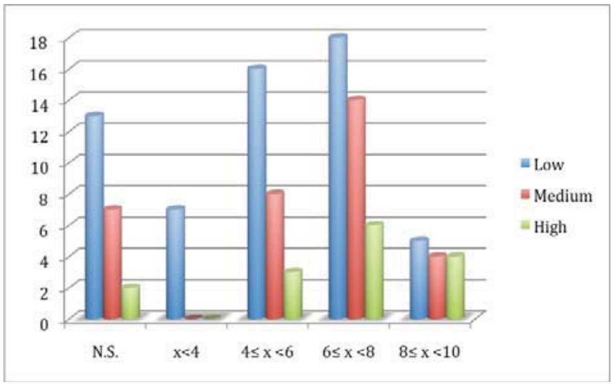

Figure 5. Distribution of the marks in AM depending on the level of competence in Calculus.

In addition, we have considered the relation between the level obtained on the rubrics and the distribution of marks in the subjects of EMI 1 and AM. These distributions can be seen in Figures 4 and 5. We have considered the following groups NS (who did not sit for examination), less than 4, greater or equal than 4 and smaller than 6, greater or equal than 6 and smaller than 8, and finally, greater or equal than 8.

In both rubrics it can be found similar patterns for the distribution of marks:

- In all groups of each rubric, most of marks in the corresponding subject are between 4 and 8; for the low level, the highest weight is between 4 and 6, and between 6 and 8 for the medium level.
- For the high and medium levels, the weight of the marks greater than 8 increases. In the case of Algebra it covers the 100%.
- All students with marks smaller than 4 in AM or EMI 1 got a low level in its corresponding rubric.
- The number of students who did not sit for examination is similar for the students with a low or medium level in the corresponding rubric.
- Only students with a low level in the rubric get a mark smaller than 4 in the subject.

The number of credits passed by the students is strongly related with the marks obtained by them in the subjects of EMI1 and AM, as Figure 6 shows: There is a linear increase in the number of passed credits in the first academic year as the results in the rubric are improved.

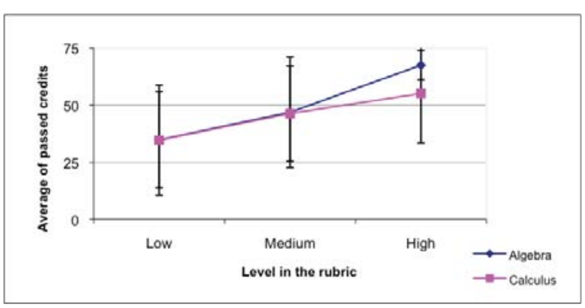

Figure 6. Approved credits by pupil vs. the level of the rubric for each group.

Finally, we have to point out that all students that did the test were also enrolled in the degree the next year. Nearly none of them has dropped out of the degree.

This was not the expected situation observed some years ago in [8]. This situation has probably happened because the test was taken during the second semester of the first academic year.

The interesting point is that we have noticed that all students who will not go on with the degree have already taken their decision in this moment of the academic course. On the other hand, the economic crisis is probably forcing the students to keep on studying at the university, as they cannot find easily a job.

V. Conclusions

To sum up, in both cases, Calculus and Algebra, the classification of the students in rubrics have similar results. This fact is an evidence of the coherent design of both, the tests and the rubrics. Therefore we can affirm that the level of competence in Mathematics acquired during High School of the students of the Computer Science degree, is strongly related with the success in all Mathematics subjects of this degree.

Also, students with lower level of competence can even pass the subjects of Mathematics. This can happen because in some cases they know the solution procedure of some problems but they do not really understand the meaning or intuition of the mathematical topics.

In any case, students with a low level of competence in Mathematics have smaller chance to succeed in the mathematical subjects of the degree. Furthermore, the level in Mathematics is strongly related with the success in the rest of the subjects of the first academic year.

The PISA reports [4] set the competence in Mathematics of the Spanish students a little below than the average of the OCDE countries. This situation is not getting better during the sequent years. The High School period has only two courses, and in the second one the students should be prepared to pass the University entrance examination. All questions and

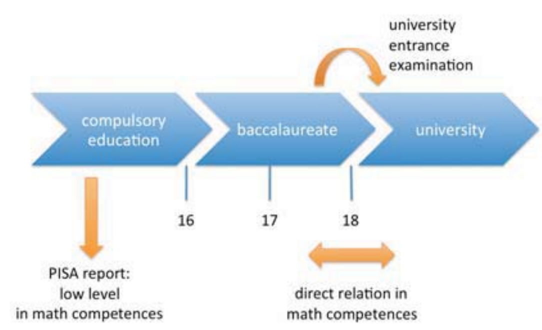

Figure 7. Diagram of the situation of the mathematical competences in secondary education and university.

contents of this examination are quite defined, so during this second course the outcomes expected are focused on solving the problems that will appear in this exam. The develope of the mathematical intuition plays second fiddle.

Since it is clear that the good level in the mathematical competences improves the success in the Computer Science degree, then the level on it should be improved. Great efforts must be done in compulsory education as the PISA reports suggest. Another option is to propose an enlargement of the Baccalaureate, probably separating the students in the last year of compulsory education depending on their interests, or adding one more year to the Baccalaureate.

Until the changes in these periods happen, the Faculties and Schools of Computer Science should try to improve the mathematical competences of their students. This can be done offering groups, during the first academic course, to support the students having great deficiencies in basic notions of mathematics. Besides, in the programs of mathematics subjects in the new Computer Science degrees, more attention must be paid to mathematical notions and concepts, despite that the number of ECTS has probably been reduced.

***Abstract*—In this paper, the results of four years of a research aimed at carrying out a comparative analysis between the application of the European Credit Transfer and Accumulation System (ECTS) and the traditional teaching and learning system (TTLS) to first-year students, in order to improve their performance in the subject Analysis of Circuits I (AC-I) are presented. The ECTS is a student-centered system based on the student workload required to achieve the objectives of a program, and the outcomes of its application have been quite positive. In order to conduct the statistical analysis of the data collected in the educational experiment and make the right decisions, at the beginning of the experiment, during the first years, both treatment and control groups were formed and several tests of hypothesis were conducted in the groups that participated in the educational experiment. Neither all the students who took the above-mentioned subjects nor all the professors who taught them participated in the experiment. However, during the last year of the experiment all the students and almost all professors participated in the experiment. Since the beginning of the experiment, satisfactory partial results have been gradually achieved, and when we managed to involve all the students and almost all professors in the last year of the experiment, the overall results where not only satisfactory but also significantly better than the ones achieved in the previous years. The students satisfaction and confidence have increased gradually, and, in general, the students under the ECTS passed more exams and with better Grades than the students under the TTLS. Also, the teaching-learning methodology strategies, tutor sessions, assessment methods, use of the virtual learning environment (VLE), student teamwork, and collaborative work among professors performed better under the ECTS than under the TTLS.**

***Index Terms*—student-centered learning system, first-year students, statistical analysis**

I. Introduction

In this paper the results of four years of research and application of a student-centered learning system (SCLS) to improve the performance of first-year students (FYS) in the subject AC-I are presented. The above-mentioned SCLS is based on the application of the ECTS [1] to the EUIT de Telecomunicación (EUITT) at the Universidad Politécnica de Madrid (UPM), and was born five years ago as a result of the adaptation of the first-year course of the EUITT-UPM to the European Higher Education Area [2].

Since the academic year 2005-2006 in the EUITT-UPM the higher education system has experienced a positive change from the traditional teaching and learning system (TTLS), which has failed to motivate students for further learning and does not take into consideration their needs and perceptions, to novel systems based on the student workload required to achieve the objectives of programs.

While in the TTLS credits are given only for student workload in class, without taking into consideration the independent and private study, and the preparation of projects and examinations either, in the SCLS mentioned in this paper credits can only be obtained after successful completion of the work required and appropriate assessment of the learning outcomes achieved.

The learning outcomes are sets of competences, expressing what the student will know, understand or be able to do after completion of a process of learning [1].

In the EUITT-UPM, both the TTLS and the SCLS consisted of 15 teaching weeks, and the subject AC-I had allocated 7.5 non-ECTS credits for the TTLS and 7.14 ECTS credits for the SCLS [3].

1 non-ECTS credit stands for 10 working hours of the students in lectures, seminars and laboratory sessions, without taking into consideration the student workload after classes, the independent and private study, and examinations.

1 ECTS credit stands for around 25 to 30 working hours and, as mentioned in previous sections, credits in ECTS can only be obtained after successful completion of the work required and appropriate assessment of the learning outcomes achieved.

Thus, due to the fact that the current emphasis is on understanding and measuring students' learning, rather than teaching [4], the content-centered approach [5] is soon-to-be obsolete and the current higher education system is moving on to the student-centered approach [5]. In the latter, developing the cognitive abilities of the students is of paramount importance rather than teaching, and it also applies collaborative and cooperative learning methodologies efficiently [6], [7], [8].

The subject AC-I is a fundamental one and it is taught in the first semester of the first-year course in the EUITT-UPM. Also, the students that take this subject can be either new first-year students or students who are taking the subject again. Several educational experiments have been conducted in order to improve the performance of the students in AC-I, and their results have shown that when the academic results of one year are compared with the ones of another year the differences between both are not always significant. Therefore, professors have to keep themselves improving the teaching and learning system continuously.

In this paper the problem of analysis of the results of the educational experiment is formulated as a statistical analysis problem and some decisions about the efficiency of the proposed SCLS on the basis of sample information are made.

II. General description of the educational experiment that have been conducted in the last four years

A. First two stages of the experiment: All first-year subjects

The beginning of the educational experiment dates back to the academic year 2005-2006. In that stage of the research the coordination among the 14 professors that decided to participate voluntarily in it was the key issue. There were professors from different departments and from all the subjects that are taught in the first academic year of the EUITT-UPM [3], AC-I was one of the subjects under study.

Generally speaking, the research group had several regular meetings during the whole academic year and, after each meeting of the research group, several important decisions regarding the curriculum development and the application of the ECTS to the EUITT-UPM were made. Such decisions were focussed on the following issues:

1) Determining the student workload and its translation to ECTS.
2) Developing new educational methods that guarantee the perfect harmony among all the subjects.
3) Promoting tutor session.
4) Applying the same evaluation methods in all the subjects.
5) Setting the standards of using the Virtual Learning Environment (VLE).
6) Strengthening the cooperation among all the subjects taught during the academic year.

Also, during the academic year 2005-2006 32 new first-year students (FYS) were chosen to participate in this educational experience. These students were chosen at random from a group of 150 new FYS that wanted to participate voluntarily in the educational experiment. Those students had both a lecture room designed to facilitate teamwork (with Wi-Fi technology, laptop computers, a slide projector and adjustable desks aimed at making the students feel comfortable in the classroom), and a laboratory room consisting of 16 student workbenches equipped with the conventional laboratory instrumentation that can be found in an electronic engineer's workbench [9].

At that time, it was decided to design each semester taking into consideration that the student workload is 800 hours and that during the examination weeks the students devote 20 hours to study each particular subject to successfully pass the final exams. The marking scheme for each subject was constructed as follows: 70 % exam paper and 30 % continuous assessment, including participation in classes and activities developed in the VLE; and for the VLE the software system used Moodle.

Furthermore, the VLE was used to provide follow-up materials online, continuous assessment tasks for their (online) discussion, homework assignments, and online activities or exercises. Also, it was used to make available the material from the professors and the scheduling of each unit of work, to participate in forums assigned by the professors, and to provide forum questions and e-mentoring or e-tutoring.

During the second stage of the educational experiment, the academic year 2006-2007, the working methodology was the same as the one of the first year, the number of new FYS that participated in the experiment was 90 and the number of professors was 17. In addition, the new FYS that participated in the educational experiment were not asked whether they wanted to participate voluntarily in the experiment. But they were all informed about the project when they came to the school to enrol in the academic year 2006-2007, and at that time the professors let the students know that some of them were going to be chosen at random to participate in the project.

Generally speaking, during the first two stages of the educational experiment, which focussed on all the first-year subjects, the overall opinion of both students and professors was quite positive. The two things that they both valued the most were the continuous assessment and the use of the VLE as a support to both the developing of student learning skills and the collaboration and cooperation among students.

On the other hand, as at university professors have also to do research on other fields such as Telecommunication Engineering, Electronics, Physics, Mathematics and so on, the general opinion of them was that the pass from the traditional teaching and learning methodology to the new one had caused an increased in their workload, at least in the first two stages of the educational research project. Also, in spite of the fact that most of the students who participated in the project were in favor of the new methodology, some of them thought that the workload was higher [10], [11].

Therefore, in order to make the system more efficient and to find one that works best for both professors and students, some decisions were made during the third stage of the experiment, the academic year 2007-2008. For instance, that academic year faculty and student mentors were introduced, and all the lecture rooms of the school for first-year students were designed to facilitate teamwork among students and to make them feel comfortable in classes.

Moreover, in that academic year there were two kind of groups of students, one consisting of new FYS and the other consisting of students who were taking the subjects again. Also, in the academic year 2007-2008 the marking scheme depended more on continuous assessment tasks (i.e., partial exams, tests, projects, homework assignments, and so on) than on the final exam paper. In fact, in AC-I outstanding students did not have to do the final exam paper, they passed the subject if their performance in the continuous assessment tasks was very good.

In order to round-up the first two stages, it can be said that there were weaknesses such as the high student and professor workload, and threats such as the lack of communication among the professors that participated in the project and the ones that did not participate in it, some professors were not 100% willing to change from the TTLS to the SCLS based on the ECTS, some professors did not consider research in Engineering Education as scientific research, and in order to improve communication, teamwork and lateral thinking, the amount of interdisciplinary lessons had to be increased.

However, on the other hand, there were also strengths such as the overall improvement of the student performance in all the subjects, the blended approach to teaching, face-to-face and e-learning, the use of interactive methods to break the monotony, the use of the VLE, the good coordination and cooperation among all the professors subjects that are participating in the project, and so on; and there were many opportunities as well, in its first two stages the educational experiment allowed us to enjoy the benefits of the new teaching and learning methodology, and to be prepared for collaboration and cooperation in excellence in engineering education with other member states of the European Community.

Taking into consideration both the positive aspects and the things that the research group had to improve from the first two years of the educational experience, it was decided to continue the research focusing only on each specific subject, instead of focusing on all the first-year subjects at the same time.

To that end, the resources were optimized and the research group tried to involve more professors of each specific subject in the experiment, which in contrast to the first two years of the experiment in the case of AC-I it has been a success since the academic year 2007-2008. Currently, all the professors who teach that subject have gotten involved in the experiment.

The next third and fourth stages of the educational experiment that will be described next (i.e., academic years 2007-2008 and 2008-2009), will be devoted specifically to describe the part of the experiment focused only on the subject AC-I.

B. Last two stages of the experiment: AC-I

During the third stage of the educational experiment, the academic year 2007-2008, the working methodology was the same as the one of the first two years and, as mentioned above, some decisions were made to make the system more efficient and better adapted to the needs of both students and professors. In this stage of the experiment 222 students who had to take the subject AC-I were chosen to participate in the experiment. Those students were chosen at random from the group of 444 students that were enrolled in AC-I in the first semester of the academic year 2007-2008 [12].

Also, those 222 students were divided into 4 groups of students with the following characteristics:

1) Group A: 50 new FYS. These students studied under the TTLS.
2) Group B: 47 new FYS. These students studied under the SCLS.
3) Group C: 64 students who were taking the subject again. These students studied under the SCLS.
4) Group D: 61 students who were taking the subject again. These students studied under the TTLS.

In addition, the number of professors of AC-I who participated voluntarily in the experiment was 4. Two of them had good experience with the application of the student-centered approach to improve the performance of students, and the other two professors had good experience with the application of the TTLS.

Furthermore, for the TTLS the marking scheme for AC-I was constructed as follows: 75% the final exam paper, which is done by the students in one specific day during the examination weeks, after having finished the 15 teaching weeks of the semester, and 25% the laboratory exam in the last week of the semester.

Taking into consideration the results of the two previous academic years, in the third stage of the experiment for the SCLS it was decided to construct the marking scheme based on continuous assessment tasks as follows: two exam papers, 30% the first exam paper (in the middle of the semester) and 37.5% the second exam paper (in the last week of the semester); 7.5% ten 30-minute knowledge tests given to the students during all the semester (two 10-questions knowledge tests given at the end of each one of the five units of work of AC-I), this activity was carried out using the VLE and the tests were made by using the platform Moodle; and 25% continuous assessment activities in the laboratory including a final laboratory exam in the last week of the semester.

Also, the professors who participated in the educational experiment prepared the knowledge tests in Moodle in such a way that none of the tests that the 222 students had to do had the same 10 questions. The questions were chosen at random by Moodle.

The 10 knowledge tests (i.e., 2 tests for each unit of work) that were given during all the semester were mandatory for the students of the Groups B and C. However, these tests were optional for the students of Groups A and D.

An example of the full version of one of the above-mentioned 10-questions knowledge tests can be found in the Appendix of [12].

Finally, during the academic year 2008-2009, the last stage of the experiment, all the FYS (i.e., new FYS and students who were taking the subject again) participated in the experiment and the number of professors who taught the subject AC-I that participated in the experiment was 7.

Moreover, from that academic year on the marking scheme was the same for all the students: 3.75% ten 30-minute knowledge tests given to the students during all the semester, those tests had the same characteristics as the ones of the academic year 2007-2008; 15% the partial exam paper (there was only one) in the middle of the semester; 56.25% the final exam paper; and 25% the laboratory exam in the last week of the semester.

As will be shown in the next section, the academic results of that year were the best, both professors and students were very happy with them and in many aspects all the effort of many years of the educational experiment started to pay back.

III. Statistical analysis of the general academic results of the students during the experiment

In order to conduct a comparative analysis between the general academic results of all the FYS right before the beginning of the experiment and the ones during the last four years of it, a comparison of the final Grades in the subject AC-I among the years 2004, 2005, 2006, 2007, 2008 and 2009 was carried out in order to say, on the basis of the evidence obtained, whether the observed differences were significant and either accept or reject the hypothesis that the students under the SCLS based on the ECTS performed better than under the TTLS.

At this point, it is important to point out that the years 2004 and 2005 are important because they were the last two years in which there was no research in engineering education in the above subject. From those years on the research started with a small group of FYS students and only 2 professors of AC-I, and at present (in the academic year 2009-2010) all the FYS and all the professors who teach AC-I are involved in it, which has been a significant step forward in the educational experiment.

The first step of this section was to conduct an exploratory examination of the data. To that end, the R system for statistical computing was used [13], the data set was loaded and the variables (Grades2004, Grades2005, Grades2006, Grades2007, Grades2008, Grades2009) accessed.

Figure 1 shows the Box-plot of the data and Table I shows some summary statistics.

Figure 2 shows the histogram and density estimate of the Grades of the years (2004, 2005, 2006, 2007, 2008 and 2009) [14]. From that figure it can be seen that the distributions are strongly skewed.

The model

$$y_{ij} = \mu_i + e_{ij} \quad i = 1, \ldots, 6 \quad j = 1, \ldots, n_i \qquad (1)$$

is considered. Here, $\mu_i, \quad i = 1, \ldots, 6$, are the mean value of the final Grades of the students, e_{ij} are random errors that follow a normal distribution with zero mean value and standard deviation σ, and $n_i,\ i = 1, \ldots, 6$, is the length of the each variable.

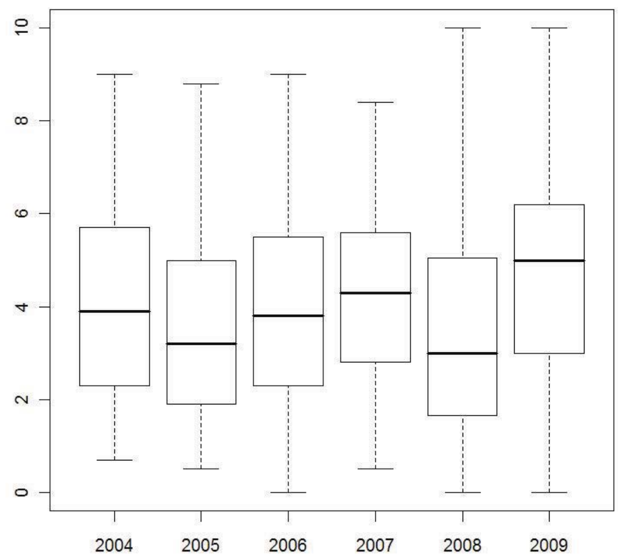

Fig. 1. Boxplot of data

Next, an F test [15] was carried out to see if the means of the Grades were equals.

The hypothesis is

$$H_0 : \mu_1 = \mu_2 = \ldots = \mu_6$$

against

$$H_1 : \mu_i \neq \mu_j \quad \text{for at least one pair } i, j,$$
$$\forall \quad i, j \in \{1, \ldots, 6\}$$

at level 0.05.

Then, the residuals were used to check the adequacy of the fitted model using a normal Q-Q Plot (see Figure 3) and a normality test statistic (see Table II).

Therefore, the model (1) is considered when random errors do not follow a normal distribution.

Now, the problem may be solved by a rank test such as Kruskal-Wallis [16], [17]. In that sense, Table III was obtained.

Then as shown by the p-value of the KrusKal-Wallis test, H_0 had to be rejected. Therefore, the statistical analysis continued with the study of the academic years in which it can be said that there were significant differences. In short, the experimental groups that led to the rejection of the null hypothesis were investigated. Such an investigation was carried out by using a post-hoc comparison test [18].

To that end, a pairwise permutation test we applied to all possible pairs of groups and as a result, for the data under analysis, it was found that there were significant differences among the final Grades of the students. This information is shown in Table IV.

TABLE I
SUMMARY STATISTICS

	Grades2004	Grades2005	Grades2006	Grades2007	Grades2008	Grades2009
Min	0.700	0.500	0.000	0.500	0.000	0.000
1st.Qu	2.300	1.900	2.300	2.800	1.675	3.025

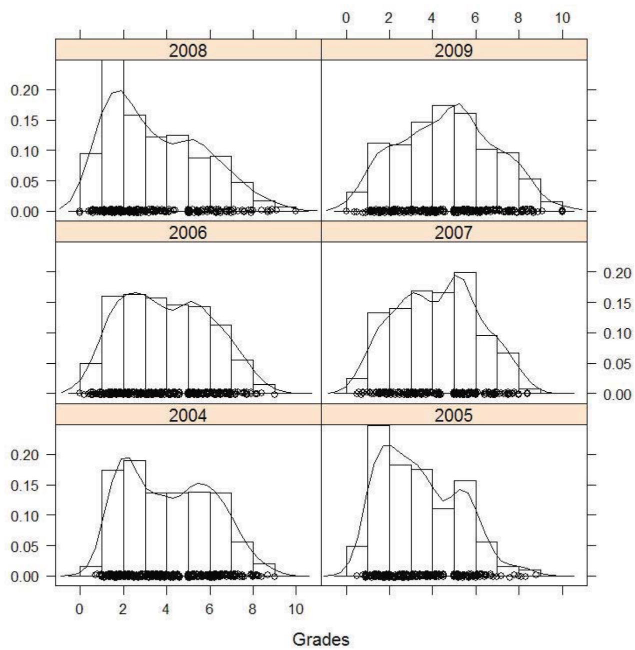

Fig. 2. Histogram and density estimate of variables

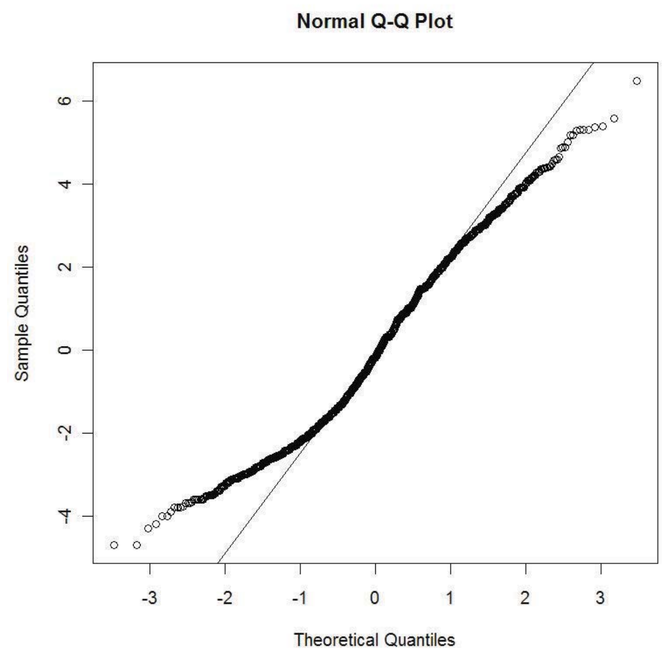

Fig. 3. Normal Q-Q plot

In Table IV, the partial p-values are highlighted with the usual R convention [13]:

Signif. codes: 0 `***´ 0.001 `**´ 0.01 `*´ 0.05 `.´ 0.1 ` ´ 1

Also, in Table IV `***´ stands for that the observed differences between the specific years under analysis were highly significant, `**´ stands for that the observed differences between the specific years under analysis were very significant, `*´ stands for that the observed differences between the specific years under analysis were significant, and ` ´ stands for that, on the basis of the evidence obtained, the observed differences between the specific years under analysis were not significant.

Table IV shows that the best year was the year 2009, the two second best years were 2004, 2006 and 2007, and the worst years were the years 2005 and 2008.

The general results of the year 2005 motivated the application of the SCLS based on the ECTS to improve the performance of the students and the general results of the year 2008 motivated a change of philosophy.

2007-2009	-0.42879216	0.015984016	*
2008-2009	-1.16851183	0.000999001	***

Such a change was necessary because in spite of the fact that the new FYS that were taught under the SCLS in the academic year 2007-2008 had significatively better performance in AC-I than the ones that were taught under the TTLS [12], and that the performance of the students who were taking the subject again that were taught under the SCLS was slightly better the ones that were taking the subject again and were taught under the TTLS, not all the students and professors were involved in the educational experience.

Therefore, taking into consideration both the positive aspects and the things that had to be improved from the academic year 2007-2008 [12], in the academic year 2008-2009 the research group focused its efforts on improving the collaborative and cooperative work among professors and among students as well, on improving the common teaching and learning methodologies, and on trying to involve everyone who was related with the subject AC-I in the experiment. Section II-B was devoted to give a general explanation of what the research group has done since the academic years 2007-2008 and 2008-2009 in order to improve the performance of the students in AC-I.

IV. CONCLUSION

The statistical analysis presented this paper has shown that the application of the SCLS based on the ECTS to improve the performance of FYS in the subject AC-I has yielded satisfactory results. In spite of the fact that there were years in which there was not a significant improvement in the performance of the students and others in which the improvement was slightly better than others, there were years in which there were highly significant differences. The best year was 2009 and the worst were 2005 and 2008.

The results of the year 2005 motivated the application of the SCLS and the results of the year 2008 motivated a significant improvement in the way the SCLS had been applied. Such improvements allowed the professors of the subject to obtain in the year 2009 the best performance of the students in AC-I in the last 10 years.

The overall satisfaction of the students and the professors that participated in this educational experiment was quite positive. Their level of satisfaction was high and their reactions to the improvements in the SCLS were quite positives.

With the SCLS based on the ECTS students have to work harder than with the TTLS but they learn more, pass the subjects with better marks and develop skills that will help them to become good professionals.

ACKNOWLEDGMENT

The authors would like to thank undergraduate students Emilio Fernández and Oscar Rincón for their assistance in the educational experiment. This research has been supported by the Universidad Politécnica de Madrid under the research projects on Engineering Education IE075902067, IE08590220 and IE09590203.

A Concept Map Approach for Introduction to Computer Engineering Course Curriculum

Gul Tokdemir*, Nergiz Ercil Cagiltay***

*Computer Engineering Department, **Software Engineering Department,

Atilim University, Ankara, TURKEY

{gtokdemir, nergiz}@atilim.edu.tr

***Abstract*— As in any discipline, in Computer Engineering, students start learning the basic concepts of the discipline in their first year through an Introduction to Computer Engineering course. The topics toughed in this course can be grouped into two. The first group includes simple concepts like binary numbering system, hard disk, memory, and I/O devices. In the second group, an introduction to the courses that they will take in the next semesters of the program which includes programming, networking, software engineering, artificial intelligence and database systems. The main objective of this course is to give an introduction about the general concepts of the field to the first year Computer Engineering students and prepare them to understand the connections between them for their future studies.**

However, students and instructors face with many problems in this course. First, because of the diversity of the concepts given in the course, it is very difficult for the students to see the big picture of the Computer Engineering domain. Similarly, it is difficult for the instructors to prepare the course content in an integrated manner at the students' level. Additionally, the perception of the theory and practice behind the hardware and software topics and their connections is not an easy task for the beginners. Moreover, the topics are mostly abstract topics, which do not allow application of any laboratory sessions. Students usually find this course difficult to understand, which decreases their motivation about the department and success of the course.

This study is established to propose a concept map approach to better visualize and discover all the connections between the concepts of Computer Engineering field which can be used in the curriculum of the programs and introductory courses of the field addressing the above problems. The proposed concept map helps to visualize the general picture of the field.

***Index Terms*—curriculum development, concept maps, computer engineering**

I. INTRODUCTION

Because of the very nature of the rapidly changing technologies, several problems have been faced with for establishing the computer engineering curriculum. The curriculum of such programs need to provide theory and practice on basic concepts of the field such as hardware, digital logics, computer organization, and architecture, programming languages, operating systems, computer networks, database systems and data structures. As declared by Nisan [1], the overall interactions among hardware, software, compilers and operating systems used to be simple and transparent enough for understanding computer systems. However the modern computer technologies have become increasingly more complex which makes it very difficult to understand the whole system of the computers [1]. Accordingly, this complex structure puts pressure on the designers of introductory courses [2] and curriculum developers of such programs. Main problems addressed in the literature can be summarized as below:

- Until their junior or senior year, potential majors do not find what the major is really about [3].
- Many students often assume that computer science education is not about ideas and creativity, but is about learning technology and syntax of programming languages [4].
- Non-majors believe that computer science is only about programming [3].
- Introductory computer science courses do not introduce students how computer scientists address important problems of the field [3].
- The curriculum of these programs provide the theory and practice on main concepts of the field however it is hard to build connections among different components of the computer systems.

Accordingly, two main problems can be addressed from these views. Firstly, for the introductory courses, it is hard to organize the course for better providing the relationships among concepts of computer engineering programs which would make students lose their interest and motivation at their first year. Secondly, while developing a curriculum of such programs it is hard to show the relationships among courses and additionally build a balance on different dimensions of the programs. Since the field of the computer engineering getting larger by including many hardware and software issues as well as the human factors, the curriculum of such programs may vary on the ratio of distribution of different tracks of the field. In that case, defining different dimensions of the field becomes a necessity. For example, for balancing the programming courses and hardware courses ratio based on the general vision of the whole program sometimes need to be considered. This helps the students as well as the program developers to see how well the program fits the expectations.

On the other hand, concept maps are the tools used to build relationships among concepts. These tools have been used in educational environments to better connect the relationships among theory and practice as well as among other concepts covered in a course. These tools also help the learners build relationships between previous knowledge and newly introduced concepts, encouraging meaningful learning rather than rote learning (memorizing concepts, no relationship to previous learning) [5].

In our university, an introductory course has been offered for the computer engineering students. The problems discussed above are all faced in this course and the computer engineering program as well. Accordingly, in this study to address these problems a concept map is developed which builds relationships among the tracks in the field of computer engineering. Main objective of this concept map was three folded:

- to build connections among the concepts given in the introductory course of the field,
- to provide a general idea about the general structure of the program,
- to build the connections among the courses in the computer engineering curriculum.

This study describes the introductory course and the curriculum of the program. Then, it provides the proposed concept map for describing general tracks and dimensions of the field. For the development of the concept map, a new approach called "Goal-Question-Concept" is applied. Lastly, it shows the relationships among the introductory course as well as the curriculum of the program. We believe that, this concept map can be used as a base to build connections about different subjects given in the introductory course and can be introduced in each course to address the relationship between the content of the course and the whole program. This would help the educators to better show the connections between theory and practice issued introduced in a specific course and their connections with the field and prepare course content according to the concept map interactions. Also it would help the students to better build the connections among different concepts of the whole computer engineering program.

II. Course Description

The course "Introduction to Computer Engineering", is taught as the first course for Computer Engineering, and Software Engineering majors. Students with diverse backgrounds and different expectations are introduced to the basic concepts of the domain. Some of them know some coding and think computer engineering is just coding, and some do not have any idea about the domain and feel very insecure and scared. The class is not homogeneous which makes the things more difficult for the instructor.

The main objective is to teach general computer engineering and engineering concepts together with programming fundamentals. At the completion of this course, students are expected to:

- Discuss computer data representation and basic computer operations
- Appreciate the use of machine language
- Describe basic components of a computer system
- Acquire basics of problem solving and programming
- Have a general knowledge on different aspects of computer engineering

Course is planned as 14 week period, 2 hours of lectures in a class environment and 2 hours of lab sessions each week. The basic concepts of the Computer Engineering are taught in the lectures, while basic computer literacy practices like word processing, spreadsheet usage are taught at the lab sessions. The lectures include broad coverage; simple concepts like binary numbering system, hard disk, memory, and I/O devices and more advanced ones like programming languages, networking, software engineering, artificial intelligence and database systems. As a text book, we follow J.Glenn Brookshear's Computer Science: An overview book. the content of the book [8] is as follows:

- Chapter 0 Introduction
- Chapter 1 Data Storage
- Chapter 2 Data Manipulation
- Chapter 3 Operating Systems
- Chapter 4 Networking and the Internet
- Chapter 5 Algorithms
- Chapter 6 Programming Languages
- Chapter 7 Software Engineering
- Chapter 8 Data Abstractions
- Chapter 9 Database Systems
- Chapter 10 Computer Graphics
- Chapter 11 Artificial Intelligence
- Chapter 12 Theory of Computation

We start introducing algorithms, history of computation, then continue with data storage concepts which include storage of bits, main memory, mass storage, representing different type of information in computer systems, numbering systems, Boolean algebra, gates, flip-flops, machine architecture, machine language and program execution. Then concepts of operating systems, networking & Internet, software engineering, programming languages, database systems, artificial intelligence and Algorithms and C language Programming Basics are taught.

As these topics are covered in 14 weeks, each related chapter from the book is referred. However, the connection between them is not emphasized anywhere in the course which creates an unclear, complex picture in the students minds. They just perceive each topic as independent from each other and can not elicit the correlation of them. They generally come up with the argument that the course is boring, has no use, difficult to understand. Consequently, since they cannot realize the importance of these concepts, they do not appreciate computer engineering area, get demotivated at their first semester in the department.

III. COMPUTER ENGINEERING PROGRAM

The computer Engineering program is a 4 years program and containing hardware and software issues. The courses offered by the department are described in the Appendix. The first digit of the course number indicates the year it is offered in the curriculum. TE courses are technical electives (students should choose 5 of them according to the their interests). For choosing the TE courses students face problems because they cannot relate the courses and the field applications. Therefore, they confuse to decide which course is more beneficial for their professional life. Remaining courses are the core courses that are mandatory. Additional to those courses students should take general purpose courses like math, physics, chemistry, and English.

Each course listed in the Appendix, provides subjects related to its own domain and no connection is built between the course and the other courses of the curriculum. The only course students integrate the knowledge they obtained during their 4 year study is the senior project courses, Compe 491-492, which are taught at the fourth year. Until that time, they do not have clear picture of which part of the real life problems of the area each course addresses and how they are linked together. They complain about how they will use the knowledge they gain in these courses some of which are pure theoretical courses. Consequently, they learn the subject without awareness and they generally conclude that other than the programming courses, most of courses are unnecessary for them, and they are wasting time with those subjects.

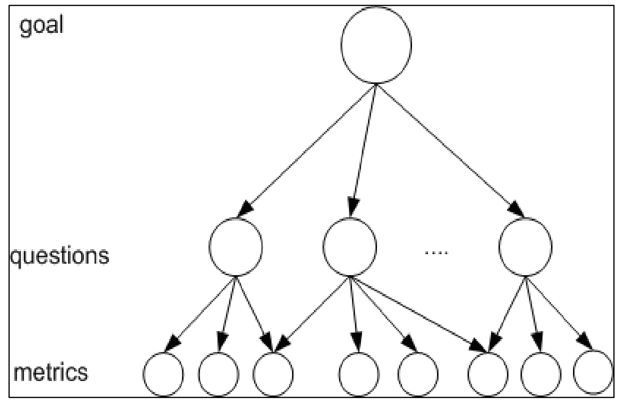
IV. PROPOSED CONCEPT MAP

We propose to use a concept map to built connections between the concepts taught in Introduction to Computer Engineering course. While preparing the concept map, we applied a new paradigm called "Goal- Question-Concept" inspired from a well-known GQM (Goal-Question-Metric) method of software engineering field. GQM was introduced to identify problems in a software process or product and define improvement goals for them for software process improvement. It builds a connection between software goals; questions to be answered for each goal and metrics as answers to the questions [6] as illustrated in Figure 1.

The ultimate goal of a computer system is to serve users by supporting them to improve their performance in their daily lives.

In order to reach this goal we have to answer the following questions:

1. What type of requirements do the users have?
2. What type of system parts needed to be developed based on these requirements?
3. What are the relations between these system parts
4. How these parts should be integrated to create the required system?



5. How this system will serve users to support their tasks?

Figure 1. GQM Technique [7]

The next step is to identify and categorize the concepts related to each question, which should be placed in the concept map. Accordingly, we came up with the top level concepts that should be considered as answers to these questions. These top level concepts can be decomposed to lower levels to reveal the partially detailed concept maps.

For the top level concept map, for answering the first question, we categorized the user requirements as shown in Figure 2.

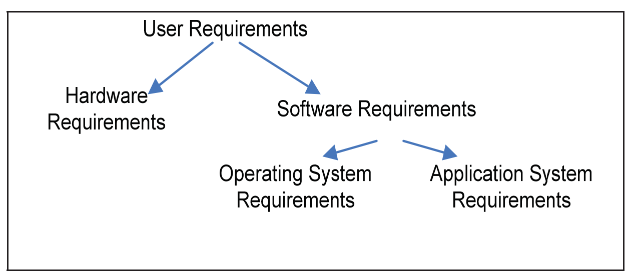


Figure 2. Requirements decomposition

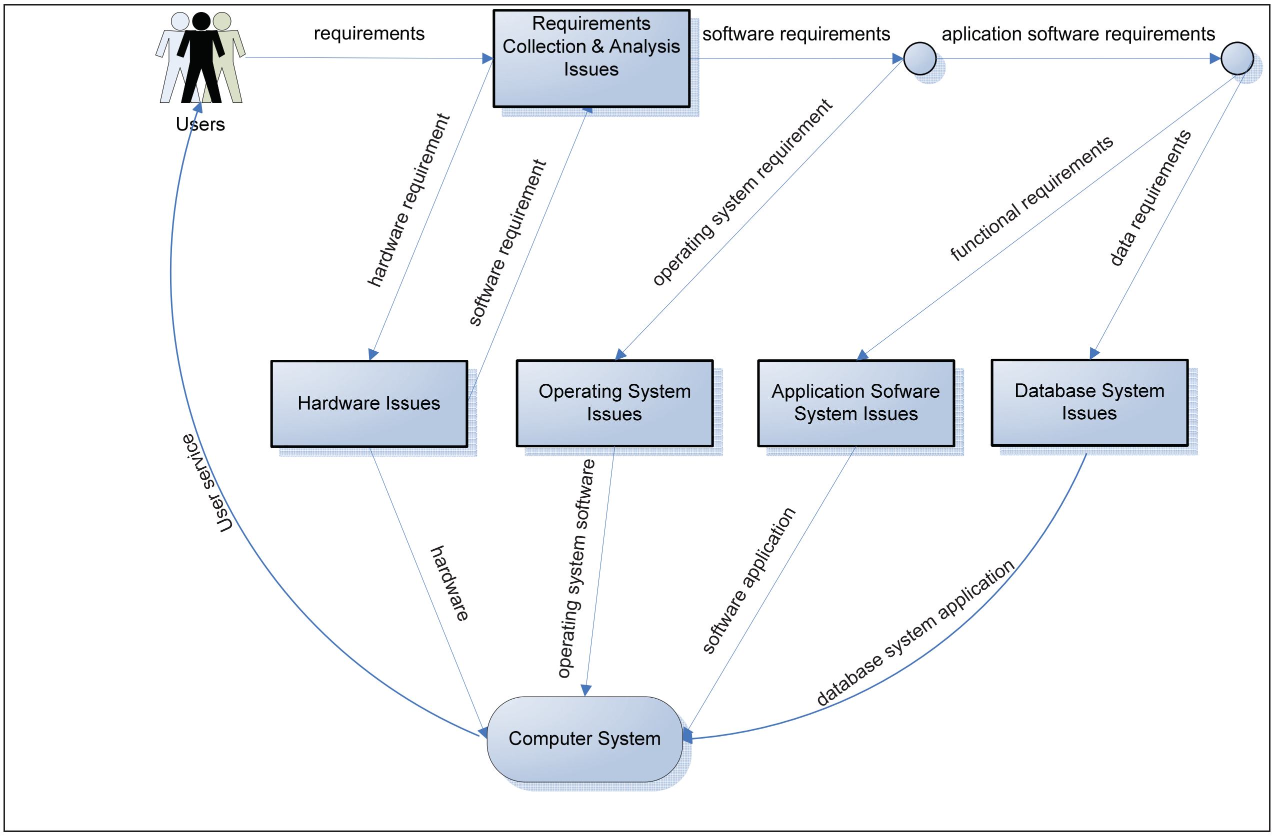

Figure 3. Concept map for Introduction to Computer Engineering course

These requirements triggers the system parts needed to be developed which will be the answer of the second question. We defined these system parts related to the following issues:

- Hardware Systems
- Operating Systems
- Application Software Systems
- Database Systems

We built the connections between those system parts related to system requirements as shown in Figure 3. The integration of those parts will establish the computer system, which is expected to serve the user requests.

Technology, all the theory and developments produced in this area is for the human beings. Main purpose is to provide support for them to work easily, quickly and effectively. Therefore, when the students, they are expected to provide solutions for computer systems to provide support to users. Additionally, they can work in academy to develop new theories, methods, and tools for this field. Accordingly, *user requirements* drive the studies in this field. Hardware requirements trigger new theories, technologies, methods, and products in this field. For this purpose, students should understand the *hardware system issues*. Therefore, in the curriculum of the computer engineering programs, we have several courses addressing main issues of the hardware type studies in this field. Accordingly, in the introduction to computer engineering course the basic hardware concepts are summarized. On the other hand, software requirements may be about the application software or operating software. In order to understand these concepts, one should understand how the application software and operating system software issues are handled. In the concept map, *operating system issues* and *software system issues* provide these concepts. These cover a broad range of design, development, and implementation, management of these systems, and their theories and methods.

The application software requirements are characterized as data and functional requirements. The data requirements triggers *database system issues*, which includes concepts like database management systems, file organization, database design, development, administration, optimization, and monitoring. Functional requirements generate *Software System issues* which cover a wide range of topics like software design, development, testing and management.

All the theories, products, and technologies related to the above-mentioned issues are integrated to construct a *computer system* to better serve for the end users. Based on the requirements, the end user can be able to get services from the computer systems.

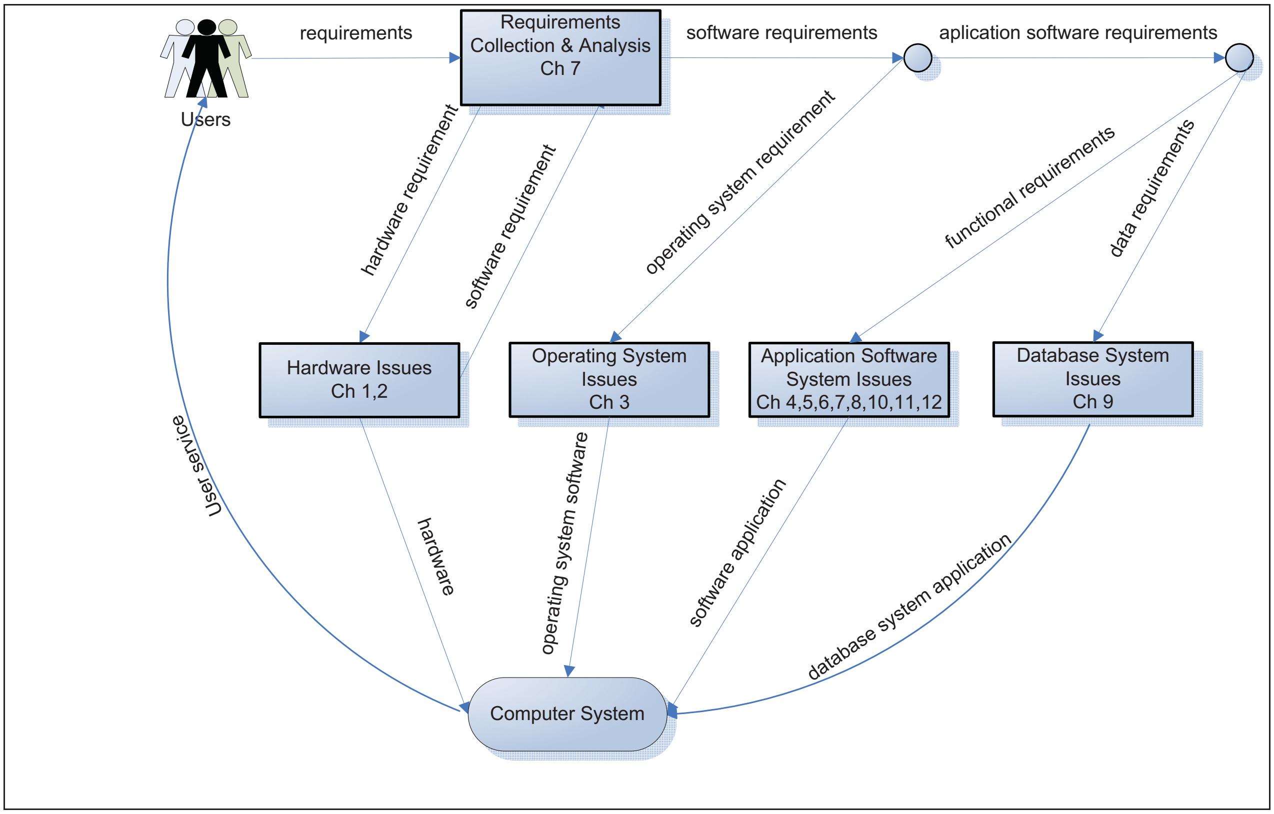

Figure 4. Concept Map- course content match

After we have developed the concept map for the course, we have mapped the chapters covered in the course with the concepts stated in the concept map as described in Figure 4. This shows that every topic covered in the course has a corresponding item in the concept map, which expresses the need for a computer system in the real world.

Describing the concept map to students at each step of the course would make them visualize the big picture and recognize the connection of different concepts they will learn in detail in their curriculum. this way, they can link their previous knowledge, with the new subject which will create a meaningful learning for them.

Additionally, we mapped the concept map with computer engineering curriculum as illustrated in Figure 5. This figure has two important results.

First, it reveals the distribution of the courses in the curriculum based on real world system requirements.

We believe that, the computer engineering issues covered in the curriculum should give insights to the students and make them realize the need for those systems in real world that motivates usage or development of computer systems in the real-life processes. They should be able to map the practical and theoretical aspects of the concepts they learn, to the real world entities where these concepts are employed.

Secondly, this map provides valuable measure to assess how much the program mission is reflected in the curriculum as well as detecting the related problems and improvements of the curriculum.

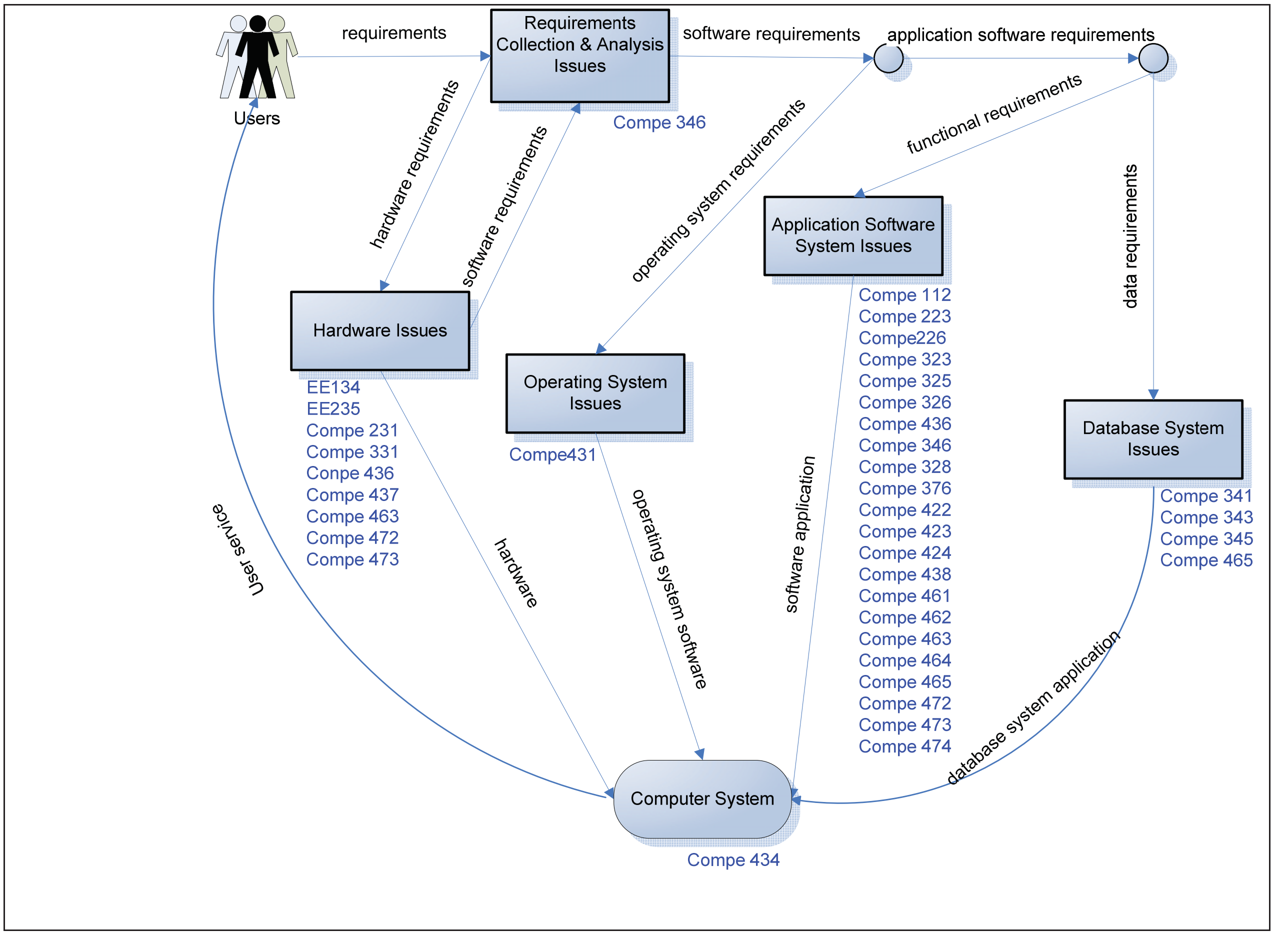

Figure 5. Concept Map –curriculum match

V. DISCUSSIONS AND CONCLUSIONS

In this study, we have addresses two main problems of the field o f Computer En gineering ed ucation: complexity of the introduction to Co mputer En gineering cou rses and t he Computer En gineering curriculum. to address these problems a concept map approach is employed. For development of the concept map a n ovel ap proach "Goal-Qestion-Concept" method has been applied.

The proposed concept maps possibly have several benefits for the Computer Engineering education programs. First, they can address the co ncepts o f In troduction to Co mputer Engineering course wh ich provides a clear v iew of the f ield for freshmans. Secon dly, th e co ncept map and curriculum match diagram helps students to address each course of their curriculum, with their c onceptual view pr ovided f or t he introduction co urse. th is h elps th em to relate their gen eral knowledge of the domain with the courses they will take.

Additionally, lower level concept maps can be prepared for each course and the sam e concept map and curriculum match diagrams can be applied to t he lower l evel, detail ed co urse contents. This wa y, st udents may master t he de tails o f t he field without getting lost in the complexity of the field.

We believe th at, if the s tudents ar e introduced with these concept maps at the beginning of each course, addressing the position of that cou rse in the co ncept m ap, t hey will build connections between the topics of the area effectively.

As a fu ture stud y, these concept maps sho uld be decomposed and detailed to lower levels and applied for each course. T he b enefits o f th is new ap proach f or the computer engineering programs should be evaluated pedagogically. We believe this approach can be applied to any discipline.

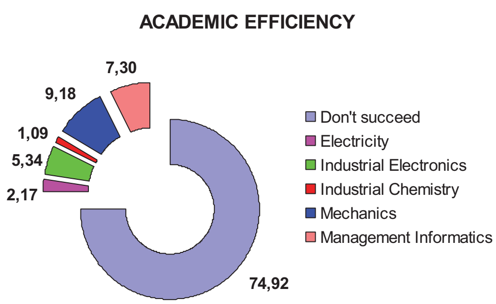

Figure 1. Outcomes of a prerrequisite validation.

I. STATE OF THE ART

On the one hand, several studies have analyzed the state of the art in the curriculum of Mathematics. On the other, it has been observed that our civilization is experiencing the "impact of a regression to the mean". Namely, the quality of the learning/teaching process (LTP) in Mathematics in students entering the university is in decline; for most students the mathematical maturity is achieved (from nursery to school) more as a product of random events outside the family environment; it should require a more rigorous mathematics education programs in compulsory and secondary school; there is a clear difference between 'mathematical thinking" and "the process of calculating"; as calculators, while excellent tools for many things, do not imply the development of resolution and reasoning strategies; … [4, 15]. For instance, when first-year students tried a mathematical prerequisite test on undergraduate contents they do not succeed (Figure 1). This study has been done at the very beginning of this course to test the mathematics mean level of 92 students entering our School. That questionnaire involves multiple-choice answer easy questions on calculus, algebra and statistics (Figure 2). Also, at the very beginning of this course a literacy study has been implemented with the students, that this year were entering the university for the first time. This short test includes numerical, schematic and written knowledge for information in prose, considered from a basic competence point of view [13]. Results have been discouraging: the mean label attained has been label one out of five (see Figure 3), although the sample studied has not been valid from a statistical consideration (the sampling error being 4.28 %). Namely, 90 % of the students do not reach level 3, which is considered the minimum desired following the international conventions.

C13. Let us assume the the following polynomial. Which is the greatest common divisor?

$p_1(x)=(x^2+1)(x-3)(x+2)(x+1)$
$p_2(x)=(x-4)(x-1)(x+1)$
$p_3(x)=(x-3)(x-2)(x-1)^3(x+1)^3(x+2)$
$p_4(x)=x^2-x-2$

1.	O	$p_4(x)$	**NS NC**
2.	O	$(x-3)(x+2)(x+1)$	
3.	O	$(x+1)$	
4.	O	$(x-3)(x+2)$	
5.	O	$(x-2)(x+1)$	
6.	O	x^2-x-2	
7.	O	1	

Figure 2. Example of the prerreqisite questionaire.

In addition, many students are not successful in developing their LTP. There is a misconception about the work method to be developed in university environments (especially in mathematics). Our students are generally not successfully developing appropriate skills and capabilities to achieve the strategic objectives for [10]. Furthermore, the Bologna Declaration has set the challenge to improve education, research and management schemes in the European Higher Education Area (EHEA), because in the corresponding curriculum the student is considered as an overall planning process. Consequently, they should expect rapid change (but hopefully not accelerated). The task-based LTP will become obsolete. The student, not the teacher, is the goal of the curriculum and the teacher becomes now a guide (in the sense of an adviser to him or a coach). Finally, but equally important, the New Information and Communication Technologies suggest future changes in climate to be given to the curriculum. That is, they bring different tools to assist the teacher in the development of any LTP. Learning and mastering these tools will help the teacher to have more resources to address the aforementioned failure. The three referred causes suggest that this might be a good time for a rethinking of the basic principles that guide the LTP from a teacher's viewpoint, so that if using the experience gained so far, there is a process of self-reflection and self-criticism to analyze and correct those weaknesses and along with the strengths observed, so as to improve in the quality of the educational process. An adequate approach is provided from the research-action methodology [8].

Figure 3. Results of the Literacy short test.

In the year 2010 the Bologna process (namely, EHEA) will be completed in the Spanish universities: changes in learning and teaching, in institutional and management levels. To improve the competitiveness of universities and the quality of higher education in the European Union curricula will be worked based on the professional responsibilities /academic competences, the student's active and ongoing learning, the flexibility and the internationalization of studies, the introduction of the European Credit for Transfer and Accumulation (ECTS), the alignment of curricular structures in two cycles and the people's mobility. The graduate profile will be a benchmark reference of the new curriculum, which is being designed at present in the Spanish university, because it will have to establish the core (basic) competences (standards for learning to learn and learning to know), crossed competences (learning to live together and learning to be), and specific competences (learning to do). That new curriculum will develop the spirit EHEA/ECTS: a Long-Life-Learning development profile of the student through a development of competences (i.e., skills, attitudes, aptitudes and values –the competence viewpoint).

As a consequence, changes are expected in the educational methodologies and in the assessment and accreditation processes of the syllabus [14]. Formative assessment will have to be emphasized since: it facilitates the development of self-assessment (reflection) in learning; it encourages teacher and peer dialogue around learning; it helps clarify what good performance is (goals, criteria, expected standards); it provides opportunities to close the gap between current and desired performance, it delivers high quality information to students about their learning; it encourages positive motivational beliefs and self-esteem; and, it provides information to teachers that can be used to help shape the teaching [7, 12]. This paper reports an experience where assessment is used to engage student's motivation, responsibility and participation using rubrics as valuation tools.

- ⌘ **C1:** To determine in detail from a theoretical/numerical perspective the key elements of deductive and inferential Statistics. Based on the contents of the subject, general strategies must be significantly implemented to get involved in the resolution of engineering problems and related matters.
- ⌘ **C2:** To derive and analyse the information inherent in a given statistical series (significant random sample), by means of numerical/symbolic computations. The use of some scientific software (SPSS, R, Mathematica, and / or Excel) of interest in engineering and applied sciences is needed. Simple examples are planned and solved, analyzing the error attributable to the process developed and studying the relationships with situations, in which students usually will find in engineering environments.
- ⌘ **C3:** To develop statistically valid conclusions in a critical way (reasoned and justified) from the results produced, that are based on an efficient management of information acquired.
- ⌘ **C4:** To cooperatively plan and develop in a coherent way a simple research paper on any contextualized chemical situation, including an oral presentation and/or written essay that describes the main steps in the implementation completed. The most relevant facts and findings must be highlighted, while verifying the management of the resources used (people, media, mathematical programs, times, concepts, ...), which the working team/group has necessitated (from a multidisciplinary perspective).
- ⌘ **C5:** To acquire working strategies and mechanisms to promote the continuing need to improve a meaningful learning throughout life, worrying about the quality of the accomplishments, making particular use of computer management through ICTs, focusing on rigor, precision and excellence.

Figure 4. The syllabus: a) The main contents; b) the core competences of the syllabus.

II. PROBLEM STATEMENT

Several studies have shown that the characteristics of the classes usually rated by the students include great challenge, but full opportunity to review and improve their work before they are qualified and, therefore, to learn from their mistakes in the process [3]. One of the advantages of the formative assessment is that it does fit simpler procedures than those used in traditional exams as outlined for summative assessment. Valuation matrices (or rubrics) are scoring guides used in assessing student's performance that describe the specific characteristics of a product, project or task at various levels of performance, in order to clarify what is expected of the student's work, assess their implementation and facilitate the feedback supply [1, 11]. Students get bored at grading [2, 16]. How can the teacher deal with this environment? This paper reflects over way to engage (in an action-research environment) undergraduates in motivation, participation and responsibility tasks challenges, since they are not accustomed to work such competences. Besides, such values are rarely treated in the first and second courses of the any university degree. That is, it is reported how to challenge students in mathematics courses, taking into account the comments provided in the preceding section.

Each course the students must complete in cooperative groups a research about a statistical problem related to the most important descriptors and contents of the syllabus (see Competence 5 in Figure 4). Consequently, the student must deal a great deal of skills that define such team-work competence: cooperative work, communicative strategies, effective meetings, tutorial reinforcement, resource management optimization, team work (of course), facilitation and supervision, and assessment, among many others. It is a quite complex competence [6, 7, 9].

The students have been proposed to get involved in all the stages of the preparation of an assessment tool for accreditation of one of the syllabus competence (i.e., team work). Figure 4 shows the structure of the course syllabus; namely, credit weight and key competences. Such a process has included: **a)** a questionnaire to decide the evaluation criteria for formative and summative assessment that would be considered in the competence rubric; **b)** a proposal to pose the quantification of the criteria applied; **c)** the use of that tool in the formative assessment to other groups; **d)** the use of the rubric to look for evidences to be added to his/her portfolio to produce the summative self-evaluation, which is discussed with the teacher at the end of the course; **e)** to provide both qualitative and quantitative justifications and reasoning about the opinion of the results obtained; and **f)** as a consequence, an improvement strategy has been derived to be applied next time.

This study is part of a cross-sectional study of a team of educational innovation (TEI) conducted in five degrees on the student's opinion regarding the competence of "team work." It includes public and private universities of the Basque Country land: 5 faculties, 6 degrees and 8 researchers are included. Here, the results of a statistics course (2nd year in a 3-year degree on Industrial Engineering where multiple teaching methodologies are used surrounding the PBL/EBL (Problem Based Learning / Enquire Based Learning) approach) will be presented and discussed (Figure 4 shows its main characteristics).

III. METHODOLOGY

The methodology has implied the following steps:

(1) Analysis of the evaluation indicators and assessment criteria, which must be considered in a given course.

(2) The assessment rubric has been designed and implemented.

(3) The rubric has been applied in the formative and the summative stages of the assessment. Also, it has been applied to valuate the product of each group, which has been presented at a conference poster session type.

(4) The process has been evaluated looking for the students' comments and valuation, altogether with the professor's considerations.

		IMPORTANCE		COURSE

Figure 5. The students' decision about the assessment indicators of the team-working competence (over 4 points).

(5) An improvement planning has been retrieved as the final outcome, where corrective, preventive and/ or improvement actions have been taken into account.

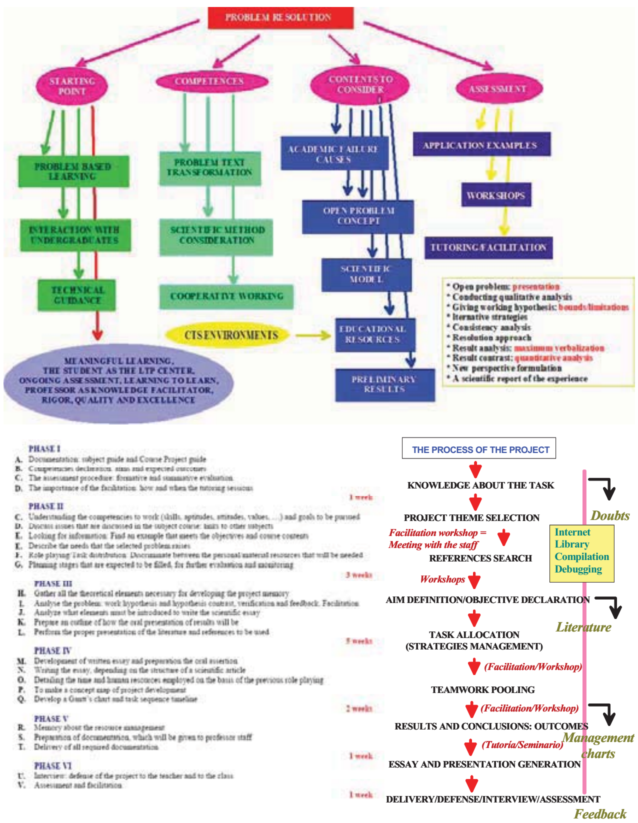

Figure 6. Problem/Project solving via a PBL/EBL approach.

The TEI has carefully considered the knowledge, abilities, skills, values, attitudes, aptitudes and virtues that can define this competence. At last, four affinity groups (evaluation criteria) with a total of 42 evaluation indicators have been produces; namely, the structure of the group (11 items), the process generated (10 items), the relations established (11 items), the appeared emotions (5 items) and the assessment itself (5 items). The students have chosen (Figure 5 shows the results of the syllabus reported in Figure 4) what items must be included in a given course (last two columns) and have decided its relative importance (first two columns) in the whole of the competence environment. Columns 1 and 3 are mean values and columns 2 and 4 are standard deviations. The mean values reported show that students think that the mean importance of this competence is 2.29 (out of 3) while the mean course is 2.24 (out of 3). In other words, the importance assumed is high and students suggest that this competence must be developed in the upper courses of the degree. To challenge this situation some explanations are necessary to engage the students, because they are accustomed to play a little role on the daily discourse of the LTP.

25 students (over 36 –that attend class regularly; i.e. 69.44 %) have answered the questionary. However, 15 students (29.41 %) did not go regularly to class: they were matriculated but they were not going to class.

Then, an analytic valuation matrix has been defined (see the Figure 14 at the end of this paper). It contains five evaluation criteria: the general situation of the (5 evaluation indicators); the procedures implied in the group development (6 items); the relationships between the group members (4 items); the treatment of the emotions that have appeared (3 items), and the assessment process (4 items). Three competence levels have been only established: "quite competent" (2 marks), "only acceptable" (1 mark) and "does not fulfil" (the task or so must be redone again). Each student has applied this tool regularly as formative assessment to decide where the group does not fulfil the necessary requirements to be competent as team work or where the group must improve its development to play the role of a real group. However, each student has token this rubric into account to analyse his/her contribution to the general development of the group itself or to analyse how the group was helping him to grow up as a person. These reflections are evidences for the portfolio that can be used to explore the performance of the student's evolution over the subject competences. As it has been mentioned, at the beginning of the course the evaluation criteria are discussed with the students and some consensus is reached. Then, each team evaluates its work which is discussed with the professor in an interview (inner evaluation) and the remaining teams do evaluate the oral presentation, which must be given (outer evaluation) in the general context of a PBL/EBL approach (Figure 6). Otherwise, the student has an opportunity to fix the minimum quality of the production result the group will have to develop, and, at the same time, there exists a non-explicit level to show the group where the excellence level is located.

It has been noticed that the team work competence must be approached quite differently at first courses or in the last ones during the implementation of the PBL/EBL methodology. Because of that, facilitation and supervision are peremptory [6]. When developing a PBL/EBL Project course great care must be devoted to the tutoring task, above all in the first courses (namely, this is the case where strengthening work in basic sciences is called for [7]); namely, focusing on improving the student's communication [9]. In this sense, facilitation must develop daily reflection: pre-session (to present a focus concerning group dynamics so that facilitative questions should be used to start reflection), ordinary supervision session (with timeouts to discuss focus and to play diverse roles) and post-session (to facilitate reflections on the focus). Furthermore, facilitation implies tutoring and supervision (sometimes, even control) to respond to student's problems in terms of meta-skills [5, 7] (see Figure 7). Several dimensions are taken into account: the intellectual dimension, the personal dimension, the social dimension, the practical dimension (with several viewpoints: providing support, encouraging independence, developing the interpersonal) and assessing research (formative assessment, creativity and originality, reliability and validity) [9, 16].

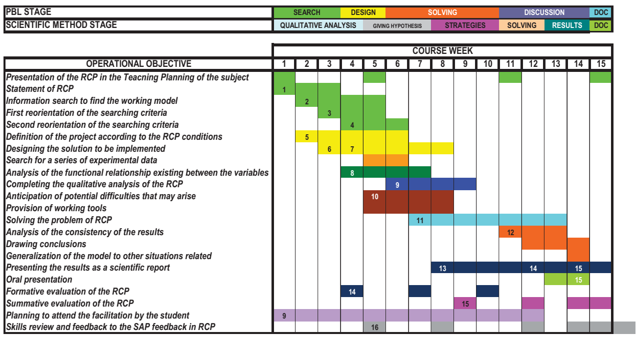

Figure 7. A Gantt's diagram of the Course Project timing.

However, the teacher's role must also be considered from a leadership point of view: from hierarchy / autocratic / consultative to autonomy / functional / contractual via cooperation / negotiation / consultative. This implies that the student/teacher relationships ought to include six dimensions: the planning dimension (goal-oriented, aims, ends and means), the meaning dimension (cognitive understanding of experience), the confronting dimension (raising awareness to individual and group resistance), the feeling dimension (addressing emotional competence and incompetence), the structuring dimension (methodology of structuring experiences) and the valuing dimension (creating a support climate that celebrates individuals) [6, 12].

This research is action-oriented (see Figure 10); so, a Deming's wheel (a Plan-Do-Act -Check cycle) must be reconsidered once again. That is, the design and the implementation being developed mechanisms and tools to look for information about the results and about the address of the research must be considered. In order to know the students' opinion a half-opened questionnaire has been given to the students (Figure 8). The following topics are considered to attain the student's point of view on the approach, development, evaluation and analysis of the team work competence. Specifically, the elements taken into consideration cover the information supplied, the initial training, the degree of initial expectation with respect to the competence itself, the degree reached in its development, the development of the teaching methodology applied, the facilitation/supervision/tutoring set up and the assessment considered.

Remembering, the result of this teaching task is to produce a scientific essay in a cooperative environment (Figures 6 and 7). So, the own subject questions the student about the contribution of this competence (see Figure 9) related to all the another competences, because its weight is 21.67 % (Figure 4). Students also write some comments in the portfolio about their viewpoints on this approach, which are given in the interview at the end of the course when they explain the evidences carried out in their portfolios.

IV. RESULT DISCUSSION

Formally, these results demonstrate the need and urgency that the students show to introduce (early) this competence in their studies (Figure 5). Students are quite surprised by what they have been presented with this methodology. All the students that have answered the questionnaires were involved in this approach, but since they were not all of the students of this subject results are not conclusive. However, this sample includes the 84.45 % of the students who went to class.

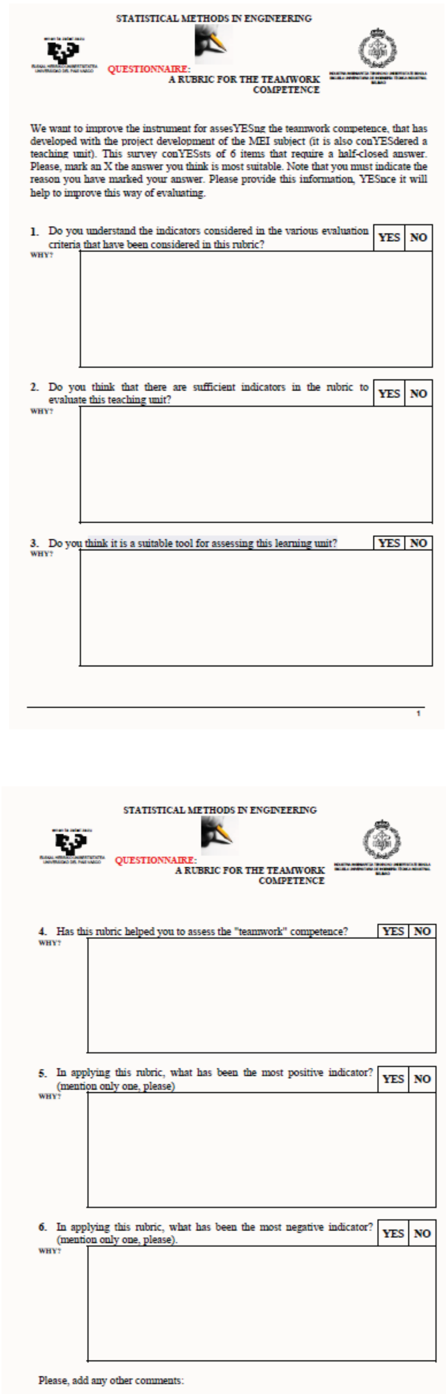
Applying this strategy, all the existing groups have succeed in their marks because they have fix beforehand a reference level to surpass in the assessment rubric (it has been degree 1 in the evaluation indicators –see the rubric at the end of the paper). Table I provides high positive answer percentages to the questions of Figure 8. In particular the most voted evaluation indicator is "21 - Evaluation modes" and the most negative "17 - Conflict resolution" in the rubric applied, because students didn't well understand it –they added in the comments at the end of the questionnaire. There is great agreement with this methodology (87.65 %) but feedback has produced interesting ways to deep in (see this section below).

TABLE I. RESULTS OF THE STUDENT'S OPINION QUESTIONNAIRE

ITEM	EXPLAINATION	Percentage	¿WHICH?
1	**The assessment criteria understanding**	95,13	
2	**The assessment criteria sufficiency**	98,83	
3	**Evaluation tool adequacy**	82,03	
4	**The rubric has been useful**	82,36	
5	**The evaluation indicator most voted**	91,23	21,00
6	**The evaluation indicator most negative**	65,23	17,00
	Mean value	**87,65**	

Table II summarizes the overall performance mean rates of this research, which the students have directly answered for. All responses ranged from zero to ten points. The general opinion about the methodology deployed is good (7.2 points), and students like the syllabus (7.6 points), but improvements can be carried out. The competences and objectives of the course are well understood (8.1 points); however, the competence here researched has dealt with difficulties (6.5 points) because the way has been worked out is a bit difficult to be followed (the students have said). Moreover, the motivation rate is good (7.8 points) but the participation index provided has been excellent (9.1 points), but problems have arise because of the responsibility indicator is not so good (7.3 points). The students demand a lot of help and care (though they are in first courses) –self-sufficiency index is 6.2 points, while they have considered an excellent level of facilitation (8.9 points), too.

The methodology implemented in Section III provides a protocol to be applied to engage students in the LTP of the syllabus, wh ere a practical learning is set do wn. B ut t his strategy implies to look after alliances with students analyzing very carefu lly tho se sy nergies th at usually appear in c lass. Results are qui te good (m ean val ues of Ta bles I and II) and they in vite to use th e PBL a pproach. However, th ese resu lts can be improved, and the students can help in such a task. The comments provided but students have declared and pointed:



STATISTICAL METHODS IN ENGINEERING

QUESTIONNAIRE:
A RUBRIC FOR THE TEAMWORK COMPETENCE

We want to improve the instrument for assesYESng the teamwork competence, that has developed with the project development of the MEI subject (it is also conYESdered a teaching unit). This survey conYESsts of 6 items that require a half-closed answer. Please, mark an X the answer you think is most suitable. Note that you must indicate the reason you have marked your answer. Please provide this information, YESnce it will help to improve this way of evaluating.

1. Do you understand the indicators considered in the various evaluation criteria that have been considered in this rubric? YES | NO
WHY?

2. Do you think that there are sufficient indicators in the rubric to evaluate this teaching unit? YES | NO
WHY?

3. Do you think it is a suitable tool for assessing this learning unit? YES | NO
WHY?

A RUBRIC FOR THE TEAMWORK COMPETENCE

4. Has this rubric helped you to assess the "teamwork" competence? YES | NO
WHY?

5. In applying this rubric, what has been the most positive indicator? (mention only one, please) YES | NO
WHY?

6. In applying this rubric, what has been the most negative indicator? (mention only one, please). YES | NO
WHY?

Please, add any other comments:

Figure 8. A questionnaire about the student's viewpoint.

(1) as **strengths**: the novelty of t he methodology, the variety of teach ing meth odologies involved, the facilitat ion prov ided and the student's implication, and

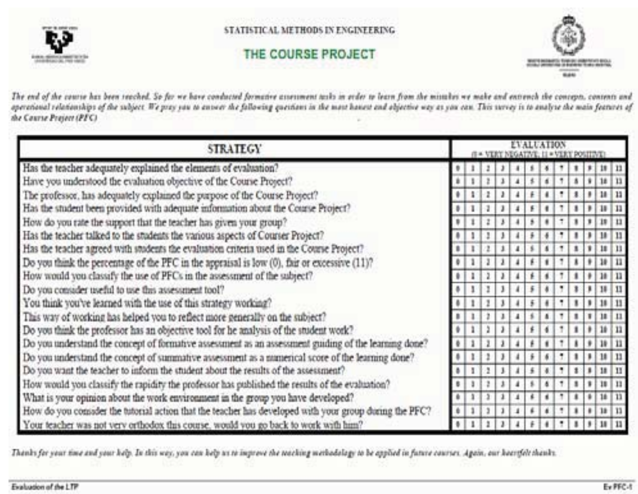
(2) as **weaknesses** of t his implementation: the har dness test, the existence of a lot information, a lot of work to be made by the student (specially that one off-class) and the peer to peer coevaluation.

The students themselves suggest some activities to cope for an **improvement planning**, as feedback:

(1) As **improvement actions** th ey propose: to reduce th e quantity of in formation and to apply other forms to ch allenge them.

(2) As **corrective actions**, t hey pr oposed dee p i n the explanation of th e stud ent's respon sibility an d what th e student is assumed to produce as final outcomes, or to provide specific examples of similar results or portfolios.

(3) As **preventive actions**, they press to give greater freedom and to use spe cific examples of the syllab us instead of being them th emselves to look for them. They are also c oncerned that this way of working implies great job, in exchange for a far more profitable, but in the long term.



STATISTICAL METHODS IN ENGINEERING

THE COURSE PROJECT

The end of the course has been reached. So far we have conducted formative assessment tasks in order to learn from the mistakes we make and entrench the concepts, contents and operational relationships of the subject. We pray you to answer the following questions in the most honest and objective way as you can. This survey is to analyse the main features of the Course Project (PFC)

STRATEGY	EVALUATION (0 = VERY NEGATIVE, 11 = VERY POSITIVE)											
Has the teacher adequately explained the elements of evaluation?	0	1	2	3	4	5	6	7	8	9	10	11
Have you understood the evaluation objective of the Course Project?	0	1	2	3	4	5	6	7	8	9	10	11
The professor, has adequately explained the purpose of the Course Project?	0	1	2	3	4	5	6	7	8	9	10	11
Has the student been provided with adequate information about the Course Project?	0	1	2	3	4	5	6	7	8	9	10	11
How do you rate the support that the teacher has given your group?	0	1	2	3	4	5	6	7	8	9	10	11
Has the teacher talked to the students the various aspects of Courser Project?	0	1	2	3	4	5	6	7	8	9	10	11
Has the teacher agreed with students the evaluation criteria used in the Course Project?	0	1	2	3	4	5	6	7	8	9	10	11
Do you think the percentage of the PFC in the appraisal is low (0), fair or excessive (11)?	0	1	2	3	4	5	6	7	8	9	10	11
How would you classify the use of PFCs in the assessment of the subject?	0	1	2	3	4	5	6	7	8	9	10	11
Do you consider useful to use this assessment tool?	0	1	2	3	4	5	6	7	8	9	10	11
You think you've learned with the use of this strategy working?	0	1	2	3	4	5	6	7	8	9	10	11
This way of working has helped you to reflect more generally on the subject?	0	1	2	3	4	5	6	7	8	9	10	11
Do you think the professor has an objective tool for he analysis of the student work?	0	1	2	3	4	5	6	7	8	9	10	11
Do you understand the concept of formative assessment as an assessment guiding of the learning done?	0	1	2	3	4	5	6	7	8	9	10	11
Do you understand the concept of summative assessment as a numerical score of the learning done?	0	1	2	3	4	5	6	7	8	9	10	11
Do you want the teacher to inform the student about the results of the assessment?	0	1	2	3	4	5	6	7	8	9	10	11
How would you classify the rapidity the professor has published the results of the evaluation?	0	1	2	3	4	5	6	7	8	9	10	11
What is your opinion about the work environment in the group you have developed?	0	1	2	3	4	5	6	7	8	9	10	11
How do you consider the tutorial action that the teacher has developed with your group during the PFC?	0	1	2	3	4	5	6	7	8	9	10	11
Your teacher was not very orthodox this course, would you go back to work with him?	0	1	2	3	4	5	6	7	8	9	10	11

Thanks for your time and your help. In this way, you can help us to improve the teaching methodology to be applied in future courses. Again, our heartfelt thanks.

Evaluation of the LTP　　Ev PFC-1

Figure 9. Student's opinion about the LTP process in the curriculum.

(2) as **weaknesses** of th is implementation: th e hardness test, the existence of a lot information, a lot of work to be made by the student (specially that one off-class) and the peer to peer coevaluation.

The students themselves suggest some activities to cope for an **improvement planning**, as feedback:

(1) As **improvement actions** th ey propose: to reduce th e quantity of in formation and to apply other forms to ch allenge them.

(2) As **corrective actions**, t hey pr oposed dee p i n the explanation of th e stud ent's respon sibility an d what th e student is assumed to produce as final outcomes, or to provide specific examples of similar results or portfolios.

(3) As **preventive actions**, they press to give greater freedom and to use specific examples of the syllabus instead of being them themselves to look for them. They are also concerned that this way of working implies great job, in exchange for a far more profitable, but in the long term.

TABLE II. PERFORMANCE MEAN RATES

PERFORMANCE RATE	VALUE
Your opinion bout this teaching methodology	7,2
Understanding of the syllabus competences/objectives	8,1
The development of the group in the "team-work" competence	6,5
The facilitation/supervision/tutoring provided	8,9
Motivation level	7,8

Responsibility level	7,3
Self-sufficiency level	6,2
In general, a mean mark for the whole LTP of the syllabus	7,6

V. CONCLUSIONS

This paper reports an engaging experience based on the methodology and the evaluation in Statistics teaching: students' involvement in building and implementing competence assessment models as a valid learning engagement alternative where the relevance of the assessment criteria is established by the students. The importance of process action research in teaching environments becomes increasingly important to improve the LTP (see Figure 10): students develop a project in groups by applying PBL/EBL techniques where the facilitation tools are essential (see Figure 11). This is one of the main cornstones

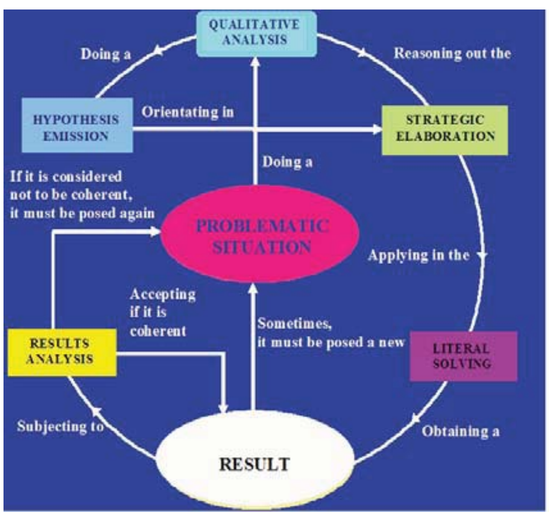

Figure 10. The process oriented research.

The student's opinion is analyzed over a given competence (team work), using such a synergy to promote students' motivation, accountability and participation via challenges. The student has been invited to take part in the design, implementation and discussion of the assessment instrument of that competence through the generation and consideration of valuation matrices. The performance indicators to be considered have been agreed, and a protocol has been established to give students the understanding throughout their formative evaluation process. The competence has been developed in diverse scenarios: the one considered in this paper deals with a Statistics syllabus through course short projects, worked from the perspective of an active learning methodology such as PBL/EBL.

ACTIVITY TO ASSESS		COMPETENCE	APTITUDE FOCUSED	QUESTION TO POSE/ APPROACH COVERED
Looking for the best information in an optimum way	FA	C4	The individualization of the LTP: task assignment	References looked up and constructed used Time used to do the seeking
Definition of the open problem based on the given standards	AA	C4	Student's proactive participation and implication	Rigour and precision of the approach proposed The way in which is declared the future implementation of the Course Project Adequate justification of the choice posed
Role playing in the team/group	FA	C5	Contribution to the cooperative spirit of the team/group	Reasoning about the given role playing proposal in the group How the group worktable has been accomplished? Has the group productivity been followed? How? Which tools have been employed?
Forecasting of the difficulties which could come up/arise	FA	C5	Qualitative analysis of the solution found out	How can be interpreted the resolution of any linear system equation in an approximate manner? Can be a qualitative analysis of the problem made?
Look for values to settle the numeric problem down	FA	C4	Coordination and linking with other subjects of the degree	How the chosen data can be disposed in order to apply the algebraic theory of the syllabus?
Resolution approach and formulation	FA	C5 Ta	sk arrangement	Which methodology type is applied? How the work is distributed among the group members? Is there any concept map about the implementation developed? A Gannt's diagram about times and role playing has been presented?
Result contrast related to the planned outcomes	AA	C4	Coherence between the obtained results and the theory applied	The results looked for have been attained? The values obtained, can be justified?
Analysis of the difficulties that have been encountered	FA	C4 In	teresting contributions	How have been solved the encountered difficulties? How the resources used have been managed? A problematic situation will be suggested (it will be a direct consequence of the project his/her group has worked
Implementation computational costs	FA	C5 Res	ult contrast	How the used method cost has been measured? Is there any cost study?
Teamwork applied methods	AA	C5 S	elf-assessment skills	Quality of the self-assessment report presented Which values are pointed out by his/her group-mates?
Scientific report of the project experience	AA	C4	Helping the use of an appropriate structure for the project approach of the group	How is used the mathematical language and the formal relations? How is it reasoned?
Oral presentation of the report	AA	C5	Coherence of the defence presented	Reasoned justification of the report presentation carried out
Last interview for assessment	FA	C5	Use of the procedural knowledge related to the subject	How does the student answer the questions that have been posed?
Attitude in the facilitation and tutoring times	FA	C4	A more emphatic relationship between undergraduates/students and the teaching staff	Is there a positive attitude in the group structure running? The group, does it appear open-minded, active, productive, efficient, effective, …? A given student, which is the position that shows in the presence of his/her group-mates?

Figure 11. Some questions that are posed to students along the help/tutoring sessions (**FA** means formative assessment; **AA** stands for additive assessment).

A survey has been designed to analyze the student's perceptions regarding the approach, development, assessment and competence analysis from the students' viewpoint. The items considered take into account aspects such as: the information provided, the training involved, the initial level of expectation with respect to the competence, the degree of development reached, the development of the teaching methodology applied, the tutorial action (in the sense of facilitation) applied and the global assessment deployed. The results of this survey are presented in this work to help refocus the teaching methodology with which that competence will be worked in the future.

coached	Step 1	What do we understand about ...? **Clarification of terms** Building a common understanding	class
	Step 2	What are the questions, problems, fields of problem? (Hypothesis?) Which problems have to be tackled first to find a solution? **Definition, Analysis, Weighting of the problems** Naming and organising the problems systematically, extracting the most important	
	Step 3	What do we already know about ...? **Connecting with previous knowledge**	
	Step 4	What knowledge do we miss? **Gap Analysis** Finding knowledge deficits	
	Step 5	**Specifying the learning targets, deriving the work packages and distributing them among students**	
not coached	Step 6	**Carrying out the work packages**	self-study
		Knowledge exchange, Synthesis	class
		Developing a solution, writing the paper	
coached	Step 7	**Discussion of the solution and the its approach with an expert**	class

Figure 12. The PBL approach working concept).

What about student's and teacher's effort? In short, it is different because this implementation is part of a broader strategy to engage students through motivation and participation, while making them see the need to involve themselves in a responsible manner. The subject of the paper lies in the learning engagement domain as student-driven assessment model, taking into account the student's participation/cooperative effort in an assessment set-up as teaching alternative. The results support this work methodology; they highlight the importance of a proper facilitation and supervision to the student progress adequately (see Figure 12) in order to determine the concept structure and the relationships of the involved mathematical units (see Figure 13).

CODE PDC	TASK TO IMPLEMENT	ACTIVITIES TO DEVELOP	OUTCOME TO MEASURE/OBJECTIVE	ESTIMATED TIME (hours)		DIFFICULTIES ENCOUNTERED
				CLASSROOM	NON-ATTENDANCE	
1	- Presentation of the subject Teaching Planning STP - Explanation of the teaching method that is the base of the Course Project - Text of Course Project as an open problem *This task is reminded from time to time to ensure that students are aware of what it really means*	- Statement of competencies involved in the Course Project - Using simple examples for explanation - Definition of objectives - Influence on the assessment	- Specific questions specific in tutoring/facilitation sessions and/or classroom - Use a daily log as a register diary	0.25		- The student feels that the documentation (delivered on the first day of class) is excessive - The subject guide may be useful to overcome this difficulty, if provided that it is very well designed
2	Finding information in books, magazines, specialised articles, reports, encyclopaedias and /or the Internet, asking to other teachers based on the descriptors of the subject, given the first day of class	The student looked for information on the sources suggested	- The student will deliver the **statement of the problem**, that will work, as openly as possible - **List of** used **references** given by the method of Harvard (examples are given in the STP) - At a later stage, the student will give a complete Problem Resolution (PR) approach, using the modelling suggested when the solution implementation be done	0.	50	- It is normal for the pupil to be disoriented as he is not accustomed to working under the scientific method - Student makes reports handwritten - It is not anything to be delivered as early
3	New reformulation of the search criteria	Very specific descriptors are provided to generate an appropriate search: dynamic system, linear system, linear approach, controllability, robustness, resonant systems, ...		0.17 0.	50	- At this stage any student needs facilitation to be addressed in the right direction - Real-time corrective feedback must be done often, either because students react in a way not intended, either because the expected progress does not materialize in the expected steps/phases
4	New reformulation of the search criteria	The student is told about the most productive topics of the subject		0.	25	
5	Open formulation of the problem, to be solved according to the PR methodology, clearly incorporating the relationships linking the proposal with other subjects of the Degree	The student will have to develop the theory underlying the model presented, linking mathematics and that interest area	- The proposed statement should make clear **the relationship between contents and descriptors** in the subject - **Analysis of the model**: the theory must be described succinctly and directly	2.	00	- The student usually shows difficulties when verbalizing his/her work experience - The difficulties that can lead the future development of the project ought to be written
6	Design of way the implementation of the solution will be addressed	- Problem analysis - Analysis tools that can be used - Locate resources that will be needed	- **List of variables** involved - The student will prepare a **concept map**, organigram or similar, where a **working and calculation strategy** will be provided, reasoning about its key points	0.50 1.	00	- The student does not have a clear idea of the tools to work as a top-down/bottom-up design - The student does not adequately link to the key concepts of the subject with the experience in the Course Project: the concept maps of the thematic units of the course must be continuously be recalled
7	Remember the theoretical concepts involved	Summary of the descriptors most needed to develop the Course Project	**Concept map of the contents covered**	0.17 0.	50	The student must be drawn to study daily
8	Deduction of the working model from the graphical representation	Analyze whether the problem is discrete or continuous, clarifying what the variables are and the relationship between them	- **Deduction of the theoretical model** - **Justified and reasoned statement of the working hypotheses**, to implement the resolution of the problem	0.	50	- Difficulties in discriminating the data and results - The variables are not discussed in the right way - No way are correct Descriptors and keywords are not correctly expressed
9	Refinement of the qualitative analysis	Giving an overview of the whole approach to see if mistakes take place	**Justified listing of the mistakes appearing**	0.	50	The student does devote no time to review and reflect
10	Analysis of the weaknesses of the approach by the teacher	Monitoring, normally permitted, the student		0.50		The facilitation session must be compulsory; otherwise, the student does not come voluntarily
11	Implementation the solution by solving systems of linear equations in the sense of least squares	Calculate the parameters involved in the model of the Course Project	**Coherence of the results obtained**	0.17 1.	50	The student often uses only pencil and paper, not making use of ICT to enhance their overall productivity
12	Deduction of conclusions	Answer in a way justified the questions raised in the Course Project discussion	Results are correct and explanations are well justified	0.	50	There are numbers, no units are provided, and typically the results obtained are not discussed
13	Oral presentation and/or written report for the Course Project	Perform a PowerPoint presentation that summarizes all the essentials of Course Project outcomes	**Quality of the report/presentation** following the criteria reported in the valuation rubrics at the beginning of the course	1.	00	- There is not too much interest to generate a document with enough presence to the university level - There is no autonomy when generating the report of the Course Project
14	Evolution of the student's evolution and progress in mastering the techniques involved in the Course Project	Interview (3 sessions of 10 minutes) with the teacher of the course on an individual basis and with other group members	Daily records	0.50		It is quite difficult to verbalize feelings and emotions in front of a teacher, and more if other students are there, albeit in a small group
15	Final evaluation of the work done with the Course Project	Personal interview Team interview Analysis of team data and student's data	Summative assessment of the Course Project with the student's follow-up, and the opinion of each group member	0.25		Initially, the student is reluctant to assess their colleagues, provided that there is no group mentality
16	Following the REDER philosophy the learning-teaching process of the Course Project is reviewed on an ongoing basis, which has the corresponding control mechanisms	Quality of the Course Project report Oral presentation of the Course Project Student's self-evaluation	Lejk's method to **evaluate the team guided work**, that has done the Course Project			Students need to comment the assessment results to them as immediate or mediate feedback

VALUATION MATRIX / RUBRIC: TEAMWORK 1/2

		COMPETENT (5 MARKS) *It has been fully met*	ACCEPTABLE (3 MARKS) *Some mistakes are evident*	DOES NOT MEET (0 MARKS) *It must be again redone*	Q
General level of the team/group	*Organization and presentation*	The report is bound and formatted: there is an index, it is well structured, indexed and paged, there are references and appendices. The important thing is the main area, the accessory is led to the annexes. The construction, syntax and spelling of the sentences is correct. The explanations are clear. The title of the report is very suitable	The memory is not well structured, but contains all the required sections. Lack of clarity in the explanations provided. There are spelling errors. Much explanation is not given. The title of the report is adequate	The report is not formatted, there is no index, poorly structured and is not paged, no reference. Misspellings abound. It is not clear. No resources are used well. The title is not suggestive	
	Contents development	It makes use of all contents and descriptions of the subject, relating them adequately	These findings indicate that some content does not appear, or the explanations are limited	The contents presented are inadequate. There are only relations	
	Argumentation and justification	The results and accompanying comments are justified, using the theoretical concepts and practical convenient descriptors	There are results and / or comments that are not justified or not based on the concepts and theoretical and practical descriptors	No reasoning is provided	
	Coherence	There is consistency between what the group has worked and the presentation conducted. It is noted that there has been a cooperative work. All the deadlines have been respected	Not all the members have managed to cover the understanding of the entire project. The group's work has been collaborative. Sometimes times have not been observed	Each member is responsible only for their share. The work has been individualistic, or only one component has worked	
	Objectives of the Course Project	The report submitted meets the all the requirements of a project	The report submitted meets the some of the requirements of a project	The documentation submitted does not represent at all a research report	
Procedures in preparing the project report	*Class attendance*	There was a total attendance of all members at every meeting	Any member has not attended any meeting. Few meetings held	There has been little meetings. It has produced an individualistic work	
	Compliance with rules	The group has met the standards that have been established. The workflow has been dynamic	The group has worked in a dynamic but in a somewhat anarchic	Rules have not been respected	
	Selecting the item submitted	The group's mission is very much in line with the selection of the work submitted. And it has a large component of elements of the subject with proper justification	The group's mission is in line with the work presented. Yet covering most elements of the subject, are well justified	The issue presented was to get by	
	Resource planning	There has been adequate foresight and planning of resources and time, and carried out according to the objectives set	Resource planning has existed, but were not always met expectations	There is no planning activity	
	Group consciousness	Group members were informed of the progress of others. There has been rotating roles. The methodology was designed in accordance with the objectives designed. Were achieved initial results expected	Group members were informed of the progress of others. There has been rotating roles. The initial results have not been reached	The group has been a complete chaos	
	Effective meetings	There have been all calls, records and evaluations of all sessions. The group's work plan has been presented and justified	There have been some calls, some records and / or evaluations of the sessions. The group's work plan has been presented and justified	No calls, no records, no evaluations of the sessions. There has been no work plan	

VALUATION MATRIX / RUBRIC: TEAMWORK 2/2

		COMPETENTE (2 PUNTOS) *Se ha alcanzado completamente*	ACEPTABLE (1 PUNTO) *Se aprecian algunos fallos*	NO CUMPLE (0 PUNTOS) *Se ha de realizar de nuevo*	PUNTOS (1)
Relationships in the group	***Work cycle in the group***	Group consciousness has been developing the qualities of the group beyond a PDCA cycle (plan-do-check-act). The cooperation has been evident. Resources have been shared	The group has worked as a PDCA cycle. It has always cooperated. Resources have been shared	It has not been reached a PDCA methodology. The cooperation has been conspicuous by their absence. There are no shared resources	
	Communication in the group	Communication within the group has been completed in the records, and is reflected the evaluation report of the group. No member of the group has given any objections over the project development	Communication within the group has failed at times, but it is also unclear in the report submitted	People have not behaved as a group	
	Leadership	There has been a person that stands out above all others. It is equally valued the contribution of the group members	It was necessary that a person in the group moved to the other so that the work was carried to fruition. Sometimes, the contributions made have not been equally valued	A person has clearly dominated over other people in the group. The other members were subject to the decisions of that person	
	Autonomy	The teacher only replied to questions made by the group	Special sessions have been required with teachers for the project to move forward	The group has completely disengaged from the process of tutoring, ...	
Emotion treatment	***Integrating the differences***	Nobody has outperformed all others, trying to involve colleagues, when necessary. It has fostered healthy disagreement and debate, working consensus. Constructive criticism has carried out	There have been problems that are resolved in a process of communication within the group. There has been disagreement and debate in a healthy manner. Sometimes, they have not produced well tolerated criticism	The friction between people have been constant. Not rated opinion of the members. The disagreement has been constant.	
	Conflict resolution	There have been no conflict because team members were very clear that what mattered was the person to achieve the objectives of the group	There have been conflicts, because no team members were very clear that what mattered was the person to achieve the objectives of the group. It was necessary to apply decision-making techniques to make some decisions	Conflicts have been continuous	
	Recognising the individuals	When it has been necessary the merit of individuals has praised. There are recorded in the reports of the group. This fact has been made public in the usual dynamic class	Only the teacher has stressed this fact in front of the class (as large group)	There have been no such indications	
Evaluation	***Transmission of knowledge***	The group has shown that there has been learning from each other	The group has not demonstrated that there was learning from one another	The group has not demonstrated that some members have helped others	
	Obtained outcomes	The objectives achieved are in line with the initial objectives. The reasoning is well structured	There have not provided all the original aims. There are errors in the reasoning	The results achieved are far from the objectives. There is no reasoning	
	Evaluation modes	The group has carried out formative and summative assessment. In addition, its members have been involved in evaluating	The group has not performed work for formative or summative evaluation. In addition, its members have not fully involved in the evaluation	They have not been involved in evaluating	
	Self-evaluation report	The group has performed a very detailed report, and all its members have participated	The evaluation report is vitiated by the no participation of its members	There has been no self-evaluation report

Analyzing self-reflection by Computer Science students to identify bad study habits

Self-reflection performed by students of programming courses on the study habits and skills acquired through b-learning supported by an automatic judge

***Abstract* — We present some preliminary results and the main conclusions of a study that we conducted at the University of Algarve, for one of the programming courses in the first year of the Computer Science degree at the University of Algarve. We analyzed the self-reflections made by the students about their study habits and about the skills they acquired in the course. This particular course uses a methodology of blended-learning supported by an automatic judge. The research data were obtained through questionnaires that were distributed and collected during the period of study between the end of classes and the exam. We took into account data from other instruments related to previous work carried out by students, in this course and in previous courses, as well as the performance of the students. We intended to ascertain to what extent the planning, motivation, previous study or knowledge about the type of examination influenced final results. The results suggest measures to be implemented in future editions of the course.**

Keywords – Blended-learning, automatic judge, self-reflections, study habits and acquired skills of programming students, learning constrains.

I. Introduction

In general, the student population enrolling in the Computer Science Programme (CSP) of the University of Algarve (UAlg) is mostly composed by young adults (with 18 or 19 years of age). These students carry to the university the knowledge, skills, attitudes, study habits, motivations, interests and expectations that they acquired in secondary education and from other cultural experiences. They also bring the weaknesses referred in [1], that we must not ignore. In any case, those motivations, interests, and expectations do not always have the expected effect in helping them achieve academic success within the prescribed time. Furthermore, we have observed that accumulated failures as a result of difficulties in developing the skills for writing computer programs that require more than superficial knowledge cause students to stay at the university as adults (say, with more than 24 years of age).

We believe that it is the teacher's responsibility to encourage students in building a deep, responsible and autonomous knowledge for the adoption of rich, diverse, motivating and demanding strategies from a cognitive point of view [2], which aim the gradual and progressive application of andragogy [1] principles (adult education), and not only of pedagogical principles, and to identify factors that can condition the development of the competences necessary for programming. Accordingly, in the academic part of the course Algorithm and Data Structures (ADS) we have been following a blended-learning approach, based on the availability of tools that support the learning process and the evaluation of results, as well as an automatic judge that automatically evaluates the programs written by students [1], thereby releasing teachers to more gratifying pedagogical tasks. Since ADS is the second course in programming in the study plan for Computer Science, students were supposed to master the basic competences that were the subject of the first course, and be able to apply them and learn new ones, such as the following: writing C programs which require the use of libraries of data structures, selecting the best data structures and the best algorithms for the task at hand, and being able to participate in programming contests, by showing that they can solve the problems that typically are presented at such contests. However, Computer Science teachers recognize the students' difficulties on acquiring these competences, and try to help them identifying their fragilities, the cause of these fragilities, and ways to overcome them. In order to fully appreciate the students' difficulties, we targeted this study to identify the cognitive competences required for reaching success in the course, that is, to obtain results that lead to a score above minimum grade.

A. *Cognitive competences of programming*

Studies based on characterizing cognitive competences of university students often refer to Bloom's six-levels taxonomy: knowledge, understanding, application, analysis, synthesis and evaluation [3]. Those studies indicate that students, in general, initiate their learning by a superficial approach, which corresponds to the first three levels, and then evolve in a gradual and progressive way to a deeper approach, which corresponds the last three levels. A more recent version of this

[1] According to Waal and Telles there are five andragogy principles: autonomy, experience, learning interest, learning use and motivation to learning.

taxonomy [4] differs from the original one on the terms used to name competences. There are now referred to by a verb, thus reinforcing the mind activity at each level: know, understand, apply, analyze, evaluate and create. The most meaningful modification is at the two top levels. As shown on the following picture "synthesis" is replaced by "create", a new competence, placed at the top level.

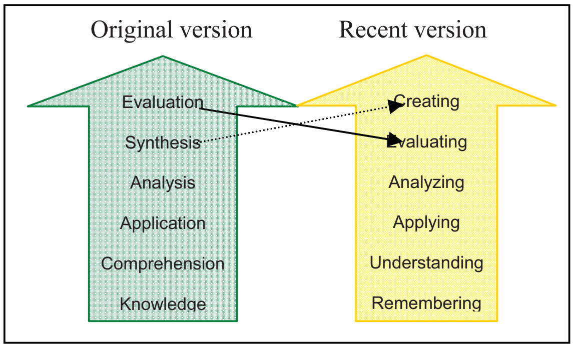

Figure 1. Changes on Bloom's taxonomy

Despite all the technical innovations that come with it, we believe that programming is still mostly a creative activity, encompassing analysis and synthesis [5], requiring a critical assessment, including self-assessment, and generating discussions with peers, centred on the resolution problems through programs and involving an important component of decision-making. All this must be supported by deep reflection and understanding of the basic principles, capable of backing up the decision that has to be made, sooner or later, in selecting the most effective programming solution for the given problem.

For the present work, we relied on Bloom's original taxonomy, which seemed more convenient to describe the natural path of an interested, motivated and hardworking college student, dedicated to learning the basic principles and good practices of programming. The student, when confronted with a hierarchy of skills he has to master, and consequent assessment he will have to go through, will certainly first familiarize himself with lower level competences, which in the case of programming means to know and understand syntactic and semantic rules of language and how to apply them to solve simple programming problems. Usually the exercises presented here should be helpful to:

- Diagnose weaknesses in students, concerning their background knowledge;
- Evaluate the degree of student difficulties in simple programming tasks;
- Elucidate and train students, preferably through effective teaching strategies, that provide them sequential action guides (say, "storylines" with step by step tasks) with the information and clues for gradual and progressive development of higher-level programming skills.

For the application of top level competences, the student should be led to solve challenging problems, which involve interpreting the problem statement, with acuity and attention, keeping in mind the principle of " divide and conquer". This means to decompose the problem into parts, as independent as possible of each other, and analyze their relationships. Assembling the parts, whose reciprocal relations must have been identified, with the aim of reaching the solution of the original problem, is the synthesis competence. Creativity in programming will reside in these two skills. Usually, it is by practicing with self-assessment on the tasks performed and with judging the value and merit of the material they created, that students improve their critical sense and their ability to take the right decisions. This seems to be the natural attitude human beings take in learning and problem solving, either everyday's problems or programming problems. But if this is the natural course of learning, why is it so difficult for the majority of students to acquire the highest level competences in programming [6, 7]? In order to find an answer to this question, we examined the difficulties and considered strategies for developing those competences in students.

1) Impeditive factors to acquire high level competences

For this issue, we considered the impeditive factors for the development of the critical and creative competences necessary to reach full success, on ADS course. We identified the following characteristics for those programming students with low capacity progression on those competences:

1. Lack of effort and persistence to apply the knowledge acquired, as a result of a lack of taste for mathematics or by a low motivation to fulfil these tasks, in this case as a consequence of the perception of difficulties or assumed individual incapacity, or even caused by competing personal interests;
2. Satisfaction on the fulfilment of the minimum requirement for the approval, for the reasons stated on the previous point;
3. Adoption of basic techniques that have been learned in the past, in other contexts, and refusal to try out new, more sophisticated methods, that, nevertheless are more effective and respect more the basic principles and good practices of programming;
4. Limits at the level of abstraction and logical thinking, of mathematical knowledge or other underlying concepts and techniques underpinning the programming problems presented;
5. Weaknesses on planning the workload, and coordinating the various tasks, a competence more important with the widespread adoption of the Bologna model;
6. Concerns caused by the amount of effort necessary to develop all the stated competences.

2) Possibilities to stimulate the development of high level competences

In an attempt to find solutions to some of these problems, we headed for a first analysis of a classic article [8], often quoted in educational circles, where Dijkstra argues that learning is a slow and gradual transformation of "new to usual", reinforcing the idea that learning programming is what he calls the "great news". Jenkins, in [6], supports the argument of Dijkstra and adds that the programming is a subject that is difficult to master, but that it should not be impossible to overcome this obstacle. Other studies promote deep learning [9, 10]. In particular, the study [9] tries to demonstrate that the strategy "peer review" promotes deep learning in programming courses. The author argues from experience that when students evaluate the work of their colleagues they think deeply, see as others solve the problems, learn to criticize constructively, thus improving the capabilities of critical thinking. The author also refers other strategies to force deep learning, stressing the importance of the implementation of reflective learning in higher education based on the application of knowledge to new situations or in different contexts.

The present work is inserted on a research line whose goal is to evaluate the efforts on the application of b-learning supported by an automatic judge [1] that automatically evaluates the programs written by students, as strategy to promote deep learning, in Computer Science students.

In this article we report the case of the ADS course, analyzing self-reflection exercise made by students in the post-examination period of the academic year 2008-2009, their study and learning habits through b-learning supported by an automatic evaluation tool, during the period of preparation for the exam, which roughly corresponded to a week between the end of classes and the day of the exam. We attempted to identify core competencies in planning the study, effort and action in accordance with the planning and execution of the exam, as factors to develop or maintain in future editions of the subject. The research data were obtained through questionnaires collected from a sample of students who attended the examination. We took into account data from another sample of students on a preliminary study conducted during the period of classes. This study was more concerned with the gradual acquisition of key programming skills by the students, and balanced out the limitations in the study that was carried out in the period of preparation for the exam. We also factored in the results of the students both in the labs (during the period of classes) and in the exam. The questionnaires were implemented as surveys, available through the webpage of the course, at the Moodle learning management system. Both surveys were designed in Google Docs [11] [12]: the first at the end of the subject course work, on the preliminary study; and the second after the examination, on self-reflection after examination. The data were treated in terms of characterizing the profile of the group of students in the course and also the individual profiles, in order to confront the results of each student with the results of the group, and also for comparing the competences that were acquired by each with the key competences that had been identified.

The goal of this research is to instil in upcoming students an awareness of the most common weaknesses, or critical points, to the development of high level competences. Equipped with these findings, the teacher will have a concrete mean to advise or help students in acquiring key competences, which will allow them to leapfrog the learning progresses. Next, we present our case study.

II. STUDY CASE

A. Preliminary study

For the analysis to the preliminary study, were considered 23 questionnaires, gathered at the end of the five weeks of classes, for the ADS course and before the period of preparation for the examination. We expected a larger number of responses, since 136 students enrolled and 56 actually attended classes. We had 17 (74%) male students, 15 (65%) full-time students, and the rest with some kind of part-time occupation (but less than 8 hours/day), 14 (60%) with ages between 18 and 24 and the rest with ages greater than 24 years. We recorded only 4 (17%) respondents that enrolled in this course for the first time, 7 (30%) that enrolled for the second time and 12 (53%) that were enrolled for the third time or more. Apparently, many students who quit on the first week of classes (and did not make it to the exam) have shown signs of lack of preparation and courage to attend this programming course. There was a clear trend of withdrawal from this course by the younger students enrolling for the first time, balanced by a large participation of former dropouts, who continue to enrol year after year, some having already reached an adult age[2]. The most common justifications for the previous failures were: a) lack of basis on mathematics, or other basic subjects, by 12 (52%) respondents; b) the short five-week compact term adopted experimentally by our university, by 11 (48%); c) lack of motivation, little effort and persistence on learning, by 10 (43%); d) high levels of uncertainty specially near the exams, by 7 (30%). So we have identified a group of respondents that are aware of their past weaknesses in programming, but that have shown signs of: a) willingness and persistence to succeed, on the opinion of 13 (54%); b) frustration and anxiety on the opinion of 11 (46%); and c) a tendency to drag the course and postpone success, on the opinion of 9 (38%). The responses do not allow us to conclude that repeated failures are an immediate motive for academic abandonment, with the exception of 5 (21%) that have shown some signs in that direction. We observed that 16 (70%) respondents stated that they enjoy programming, but 13 (57%) did not liked mathematic and, curiously, only 7 (30%) were motivated by both programming and mathematics. We also detected 3 (13%) dramatic cases of students who like neither programming nor mathematics. These are disturbing results, but they match those from [1]. We then analyzed the degree of satisfaction in relation with activities preformed as part of the course, in relation to the usage of Moodle platform, of the automatic evaluation tool, Mooshak[3], and also in relation to the competences acquired, personal interests, programming skills, expectations for the ADS course, and their relation with the results obtained in the mid-exam (an average of 12.4 values), before the final exam.

1) B-learning supported by an automatic evaluation tool

B-Learning, supported by the automatic judge Mooshak, was the learning strategy adopted for the ADS course, to support on-class learning, on the one hand, and to induce autonomous work, on the other hand. The information on course goals, learning outcomes, assessment methods, and types of work required were presented form the beginning. The lectures were recorded on video and made freely available on the Moodle platform, in order to reinforce learning and

[2] Therefore one of the competences to improve, on future editions of the subject, will be to avoid the postponement of success.

[3] *Open-source* automatic judge applicable to programs with text entrances and exits, developed by José Paulo Leal, from Porto University.

stimulate autonomous work at the rhythm of every student. So-called "continuous evaluation" was performed by: 4 "storylines" in total, with a detailed description of the tasks to be performed, matching the decomposition of the given problem in sub-problems, with instructions or suggestions on how to write programs for them and also on how to test the sub-problems and then how to weave the programs for the sub-problems in to the full program, this way paving the way towards the gradual and progressive acquisition of high level competences; 3 problems of the style used in programming competitions to apply those competences; and self-evaluation quizzes, after each lecture, to consolidate the subjects taught in the lecture. In this case, 3 (13%) respondents tried to make all the quizzes, 8 (35%) considered them useful, 1 (4%) fun and 7 (30%) have agreed that they helped remembering the issues discussed during the lecture, while 3 (13%) considered some questions took too much time to answer. All programming tasks were evaluated with automatic return, either through Mooshak[4], and either by the Moodle platform. There were also written reports on the "storylines", submitted through platform. These reports were read by the teachers, and scored by hand. Remarks were sent to each student by the teacher, again using the platform. We observed that 14 students (61%) agreed with the evaluation system used in the course, while and 7 students (30%) had some concerns and hesitation about the rules. On the issue of the interaction between teachers and students, 16 students (69%) agreed that the communication through the platform was effective and 12 students (52%) considered that the teacher's face-to-face feedback should be emphasized, again a situation similar to the one of reported in [1]. However, there were 8 students (35%) who stated the course required too much work, and 7 students (30%) revealed uneasiness on time management. Likewise, 16 students (69%) agreed that learning activities took more time than expected. Some respondents said to have acquired, through the use of Mooshak and the Moodle platform, essential study competences, such as: a) more careful on planning activities and meeting deadlines, with 15 (65%) agreements and 5 (21%) hesitations; b) more rigor on the activities fulfilled and submitted, expressed by 15 (65%) agreements and 6 (26%) hesitations; c) more motivated to fulfil the activities, with 16 (70 %) agreements and 3 (13%) hesitations; d) 14 (61%) have felt some learning progresses and 6 (26 %) hesitated; e) 16 (70%) developed critical spirit, creativity and problem resolution capacity and 6 (26%) hesitated, f) 12 (52%) have recognized that the evaluation system was fair and transparent and 6 (26%) hesitated; g) 10 (43%) agreed that the variety of exercises have measured their knowledge and competences, with 9 (39%) hesitations; and h) 11 (48%) said to have improved their academic performance, despite the 8 (35%) hesitations.

Based on the calculus of the average ranking (AR), through the weighted average of the four items rated using a Likert[5] scale, presented in the previous table, it was showed quite favourable behaviours (with values above 3) on the respondents' attitudes in relation to the study:

TABLE I. AVERAGE RANKING OBTAINED IN THE PREDISPOSITION IN RELATION TO THE STUDY

Aptitudes in relation to previous study	AR	Comportment
1. *I actually face the study* with seriousness and as an obligation to satisfy my interests	4,1	Favourable (with 17% of uncertain)
2. Usually I fulfil the terms of my study plans, even if arising calls for fun.	4,0	Favourable (with 17% of uncertain)
3. When I can't fulfil the obligations (delivering of works...) I'm frustrated.	4,1	Favourable (with 17% of uncertain)
4. *Not passing on* is something that bothers me a lot.	4,3	Favourable (with 13% of uncertain)

In this case, 19 students (83%) stated, some (10) with more conviction than others (9), that faced study with seriousness and as an obligation to satisfy their interests, 4 (17%) have revealed hesitations and 1 (4%) depreciated the study. Furthermore, 18 students (78%) said they pursued personal fulfilment and 19 students (82%) wanted autonomy and independence from the family. In this case, only 1 student (4%) showed signs of hedonism (4%), 3 students (13%) showed signs of indifference towards the study, and 1 student (4%) wanted with desire to exert authority, influence and enhance public image. Yet, despite the visibly favourable results, study commitment beyond favourable predisposition requires task planning, effort and actions in accordance with the plan, even if in programming, the capacity for action is, in most cases, a direct consequence of the students' abilities. Accordingly, we sought to analyze the abilities acquired in programming, through the following table:

TABLE II. AVERAGE RANKING OBTAINED ON PROGRAMMING ABILITIES

Abilities in programming	AR	Comportment
1. I'm able to solve the most trivial problems of the subject.	3,6	Favourable (with 26% of uncertain)
2. I know and understand the rules of the C language and I apply them in the most trivial exercise.	3,5	Favourable (with 17% of uncertain)
3. I acquired skills for problem solving typical programming contests.	3,4	Favourable (with30% of uncertain)
4. I'm able to analyze challenging problems, its decomposition, relationships, joint parties with the aim of reaching the solution.	3,3	Favourable (with 39% of uncertain)
5. My logical or mathematical reasoning has been effective in most evaluation work.	3,5	Favourable (with 30% of uncertain)
6. I acquired skills to decide on the best programming solution to a unique problem.	3,3	Favourable (with 35% of uncertain)
7. I rarely commit lapses in programming.	2,1	Unfavourable (with 30% of uncertain)

The table presents an analysis of data provided by respondents in relation to their ability to programming. The existence of positive behaviours can be inferred, although these are not as massive as those found in table I, as shown by AR variables and the high rates of response with hesitation. It

[4] After the submission of each task, this automatic judge returned one of the feedbacks: Accepted, Presentation Error, Runtime Error, Compile Time Error, Time Limit Exceeded, Memory Limit Exceeded, Wrong Answer or Invalid Function.

[5] The scale was scored in a way that 0 was "don't know how to answer", 1 to "strongly disagree" and successively until 5 for "strongly agree". A value lower than 3 for each item corresponds to a favorable comportment of the students; a value below 3 to an unfavorable comportment caused by some contrariety; and value 3 corresponds to an uncertainty comportment, that can be a sign of fragility or indifference.

should be noted that the uncertainty has increased and the AR decreased with the increase complexity of the exercises and of the workload in general. The results point to greater difficulties in acquiring high-level skills, visible in sections 3, 4, 5 and 6 of Table II, that are fundamental to the full success in the subject. The last variable implies unfavourable behaviours, despite the uncertainty of 30 %, where it appears that most respondents admitted committing errors on programming caused by lack of attention to detail, or so they think.

We then analyzed the expectations of the students in relation to the final results in the subject, after the examination. In this respect, we found that 13 students (57%) were not very ambitious, and would be happy if they achieved the minimum score for approval, 5 students (22%) were undecided and the remaining 5 students (22%) expressed dissatisfaction in getting minimum levels. In this case, the respondents were trying to be modest when expressing they would be satisfied if they could reach the minimum requirements for approval [6], possibly because of the too many failures in past editions of the course, and also because they are aware of the weaknesses of their programming skills.

B. Self-reflection of students after the ADS examination

After the ADS exam we collected data from 10 questionnaires, from a set of 28 possible respondents who attended the exam. Thirty seven students took the exam, with relatively good performances in the evaluation carried out during the period of classes. Indeed the average for those students that came to the exam was 12.4 points, for a maximum of 20 points. The average score in the exam was 8.0 points. There were 12 that passed, 6 of them with grades above or equal to 12 points (12, 13, 13, 15, 15, 18) and the remaining 6 with a grade between 10 and 11 values (10, 11, 11, 11, 11, 11). Of the remaining, 16 students failed and 9 were absent. These results are very disturbing and more so because of their persistency over the years. It is difficult to find an explanation other than poor study habits of students.

Therefore, it is interesting for the students to do an exercise of self-reflection, after the exam, concerning their study habits, and compare the results with those of the preliminary study. We can also relate the results to the effort and actions conducted in preparation for examination, the examination itself, and if the effort was worth it and the perception of whether the preparation effort was worth it. The data indicated that on the exam 9 respondents were male, 6 were young adults and 4 were adults over 24 years of age.

1) Planning carried out during the pre-preparatory study

The planning of the study is a key skill for any student. Essentially, it consists of a reflection on the preparation, visualization and design of the tasks to be performed. At this point it was noted the following questions had at least 50% of expression of interest: Qpl_1) hot trends, that were likely to be at the exam; Qpl_2) questions frequently asked by the teacher during the lectures; Qpl_3) more profitable time of day; Qpl_4) the favourite place to study, Qpl_6) ways to avoid distracting factors, Qpl_7) definition of learning goals, materials or technology necessary; On the downside questions Qpl_5) profitable study hours and Qpl_8) the distribution of study and rest times and what strategies to use to avoid anxiety states obtained 40% of records. In the respondents reflections after having seen the exam was verified that only 20% of them, corresponding to R1 and R2 of the following table, defended the way they prepared themselves, since considering to have obtained a good result, even if R2 admitted a final result below his expectations. The key issues envisaged by all respondents, and advised to be improved by some or maintained by others, are in the following table:

TABLE III. QUESTIONS PONDERED ON STUDY PLANNING

	Qpl_1)	Qpl_2)	Qpl_3)	Qpl_4)	Qpl_5)	Qpl_6)	Qpl_7)	Qpl_8)
Respondents	R1	R1	R1	-	-	R1	R1	-
	R2	-	R2	R2	R2	R2	-	-
	R3	-	R3	R3	-	R3	R3	-
	-	-	R4	R4	-	-	-	R4
	R5	R5	-	-	-	-	R5	R5
	R6	R6	R6	R6	R6	R6	-	-
	-	-	-	-	-	-	R7	R7
	R8	R8	-	R8	R8	R8		R4
	R9	R9	-	-	R9	-	-	-
	R10	-	-	-	-	-	R10	-

2) Action and effort in preparing for the exam

The effectiveness of the preparation for the exam will be greater if the planning is good and if the subject studied during the classes have been consolidated.

Usually this period of preparation for the exam is used to review the course, overcome the perceived remaining difficulties, solve again tests, exercises and problems that have been done, invent of new exercises, etc. At the end of the study, and before the exam, it is important to make a self-assessment of learning, so that the students themselves feel responsible for their study habits and results they will obtain. In the case we analyzed, all respondents used the preparation time to study, as shown in the following table, and the study was always or almost always conducted with the support of materials and technology available on the platform:

TABLE IV. TIME DEDICATED TO STUDY WHILE PREPARING FOR THE EXAM

	R1	R2	R3	R4	R5	R6	R7	R8	R9	R10
Days / Hours of study in a week	3/40	4/80	2/14	5/15	5/45	3/12	3/12	3/42	3/15	2/10
Hours devoted to the study were profitable	fully agree	agree	agree	neither agree nor disagree	agree	neither agree nor disagree	agree	agree	neither agree nor disagree	agree

The data confirmed that respondent R1 was the one who was confident that the hours dedicated to study were profitable. On the other hand, we observed that in relation to the questions presented here: Qac_1) all respondents reviewed the theoretical materials; Qac_2) 70% analyzed previous exams used in past editions of the course; Qac_3) 50% solved again the exercises presented during the course; Qac_4) only 10% invented new exercises from the ones made available on the platform, the

[6] To avoid satisfaction in obtaining minimum grade on the subject is other competence to be developed in future editions.

remaining 50% despite agreeing to the effectiveness of their study strategy did not show it clearly and there were 40% of hesitation; Qac_5) no respondent claimed to have solved the proposed exercises for which a solution was not available for reference; Qac_6) 50% revealed, but without much conviction, to have made self-assessment of their learning, 10% hesitated and the remaining 40% stated they did not; Qac_7) 30% of respondents said that throughout the study were able to formulate their own questions and that therefore there was no reason for being anxious before and during the exam, 30% hesitate and 40% disagreed; Qac_8) interestingly, 80% of respondents studied alone; Qac_9) for doubts that arose, 40% relied on colleagues (in person or in forums), 30% referred to other means and no one tried to reach the teachers during this period. It is important to notice that 40% of respondents indicated that the effort in the preparation paid off for having gotten a better mark than the one they would have got if they had not prepared themselves. The effort and actions conducted by these respondents is showed in the next table:

TABLE V. ACTION AND EFFORT WHILE STUDYING FOR THE EXAM

Qac_1	*Qac_2)*	*Qac_3)*	*Qac_4)*	*Qac_5)*	*Qac_6)*	*Qac_7)*	*Qac_8)*	*Qac_9)*
R1	R1	-	-	-	R1	R1	R1	-
R3	R3	R3	-	-	-	-	R3	-
R6	R6	-	-	-	R6	-	R6	R6
R7	R7	R7	R7	-	R7	R7	R7	-

By analyzing the Table V, the respondent R7 distinguished himself from the others for, besides all the effort and action in the preparation for the exam, having been the only one to reaffirm that he tried to imagine new exercises from the ones available at the platform and for presenting himself as the more convinced that his study strategy was effective to relax and avoid anxiety. It was found that, like R7, R1 also maintained a positive spirit during study and examination. These two students have thus shown skills of self-motivation and the capacity to formulate their own questions in situations where normally in order to find the answers one must have a thorough knowledge of the subject. Respondents R1, R6 and R7 also performed the self-assessment of their learning, thus taking self-responsibility for their actions in the study. However 40% of the respondents felt that the effort of preparation was not worth it because they obtained a mark below their expectations. The effort and actions conducted by these respondents are given below:

TABLE VI. ACTION AND EFFORT WHILE STUDYING FOR THE EXAM

Qac_1	*Qac_2)*	*Qac_3)*	*Qac_4)*	*Qac_5)*	*Qac_6)*	*Qac_7)*	*Qac_8)*	*Qac_9)*
R2	R2	-	-	-	-	-	-	-
R5	R5	R5	-	-	R5	-	R5	R5
R6	R6	-	-	-	R6	-	R6	R6
R8	-	R8	-	-	-	-	-	R8

In this case, no respondent stood up with enough self-motivation to formulate their own questions, although Table IV shows that these were the ones who have dedicated more time to study during preparation time. We observe that respondent R5 also took personal responsibility for his actions. It is worth noting that R6 respondent considered that this effort allowed him to get a better grade than he would have got if he did not make some effort. Still, he was not happy, because the grade below his expectations.

3) Making the ADS exam

During the exam, we observed that the study strategies used specially by R1 and R7 worked as a key competence to grant success at the course. Next, we present a graphical summary of the main difficulties felt by this group of respondents during the exam:

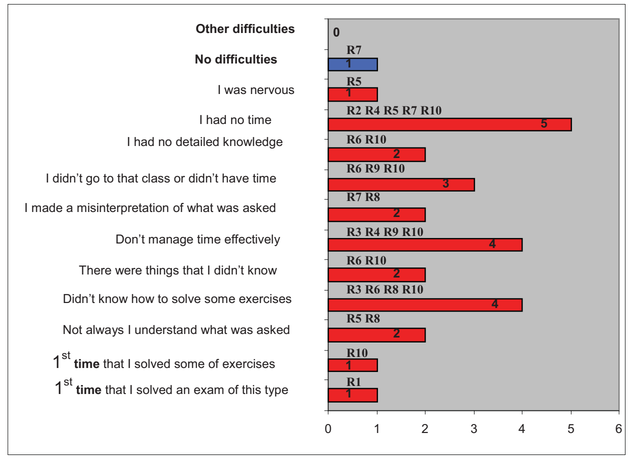

Figure 2. Difficulties on the ADS exam

R7 was the only to affirm not to have felt any difficulties, while R10 was the one who felt them the most; R5 assumed some anxiety. The most limitative fact or for this group of students was time. Thus, this must be one of the key competences to be improved on future editions. Like on other areas of study, for exams in programming courses, it is always necessary a deep acquaintance with the subject, so that the right answers come to mind faster, with the self-confidence and self-control. These are fundamental aspects that help to dissolve the fragilities of time management, anxiety, etc.

The exam was structured into five groups, as follows: the first group is a quiz similar to the ones used for self-evaluation questionnaires after each lecture; the second group with a simple question about the output generated by a "mysterious" function that implements in disguise one of the algorithms studied in the course; the third and fourth groups have questions that apply the knowledge acquired in the context of a new set of functions; the fifth group is a problem requiring a complete program, like the tasks submitted to Mooshak, typical of programming contests, using some data structures and some algorithms that the students must have learned during the course. Accordingly, we analyzed the key competences to maintain or improve on the resolution of the first, second, third and fifth groups of the exam (given that the fourth is equivalent to the third):

TABLE VII. STRONG AND CRITICAL POINTS IN THE RESOLUTION OF THE THREE FIRST GROUPS OF THE EXAM

Key competencies to maintain (bold) or to enhance (normal)	**1st Group**	**2nd Group**	**3rd Group**
Many difficulties	R6	-	R8, R10
Withdrawal at first attempt	-	-	-
First time I do these exercises	R1	-	-

I kept calm and was careful	**R1, R3, R4, R6, R8, R9, R10**	**R1, R4, R6, R7, R8, R10**	**R4, R6, R10**
For not to make mistakes I preferred not to respond	R6, R10	-	-
Not studied in detail	R6, R10	R10	R4, R8, R10
I memorized this matter	-	-	-
I recognized the matter and was able to apply it in context of these exercises	**R1, R3, R4, R5, R6, R7, R8**	**R2, R3, R5, R6, R7, R9**	**R1, R2, R3, R6, R7, R9**
I had no detailed knowledge that would allow me to respond well	R2, R6	R10	R5

On the execution of the first group (the quiz), we draw attention to respondents R3, R4 and R8 who revealed more key competences. On the next level we have R1, R5 and R7. On the other hand, R6 was the one who presented more weaknesses on the quiz, followed by R2 and R10. On the two following groups, to implement functions, the emphasis goes to R6 and R7, with key competences to maintain, followed by R2, R3, R9 and R1. On these exercises, R10 was the one with more difficulties, followed by R8, R4 and R5.

TABLE VIII. STRONG AND CRITICAL POINTS, ON A RESOLUTION OF A PROBLEM TO APPLY HIGH LEVEL COMPETENCES

Key competencies to maintain (bold) or to enhance (normal)	5th Group
Many difficulties	R9, R10
First time I do these exercises	R10
Withdrawal at first attempt	R10
I kept calm and was careful	**R1**
For not to make mistakes I preferred not to respond	R10
Not studied in detail	R7, R10
I recognized the matter and was able to apply it in context of this problem	**R1, R2, R7**
I had no detailed knowledge that would allow me to respond well	R3, R6, R8, R10
I should have studied the matter thoroughly to respond quickly	R3, R10
I correctly interpreted the statement of the problem	**R1, R4, R6**
I identified the data to solve the problem	**R1, R2, R5, R6, R7, R8, R10**
I was able to build a mental algorithm to solve the problem	**R1, R6, R8**
I decomposed the problem into parts independent of each other	**R1, R2, R3, R6, R7**
I analyzed the relationships of the parties, which could resolve	**R1**
I joined the parties well linked, with the aim of reaching the solution of the problem	**R1, R7**
I'm aware that I presented the most efficient solution that it is possible	**-**
I had difficulty in applying the knowledge in the context of the problem	R5
I had difficulties in my reasoning	R3
I couldn't reach an initial settlement proposal	R3, R4, R5, R10
I wasn't able to understand what was meant	R10
There were steps which I couldn't perform	R6

In the last group of the examination, on a typical problem of programming contests, respondent R1 stood up positively, showing a deeper understanding of the subject, and its application in the context of the problem presented, despite not being sure that the solution he found was the best. This is a core competence to be developed by all students of this case study, in a course on Algorithms and Data Structures. R7 stood in a significant distance from R1, followed by R2 and R6. In this group, as in others, the respondent who had more difficulties was R10, followed by R3, R4 and R5 who also showed reduced ability to apply knowledge to new situations. Thus, it's not a surprise that the more superficial approaches to the study lead students, whenever asked differently, to difficulties in understanding the meaning of the problems.

In the exam, in general, the respondent who stood with the largest number of core competencies to maintain, and with self-motivation to develop the subject, was clearly R1, followed by R7 and then R2 and R6, although the latter two have presented some weaknesses in the first group. The respondent with more difficulties in terms of the various groups was clearly R10, followed by R3, R4 and R5, although the latter three, with surface trends, presented skills to keep on the quiz, and R3 also in the second and third groups.

4) Post-exam reflection over key aspects to maintain or improve, or if the effort was worth it

After the reflections over how study habits have influenced exam performance, the respondents reflected over key aspects to maintain or improve in the way they prepared themselves. We observed the following:

- 20% (R1 and R2) defended the way they prepare themselves, since they considered to have obtained a good result, although R2 admitted that the effort did not pay, since the grade was below his expectations. On the opposite, R1, R4 and R10 considered their effort rewarding, since they learned things they did not know. However, both R4 and R10, which presented more weaknesses at the level of acquired key competences, considered to change their preparation way by making more exercises;
- 60% (R1, R2, R3, R4, R7 and R10) considered that the effort was rewarding, since they liked programming, with the exception of R2. On the reflection on the aspects they would change on the way they prepared themselves, R3 referred he would study more deeply certain parts of the course, and R7 that he would have made more exercises;
- 30% (R1, R3 and R7) defended that their effort paid off, since they got a better grade than the one they would have if they were not prepared, despite the fact that R3 did not present signs of having a good grade;
- 40% (R2, R5, R6 and R8) considered the effort and action was in vain, since they had a grade lower than they expected. On the reflections of R5 and R8 on what they would change in the way they prepare themselves, they mentioned making more exercises, while R6 would have paid more attention to the quizzes;
- At last, also R9 did not felt any advantages on the effort, considering that he did not have time to prepare for the exam. Still, he referred that he would have made more exercises, if he had had time.

In this case we can conclude that a significant percentage of the respondents assumed the responsibility for bad study habits, caused not by the lack of study hours, but for the lack of a deep study on matters that require more than superficial knowledge. In this case they all agreed that the exam was within reach for most the respondents, and that it covered the subject discussed in the course, in the lectures and in the labs.

III. CONCLUSION

The set of results presented in this paper may not represent the reality of what is happening in programming courses that are part of Computer Science programs in Portugal. Nonetheless, we believe significant and interesting. The study reveals that, despite concerns expressed by respondents for personal achievement, through the attainment of academic and professional success, and autonomy and independence of families, and a favourable dispositions for the study, only a comparatively small part (21%) of students of the first year programming course we analyzed achieved competencies and skills necessary for writing programs with the required in-depth understanding, which requires more than a superficial knowledge, for full success in this subject. The exercise of self-reflection carried out by these students on their study and learning habits through b-learning supported by an automatic judge reflects the skills of self-knowledge that are part of the experiments and experiences in university. Indeed, they are key skills for the current knowledge society.

It is important that each student remain aware of both the critical points for the development of his high-level skills and of his abilities to manage his one academic path, so that he can prepare himself to successfully face the challenges of university life and reach the goals he has set for himself. It is interesting to note that if a student considers lack of effort as one of his critical points, this understanding will favour him since he knows he has to work harder. Nevertheless, if he has a lack of appetence for programming, a condition that is difficult to overcome by reason alone, he will feel that he is not able to control the situation and his chances to succeed are less.

We conclude by presenting the competences of the more successful respondents, that have emerged of this case study: a) self-motivated to carry out the various course activities, to formulate their own questions and to work independently, b) self-motivated for wanting more than obtaining minimum passing score, and for not procrastinating success in the course, c) self-disciplined and rigorous in planning and implementing activities, as well as in meeting the deadlines, d) with good work habits and effective study strategies, e) with ability to program, f) with handling capabilities of the technology available on the platform, g) with a desire to learn and participate in the forums and in the class room, h) with the ability to communicate through the technology available on the platform or in person.

Abstract - **From 2005, Active Learning in Computing partners Newcastle and Durham University (ALiC), part of the UK CETL initiative,[1], introduced a collaborative learning model of Software Engineering to level 2 Computing Science students that reflects global industry practice by focusing on cross-site software development. Assessment for this effort focuses on measuring students' development of both the technical and transferable skills associated with the practice of being a software engineer. However, it is often difficult for the student to perceive and articulate what skills they have learned during the project based on marks and feedback from lots of separate elements of coursework. In this paper, we propose that assessment of Software Engineering team projects should focus on the development of a range of competencies that could be measured in a style that relates directly to professional performance appraisal. We describe the current assessment methods we use and then outline a set of alternative competencies and appraisal methods that could be used to help staff and students better evaluate levels of achievement and skill development in qualitative terms during undergraduate team projects in Software Engineering.**

Keywords: Software Engineeering, Competency, Skill development

I. INTRODUCTION

The Centre of Excellence in Teaching and Learning, (CETL), Active Learning in Computing, (AliC), which commenced in 2005, is a consortium of North East UK universities comprising of Durham University (CETL lead), Newcastle University, Leeds Metropolitan University and the University of Leeds. The initiative aims to identify and enable ways in which students can become more actively engaged with the Computing Science curriculum in their learning. Through promoting project and group-working, ALiC has implemented new learning approaches, enabling students to move towards independent learning guided by appropriate support materials. To that end, AliC partners Newcastle and Durham have introduced a collaborative learning model of Software Engineering to level 2 Computing Science students that reflects global industry practice by focusing on cross-site software development. Industrial software is often produced clollaboratively between teams located at different geographical sites. The pedagogical aims of this cross-site collaboration activity are therefore: to give students an insight into Software Engineering in an industrial context; make problem-solving more realistic in student team projects; allow staff and students to use and evaluate various technologies for cooperative working and encourage the development of transferable skills such as communication, organising and team-working. Skills outcomes for the module at Newcastle were and still are listed as: initiative; adaptability; teamwork; numeracy; problem-solving; interpersonal communication and oral presentation. Overall, students have reported good learning outcomes in questionnaires and focus groups set up to evaluate the module design and their experiences. However, assigning marks to students during and at the end of the module on many separate pieces of coursework [2] means that student achievement is "abstracted into just a few numbers" so it is often difficult for students to perceive and articulate what software engineering skills they have learned and how these skills have developed during the project.

In this paper we describe the learning design of the cross-site development project. We review the assessment methods currently used to evaluate student performance and measure student learning outcomes. We propose that assessment of undergraduate team projects in Software Engineering should focus on the development of a range of competencies similar to those identified by Turley and Bieman, in conjuncton with the assessment of technical and team work products in a style that relates to professional performance appraisal [3]. This approach would give students a richer view of their achievements and a more useful and realistic performance review of how their competency has changed and developed throughout the project. We outline a set of alternative competencies and appraisal methods that could be used to provide staff and students with a better understanding of levels of achievement and skill development during undergraduate team projects in Software Engineering.

II. LEARNING DESIGN OF THE MODULE

At the beginning of the academic year, teams are formed from the Software Engineering module cohort at Newcastle and each one is then paired with a corresponding team at Durham. The major project task is the design and implementation of a large software system – (e.g. in 2005 the task was a tour guide application that could be loaded onto a PDA or mobile phone, in 2006 they had to create a logistics system for UK-wide distribution of personal care products and in 2007, teams had to develop a virtual geo-caching application). The aims of the module are to introduce the real world experience of team working and to provide practical experience of large scale software development. The teams of students work must work together as a 'virtual' enterprise across the sites for the whole academic year, using communication technologies to facilitate their collaboration.

There are some differences as to how Software Engineering is taught at Newcastle and Durham and through four iterations of the cross-site development project we have altered our practices to accommodate these differences and make the module a more cohesive experience for students in terms of our approach [5]. In our learning design for Software Engineering at Newcastle we 'front-load' the lecture component of the module and give our students 10 one hour introductory lectures on the basics of Software Engineering including an overview lifecycle models and phases and their associated techniques and tools. In operational terms, Newcastle take a problem-based learning approach – where students must rely on their existing programming knowledge and direct their own learning to solve the problem after the introductory lectures. Durham have adopted a hybrid-approach of traditional Computer Science teaching mixed with partial problem-based learning. They allow students to make all the team decisions but provide lectures and supervised laboratory practical sessions for the whole year to support the student development effort. The decisions the virtual companies are responsible include the definition and allocation of roles; the outline and implementation of a company management structure; the allocation of tasks to each member; the definition of the project plan; the choice of development methodology; tools to be used to deliver their software and documentation at the end.

Other deliverables for the project include coursework elements that are to be completed on an individual or local team basis e.g. a personal skills assessment, a contract, as well as product demonstrations. Each iteration of the cross-site model has seen minor changes to the nature of deliverables depending on the size of the cohort and also the nature of the problem to be solved. We have also evolved the way we teach the module each time it has run, making changes based on student and employeer feedback.

III. CURRENT ASSESSMENT METHODS

One element of the project that remains unchangeable is the need for each individual institution to take responsibility for the assessment of their students. It is likely that any institution's policy would dictate the need for this in a cross-site development project in order to ensure that institutional standards and integrity are maintained. Separate assessment protects students from the possible consequences of working with poorly performing students at another institution. In practice, this has meant that staff at both institutions work closely to ensure that students are fully aware of the aims and motivation of the assignment as early as possible and to ensure that a mark for any work product reflects their institution's students' contribution. Good assessment is fair, valid and reliable. We believe that it should relate to real tasks and realistic contexts, make expectations and criteria clear and provide feedback that allows a student to progress in their learning. It should also accurately measure skills and qualities that are practiced, demonstrated and improved throughout the student's learning experience.

There are a lot of assessments for the project throughout the year, (approximately 17). Before the CETL altered the learning design, there were 34 assessments each year. Table 1 illustrates the current set of assessments on the module and their type i.e. whether they are individual or team efforts. The rationale for having so many was to ensure that students had as many opportunities as possible to demonstrate and practice their skills and improve on their learning. Having many assignments also ensured that teams were kept busy and had enough work to distribute amongst their members. As part of the changes we made for the cross-site work, we also removed some of these assessments as some skills were over-assessed during the module in previous years e.g. presentation skills were assessed three times in pre-CETL iterations.

TABLE I. ASSESSMENT TYPES

Assessment	***Type***
Strengths Essay	Individual
Review	Team
Interim Requirements (F) *	Team
Group Structure	Individual
Contract	Team
Interim Design (F) *	Team

Project Plan	Team
Testing Strategy	Team
Final Requirements	Team
Final Report	Team & Individual
User Manual	Team
Final Design	Team
Software Submission	Team
Peer Assessments	Individual
Software Demo	Team
Monitor Observations	Individual

a. (F) – Formative Assessment – feedback only

The students are given formal templates for both the Requirements Specification and Design documents and allowed to submit a copy of these for formative feedback (as indicated by (F) in Table I before submitting their final efforts for grading. Students find this reassuring and it means they can make mistakes and improve their performance during the module, rather than retrospectively as in most forms of academic assessment.

There is a lot of emphasis in the module on documentation and on assessing team processes as well as products. At Newcastle team processes are *monitored* once aweek by members of staff who observe each team's formal meeting. These observations of interaction and participation are given a grade by the monitor at the end of the project and act as a weighting for the overall team mark. One reason for the emphasis on documentation are to help students to realise the importance of industry-standard notations such as UML in describing design. Having documentation that is assessed also ensures those students who are weaker in terms of coding proficiency can contribute in valuable ways to the whole team effort and be rewarded.

Table I also illustrates that there is a lot of joint assessment between sites. With each iteration of the cross-site work we increased the dependency between the teams for grades and the level of joint marking. The reason for increasing this dependency between teams was to increase their motivation to collaborate properly. However, the downside to the increase in dependency between sites is that it has also increased the level of anxiety students have about team assessment. This means that staff at both institutions have had to work hard on specifying common marking criteria that suits the aims of their separate programs and is also explicit in determining how an individual grade will be derived from all the cross-site and local team efforts.

A. Defining Individual Contribution

Students are often nervous or anxious about assessment fairness when involved in a group effort and cross-site working further exacerbated these fears. So, in order to ensure the student contribution at each site was differentiated clearly we mandated that students use a simple contribution matrix to help ensure recognition of individual effort. The matrix illustrates the type and amount of effort each individual contributed to an element of assessment, regardless of their base location. An example of a design document is given in Figure 1. In this matrix, the sections of the design document are outlined and then each student's contribution is defined in terms of whether they created the section, modified it or reviewed it in some way. The contribution matrices take a lot of effort to fill in for students especially for larger pieces of work such as coding but this ensures they are specific about the nature of the work they have done and the pieces of work they have contributed to.

Figure 1. sample contribution matrix

The use of these matrices helped to alleviate some of the assessment fears faced by students about working in a group e.g. the impact of non-participation of some members or the fear of not getting enough credit for their efforts. However, even though we were very specific about marking criteria and students reported that the matrices helped, they were still anxious about assessment so we decided to review all our assessment methods.

B. Coders and Non-Coders

We examined student grades from the Software Engineering module at Newcastle for 2 years before and 2 years after the implementation of cross-site work in order to determine how the changes we made had impacted on student performance. Because of the differences between cohorts each year and the subtle changes we made in each iteration to deal with operational problems, we could only infer this impact and note general trends. We analysed student grades, team reports and individual reflective reports from the years 2003-2007.

We found that, in general, students who did not contribute largely to the coding of the product during the project, received lower grades, on average, across all the years.

As can be seen in Table II there were 109 coders (34% of the total number of completing students) and 215 coders. The data indicated that 57% of non-coders scored less than their team's average mark and 39% of coders. These figures were quite worrying considering that the coding effort and subsequent software produced is worth only 5% of the total module marks available. The reason that the product is worth so very little in terms of grade percentage is because we want to emphasise all the other aspects of Software Engineering that are equally as important as the end product. Students tend to focus very much on the product and view programming as the only real important part of the work they are doing. As tutors we need them to recognise that Software Engineering is more than just programming, therefore we place more emphasis and give more academic credit to other deliverables and processes.

TABLE II. MARKS OF CODERS AND NON-CODERS FROM NEWCASTLE

Implement	1^{st}	2.1	2.2	3rd
No	26	42	31	9
Yes	67	91	46	8
Total	93	133	77	17

The intended learning outcomes for the module are divided into knowledge and skills outcomes as illustrated in Table III. These learning outcomes are sufficiently broad to cater for a range of abilities amongst the student cohort and terms such as *practical experience in design and implementation* (see Table III: Skill Outcomes column), should cater for all the processes associated with the design and implementation of a system, including the non-coding aspects. If a student has demonstrated these learning outcomes (to varying levels), then the differences between coders and non-coders should be irrelevant. The results from our analysis of marks made us wonder are coders better Software Engineers or even just better students? Ideally, for us, assessment in the module should be based on performance and not innate ability (although this is a factor that cannot be ignored) – however it is all too easy to specify a set of criteria for performance based on our perceptions of ability rather than what students actually do.

IV. Measuring Learning Outcomes

The worries over assessment of contributions the differences in marks between coders and non-coders set us thinking about what we really are assessing and what the student gets out of the module in terms of learning outcomes and skills. We had lots of questions that needed an answer e.g. does the mark generated by the assessment of all the deliverables and assignments give a true reflection of what the student has learned about Software Engineering? Is a mark for the project a sufficient indicator for an employer in industry of the skills a student possesses? Does the module give the student real tangible skills that can be used as soon as they go into a job?. Does it matter if they programmed the system or took some other role in the teamwork? Can students interpret what they have learned in the module as a realistic software engineering experience? Can students see how their skills have progressed and developed during the project?

TABLE III. module Learning outcomes

Intended Knowledge Outcomes	Intended Skill Outcomes
An understanding of the issues that relate to planning and execution of a team-based software project	Practical experience in the design and implementation of a large software system.
An understanding of the software engineering process, process mode ls and stages	Practical experience in issues such as te am structure, document preparation, project management.
	The ability to work as a member of a team, to fulfil appropriate roles within a team
	Evaluate own learning, progress and quality of solution objectively.
	Technical writing. Report writing
	Critical self-evaluation, peer evaluation
	Presentation of results.

As part of the module we run a series of mock interviews with real employers. Each student applies for a position, sending their CV and a covering letter. The employers taking part often complain that students do not present themselves as well as they could at interview. Some of the problems are definitely due to a lack of confidence but also many students focus only on their technical skills in the CV and at the interview and ignore the 'soft' skills that we also want them to learn during the project. Most employers want a more rounded individual with the potential to grow and change in the organisation, a self-starter that works well both in teams and on their own. So students need to be able to articulate what the module has taught them both in terms of technical software engineering skills and other transferable skills e.g. communication and leadership. One thing that we currently do well is get students to complete a self-assessment skills ticklist and essay at the start of the year. We give them a set of broad categories based on an old version of Belbin team roles [10]. Students are asked to identify their existing skills and where they might fit in the common stages of the software lifecycle e.g. would they fit into a design role, are there skills they have that could be used in all phases of development?

We ask the students to complete a self-assessment report at the end of the module (Final Report, Table I). This report encourages the student to reflect on their project experience and discuss any skills they have developed, improved or learned for the first time. They are asked to compare their initial skills assessment to their skill levels at the end of the project. Over 4 iterations of the project, by reading these reports and conducting focus groups with the module cohort, it has become clear that students do not always know the reason why they are doing a particular assessment or task during the project. Some students also have had difficulty grasping the importance of formative assessment of large work products and often fail to use the feedback we give them to improve their grades. Others have difficulty in articulating how their skills have changed or what new skills they may have gained during the project.

Our experiences tell us that students have not reached a critical understanding of many of the important aspects we are trying to teach them and we feel that this is caused by the nature of the assessment tasks we set them – they are, to some extent mismatched with what we are trying to achieve. According to Ambrose "the extent to which students engage in critical reflection in large part depends on the extent to which the assessment methods employed have developed critical understanding as their goal." [8]. We feel this is an area where our assessment design could be improved. Our assessments are too academic and bureaucratic in nature. Whilst work such as the Requirements and Design documents gives students practice using formal notations and techniques associated with Software Engineering, students receive numerical values and feedback for each single document or software item (which is collaboratively-produced) as a measurement of their proficiency and competency-levels in the discipline. This makes it difficult for them to get an overview of their personal performance as a software engineer. Individual assignments such as essays, presentations and reports don't really test or assess their practical skills – merely their reflective skills. Practical skills are treated as a group commodity and often assigned one grade or a weighted grade but the feedback is common to all. We use methods to derive an individual's marks for the large products, but not individual feedback. Observations made by monitors can be subjective and don't reflect a true picture of the practical work students do outside of formal meetings and class times. The *process* is not being measured as accurately as it could be and feedback to students needs to be more meaningful on an individual level in order to capture the wealth of learning they have experienced and give them a real sense of their ability as a software engineer.

V. Assessing competency

Competency matrices, such as those used by Smith and Smarkusky for self and peer assessment [6] could be used instead to capture learning and give students rich feedback on their abilities and skill levels. A competency matrix captures team knowledge and skills in various categories (process, communication, interaction, contribution and responsibility). These matrices then allow an assessor to assign a numerical range of proficiency in each specified competency – individuals are evaluated by selecting a class rank to indicate the baseline competencies expected of the individual. In this work, peers assess whether an individual has met the expectations, exceeded the expectation by various amounts or requires improvement (varying amounts of improvement can be denoted e.g. we have used first, second or third class performance). An abbreviated example adapted from the work of Smith and Smarkusky is given in table IV.

TABLE IV. SMITH AND SMARKUSKY'S COMPETENCY MATRICES

CLASS RANK	1ST	2ND	3RD
Process	Steps required to complete project		
Task Performance	Exhibits on tasks behaviour consistently	Supports others in completing tasks	Motivates others to independently stay on task
Leadership skills	Learns about leadership skills	Rehearses leadership skills	Exercises leadership skills
Communication	Oral and written means by which students share ideas and information.		
Shares ideas	Shares ideas especially when asked	Shares ideas readily	Mentors others in sharing ideas
Asks questions	Asks questions for communication	Asks questons related to prioject fundamentals	Asks question that directs conversation toward project solution
Interaction	Ways in which students interact socialy, their interpersonal skills, how they resolve conflicts.		
Team problem-solving skills	Uses critical thinking to develop a project solution	Encurages a team decision by examining project criteria and supporting evidence of each alternative	Uses ethodology to make a team decision and presents problem solution with supporting evidence from each team member.

Currently, our module learning outcomes for the Software Engineering Team Project are quite explicit in that we expect students to undertake roles, practice project management skills, communication skills etc. but in terms of Software Engineering competency – our assessment instruments are weak. Ambrose [8] suggests we need to provide an holistic view of a person's competency and for this to happen students need to develop self-efficacy where they can make judgements not on what skills they have but what they can do with the skills they possess. We do this in a small way at the start of our project, by getting the students to evaluate their skills in broad terms using a reduced Belbin form [10] that denotes broad team characteristics and behaviours team members might exhibit or possess innately e.g. an Investigator personality is good at finding things out, will be particular about finding new ways to solve problems etc. However, we do not retain the focus on skills in other pieces of coursework throughout the year or at the end. The focus on skills tends to get lost in the creation and assessment of the software engineering products that we ask the students to complete and the broad criteria that we use to assess them. Feedback for the module tends to focus on one piece of coursework at a time and does not give the students an overarching view of how they are performing during the project or at the end. Ambrose's work and the work of Marakas et al [9] in the area of measuring competency suggest antecedents to self-efficacy include verbal persuasion by a credible mentor, social comparison, (by observing someone else performing similar tasks) and the degree and quality of feedback and perceived effort can all enhance or decrease self-efficacy beliefs. As outlined by Ambrose, traditional measures of programmer's competencies include experience, professional references, training, transcripts and academic references, professional certification, written, oral and other demonstrative assessments during job interviews. These are all useful ways to find evidence of how well a professional is viewed and has performed in the field but don't really provide us with a guide to assessing students who are novices to the discipline of software engineering and whose degree program is not totally focused on software engineering. So how can we evaluate software engineering competency in an educational setting? We believe an adapted set of competency matrices could be used as part of an overall appraisal-like process for students throughout the whole project. Students would have to evaluate themselves and the performance of others in their team. They could be provided with examples of how to assess in a workshop before the project commences to instruct them on how to approach appraisal and fill in the matrices for themselves and others.

As these judgements could be subject to bias, other forms of assessment such as summative grading of work products, the use of signed and agreed contribution matrices for tangible deliverables and an individual report and interview at the end of the process would be used. The student evaluations could be used in conjunction with those of staff. Staff would use the same matrices and criteria to assess students as the students themselves and then compare matrices in order to assign grades based on a scale defining if they have met expectations, exceeded expectations or if they need to work on certain areas. This would give a sense of continuity, a transparency in assessment and a shared language for staff and students to discuss performance. This method would also give students some experience of 'social comparison'. Students very rarely get to view the results and feedback given to others and therefore find it hard to compare their performance to that of others in their class in a formal or managed way. A competency matrix would also give students early feedback as to their progress so they can correct poor behaviours. We could use the matrices periodically to get students to evaluate how they think they are performing along a set of pre-defined competency areas.

VI. Software Engineering Competencies

We propose that the competencies that should be measured via peer, self, formative and summative assessment are along the lines of those discovered by Turley and Bieman when conducting a study of exceptional and non-exceptional professional software engineers [4]. They identified 38 competencies including – helps others, willingness to confront others, responds to schedule pressure, focus on user/customer needs, team-oriented, writes / automates tests with code etc. We would use these in conjunction with the assessment of technical and team work products. Many of the behaviours Turley and Bieman identified with non-exceptional performance "can be viewed as the behaviours of inexperienced engineers" because a beginner "will be unsure of their own skills and capabilities" and therefore defining levels of proficiency or development in these behaviours should give our students more confidence as to how they have improved during the year. Suggested competency areas are 24 of the 38 that were identified by Turley and Bieman, (as illustrated in Table V).

TABLE V. Turley and Bieman's essential competencies

Team Oriented	Seeks Help	Helps Others
Use of Prototypes	Writes Tests with code	Knowledge
Obtains Necessary Training/ learning	Communication	Methodical Problem Solving
Uses Code Reading	Response to schedule pressure	Sense of mission
Attention to detail	Perserverance	Innovation
Desire to improve things	Focus on user or customer needs	Sense of Fun
Lack of Ego	Thinking	Skills/Techniques
Quality	Elegant and simple solutions	Thoroughness

The authors define competencies as "the skills, techniques and attributes of job performance" [3, 4]. They conducted an in-depth interview with 20 professional software engineers, (10 'non-exceptional and 10 'exceptional') who were employed by a major computing firm, (using the Critical Incident Interview technique as outlined by John Flanagan in 1954, the precursor of competency modelling) [12]. They also analysed competencies identified by software managers. The competencies they identified provide an alternative way of looking at the job of software engineering. The competencies are organised into four categories – *Task Accomplishment, Personal Attributes, Situational Skills and Interpersonal Skills*. In Table V, for example, Task Accomplishment competencies are Methodical Problem Solving, Obtains Necessary Training/Learning and Skills/Techniques. The authors provide examples of each competency e.g. Skills/Techniques is defined as proficient in using design techniques, debugging skills and easily makes technology choices. The authors concluded that although "most of the competencies cannot be used to distinguish between the exceptional and non-exceptional subjects, the derived competencies offer a unique view of the skills of professional software engineers" [3]. These competencies could be used to in conjunction with graded or evaluated competency matrices to help us illustrate the progression for the student on a software engineering module or even a whole software engineering program. This would mean they would get feedback on their skill development as opposed to only grades for a series of documents and work products that may not give them a complete picture of their learning or of what is expected in terms of the behaviour of a professional software engineer.

VII. The Student-Appraisal Method

We propose that an initial skills assessment is used before a team project begins in order to define the starting position, and past experience of students.

This will give students an idea of the skills they already have and how they could be best put to use during the project. At intervals during the project, (perhaps at the end of software development phases), staff could use the matrices to rate students based on observation of meetings and their performance in presenting or talking about their work. Students could use the same matrices to rate themselves and their team mates according to those competencies identified by Turley and Beiman, for example on:

- Using knowledge
- Researching, Investigating, Problem-Solving
- Communicating with the rest of their team – methods and quality
- Developing solutions
- Speaking and presenting in groups
- Technical appreciation – use of software, hardware
- Taking initiative and responsibility
- Understanding of main duties and responsibilities
- Their most important achievements of the phase of development
- Their planning and response to schedule pressures.

These matrices would help us gauge the level of confidence a student has in their abilities and could also help initiate a discussion of roles and possibilities for learning during the project. We would then use a further set of matrices during the project, to measure the new competency levels of the students and assign grades. The matrices would also help us determine target competencies for students to work on and improve during the rest of the project phases. The matrices could also help us determine the group level of competency and provide early interventions if teams are failing. This type of assessment, from self, peers and tutors (similar to an employee 360^0 appraisal review by subordinates, peers and superiors) would give students an insight into how their professional work will be assessed by employers and colleagues. The matrices would be used in conjunction with the traditional assessment of technical work products and tangible deliverables such as code and documentation. This assessment approach would also include an interview on experiences and skills at the end of the project. We believe that although an individual interview may add to the resource burden of teaching for team projects, the incorporation of an interview will give students a more rounded and personal review of their performance. All team project experiences are designed to give students a realistic experience of working on a large piece of software and an insight into what it is like to work on real problems within development teams. The proposed methods of assessment we outline here offer an opportunity for students to receive higher quality feedback on their progress and development as software engineers and to determine how to further develop their skills, in a safe environment – which is the point of most team project exercises in higher education at undergraduate level.

The work outlined here could be adapted quite readily for other disciplines and not just Software Engineering. The current matrices that we have created and proposed focus on skills and knowledge that has been identified in practice and in the literature as key to the work of professional engineers, however it would be feasible to identify generic skills and competencies required in team working scenarios for other disciplines. Rarely does a professional person work in isolation these days and generic skills such as communication, leadership, negotiation and problem-solving are required of most professionals in the modern workplace. These generic teamworking skills could be substituted in the matrices and used as a basis for the competency evaluation and the student appraisal method we have outlined here.

VIII. Conclusions

In this paper we have described our cross-site software development project and some of the difficulties students have with our assessment methods and with determining their progress and skill development as software engineers during the project. A lot of the problems that students face are due to our use of academic assessment methods that provide a numerical grade and feedback on separate pieces of work, some of which has been constructed by the team. We have outlined a new method that seeks to give individual students feedback on their progress during the project in a richer and more holistic manner. We have introduced a contribution matrix method to help ensure individual effort and contribution are noted and the correct grades attributed to each student. We review competency matrices and competency definitions outlined in previous work and propose a new appraisal method that uses self, peer and tutor assessment of alternative software engineering competencies and skills. We believe this new appraisal-style method will help students to get better feedback on their performance, make assessment criteria more transparent and help students recognise and articulate their development and skills as software engineers more clearly.

IX. Further Work

Some of the positive impacts of the cross-site work described here are greater students' awareness of how differences in working practices, organisational culture, team structure, task allocation and project management styles between teams can impact on project outcomes. However assessment and feedback are areas that need improvement. We are continuing to develop and refine our competency-based approach to assessment and hope to develop a wider framework for assessment of undergraduate software engineering team projects and automated tools to support them.

Abstract—**A Knowledge based system model to face the new methodological strategy on Higher Education in Colombia is presented: the propaedeutic cycles. A great challenge is presented to Superior Education Institutions: to establish the link between traditional cycles: technical, technology and professional ones with the secondary, basic and media levels. Our solution is presented linking each phase with a propedaeutic component discussed in a model. The model is dialogically integrated by cognitive an informational components.**

A structural system to determine and analyze the cohesion and coherence of the propedaeutic cycles between competences and the curriculum knowledge. This construct enables curricular knowledge management inside the media and higher education. Several types of matrices are developed; firstly regarding columns: the longitudinal one in time (semesters); secondly the cross one grouped by curriculum subjects, (additionally each cell of them can be expressed by fuzzy values); thirdly regarding the structure: the input/output for optimization purposes.

An individualized model of student productivity to be integrated to counteract the stereotypes which considers the technical and technological cycles as relegated careers in higher education. This model is an intelligent knowledge based one which was validated with a software prototype just implemented in the FESSJ. This construct has as its mission the guarantee of quality assurance of student's propaedeutic cycles.

A multidimensional flexibility system supported on university autonomy for managing student, pedagogical, and curricular knowledge which enables the management of the heterogeneous and complex environment; this subsystem is intended to ensure continuity and permanence of the student.

The earlier is framed within a construct of curriculum knowledge and information. From this it is intended to reduce the high complexity of the harmonization and articulation of the propaedeutic cycles which face the universities when undertaking these projects.

Moreover, it is pursued to offer major clarity to the educational community and in this way to contribute to the democratization of the involved knowledge within this methodological strategic articulating efforts according to the policy of the Colombian Government which seeks not only to increase the educational population but also to a major access of the marginalized social population and of those of lower revenues in order to fulfill the right to information executed by the National Constitution of this country

Keywords- Propaedeutic cycles, media and Higher education, model, matrix of curricular coherence, student's model, expertise, knowledge management, intelligent knowledge based system, ICT

I. RATIONALE

The higher education system model by propaedeutic cycles that has been named FESSJ-PROP is a complex curricular architecture for implementation and analysis in all Higher Education Institutions in Colombia. A great challenge is presented to Superior Education Institutions: to establish the link between traditional cycles: technical, technology and professional ones with the secondary, basic and media levels. This Architecture is integrated to the Plan of Studies coherent of the three Propaedeutic Cycles; Professional Technical, Technology, and Professional. The model is supported on several dialogical components; structural components or matrix model for curriculum coherence verification and knowledge management, the management system of flexibility, and the student's productivity formation. The tests and validation of the model were initially supported on the rational on the use of the mathematical and computational instruments and, then, on the approach of the system measurement, the same rationale of the study theoretical frames, contrasting then, with the real application of the curriculum coherence matrix during the inspection on quality conditions of the Academy Peers for testing in Bogotá (March and April 2009) in all verified programs; additional a computer simulation model was designed and implemented for complementary validation. The consistence and the prediction power of the model was demonstrated along with the development of other information construct called iCOACH as a learning prototype , which is working to an experiential learning ; iCOACH is an intelligent system based on knowledge used as a student's individual productivity tool.

A. Objetives of FESSJ-Prop Model

- To reduce the high complexity of the propaedeutic cycle harmonization which are facing the Colombian Universities undertaking these projects
- To offer major clarity to the educational community
- To contribute to the democratization of the involved knowledge within this methodological strategic.
- To articulate efforts within the policy of the Government of Colombia that seeks to increase the educational supply to a major access of the marginalized social population and of those of lower income in order to fulfill the right to information and to the democratization of knowledge executed by the National Constitution.
- To improve the prospective scope as a tool for constructing future in institutions.

B. Specific Objectives

- To enable the curriculum analysis in time power, by periods, and in the knowledge power by areas and assignments.
- To quantify the university production in knowledge development for the student by propaedeutic cycle.
- To apply the new tendencies of engineering which are approached by models: model driven engineering, showing the good applicability of the model by propaedeutic cycles
- To enable the comprehension and management of the methodological strategic by propaedeutic cycles.
- To face accurately, the complexity involved in multiple dimensions.
- To demonstrate that the student productivity and higher education quality run hand in hand in each propaedeutic cycle.

C. Final Objective

It is intended to structure a computational pedagogical model from pedagogic models: the institutional one and the engineering based on multiple intelligences, defined in the Institutional Educational Project PEI.

II. Model Description

The model of the Higher Education System Model by propaedeutic cycles as mentioned earlier is complex curriculum architecture for analysis and implementation in all Higher Education Institutions. It is carried out by supporting on 3 components. Linear Model of Curriculum Coherence, Flexibility, and Student's productivity. These components are described next:

A. Linear Model of Curriculum Coherence

It refers the logical-cognitive relationships among the architecture parts of an educational system. It is as much an analysis instrument as a linear mathematical structure that communicates (all communication action is a pedagogical one), enabling the justification of a study plan and giving it as an organized and complex totality interlinking the interior and external coherency and consistency.

Among the objectives are:

- To manage knowledge enabling a morphologic analysis to a study plan on higher education.
- To eliminate inconsistencies and make viable the curriculum optimization of the PEI.
- To improve the prospective scope of the PEI.
- To quantify the production of the universities in the development of knowledge in students (competence culture) by propaedeutic cycles to redesign the expertise areas in each cycle as well as the know-how.
- To give priority to and classify the competence areas.
- To contribute to develop a curriculum without errors and ambiguities.
- To construct the input/out matrix or as a foundation of the optimization and structural analyses.

Among the objectives and scopes of the curriculum coherence linear model is:

- Non-complex comprehension of the methodology strategy by propaedeutic cycles.
- Optimization of university resources.
- The curricular coherence model is expressed as a matrix which is as much an instrument analysis as a lineal mathematical structure, enabling the justification of a study plan, which gives a sense as an organized and complex totality.

The curriculum coherence is the strategic alignment between a study plan with its objectives, justification, given the purpose and view, duly articulated with the PEI, The external coherence refers to the alignment of the educational style of FESSJ to the professional profiles and intellectual capital which demand the industry, the government, science, and technology in a global society. The model based on educational processes according to the curriculum study plan, where an assignment (including classes, workshops, tutorials, laboratories etc.) is associated to an expertise unit. The matrix method is of morphological type to obtain a system contradictions free without the unwanted entropy. The coherence also implies harmony, and articulation between teaching and apprenticeship, alignment, and synchronization.

The system diagram of the matrix model is expressed as follows: rows representing expertise of each level against columns in which the corresponding curricula subjects is arranged (See the Matrix bellow).

In the figure 1 the link is expressed as a propaedeutic component formed by the intelligent iCOACH in order to increase the student productivity in each cycle and also some assignments of connecting in order to meet the prerequisites of each cycle. It is suggested to have both a terminal cycle with their corresponding competences with and the cycle for following higher levels. We did the design for Systems engineering and it was presented to obtain the Qualified Register of the program.

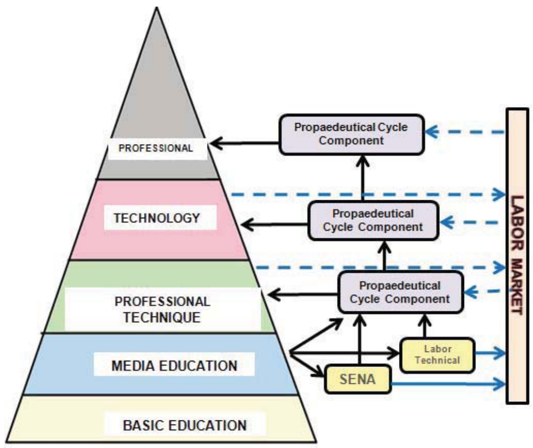

Figure 1. Propaedeutic component formed by the intelligent iCOACH

The Coherence additionally implies:

Characteristic: Holistic and integral view i.e. the entire complexity of the curricular system transcends knowledge in all its conceptual administrative, methodological, educational, normative dimensions.

Academy management is coherent with the PEI when the difference between the achieved in face to the wanted is null, curricular coherence.

The PEI is the expression of the proper philosophical comprehension of the educational task and it acts as definition of identity, exercising the university autonomy, recognized by the Constitution and Law.

B. *Matrix Description*

Several types of matrices were developed (figure 6); firstly regarding columns: the longitudinal one in time of the study plan (academic semesters); secondly the cross one grouped by curriculum subjects according to their applicability; additionally each cell of each matrix can be expressed as fuzzy values. The groups are: (1) Basic Fundamentals, (2) Scientific and technical fundamentals, (3) Professional Basic, (4) socio-humanistic and business, (5) Professional components, (6) Experimentation Scientific/Technical and (7) Advanced Topics, and thirdly regarding the structure: the input/output for optimization and structural analysis purposes.

The matrix presented bellow is formed by 4 blocks: Technical Labor Degree designed for students from basic education (9th grade), Professional Technical for students from high school (11th grade), Technology and Professional.

C. *Basic Matrix*

In general this matrix A is of M x N for knowledge management, where:

M rows represent the levels of the competence expertise of the curricular organization.

N columns represent the assignment subjects (knowledge offering) as functional and unitary areas educational processes involving classes, workshops, tutorials, laboratories ,etc of knowledge of the plan.

Each coefficient (cell), is of the binary type, e.g can be $a_{i,j} = \{ 0, 1\}$

It is 1, if exists direct implication between the expertise area and each assignment of the cycle study plan. It is 0 otherwise: values fuzzy dashboard in the basic matrix.

D. *Fuzzy Matrix*

On the other hand, each coefficient (cell) representing the cohesion and coherence of each assignment with the competence, can have other qualitative values / fuzzy logics, i.e.:

Ai,j = (null, middle, high) represented by colors in the matrix: [blank, red, blue].

This type of Matrix can be of two classes: the longitudinal in time (i.e. by academic semesters of the study plan and the transversal knowledge, where the curriculum knowledge of the subject is grouped as mentioned above. Below is presented a longitudinal matrix with fuzzy values just specified earlier..

E. *Curriculum Quantification from the Matrix: Cognitive Contribution*

The cognitive contribution of the j subject is obtained by the following matrix:

$$\sum_i a_{i,j} n_j = d_j \qquad (1)$$

Where n_j is the corresponding subject credits d_j is the cognitive contribution of the j^a subject for each propedaeutic cycle (columns).

F. *Other Metrics Obtained from the Matrix: Production*

The cultivated expertise is given by the production i as follows:

$$\sum_j a_{i,j} n_j = b_i \qquad (2)$$

Where b_i is the i^a production expressed as cultivated expertise for each competence unit (rows). For each cycle see bellow the corresponding values obtained.

The expertise approach implies the competences development as a dynamic continuum and is associated to formation processes during long life of an individual and also are affected by technological changes and social practices. In the knowledge society the competences structure is variable and also intectually more demanded.

Other significant figure shows a measure of how well the different subjects of the Study Plan within a propaedeutic cycle work together to provide a specific expertise of functionality of the competence system displayed above in the transversal curricular coherence matrix.

III. Required Flexibilities per Propaedeutic Cycles

The actual Education System is rigid, hard and forces the student to reentry as contrasting with propaedeutic cycles in which the flexibility is mandatory. The curriculum is defined as the set of criteria, study programs, methodology and processes contributing to the integral formation and to the national identify construction, including aids the scholar human resources to put into practice the policy to carry out the PEI, the institutional educational project. The flexibility refers to the curricular, academic, pedagogical and administrative ones, that is, the use of the university autonomy to manage knowledge as well as the study plan for whom do not accomplish with the requirements to come up to higher cycles, and besides to relocate learning contexts supported by ICT.

Curricular flexibility is the structure defined as the content organization, methodologies, and selected vocational training to develop study plans of school programs in which the contents are selected according to their importance, pertinence, appropriateness, technological, scientific, social and economic impact on account of the competences wanted to be cultivated and developed in the technician, technologist, and engineer.

The structure has been provided with a solid common nucleus in each cycle and elective subjects which will consult the stage of this art. The broad experience of FESSJ in the first cycle consolidates the possibilities of this flexibility.

Academic flexibility is an open and dynamical organized system which intends to transform the rigid structures which are uncoupled as it corresponds, wherein prevails the integrated work in the application and search of knowledge, defining the professional area. An open system promotes self management and self regulation. The strategic alignment of an institution is an imperative: PEI

The pedagogical flexibility that applies the educational strategy as a coherent unified, and integrated framework of school decisions promoted by the educational model, underlies the mentioned self-regulation and self-control by a student in his learning enabled by the ICTs, which allows him to enter to diverse learning spaces and environments tending to new educational communicative and interaction forms and also knowledge access In the same way the controls on the student about how to reach knowledge are implemented via electronic, information, and cognitive micro-worlds cultivating the competences which were already explicated as well as the involved strategies in the educational model that:

- Considers the integration of Academic Credit units of each engineering aspect.
- Creates educational mastery linking education, research, and social projection as pointed by FESSJ, and
- Entails to new virtual spaces and contexts of personal autonomy in the students' learning, besides admitting that they performs project of each propaedeutic cycle.

Administratively, the flexibility supposes a range of possibilities to the educational offer within the culture of educational service to the research, the academic units which compose a outstanding institution as FESSJ from the policies which assigns it for relevant, important, and appropriate making-decisions according to the Development Plan 2008-2015. This flexibility entails to the necessary reengineering of the administrative processes for its ISO certification

To change, if required, the policies and flexible strategies, that is, it is necessary to state the actions in different university forms for the adjustment to the organizational change that implies to manage the Technique Professional cycle to a broader level the Technology and the Engineering level. The earlier requires thinking over the sense, purpose of the Management Model, the curricular and scholar systems, which are coherent, appropriate, and suitable to the FESSJ as a Higher Education Institution.

A. Student Productivity

Dropout university rates at national level are critic by its cultural, economic, familiar, and institutional implications. Several Higher Education Institutions have carried out studies, some of them by the Office of Higher Education, evidencing a prevalent and regular problem. For the first time, the design and construction of a tool iCOACH is presented. This one is based in knowledge and is powered by technology on artificial and computational intelligence apart from knowledge engineering as instruments of high information to record each student and assignment of the first semester. The architecture of the system involves three components: an edumatic constructor of tests and exams (professor's tool), a subsystem based on the student's modeling, and in another administration and security modeling. Several developments have preceded this project, which makes of the framework along with its methodology very reliable; on the other hand, it is intended to work according to international standards in order to obtain a good quality of the implemented product, to construct a system for checking the student concepts; the project was performed within Edumatic and the synergy Architecture and Software Engineering to set up the planning, the analysis, and the determination of the educational requirements to specify the design of an intelligent and systematic edumatic system with student's cognitive assessment for virtual modality.

B. Components

Several presentation matrices mentioned above were identified and grouped. Each of them is composed of various sub-matrices and vectors which highlights the coherence for each propaedeutic cycle. The feedback sub-matrix, corresponding to the objective cycle which allows quantifying the knowledge articulation of the current cycle of further cycles to strengthen the implicit competences. The feedforward sub-matrix allows quantifying the articulation of the current cycle processes and its feedback to the formation of the superior cycle competences. Within the vectors are those of production or cultivated competence vectors for each cycle and the cognitive vectors, among others. The solution is complemented with a system architecture framework to display the complete outlook of the curricular information or visor 360° of the academic logic, whose complexity deserves to be approached with accuracy methods and techniques.

IV. Conclusions

We have accepted the challenge proposed to the Superior Education Institutions: to establish the link between traditional cycles: technical, technology and professional ones with the secondary, basic and media levels.

Our solution is presented linking each phase with a propedaeutic component discussed in a model.

The Coherence Matrix is a kind of macroscopic of great quantity of curriculum information and competences, allowing the corresponding knowledge management.

This initiative sets up a way toward the architectural of information of IES on account of Colombia Education Law 1188 which is explicit about the curriculum complexity.

The model seeks to be an institutional learning instrument in the community and handles knowledge, thereby from these experiences is expected that IES go beyond of the simple management of the ICTs.

It is seen that is entirely feasible an ethos for research and knowledge in the technical and technology institutions. Likewise it is also seen that this policy based on propaedeutic cycles far from being a utopia really enables the democratic way to knowledge as proclaimed in the world summits on information society: Geneva and Tunisia

The construction of visor 360° not only as analytic instrument but also as support to architectural documentation a long with the model generates great expectation as credit of high quality in Higher Education with the prototype iCOACH, which has been performed. It evident one more time the flexibility of its professional implementation for the national academic community.

ACKNOWLEDGMENT

To "Fundacion de Educación Superior de San Jose", to Lecturers and Officers, especially to SAN JOSE EIDOS RESEARCH TEAM including Giovanni Rozo, Leyini Parra and Miguel R. Ortegón Gutierrez, to all of them a debt of gratitude..

Abstract—**One of the current educational challenges is how do we educate engineers to systematically solve open-ended real-world design problems? The capstone design course often plays a critical role in this, but there are numerous questions on how best to teach design and what are the characteristics of realistic design problems which provide excellent learning opportunities. This paper reports on a controlled evaluation of the effects of design problem complexity on students' ability to functionally abstract a design problem and its effect on their perceived value for variety of design methods. It is important for students to learn a systematic approach to the design process and to perceive its effectiveness. Students' perceptions and functional modeling skill are measured. Results, while preliminary due to limited sample size, indicate the complexity of the design problem is a critical factor in teaching design methods. There is a statistical interaction between the complexity of the design problem and opinion of functional modeling on their ability. Results also indicate that students who work on more complex design problems are more likely to expect to use functional modeling in the future. More complex design problems lead to a more positive student opinion. Further development of the functional modeling quiz is needed as is a larger sample size. Overall, results indicate that more complex design problem demonstrate to the students the effectiveness of the methods.**

Keywords- Design methodology; engineering education; functional modeling

I. INTRODUCTION

The Engineer of 2020 Report recognizes that creativity, invention and innovation are indispensible qualities for an engineer [2]. These skills must be understood, developed and taught. Critical research questions exist on how engineers develop their innovation skills and how innovation can be supported. The senior capstone design course plays an important role in teaching engineering students a systematic design process to enhance their innovation skills and guide them in applying their technical knowledge to real-world problems.

Systematic method approaches to the design process, such as the ones frequently taught in capstone design courses, have been shown to improve the process by increasing designer efficiency and the quantity along with the quality of designs [3, 4]. Teaching engineering design is seen as important enough to have dedicated special sessions and conferences [5]. The capstone design experience is viewed as a critical part of the undergraduate engineering curriculum but there is little agreement on how best to teach design to undergraduates [6].

This paper explores one aspect of the capstone design course, the design problem complexity and how it influences learning and student perceptions. The complexity of a situation (design problem) has been shown to affect skill development in other domains such as accounting [7]. One critical design skill is the ability to select useful abstractions, generate them and use the results to guide their designs [8]. Functional modeling is one class of methods focused on creating abstractions of a device. A function is what the device does independent of a particular form. For example, a car battery, a flywheel and a spring, all solve the function of storing energy (a battery through a chemical reaction, a flywheel through kinetic energy and a spring through mechanical material deformation). So a functional model would represent all three in the same manner as a device that stores energy.

The complexity of the design problem may also affect students' opinions and perceptions about the various design methods taught. Students' perception may influence how well they learn a particular design skill and the choice of using a particular design method in the future is often up to the designer. The paper employs a controlled experimental comparison of teams working on a more complex design problem (a lunar rover) to teams working on a less complex problem of only a single module of the lunar rover. The following sections provide additional background on the design course and functional modeling, then describe the experimental design, the results and conclusions.

II. BACKGROUND

A. Introduction to Mechanical Engineering Design MEEN 401

MEEN 401 Introduction to Mechanical Engineering Design is a two-semester capstone design course where students work on a year-long open-ended design project [9]. The course focuses on teaching systematic approaches to systems engineering [10]. The course contains one large lecture and studio sections of approximately twenty students. All students attend the same main lecture where the various design methods are taught and includes topics such as need analysis, functional modeling, interface identification, FMEA and project planning [9]. Students learn the design methods as they apply them to their design project.

The first semester begins with each team of students working on the same design problem, for example designing a lunar rover. Students typically work in teams of three to four in a class of approximately eighty to one hundred students broken down into design studios of approximately twenty students. During the first semester, each team identifies the needs, requirements and moves through concept generation for the system level design. Approximately half way through the first semester, each studio sections selects a final system level concept and then each team within the section works on one of the sub-systems, for example the life support system. The following semester each studio selects a particular sub-system for detailed design. This course design is in contrast to less complex designs that can be completed in a year by a single team of students.

B. Functional Modeling

Functional modeling is an abstraction of a design problem which focuses on what a device does, not the specific embodiment of it. There are multiple methods for functional modeling including the FAST Method, Hierarchical Functional Models [10] and Flow-Based Functional Models in the Function and Flow Basis [1]. Fig. 1 shows a hierarchical functional model which breaks the main function of a coffee grinder, “make coffee grounds”, into smaller pieces of “input power” and “chop beans”.

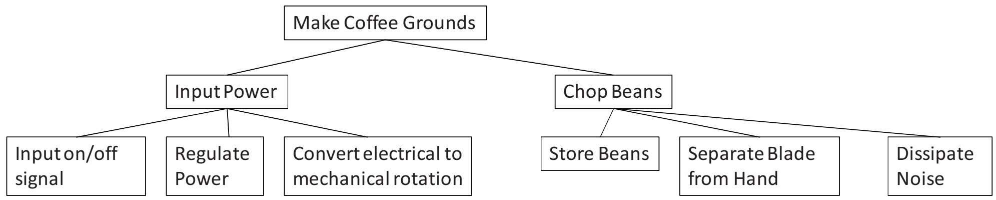

Figure 1: Hierarchical Functional Model for a Coffee Grinder

Another method for functional modeling is displayed in Fig. 2, a Flow-Based Functional Model for a Mars Rover Probe. The purpose of the probe is to break down rocks and analyze them. This functional model shows the materials, signals and energy that enter and leave the system. It also illustrations how the flows (materials, signals and energy) are changed by the functions.

The purpose of functional modeling is to focus the designer on what the device does and not on the specific form of a solution. It also reduces design fixation on a particular solution and assists with breaking down the problem into smaller pieces which can be more easily solved.

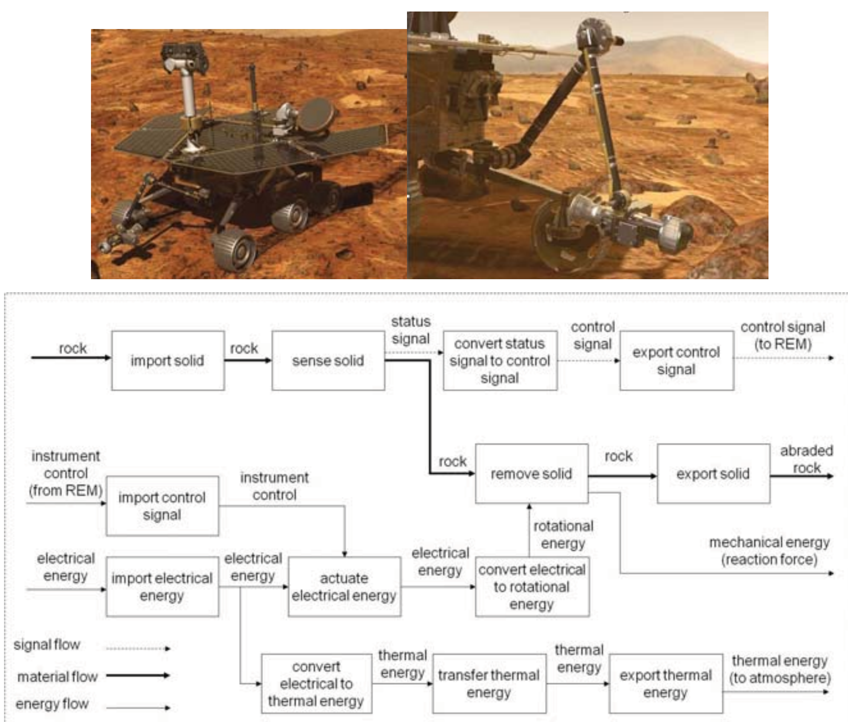

Figure 2: Flow-based functional models for a Mars Rover Probe shows how materials, signals and energy flow through a device and are acted on by the functions [1].

III. METHOD

A controlled between-subjects experiment measures how the complexity of the design problem affects student learning and perceptions of the methods. We make the following hypotheses based on the literature and discussions with experience capstone design instructors:

Hypotheses

Functional Modeling Skill Hypothesis: Students who work on a more complex design problem will achieve greater skill in functional modeling.

Student Perceptions of Functional Modeling Hypothesis: Students who work on more complex design problems will perceive functional modeling to be more valuable and are more likely to expect to use the method in the future.

Design Method Perception Hypothesis: Students who work on more complex design problems will generally perceive the design methods to be more valuable and will be more likely to expect to use them in the future.

Based on past observations it is believed that the more complex design problems such as the design of a lunar rover assist students in observing the need and impact of design methods and also provide an effective learning opportunity. It is possible that while students are learning the various design method, a more simple design problem would facilitate a deeper understanding of functional modeling.

A. Design Problems

The two design problems used to measure the effects of design complexity are (1) the more complex problem of a lunar surface vehicle and (2) the power transmission device (PTD), a module of the lunar surface vehicle. Both projects were presented to the students by an engineer at NASA who also acted as the project sponsor. The lunar surface vehicle design problem is to develop a device to aid crewmembers in exploration of the moon and transport cargo. The PTD's primary purpose is to provide mechanical power via a shaft to perform external work. Both design problems include more detailed specifications. For example for the PTD additional specifications presented at the beginning of the project included:

- shaft provides 75 horsepower at between 500-3000 rpm (variable)
- needs to be removable by crew (lightweight) with no/minimal tools
- electrical power for device provided by Rover
- extendable reach of 2 meters, capable of 500 pound lift
- swivels 360 degrees at Rover base with intermediate joint
- mechanism to be sealed with replaceable dust covers at rotating interfaces
- design to allow (not preclude) external attachment to:
  - *operate in-situ mining equipment*
  - *provide alternate power for rover movement*
  - *operate drill for recovery of soil samples*
  - *translate smaller cargo on/off Rover*
  - *play out/rewind communication/ power cables or large flexible antenna*
  - *assist in emergency translation of rover past obstacles (drive a wench/jack)*

B. Participants

A total of 64 participants were involved in the study, 48 in the Complex and 14 in the Simple Condition. Participants were recruited by offering them extra credit for filling out the method perceptions survey and their data were also correlated with a quiz which evaluated their functional modeling skill. Students were senior mechanical engineers at a large public university in the United States.

Students work in teams of three to four students. All students attend the same lecture for the design class and then are divided into design studios of 15-25 students. Each design studio has a different professor. Within each studio, one team was in the Simple Condition and the remaining teams in the Complex. Two of the Simple Teams were randomly assigned and two teams chose the Simple Condition based on very limited information about the design problem. All teams were supposed to be randomly assigned but this was not clearly communicated to the design studio instructors. The set-up of the teams allowed for the effects of the different studio instructors to be controlled.

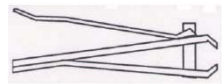
C. Measures

Two measures are used to evaluate the effects of the design problem on student learning. The first is a functional modeling ability quiz and the second is the students' opinions of the various design methods taught in class. Both measurements were made at the end of the first semester.

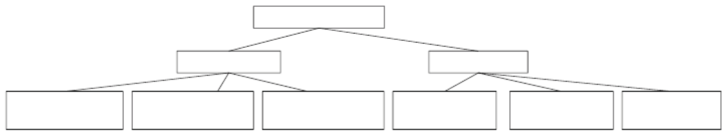
1) Functional Modeling Ability Quiz

A short quiz was created to measure the students' functional modeling ability (Sample questions in Fig. 3).

List four functions of the finger nail clipper shown.



3. Fill in the correct functions in the partial functional model for a coffee grinder from the list below.



Input on/off signal	Convert electrical to mechanical rotation
Input Power	Make Coffee Grounds
Separate Blade from Hand	Dissipate Noise
Chop Beans	Regulate Power
Store Beans	

In your opinion, what is the value of each of the following for a **DESIGN PROBLEM THAT REQUIRES AN INNOVATIVE SOLUTION?**

	Zero value	A little value	Medium value	High value	Extremely valuable	Don't Remember Method
Background research / Literature review						
Need Analysis						

In your opinion, what is the **GENERAL VALUE** of each of the following for a **TYPICAL DESIGN PROBLEM?**

	Zero value	A little value	Medium value	High value	Extremely valuable	Don't Remember Method
Background research / Literature review						
Need Analysis						

Figure 1: Example questions from the functional modeling skill quiz and method perception survery.

Students were given approximately 45 minutes to complete the quiz and it was given in-class. The quiz was created by the first author for evaluating the students' functional modeling skill and this was the first time the quiz was implemented. Quizzes were scored by a teaching assistant.

D. *Students Opinions of the Design Methods*

A survey (Fig. 3) measured the students' opinions of the various methods listed in Table 1. For each design method, the survey measured the student's perceived value for design problems requiring an innovative solution. The survey also measured their opinions on these same methods for more typical design problems (design problems not requiring innovative solutions). The students' expected future use was also measured for each method. Perceived value and expected future use were scored on five point scales from zero value to extremely valuable (zero value, a little value, medium value, high value, extremely valuable and don't remember method) and from very unlikely to very likely (very unlikely, unlikely, neutral, likely, very likely and don't remember method), respectively. Do not remember method was included so that students' only gave their opinions for methods they remembered. Newton's Law and the Bernoulli equations are controls since it is expected that especially for Newton's law all students would see this as valuable and expect to use it in the future if they become engineers.

IV. RESULTS AND DISCUSSION

Much of the focus of this study is on how well students learn functional modeling and their opinions of various design methods. Students who worked on more complex design problems were significantly more likely to expect to use functional modeling in the future (Fig. 4). Since the opinions are on a five point ordinal scale, Wilcoxon's Rank-Sum Test [11], a non-parametric statistical test, evaluates the statistical significance (Wilcoxon's Rank-Sum Test W_s=351.0, p=0.1 [12]). This does indicate that the complexity of the design problem does have on influence on student's perceptions of the method. As students leave the classroom environment and move into industry, it is often the designer's choice to use a particular method or not. Therefore it is important to understand students' impressions of the various methods.

Table 1: Methods [10] measured for Students' Perceived Value and Expected Future Use

Methods
Background research / Literature review
Need Analysis
Function Structure
Brainstorming
Identification of Interfaces
Failure Modes and Effects Analysis (FMEA)
Work Breakdown Structures
Drawing Trees
The general systematic approach to design taught in this class.
Newton's Law F=ma
Bernoulli's Equation

No significant difference is observed in students' functional modeling skill as a result of which condition they were in (Fig. 5). A rather small standard deviation (6.0) in quiz scores indicates that either the quiz is not doing an adequate job at evaluating students' functional modeling ability or the students' do not vary significantly in this skill (Fig. 6). There is significant range in the students' scores from 15 to 44. Further examination of the quiz results on an individual question basis and validation of the quiz is needed. Based on instructor observations the skill of the students is believed to vary substantially so a better measure of functional modeling skill is needed.

It is also likely that a students' opinion of a method could interact with how well they learn a particular method. If they do not perceive it as valuable then they might not effectively learn a method. For the current sample, an ANOVA does show an interaction between the condition and their predicted future use [Condition: F(1, 54)=0.48, p=0.19, Future Use Opinion: F(4,54)=0.58, p=0.49, Interaction: F(3,54)=2.15 p=0.1 and MSerror=24.80]. This indicates that the interaction of the students' opinion and the design problem condition they were in has a significant effect on their functional modeling ability. The sample size for students in the simple condition is currently 14 so more data are required to draw conclusions.

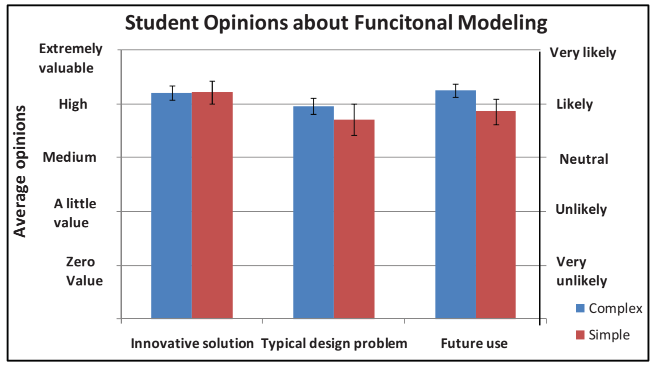


Figure 4: Students working on more complex design problems were more likely to expect to use this method in the future error bars are (+/- one standard error).

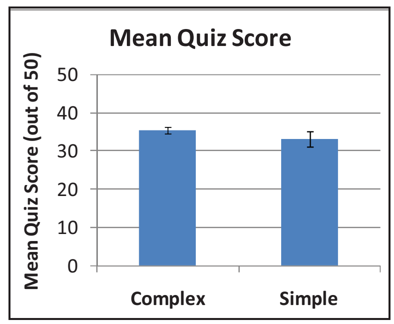

Figure 5: No statistically significant difference in quiz scores but the Complex Condition tended to be higher (error bars are +/- one standard error).

A. General Trends In Student Opions Across the Method

The complexity of the design problem does appear to have some influence on students' perceptions of the design methods (Fig. 7-9). Work Breakdown Structures show a consistent pattern across the three perception measures, students in the Complex Condition expect to use it more often in the future and perceive it to be of greater value than students in the simple condition. Only the perceived value for a typical design problem is statistically significant and the rest are close (future use W_s=353.5, p=0.17; innovative design problem W_s=308.5, p=0.17; typical design problem W_s=328.0 p=0.10). There is also a significant difference for expected future use of drawing trees (W_s= 254.5, p=0.03). The design methods are also generally seen as more valuable for design problems that require an innovative solution as opposed to more typical problems but there are no general trends across the design methods comparing students in the simple versus more complex design problems.

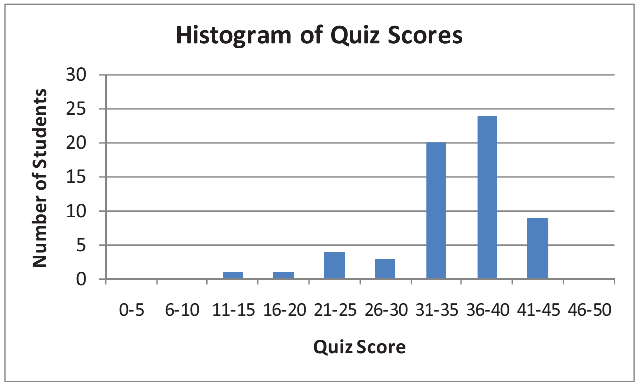

Figure 6: The scores are biased toward the high end of the scale with realively low variance (S.D.=6.0).

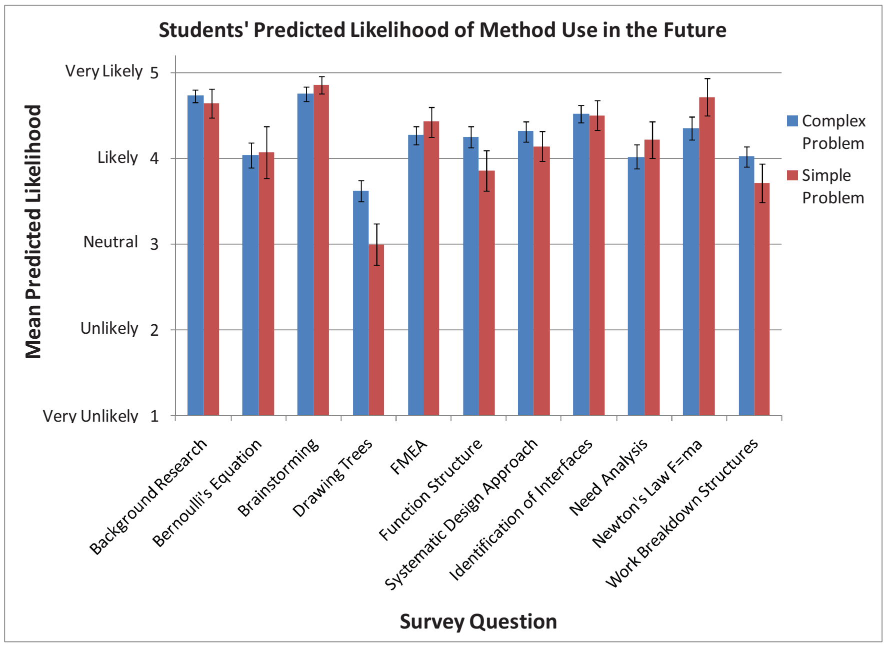

Figure 7: In general, for typical design problems, students' opinions did not vary depending on the type of design problem they had. Some methods did show statistically signifcant difference (error bars are +/- one standard error).

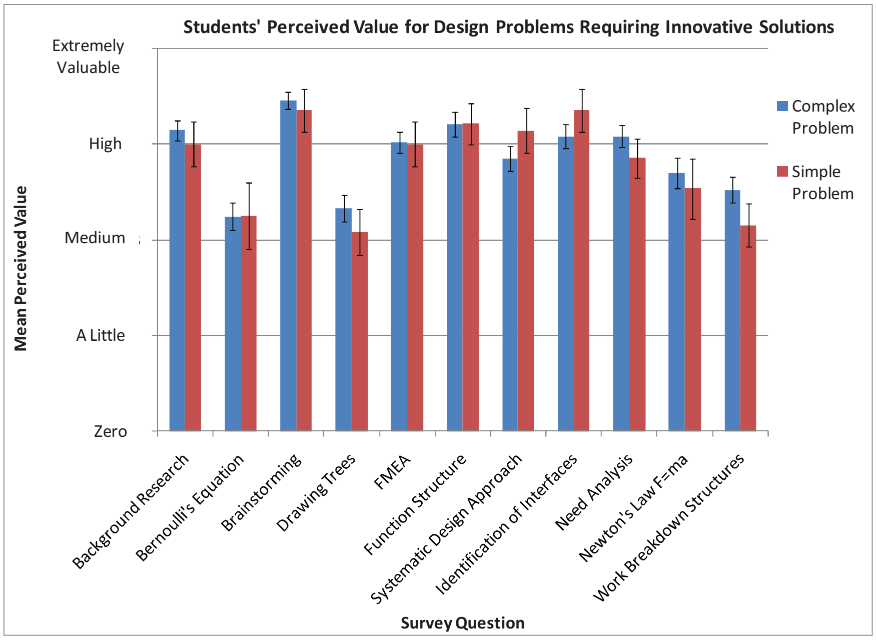

Figure 8: In general, across the different design methods, students' opinions for a method's effectiveness for problem requiring innovative solutions did not show any general trends with respect to the type of design problem they had. There are statistically signifcant trends for some of the methods (error bars are +/- one standard error).

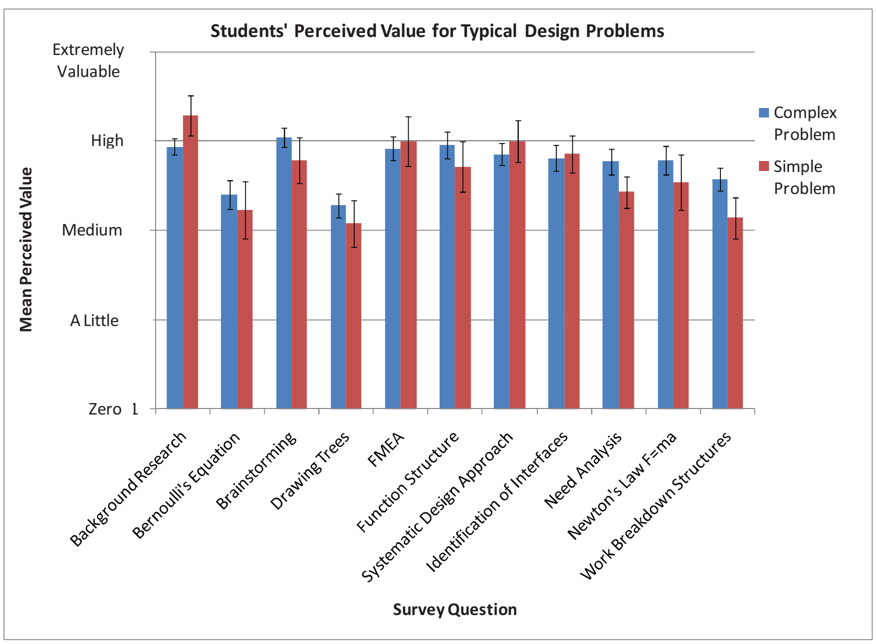

Figure 9: In general, for typical design problems, students' opinions did not vary depending on the type of design problem they had. There are statistically signifcant trends for some of the methods (error bars are +/- one standard error).

V. Addressing the Hypotheses and Recommendations

Functional Modeling Skill Hypothesis: The interaction of the complexity of the design problem and the students' perceived future use does significantly affect their functional modeling skill. A larger sample of students in the Simple Condition is required to further confirm this results since the current sample size is limited. This study cannot determine if there is a causal relationship between the students' opinions and their attainment of functional modeling skill. It is possible that if students' do not perceive functional modeling to be a valuable skill then they also tend to put less effort into learning it.

Student Perceptions of Functional Modeling Hypothesis: There is some indication that students who work on more complex design problems will be more likely to expect to use the method in the future and this was statistically significant. There was no evidence that students with the more complex design problem valued it more.

Design Method Perception Hypothesis: In general, students who work on more complex design problems do not place greater value on the methods nor are they any more likely to use them in the future. Some of the methods show trends of greater perceived value and students expecting to use them in the future more often but these are not statistically significant with the current sample size. Future work will continue to investigate this issue.

Recommendations: When the goal is to teach students the design methods, for example in a first design methods & theory course, more complex design problems should be used. More complex design problems clearly demonstrate the effectiveness of design methods.

VI. Conclusions & Future Work

Effectively teaching students to design and apply their technical knowledge to solve real-world problems is critical. There is no clear consensus and little empirical data on what factors influence student learning and perceptions in design courses. This paper explores one factor that likely influences student learning and student perceptions of systematic design methods, the complexity of the design problem. Through a controlled comparison, this paper evaluates the effects of design problem complexity on student learning of functional modeling and their perceptions of various design methods.

The complexity of the design problem does affect student perceptions and their functional modeling ability. More complex design problems result in more positive student perceptions. Results indicate there is an interaction between student opinions and the complexity of the design problem that affects their functional modeling ability. This effect needs to be further explored with a larger sample size since in the current experiment the Simple Condition contained only 14 students. In addition, further improvements to the functional modeling measure are needed.

There are numerous other desired learning outcomes such as the ability to troubleshoot problems and make accurate assumptions that are not measured by the current study. This study evaluates a single design skill but many other skills are also critical to the design process. Future work will also focus on these other skills and other issues associated with implementation of capstone design.

Acknowledgment

The authors would like to thank the MEEN 401 Introduction to Design class and their professors, Thomas Lalk, Mike Schuller, William Schneider and Arun Srinivasa, for their support and participation in this project. The authors would also like to thank Nicole Esposito for assisting with the data analysis.

***Abstract*— It is a global trend that those engineers who are proficient with the principles of business and management are rewarded with leadership roles. With the growing interdependence between technology, industry, economy and society, more opportunities will be available for engineers to exercise their potential as leaders, not only in business but also in the nonprofit and government sectors.**

In this paper, the following questions are addressed: What does it mean for engineers to have business and management competency? How can engineering schools prepare their students to attain the type of business and management competency demanded by industry? The analysis presented in this paper addresses the above questions in the following ways. First it defines the meaning of business and management competency for engineers. Second, it offers a minimum learning criterion for the business and management competency of engineers and a set of three learning outcomes of engineering management education. Third, this paper shows the results of an industry demand survey for engineering management education as well as provides a review of the global educational trends in this field in the U.S., Japan and Korea. Finally, the leading examples and lessons learned from engineering management education at Yonsei University are presented, and recommendations are made.

Keywords- engineering management; business competency; learning outcomes; accreditation

I. Introduction

It is a global trend that those engineers who are proficient in the principles of business and management are rewarded with leadership roles. Being able to understand both advanced technology and its corresponding management strategy is the key to securing a competitive advantage in any high-tech firm or industrialized nation. With the growing interdependence between technology, industry, economy and society, more opportunities will be available for engineers to exercise their potential as leaders, not only in business but also in the nonprofit and government sectors. Policy decisions in a technology-driven society will require the attention of leaders who understand the strengths and limitations of science and technology and their impact on society. What engineers design becomes a core component of the critical network of engineering systems, which affect physical, human, and political infrastructures. New levels of sophistication will be needed of engineers as decisions that define priorities and objectives for a community, region, or nation should be viable not only technologically and economically but also socially and environmentally [1].

In this context, it is now indispensable for engineering schools to equip their students with management skills and business leadership. However, current engineering management education is separately or only partially offered outside of traditional engineering curriculum. A survey in Korea shows that engineering students evaluate their undergraduate engineering education as only 50 out of 100 on a satisfaction scale. A major reason for the low satisfaction level is the impractical engineering education they received. The contents of the coursework were only remotely related to the real-world business problems that the students had to face upon graduation. Furthermore, the students felt that they needed to have more business and management competency in day-to-day corporate operations [2]. In order to meet this student demand, engineering management education should be better integrated with exiting engineering curriculum [3]. On the industry side, a majority of employers feel that educational support is currently insufficient for the enhancement of students' and their employees' business and management aptitude [4]. Engineering management curriculum must become better aligned with industry needs.

Designing an engineering management curriculum to meet the needs of students and employers requires an understanding of modern engineering work and the type of business and management competency expected of engineers. Also important is a well-defined framework to evaluate the success of the engineering management curriculum and continuous improvement of the learning contents and methodologies. Therefore, in this paper, the following questions are addressed: What does it mean for engineers to have business and management competency? What are the learning outcomes of engineering management education? How should one measure success in the proposed learning outcomes? Examining these questions will provide insight into prioritizing the business and management course contents that should be integrated with traditional engineering education and enhancing the learning achievement measured against the learning outcomes.

The analysis presented in this paper addresses the above questions in the following ways [4]. First it introduces the concept of business and management competency for engineers. Second, it offers a minimum learning criterion for the business and management competency of engineers and a set of three learning outcomes of engineering management education. Third it uses this criterion to establish a typology of emerging methods to support business and management learning for engineering students. Fourth, it introduces an engineering management curriculum of Yonsei University, as an example of a type of education experience that is expanding globally. Finally, the paper offers a test application of the learning criterion and learning outcomes by using them to conduct and present summative assessments of student learning in the Engineering Accounting course at Yonsei University, and to discuss the strengths and limitations of the current curriculum.

II. Business And Management Competency For Engineers

A. What Engineers Do in Today's Workplace

Science and technology are a source of product and service innovation and economic growth. Engineers apply the principles of science and mathematics to develop solutions that satisfy the technological and economic constraints of engineering designs. Their work transforms scientific discoveries into commercial applications that meet societal and consumer needs.

Engineers perform a number of tasks. They conduct research and development (R&D) in order to discover new technologies and apply them to various engineering systems and processes. Engineers are concerned with the design, production and operation of new engineering devices. Many engineers are engaged with new product development. In so doing, engineers must consider several factors. For example, they need to: precisely specify the functional requirements of a new system, design and test its components, integrate the components to produce the final design, and evaluate the design's overall effectiveness, cost, reliability, and safety.

In order to make sure the new systems meet various technological and standards, they conduct testing, which occurs in all stages of R&D and production. In addition, many engineers work in production or maintenance as they supervise production operations, determine the causes of component failure, and test the quality of manufactured products. Engineers also estimate and manage the time and cost to complete projects. Sales and marketing professionals work closely with engineers to assess user requirements and incorporate them into new products and services. Engineers are concerned with the economic, social, and ethical aspects of new products and services. Some experienced engineers are placed in management positions where their engineering background helps them examine technical aspects of a product and assist in planning its installation or use. Such engineers with managerial responsibility oversee all the tasks listed above performed by individual engineers and teams [5].

In most projects, engineers work in teams, whose size range from a few to hundreds of people, on a complex problem, such as designing computer chips or an aircraft. Teams usually include non-engineers such as technicians, marketing and service professionals. The team leader is responsible for communicating the progress and has to make sure that all of planning, developing, testing, and building is carried out correctly. In this regard, engineers must be good at planning so that money and time are spent efficiently on projects [6].

Because engineering work spans over all aspects of product planning, development, production, and even some degree of marketing, engineers must have competency not only in technical disciplines, but in areas of business and management. In particular, engineers must have an economic mind with which to view their engineering designs. Because of limited material, monetary and human resources, engineers are asked to maximize the technological performance as well as the economic efficiency of their solutions. If economic efficiency is ignored, engineering solutions often do not have practical value for the consumer market. To achieve economic efficiency, engineers must make strategic decisions including the purchase of capital equipment, target costing of new products and services, and investment sizing of engineering projects.

B. Maintaining the Integri in Today's Workplace

Science and technology are a source of product and service innovation and economic growth. Engineers apply the principles of science and mathematics to develop solutions that satisfy the technological and economic constraints of engineering designs. Their work transforms scientific discoveries into commercial applications that meet societal and consumer needs. The above discussion illustrates the importance of both technical and non-technical knowledge and skills for engineers. Among non-technical skills, the business and management competency of engineers cannot be over-emphasized in today's organizations. In 2007, over 50% of newly appointed executives in large Korean enterprises held engineering or science degrees [7]. Government is broadening opportunities for engineers and scientists to hold public service positions because technical knowledge is essential in many public sectors, including: health/medical services, energy/environment, transportation, communications, agriculture/fisheries and national defense [8]. Companies also look for interdisciplinary knowledge of both technology and management even when hiring R&D personnel [9]. These facts clearly demonstrate the ever increasing demand for science and engineering professionals with excellent management skills in this new economy [10].

C. Yonsei Engineering Management Curriculum

Drawing from this industry demand, Yonsei University College of Engineering developed an Engineering and Technology Management (ETM) curriculum to enhance the business and management competency of engineering students. To define the ETM curriculum, an analysis was carried out to describe the strengths and weaknesses of current engineering students in terms of their aptitude, skills and knowledge. Based on these and an industry survey, engineering management education should focus on teaching the following abilities: economic analysis skills, strategic mind for product development and marketing, leadership and professionalism, and organizational and human resource management skills. These skills are grouped into three areas: 1) corporate management, 2) industry and economy, and 3) strategy and leadership, so that engineering management courses could be designed for each area. Table 1 shows seven ETM courses developed through this process. In the corporate management area, Technical Human Resource Management is offered to enhance students' understanding about the strategic management of organizations and human resources (scientists and engineers in particular). Engineering Accounting combines traditional financial accounting with cost accounting for engineers and provides engineering students with a fundamental understanding of the economic impact their R&D activities have on profit-making. Engineering Economics, which mainly addresses the economic valuation of technology and engineering systems, is offered in the industry and economy area. Techno-Leadership and Entrepreneurship is a course for the strategy and leadership area that sculpts the mind of a leader and entrepreneur to create new value in corporate and government organizations.

These courses are created to cultivate engineering students' aptitude, skills and knowledge in areas where they have weaknesses and industry demands are strong. They are electives integrated with engineering accreditation so that students can take up to two courses from the ETM curriculum during the sophomore to senior years. With this curriculum, Yonsei University, a leading engineering school in Korea, has been offering seven ETM courses for over 800 undergraduate students every semester. An increasing number of engineering schools in Korea are offering engineering management courses as part of their core electives. For example, Ventures and Patent Strategy is the most widely-taught subject in Korean engineering schools, including KAIST and Seoul National University [11].

Table 1: Engineering and Technology Management (ETM) Course Development

Curriculum Areas	*ETM Courses*
Corporate Management	Engineering Accounting
	Technology and Product Marketing
	Technical Human Resource Management
Industry and Economy	Engineering Economics
	Economic Trends and Business Opportunities
Strategy and Leadership	Techno-Leadership and Entrepreneurship
	Ventures and Patent Strategy

III. A Learning Criterion For Business And Management Competency

Drawing on the discussion of the previous sections, the proposed learning criterion for the business and management competency of engineering students is as follows:

Through course instruction and participation, students will acquire the knowledge, ability, and mindset to design economic engineering solutions efficiently and effectively with market and customer orientation.

Learning criteria are broad statements that guide the development of learning outcomes, which then guide the creation and assessment of courses and curricula that are designed to help students satisfy the criteria [12]. The words economic and efficient mean minimizing resource waste or cost input while meeting the target goals for scheduling and performance. Unlike the traditional cost-plus pricing method where materials, labor and overhead costs are measured and a desired profit is added to determine a selling price, an acceptable price for a new product or service is determined based on market information. Then, a target cost is the maximum cost that can be incurred on a product while the firm can still earn the required profit margin given the particular selling price. Thus engineers should be able to reduce the overall cost of a product over its entire life-cycle. Engineers also need to view the financial statements of their company and determine how the engineering division could help improve the financial performance of the company.

The word effective is closely tied to the capability to manage engineering teams successfully. Engineers must communicate with all the stakeholders involved in a project as to what actions are to be taken, by when and how much money can be spent on each activity. The engineers and related members get together regularly throughout the project to check the progress and to deal with any issues that may come up. Thus good project management, which also necessitates leadership and strategic employment of technical human resources, is the key to success in any engineering work.

Finally, market and customer orientation leads to the capability to design new systems to meet the needs of the customers and to have market power in order to generate significant revenue. Engineers should care about how new products and services will be marketed to target customer groups and increase sales. Engineers should also utilize their R&D results to generate revenue in a variety of other ways. The revenues sources include not just final products and services but also patents, licenses and other interim results of the R&D work. In today's open innovation era where market and customer groups quickly expand as firms look to advance their technology through the use of external ideas and knowledge [13], it is vital for engineers to seize every opportunity to make profits from their R&D work. The proposed learning outcomes for the business and management competency of engineers are:

1. Students will demonstrate substantial knowledge of the business operations (R&D, manufacturing, and marketing) as well as financial data (revenues, costs, and profits)

2. Students will demonstrate substantial ability to manage R&D teams, analyze customer needs and apply economic analysis.

3. Students will display a mindset to care about efficiency and value maximization in R&D work and to continue to make the engineering solutions evolve to fit the market demands.

The learning outcomes point to the importance of learning about delivering innovative engineering solutions efficiently and effectively and linking engineering work with market demands. The first component of the criterion and proposed learning outcome focuses on knowledge. A successful learning experience in business and management enables students to gain a factual understanding of how engineers in the real world deal with non-technical issues such as managerial, financial, and marketing issues and the ways in which such non-technical considerations impact their engineering work.

The second component of the learning outcomes is ability. An engineer with business and management competency is someone who has progressed beyond “awareness skills” to achieve “process skills,” which combine the new form of knowledge into day-to-day practices of engineering work [14]. The process skills, which are gained through practice, indicate the ability to apply various methods of economic engineering design and organizational management skills in engineering work.

The third component/outcome is mindset, which is more difficult to identify and assess, yet it is as equally important as the previous two. The term, “mindset” does not indicate inherent features of character or personality, but refers to learnable tendencies or patterned actions that are observable by others [13]. It is the mind to treat engineering work as an integral business function and an object of management in order to create winning products and services in the market. As a result, engineers gain a macroscopic view on all corporate functions where engineering work is aligned to meeting business goals.

The Accreditation Board of Engineering and Technology (ABET) provides only a general program outcome related to the business and management competency of engineering students. One of the ABET program outcomes states, “Graduates have a respect for diversity and a knowledge of contemporary professional, societal and global issues [15].” The Accreditation Board of Engineering Education in Korea (ABEEK) realized the need to make this statement more specific toward the non-technical competency of engineering students as it says, “Graduates have a broad education which is necessary to understand the impact of engineering solutions in a global and societal context…knowledge of contemporary issues in the society, economy, environment, and law [16].” However, neither one clearly states the competency in business and management for engineers.

In this context, it is now necessary to articulate what business and management competency is required of engineers. The key element in this learning criterion is the descriptive image of engineers who bring out innovative engineering solutions in the most efficient and effective way with market and customer demands in mind. The learning outcomes accept the view that acquiring knowledge and experience in business operations, financial analyses and technology management skills leads to the achievement of the business and management competency required of engineers. The engineers with business and management competency then design products and services that best respond to customer needs and therefore maximize the probability of success in the market.

IV. Preliminary Assessment of Engineering Management Education

The first step for engineering students to gain competency in business and management is to have concrete knowledge about business operations and experience in financial analyses and technology management skills. As displayed in Table 1 Yonsei University’s College of Engineering developed an Engineering and Technology Management curriculum with 7 foundational courses based on industry demands and the strengths and weaknesses of engineering students. The subject categories were corporate management, industry and economy, and strategy and leadership. This section introduces a preliminary assessment result of the learning outcomes of the Engineering Accounting course, which teaches students the principles of accounting in the ways engineering work is related to managerial and cost accounting and how corporate functions act together from financial perspectives.

A. *Course Outcomes*

By introducing the fundamentals of accounting and accounting issues that are related to corporate management and R&D work, the Engineering Accounting course helps students gain the knowledge and skills to analyze financial statements, manufacturing costs and tax issues from the engineer’s perspective. Three learning outcomes of the course are:

1. Students will demonstrate substantial knowledge of the fundamentals in accounting including the meanings of financial accounts and costs and interpretation of financial statements.

2. Students will demonstrate an ability to analyze and recommend ways to improve the financial performance of a company using various parameters measuring the financial outcomes of R&D and other business operations.

3. Students will demonstrate a mindset that realizes the importance of minimizing cost from R&D planning stages while maximizing the value of new engineering designs. They are conscious of meeting customer demands and aligning engineering work with the business goals of the company.

These outcomes are more specific to the topics of Engineering Accounting; therefore, they deviate somewhat from the learning outcomes introduced in Section III. The reason for this is that Engineering Accounting is only one of the 7 courses in guiding engineering students toward business and management competency. Fully attaining the outcomes presented previously is not easily accomplished by taking a single course in each topic, but the combination of the 7 courses is designed to equip engineering students with fundamental competency to deal with business and management issues that arise in engineering work. Rationalizing this leads to the more operative learning outcomes:

- Learning Outcome 1: In achieving this outcome, students come to understand accounting as a business language that expresses the state of the company through financial data expressed in certain standard formats. They also understand that accounting is a way to provide financial information to various stakeholders of the company, which engineering students have rarely thought about. The subject topics to help students achieve this first outcome include the role of accounting in corporate management, reading financial statements, and costing of R&D projects.

- Learning Outcome 2: The second outcome develops the ability to analyze the financial performance of a company using various accounting parameters. Students get exposed to a number of financial statements of different companies and are asked to analyze them. Students also learn to analyze the break-even points for engineering projects, to assess the financial performance of the engineering division, and to make various business decisions such as outsourcing. They also get exposed to the methods of activity-based costing, target costing, and taxation for start-up companies.

- Learning Outcome 3: Achieving outcome 3 is probably the most difficult for students in one semester. To broaden the mindset of engineering students, it is necessary to expose them to as many real world issues as possible. That way, students will learn to see how engineering work is related to broader areas in the company, economy and society. In Engineering Accounting, professionals (i.e. certified public accountants and accounting consultants) are invited at the end of the semester to tell engineering students about real world issues, why it is important for engineers to know accounting, and how engineers can proceed to business and management careers. The satisfaction level of such special lectures has been exceptionally high. The lectures of the invited speakers have had a positive impact on shaping the mindset of engineering students, and some engineering students even find a new career opportunity that combines their engineering knowledge with business and management.

B. Course Outcomes

To date, Engineering Accounting has been taught in five consecutive semesters. Each semester, around 150 students from all engineering departments are registered. Sophomores make up around 50% of the class, and a good number of juniors and seniors also attend the course for academic credit. Formats include lecture/discussion in large classes as well as 100 percent online lectures to help students preview/review class materials. Thus in-class activities focus on the presentation of important concepts in depth as well as exercises with accounting problems and short business case studies. At the beginning of each class session, a short quiz is given to help students grasp the fundamental concept of the day. A web board is heavily used for informal writing with student responses posted through online threaded discussions, autobiographical statements, and dialogues. Formal writing has included research reports, in-class exams, and reflections assignments. In addition to the Engineering Accounting textbook, a couple of introductory books, one of which is a business novel that depicts a career progress of a novice in accounting, are given for students to read over the course of the semester.

C. Assessment

Formative class evaluations have been conducted every semester since Engineering Accounting was first taught, and revisions to the course have been made. However, the evaluation questions were only general to assess the program outcomes of ABEEK [16] as discussed above. The faculty members who were teaching the 7 ETM courses realized that a simple program outcome statement of ABEEK was not effective to assess the learning of the business and management competency of engineering students. Thus, the learning criteria and outcomes, as well as a new assessment framework, were designed in 2007 in order to assess the engineering students' learning achievement in business and management competency. The focus of this section is on the summative assessment conducted in Fall 2007 to evaluate the extent to which engineering students accomplish the three learning outcomes for business and management competency mentioned earlier. The summative assessment included three instruments that map across the learning outcomes: a short pre/post quiz to measure learning outcome 1, a term project to measure learning outcome 2, and a final survey/reflection to measure learning outcome 3. Data from the final survey/reflection also provide additional evidence for learning outcomes 1 and 2. In this paper, the students' responses to an end-of-semester survey in an Engineering Accounting class are shown. A core set of questions was used and several additional questions were asked of students to assess the effectiveness of textbooks and teaching methods used. Only questions on this survey that were relevant to course outcomes are discussed below.

The survey asks students to indicate their level of agreement with a set of statements. A high percentage of students either “agreed” or “strongly agreed” with each statement. Roughly 85 percent of 90 students agreed that they “gained significant knowledge from this course about accounting and its importance for engineering work.” 80 percent agreed that they are “better prepared through lectures and homework assignments to consider financial aspects in engineering work” and 78 percent agreed that they gained “critical skills to analyze the corporate financial performance and suggest ways to improve weaknesses.” Importantly, the survey asks students to assess how their mindset has changed upon completing the Engineering Accounting course. 78 percent of the students agreed that they have “increased interest and passion in engineering management disciplines” and around 80 percent indicated that “the special lecture contributed to both deeper understanding and change of attitude toward the importance of business and management competency of engineers.”

The student survey results support the findings for learning outcomes 1 and 2, but more importantly, they provide evidence for learning outcome 3, development of a mindset to regard engineering work as having to improve corporate financial performance while minimizing cost input. The reflections that one student wrote in the survey stated, “I had no knowledge about accounting but this course helped me not only learn the principles of accounting but have the mind of a CEO to view engineering work as a critical business function.” Another student noted, “This course is a must for all engineering students. I am now more confident to have the knowledge and business-oriented eyes necessary throughout my career as an engineer and a future CEO.” Similar reflections are gathered in every semester. This clearly indicates the success of learning outcome 3.

V. Summary and Conclusions

The descriptive image of an engineer with business and management competency is someone who can successfully manage the development of innovative engineering solutions in an efficient and effective way with market and customer demands in mind. Through course instruction and participation in such activities as case studies, design projects and internships, engineering students acquire the knowledge in business operations, economic analysis and organizational management skills, along with a strategic mind for product development and marketing.

Based on the lessons learned over the last two years, the ETM curriculum of Yonsei University is being improved. First, it is necessary to diversify and customize the ETM courses to respond to the needs of each industry sector and engineering major. For example, civil and environmental engineering students feel that an environmental management course will be valuable to them. For architecture and construction engineering majors, a course in large-scale project management is necessary.

In addition, course evaluations suggest that specialized tracks be developed where students can take advanced courses in a field of their choice. For the case of Engineering Accounting, students were very interested to learn more about product development and target costing as well as taxation issues related to new business ventures.

A number of students indicated the need for more problem solving and case studies. It is not possible, however, to cover all aspects of theories, problem solving and case studies in class. It may be effective to break the class into small groups to hold help sessions. In fact, the large class size has been consistently pointed out as an area in need of improvement. More instructors who are familiar with engineering work and have competency in a business and management discipline should be hired. Also, as indicated earlier, undergraduate-level case studies should be developed and provided online so that students can access them at their convenience to augment their learning. Also, a global network of engineering management education should be expanded through more frequent dialogues and open exchange of information.

Authoring Learning Contents, Assessments and Outcomes in an Integrated Way

Israel Gutiérrez Rojas (igutierrez@inv.it.uc3m.es)
Carlos Delgado Kloos (cdk@it.uc3m.es)

Telematic Engineering Department
Universidad Carlos III de Madrid

Abstract—**Developing learning material is a tedious task mainly due to two factors: their variety and their cycle of continuous update. Based on the utilization of DocBook for developing material, a solution is proposed to solve both problems. The proposal is to establish a special markup inside the DocBook format that permits to define multiple kinds of learning material in the same macro-document.**

Keywords- DocBook, authoring, learning material, learning assessment, learning outcomes

I. Introduction

In the context of learning material development there are two aspects that make this task cumbersome for the authors. The first one is the variety of the materials. Authors have to create units of learning for the students, scripts for the classes, test for assessment purposes, practical sessions, simulations, problem sets, flashcards (what we are calling *learning pills*), etc. Besides, all these documents can contain multimedia materials. Due to this variety of learning materials, their production becomes quite complex. The second problem is the cycle of updating materials. It is not easy to update all the references to a concrete subject that has changed. This is particularly a great problem in the technology environment because updates are more often than in other knowledge areas.

Some authors use standard formats for developing learning content. The DocBook format [1] is a schema maintained by OASIS [2] for books and papers that can be also used for the development of learning content. The objective of this paper is to present a special markup used in the DocBook format to provide it with a series of features that can solve the main problems of material authors. This markup also takes into account other aspects in a preliminary stage, like learning outcomes and objectives management and generation of evidences that prove these learning outcomes.

II. State of the Art

In [3], the advantages of using DocBook format files as a single source for authoring learning material have been presented. The use of XSLT transformations is presented as the main solution to the necessity of different formats to printed material (PDF) and web material (HTML). The packaging of these types of learning content using standards is studied in several articles, like [4] and [5]. In [5], the concept of reuse of existing learning documents is introduced, including several types of formats like Latex, DocBook and Word.

The idea of merging different types of information in the same shape is not innovative. Donald Knuth developed this same idea in his conception of Literate Programming [6]. This paradigm consists on writing programs in the order of demanded order and flow, not attached to any computer needs. Developed programs mix programming code and documentation. Literate program was subjected of a series of processing in order to obtain two outputs: one file with the code to be compiled and another one with the program documentation. This processing follows the same procedure as a demultiplexer (from one input, a set of outputs is obtained). One of the main ideas of this document is to present a mechanism that improve the work of content authors because they could, like in the literate programming paradigm, write learning material in any order as the ideas come to their minds.

The idea of defining a DocBook markup for including various types of content was also used in [5]. A variety of learning content can be extracted from the unique DocBook source (including the course itself) if the author follows a concrete markup during the authoring process: instructor annotations, slides including highlights of each section and extract chunks of learning material as reusable learning objects, that can be packaged following standards and integrated in Learning Management Systems (LMSs).

The rest of this section consists of the study of the main formats and tools used in this development. These are DocBook v4.5 as the basis format for material authoring, XSLT for obtaining individual material from the defined macro-document (as presented in next section) and ADA [7] as the tool used by authors in Carlos III University to produce learning multimedia materials.

A. DocBook

DocBook is a schema well suited to books and papers maintained by the DocBook Technical Committee of OASIS [8]. The DocBook Technical Committee maintains both SGML and XML versions of the DocBook DTD and XML versions in several other languages. It was originally intended for writing technical documents like books and papers, but it can also be used for other types of documentation like learning content for a course.

Initially, DocBook was a SGML document type but due to the emergence of XML a XML DTD was also developed. DocBook is a semantic language that provides authors with the possibility of publishing material in a variety of formats like

HTML or PDF. Dozens of organizations are using DocBook for millions of pages of documentation, in various print and online formats, worldwide.

DocBook provides a large number of semantic elements, which are divided into three broad categories as specified in [9]: structural, block-level, and inline.

Structural elements specify structural information like set (of books), book, navigational components (table of contents, references, index, list of titles), title, chapter, preface, glossary, appendix, section and so on. These include also meta-information elements like author, title, publisher, etc.

Block elements are elements like paragraph, lists, admonitions, examples, figures, tables, questions and answers and so forth. Not all of these elements can contain actual text directly (like xref component). Sequential block-level elements are expected to be rendered one below another.

Inline components are elements like emphasis, hyperlinks, phrase, footnote, mathematics, etc. They wrap text within a block-level element. These elements do not cause the text to break when rendered in a paragraph format, but typically they cause the document processor to apply some kind of distinct typographical treatment to the enclosed text, by changing the font, size, or similar attributes.

Finally there is a set of common attributes attached to all DocBook elements. The main attributes according to the development of the markup of this paper are:

- Role attribute contains a string used to classify or subclassify an element.
- The condition attribute provides a standard place for application-specific purpose.
- ID is an identifying string for the element. It must be unique at least within the document and must begin with a letter.
- Remap contains an element name or similar semantic identifier assigned to the content in a previous markup scheme.
- XrefLabel attribute holds text to be used when a cross reference is made to the element.

B. *XSLT and XPath*

XSLT [10] is a language for transforming XML documents into other XML documents. The original document is not changed; rather, a new document is created based on the content of an existing one. The new document is serialized by the XSLT processor in standard XML syntax. XSLT relies upon the W3C's XPath language for identifying subsets of the source document tree, as well as for performing calculations.

XPath [11] is a language for addressing parts of an XML document, designed to be used by both XSLT and XPointer. XPath also provides a range of functions, which XSLT itself further augments. This reliance upon XPath adds a great deal of power and flexibility to XSLT.

C. *ADA*

ADA stands for “Agile and Distributed Authoring” and is an authoring tool developed in the Telematic Engineering Department of Carlos III University. It is used for material production and publication in complex contexts: large number of resources (multimedia materials) and several authors working in a distributed environment.

ADA is also intended to deal with the authors’ problem of continuous update of learning materials and it provides mechanisms to solve this problem. For this purpose, it uses a distributed repository of material. If some parts of the material are changed, ADA will include these changes in all the subsequent produced and published documents.

III. Definition of the Proposed Markup

In order to deal with the material authors’ problems using DocBook, the inclusion of new features has been proposed. These DocBook add-ons can be implemented in two ways:

- Extending elements and attributes of DocBook format. That is, defining new tags as needed for the new behaviours that were required. For this purpose, a new namespace has to be defined and a DTD or XML Schema.
- Using a special markup maintaining the DocBook format taking advantage of general attributes. There are some attributes like condition that are application-specific and are not taken into account in the DocBook document processing.

The second option has been chosen because maintaining the DocBook format without extensions provides us with a series of advantages like the compatibility with DocBook editors and the validation of the XML can be achieved without extending the DocBook DTD or XML Schema. Thus, the methodology used has been to define a set of markup procedures using DocBook elements and attributes in order to accomplish the proposed objectives.

As commented before, a series of new elements have to be added (using its internal markup) to the DocBook format in order to improve the management of learning material in the same document. That is, the author will be able to develop different learning materials in the same document; thus, the creation process has been improved because the author can reflect whatever comes to his/her mind in the same document and just in time.

The author has to follow a set of markup instructions in order to indicate what type of material he/she is creating. A great macro-document is the result of this process, which will be post-processed conveniently in order to obtain the set of documents that the author intended to create. XSLT technology has been used for this post-processing purpose, so a series of templates (one for each learning material type) have been developed. In the development, the considered learning material types have been: units of learning (student lessons), assessments, learning pills and problem sets.

The markup defined for the DocBook format provides the following features:

- Possibility of indicating the learning outcomes associated to a content section.
- Definition of variables that can be evaluated all across the document. This feature alleviates the problem of continuous material update.
- Introduction of multiple choice and true/false questions that can be used in assessments. These special questions can include also other metadata like hints, duration or indication of incompatible questions.
- Possibility of defining learning pills in the macro-document.
- Creation of sets of open questions from this same macro-document.

All these features are explained in detail below.

A. *Learning outcomes indication*

Nowadays, one of the main required practices in the e-learning environments is the use of competences. One of the European projects that deal with this affair is the ICOPER project. ICOPER [12] is an eContentplus Best Practice Network that started its work in September 2008. As part of its objectives, ICOPER will provide a *Reference Model* and mechanisms to ensure European-wide user involvement, cooperation, and adoption of standards in the educational framework. To accomplish this goal, the project will systematically analyse the specifications and standards available and in use, to draw conclusions on their validity. In the context of the ICOPER project, an effort is under way to relate learning outcomes and assessment results through evidence records.

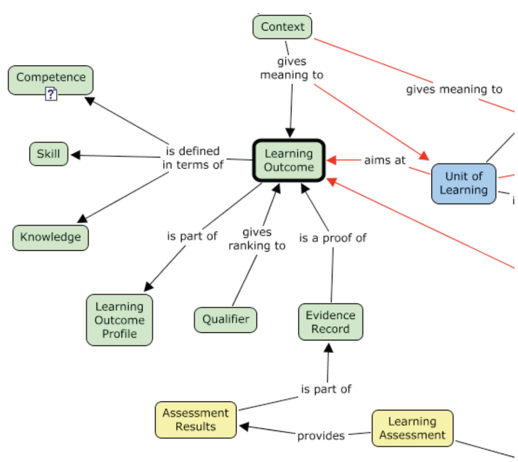

Figure 1. ICOPER Reference Model detail

As part of ICOPER Reference Model (see Figure 1), a conceptual map modelling key concepts for learning scenarios is being developed capturing key concepts and related specifications, but emphasizing on a competence-driven approach as well as the pedagogic underlying layout and the European-wide scope. It is important to define a set of concepts in the domain of e-learning, on one hand to clarify the terminology used and, on the other hand to establish the relationships between these concepts.

Following the European Qualifications Framework (EQF) learning outcome is a combination of competencies a learner should have (when successfully finishes a learning unit, course or curriculum) which include knowledge, skills and personal, social and/or methodological abilities. Learning outcomes are divided in three categories: knowledge, skills (know how to solve problems and tasks) and competences (proven ability to use knowledge, skills and personal, social and/or methodological abilities, in work or study situations and in professional and personal development). Thus, in the following references to this subject the term “learning outcomes” will be used (that includes competences meaning).

One of the goals of this study is to provide a methodology to attach learning outcomes to courses. At a lower level, these learning outcomes are composed by learning objectives that can be attached to a chapter (or section of it). As explained before, this part of the development is in a early stage and only partially implemented. The DocBook markup used for learning outcomes is to define a paragraph (para) attached to the metadata of the section or chapter (i.e. section/sectioninfo/abstract) using the attribute role with value “learning outcome”. The competence itself will be defined as text inside this paragraph. In the post-processing of the macro-document the learning outcomes will be presented in the teacher lesson (but not in the student). In future developments, the questions obtained from this chapter/section that the student response correctly will provide evidence record that is a proof of a learning objective (and then of a learning outcome).

B. *Cross-reference definitions*

In the DocBook format there are some mechanisms used to reference parts of the content from some points of this same document. The *xref* tag is used for this purpose indicating the ID of the referenced element by means of the attribute *Endterm*. To include text the tag *xi:include* should be used, using attribute *href* to indicate the source file and *xpointer* to select a part of this file.

As this macro-document will be divided in several documents, it is necessary to define a way for not missing these references. Thus, the elements that will be referenced from other part of the macro-document will use the attribute role with the value id. In post-processing tome, this markup allows to get all this referenced elements and move them to all the generated documents. They will be placed as metadata of the chapter or section (i.e. sectioninfo/abstract).

This mechanism for cross-referencing text is a great solution for the problem of continuous material update because it allows not changing any reference to a concrete subject that has changed, but update just the original reference.

C. *Assessments questions*

DocBook format only allows one way of defining questions and answers: the qandaset element. This element is intended for Q&A sections of books or FAQs. So it is not suitable for assignments by itself (just for open answer questions without automatic correction). If learning material were being developed, it would be a good feature the possibility of defining other question types in order to be used in assignments and that allow automatic correction.

The FREMA model [13] is a reference model for student assessment scenarios that captures key concepts and related specifications in the e-assessment environment. The questions types defined by this model are the followings:

- Constrained: question whose response is constrained to a space of solutions. That is, the student does no need to write any words just selects an option from a set. Examples of this type of question are multiple choice questions (MCQ), multiple response questions (MRQ), true/false (TF) and matching.
- Constructed: question whose response is open, that is, it is constructed by the student. Examples of this type of questions are short-answer questions, essay, fill in the blanks (FIB), crossword and so on.
- Miscellaneous/mixed: questions that do not fit in the previous categories, like practice sessions, simulations, etc.

Taking into account this classification, the questions supported by DocBook are constructed ones. So it would be nice to have constrained response questions also available because they can be used to assess other learning outcomes and they allow automatic correction. Miscellaneous questions would be also appropriate and its inclusion will be developed in future versions of this tool.

The DocBook markup for this behaviour is the use of the attribute role to indicate the question type attached to a qandaentry entity. The new questions types that the defined markup allows are multiple choice questions (role=”MCQ”), multiple response questions (role=”MRQ”) and true/false (role=”TF”). The correct response indication has been achieved using the condition attribute in the answer entity that corresponds to the correct response with the value correct (condition=”correct”).

Another feature included related to the assessment is the possibility of indicating incompatible questions. That feature is necessary when the question wording is created in several ways (for example, to use it in assessment, problems or examples). In the metadata of the question (qandaentry/blockinfo/abstract) a paragraph (para) element is included with the role value of incompat (role=”incompat”). The content of this paragraph will be a reference to the question ID that is incompatible with the current question.

On the other hand, the assessment technique using questions is a successful and well-known strategy. It has been applied to assess the knowledge of student (summative assessment), but also to acquire knowledge during the learning process (formative assessment). Student assessment using questions is usually carried out at class, as a learning activity belonging to a course. This assessment type can be performed using intelligent tutors due to the advantages (effectiveness and utility) that they offer as explained in [14].

There are a variety of strategies related to the hint provision. The subjacent concept behind the hint provision is that the student can ask for help in case he or she were not able to solve a problem. Using hint, the student will have more possibilities to get to the problem solution following a reasoning process (discovering during learning process).

For all these reasons a hint system have been included in the question definition. This information is attached to the metadata of the question (qandaentry/blockinfo/abstract) in a paragraph (para) whose role attribute is declared as hint (role=”hint”). The content of this paragraph will be the representation of the hint that can be textual, an image, or whatever the author want to include.

In this way, it has been determined as convenient the inclusion of information about the time that a question is supposed to be solved. That feature provides the author with the possibility of estimating that time that a question is going to take to the student. Using a simple processing, the estimated time for complete exams can be obtained.

The duration of a question is marked in DocBook in the metadata section of the question (qandaentry/blockinfo/abstract) in a paragraph (para) whose role attribute is declared as duration (role=”duration”). The content of this paragraph will be the estimated duration of the question expressed in minutes.

D. Learning pills

Flashcard [15] is a set of cards bearing information, as words or numbers, on either or both sides, used in classroom drills or in private study. One writes a question on a card and an answer overleaf. Flashcards are widely used as a learning drill to aid memorization by way of spaced repetition.

A widely used method to efficiently use flashcards was proposed by the German scientific Sebastian Leitner in the 1970s. In his method, known as the Leitner system, flashcards are sorted into groups according to how well you know each one in the Leitner's deck. This is how it works: you try to recall the solution written on a flashcard. If you succeed, you send the card to the next group. But if you fail, you send it back to the end of the current group. Each succeeding group has a longer period of time before you are required to revisit the cards.

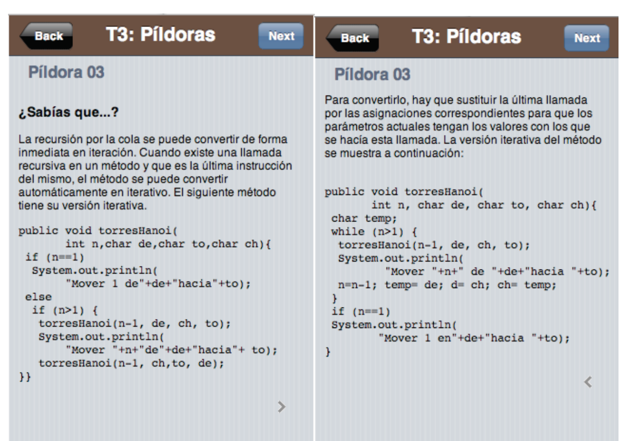

Figure 2. Learning pill example (front and back)

Leitner's flashcards is what is called learning pills in this article. But, instead of referring to physical cards we are referring to learning pills as electronic material (see Figure 2). They are constructed using HTML and JavaScript in order to achieve the effects of flipping the card and deck of cards management.

Regarding to the DocBook markup, block and inline elements are used like para or phrase but using the attribute role to indicate the learning pill question (role="learnpill_question") or he learning pill answer (role="learnpill_answer"). In order to indentify the question and answer that compose the same learning pill, the attribute condition has been used to indicate the learning pill name (ID cannot be used because it has to be unique in the document).

E. *Other features*

One of the materials that teachers provide to course students is a problem set. This type of material is very useful to students in order to prepare assignments and to learn practical part of the course. The problem set is composed by open questions that the teacher obtains from the learning material (assessment and learning pills).

The proposed DocBook markup for this type of content is simple: the remap attribute is used to indicate questions (or learning pill questions) that belong to the set using a special value (remap="question_set"). It is important to point out that the selected questions will compose a set of open response questions. So, the selected answer will have to maintain their meaning without including responses.

Another type of markup defined for learning material in the macro-document is the indication of appearance of certain content in the student lesson. This exclusion can be marked by the author because some part of the content can be intended only for the teacher, like comments and estimated time for explanations, assessment question for the final assignment and so on.

This markup has been defined using the attribute condition of the child elements of the current section or chapter. The value for this attribute is no_show (condition="no_show") in case the author do not want this element to appear in the student lesson. If this attribute has a value in the selected element, it is possible to indicate several values of this attribute separated by commas (i.e. condition="learnpill_example,no_show").

F. *DocBook markup summary and complete example*

As a summary of the previous defined markups has been defined in a table (see TABLE I.) for quick reference.

TABLE I. QICK REFERENCE MARKUP

Feature	**DocBook reference**	
	Meaning	***Markup***
objectives	Learning objectives attached to a chapter or section.	section/sectioninfo/ abstract/para role="objective"
cross-references	Identification of elements that can be referenced all across the document.	xref endterm="refered_ID" xi:include xpointer="path"
new question types	Definition of new question types.	qandaentry role="MCQ/MRQ/TF" ID="question_name"
hints	Hints attached to a question.	qandaentry/blockinfo /abstract/para role="hint"
duration	Duration of the question.	qandaentry/blockinfo /abstract/para role="duration"
incompatibility	Incompatibility between questions indication. This value can be multiple.	qandaentry/blockinfo /abstract/para role="incompat"
correctness	Correct response indication.	answer condition="correct"
learning pills	Learning pills definition.	role="learnpill_answer" role="learnpill_question" ID="learnpill_name"
not show	Content not showed to the student.	condition="no_show"
question set	Question set indication.	answer/learnpill_answer remap="question_set"

G. *XSLT processing and ADA integration*

As stated before, XSLT technology has been used for post-processing the macro-document. A series of templates (one for each learning material type) have been developed using XSLT. In this development, considered learning material types have been: units of learning (student lessons), assessments, learning pills and problem sets, so a XSLT for each of them has been developed. The process is detailed graphically in Figure 3.

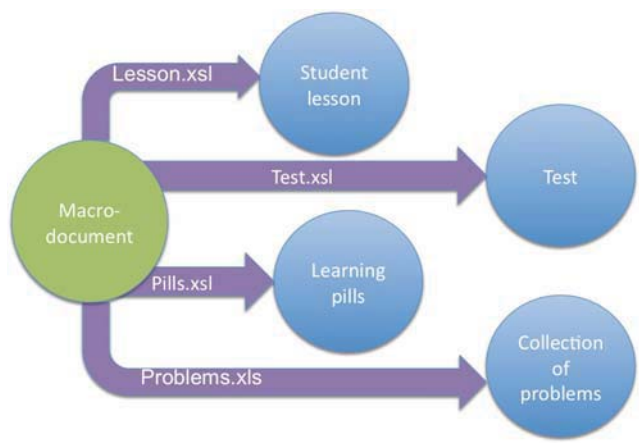

Figure 3. XSLT processing

Finally, integration in ADA production system has been achieved. A properties file (Properties.txt) is used in order to indicate the processing parameters used for the XSLT transformation. But in this case, the process of XSLT transformation has to be performed several times (one for each material type), what is not concerned by the tool. For solving this problem a module programmed using Apache Ant [16] has been developed specifically for macro-document processing.

H. Complete example

A chunk of a complete example of a macro-document is also provided in Figure 4. In this example, some of the explained features are shown. At section level a global learning objective is indicated using metadata markup (*sectioninfo/abstract*) and the attribute role with value *objective*. That exemplifies its simple usage for the material author. After that, some chunks of text have been marked with an ID (*phrase*, *programlisting*) so they can be referenced from anywhere in the document through *xref* tag and *xi:include* if some content should be included. This referencing is also exemplified in some *answers* of a *qandaset*. This same question is defined as a multiple choice question (MCQ). In the metadata of this question have been also included incompatible questions, duration and hints using the suitable roles. Finally, a learning pill answer is presented that reuses some text of the student lesson. Thus, flexibility and reusability features of the defined markup are shown.

IV. Conclusions and Future Work

A markup using DocBook has been defined in order to solve the main problems of material authors: material variety and continuous update. The solution developed also includes tools for learning outcomes and objectives management and evidences automatic generation.

In order to test the validity of this development it has been integrated into the tool of material production ADA. In the near future it will be used to create material for some subjects in the Carlos III University in the second semester of the current course (2009-2010).

As future works for this development, the learning outcomes management is in a very preliminary stage because it is only defined at section level (learning objectives). The learning outcomes management definition at course level will be the next step. Besides, the automatic creation of evidences as a proof of the section objectives and then the course level learning outcomes. In this way, it would be necessary the introduction of new types of assessment types like practice seasons or simulations. It would be also a great feature the possibility of creating adaptive questions using hints.

Finally, an evolution of the markup is proposed in order to define high-level concepts and to automate more widely the creation of material. This markup should be defined out of the DocBook schema and should be composed by high-level concepts like definition, concept, taxonomy, etc. In this way, some material like assessments or learning pills can be automated.

thomas.fuhrmann@hs-regensburg.de

Abstract— **Within the curriculum of the Bachelor Electrical Engineering there are obligatory lab experiments for electrical measurement. In this lab ready-made standard experiments with defined results are carried out by students. As an alternative to these standard experiments individual development projects for interested students are offered. In one series of projects an Optical Spectrum Analyzer (OSA) is going to be realized by students. The complete opto-mechanical hardware was sponsored by a measurement company and groups of students develop additional components to complete the OSA. Currently all important electronic subsystems of the OSA are developed and tested. These are integrated into the whole system and a software environment for controlling the whole system is built. The high learning success of the student groups and the consistently positive feedback from the students is encouraging. Currently this type of project is expanded to other topics.**

Analog circuits; Educational technology; Electronics engineering education; Optical spectroscopy

I. Introduction

In the study course Bachelor of Electrical Engineering there are the lectures Electrical Measurement part 1 (in the second semester) and part 2 (in the fourth semester) with the laboratory courses Electrical Measurement part 1 (in the third semester) and part 2 (in the fourth semester) where groups of usually three to four students carry out experiments for gaining practical experience in electrical measurement and analog electronics. During the lab course 1 some basic skills like handling measurement instruments and doing elementary experiments are taught. In the second lab course more advanced experiments are done to increase the practical electric measurement skills of the students.

Some years ago skilled and motivated students asked for projects instead of the standard lab experiments to gain industry relevant experience. Due to this demand the project "OSA development" was created where student groups develop a new electronic and software environment around an existing opto-mechanical OSA hardware block. This project takes a whole semester with an estimated work load of about 30-40 hours for each student. These projects are voluntary instead of the standard lab experiments. This leads to a high intrinsic motivation of the student groups [1].

The opto-mechanical hardware for the Optical Spectrum Analyzer and a laser source were sponsored by JDSU. The I/O-Board for connecting the OSA to a PC was sponsored by National Instruments.

II. Scope of Project

In the German Universities of Applied Science the education of engineers connects theoretical knowledge with industry relevant practical experience. In Industry most projects contain theoretical and practical parts which are carried out within a team. A technical framework is already given before the start of the project and new parts or functions which interact with the framework have to be developed.

Here the students train this industry relevant type of project and get practical engineering skills which are essential for their professional life. They see the difference between theoretical knowledge and practical work. For many of the students it is their first practical hardware development within a team and they learn how to divide a project into different work packages, carry them out and combine them to a complex device.

The technical basis for this professional training is the development of a working OSA which has challenging electronic building blocks. The goal is to finish an OSA with working hard- and software to use it for lab education.

III. Project Organization and Phases

After the student group received their project specification and an introduction lesson into the functionality of an Optical Spectrum Analyzer the group is requested to organize the project by itself. The adviser of the lab course gives hints if technical problems arise which cannot be solved by the group alone. If problems between the students arise mediation can also be required.

The project scheme is usually chosen by the students as follows:

- They start to become familiar with the tasks and with the given hardware.
- The students separate the project into parts and distribute the tasks among the team members.
- They develop electronic circuits, calculate and simulate the performance. With feedback from the adviser they optimize the performance of the circuit.
- The students look for appropriate electronic parts at the manufacturers' web sites and order samples.

- With these parts they build a first test circuit and verify the correct operation. Problems are found and fixed and sometimes the circuit is further optimized.
- From the experience of the first circuit the students draw a layout for an etched printed circuit board (PCB). It is made, assembled and tested. The parameters are measured and compared with theory.
- After the hardware works the students have to present their results to the other lab groups. They usually prepare a PowerPoint presentation where the highlights of the project are depicted.

During the whole project the students must document the project work and their results. This documentation is stored as a basis for following project groups.

IV. Given Opto-Mechanical Hardware

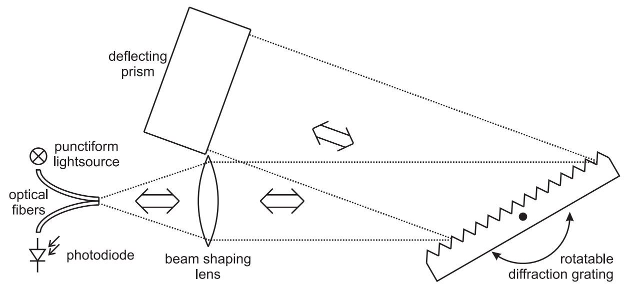

Figure 1. Optical setup of OSA

The given opto-mechanical hardware is from a JDSU OSA-201 [2][3]. The principle of the optical setup is shown in figure 1. It is a single monochromator in littman configuration where the diffraction grating is passed twice for high spectral resolution. The grating is rotated using a scanner motor with flexure bearings. Light is coupled via single mode fibers into the OSA. At the output side photodiodes convert the optical output power into a proportional electric current. A wavelength reference (which is not shown in fig. 1) with an infrared light emitting diode (LED) and an acetylene gas cell is integrated which can be used for wavelength calibration during operation. The wavelength range of the OSA is from 1250nm to 1650nm which is limited by the maximum angle of the scanner motor. Figure 2 shows a photo of the opto-mechanical hardware.

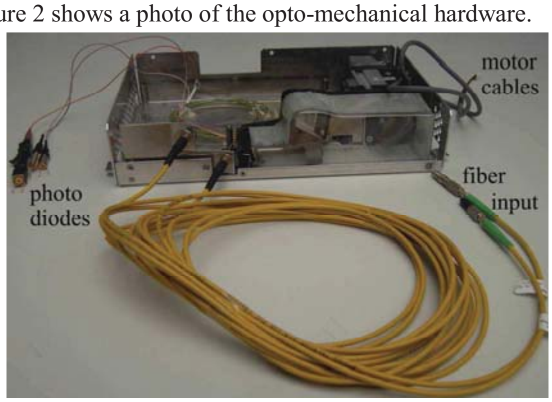

Figure 2. Opto-mechanical hardware of OSA

V. Reached Project Status

Up to now the main building blocks of the OSA electronics are developed and tested. The system is integrated and a first version of the control software is written. The following projects of the OSA development are realized:

A. *Summer semester 2008*

1) *Linear transimpedance amplifier*

This was the first test project to see if the new concept for the electrical measurement lab works. One group of two students had to build a linear transimpedance amplifier to convert the photodiode current into a proportional voltage. After designing the electronics and selecting the components they soldered a test circuit on a grid-style PCB and verified the correct function. In a second iteration they made a layout, fabricated an etched PCB and tested the correct function of the circuit. In the third iteration they added a low pass filter for improved noise performance, fabricated a new PCB and documented the results. In figure 3 the last version of the transimpedance amplifier is shown. The left operational amplifier converts the photodiode current coming through the red cable into a voltage. With the right operational amplifier an active low pass filter is realized.

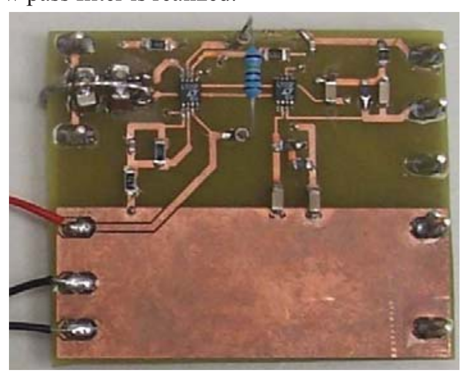

Figure 3. PCB circuit of linear transimpedance amplifier

B. *Winter semester 2008/09*

1) *Logarithmic transimpedance amplifier*

The logarithmic transimpedance amplifier converts the photo diode current into a logarithmic voltage. This has two advantages compared with a linear amplifier. First the current range of many decades is measurable with one amplifier and second the output voltage can be directly displayed in a logarithmic scale which is usual for optical telecommunication applications.

A group of four students developed this project. They first became familiar with the theory of the concept and then calculated the properties of the circuit. A rail to rail operational amplifier with low noise was selected from a vendor's homepage and the calculated circuit was simulated. After drawing a layout, building a PCB and assembling the parts they measured the response curve of the amplifier (fig. 4). The photo current is on the logarithmic abscissa and the output voltage is on the ordinate. The circuit shows a good logarithmic behavior which is in line with theory.

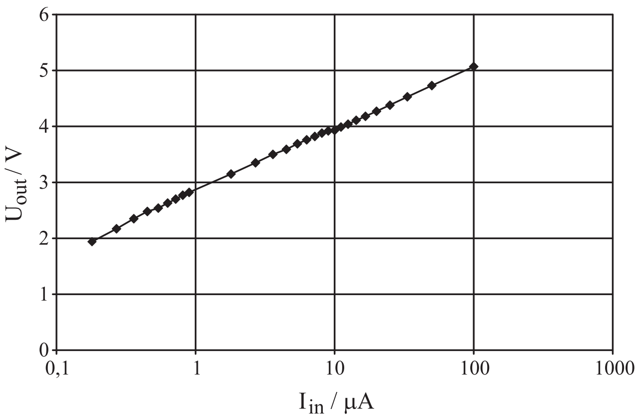

Figure 4. Response curve of logarithmic transimpedance amplifier

2) Motor driver using a microcontroller

One group had the task to develop a drive electronic for the motor. The intention from the supervisor was the development of a linear driver with an H-bridge. This was not clearly enough communicated to the student group so they decided to use a microcontroller and switching transistors for powering the motor. The controller was programmed with a constant velocity ramp and depending on the motor position the pulse width of the switch transistors was changed. This project succeeded but it was not possible to integrate this circuit into the system. Therefore it was decided to repeat this development during the next semester with more precise specifications.

3) Driver electronics for wavelength reference LED

The infrared LED for wavelength referencing must be supplied with a constant current. This current is controlled using an integrated monitor photodiode which detects the output power of the LED. A current source was developed by the student group which supplies a constant current independent of the LED and environmental conditions. A test board was developed using a blue LED where the functions can directly be seen. A current limiter with a limit of 200mA was implemented to protect the LED from destruction. A PCB with the final circuit was built and verified.

C. Summer semester 2009

1) Angle sensor electronics

In the scanner motor a capacitive angle sensor is integrated. This sensor is driven by an external DC-voltage and outputs two currents with the angle proportional to the difference of these currents. A group of four students realized this demanding project with their main scope on a low noise circuit. After learning the noise theory, designing the circuit and selecting the components they calculated the amplifier noise. They saw that this was much lower than the noise from the position sensor and so they built up this amplifier.

Figure 5 shows the block diagram of the angle sensor. The output currents of the angle sensor are transformed into voltages by transimpedance amplifiers. These values are added and the sum acts as a control input for the angle sensor supply. The current difference is the output signal of the sensor electronics and proportional to the scanner drive angle.

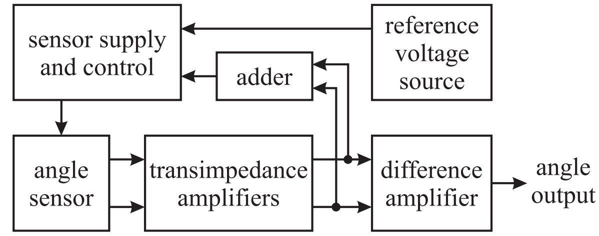

Figure 5. Block diagram of position sensor

2) Linear motor driver using an H-bridge

The project for building a motor driver electronic was again offered. In the tighter project specifications an analog input voltage with a proportional output voltage was demanded. The student group chose an operational pre-amplifier which transforms the range of the input voltage to an appropriate voltage for the bipolar H-bridge transistors. With a feedback loop from the output of the H-bridge to the input of the pre-amplifier the distortions around the zero voltage output of the H-bridge are compensated.

Together with the student group developing the angle sensor they built up a test set up with a scanner drive and their electronics to show the function of the whole motor drive and position sensor system.

D. Winter semester 2009/10

1) Connecting the hardware parts and creating a control software using LABVIEW

The opto-mechanical OSA hardware was connected to the motor driver, the position sensor and the logarithmic transimpedance amplifier. These parts were connected to a PC using an interface card with analog/digital and digital/analog converters. The student group used LABVIEW to set the driving voltage for the motor and read out the voltage of the logarithmic transimpedance amplifier. By stepping the motor voltage over the whole range while reading out the amplifier values an uncalibrated optical spectrum was constructed and shown on the screen. Two fabry-perot laser diodes with 1310nm and 1550nm wavelengths were coupled into the OSA input fiber. Figure 6 shows this first measured spectrum with the two lasers in it.

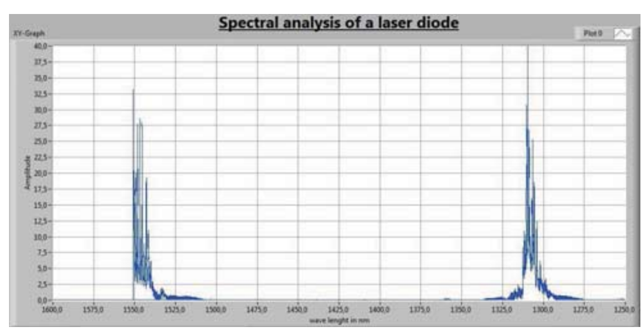

Figure 6. First measured spectrum with OSA

VI. Feedback from Students

After each project completion systematic feedback from all students was gathered. Here the main points which were highlighted by the students:

- Summer semester 2008, transimpedance amplifier: The project was very interesting because of the different tasks. It was very good to see the results and the success. A better explanation should be made how parts are sampled and PCBs are ordered. At the beginning the work load and the division of the project among the students were unclear.
- Winter semester 2008/09, LED driver: It is better than lab courses with fixed experiments because of a higher motivation, learning from own mistakes, having a free time schedule.
- Winter semester 2008/09, motor driver: The learning effect was very high but the project was also very time-consuming. The group work was a lot of fun. It was better than the standard lab experiments.
- Winter semester 2008/09, transimpedance amplifier: Positive was the own development of an electronic circuit, independent work made fun. The main disadvantage was the high work load.
- Summer semester 2009, position sensor: The advantages were the free time schedule and the creative work. The project matched with the theoretical lectures during the fourth semester. The project was an instructional experience and a good alternative the normal lab course.
- Summer semester 2009, motor driver: The expenditure of time was higher than expected. The development of the electronic circuit was challenging but funny.

VII. Conclusion

From advisers' side we saw that during these projects the students got a higher knowledge increase than with the prepared standard experiments. This was also confirmed by the written test at the end of the lab course. The grades of the project students were better than the average course value.

The students already had a lecture of analog electronics but for many them this project was the first practical experience with the design and assembly of an electronic circuit. At the start of the project many students had great difficulties to transfer the theoretical knowledge into practice. During the project they learned how to build a working electronic board with all practical problems.

The groups had to organize itself. They divided the individual tasks among the project members and combined the parts to one solution. At the beginning this was challenging because no adviser gave them a detailed instruction how to schedule the work. During the project the students formed a team where one could rely on the others.

At the end of the project the students had to present the work results in front of the advisers and the other students. This was a challenge for the introverted ones but in professional life it is inevitable to present the work in an appropriate way.

We also saw some risks during the projects. The way how to solve the project was open, so some groups found impractical or wrong solutions. If the students came during the project work to a dead end they spent a lot of time without finding the further way. The consultation of the adviser was very late so the groups lost a lot of time or presented an unrealistic solution. It is important from the advisers' side to clearly tell that consultation and discussion does not lead to grade degradation. It is also important to ask for one or two interim reports to see how the project is going on and how much time is already spent.

During the first semesters the project specifications were short to give the students maximum freedom for developing own solutions. This was considered negative from some groups because students were uncertain which technical solution they should choose. Therefore in the last semesters the specifications were detailed and the problem disappeared.

VIII. Planned Work and Outlook

After the winter semester 2009/10 semester we have finished the first version of a working OSA system. During the next projects two main work directions are planned.

During integrating the OSA some problems with the actual transimpedance amplifiers arose concerning speed and value range. Therefore it is planned to build new amplifiers with improved characteristics. The second goal is the improvement of the measurement algorithms with filtering the position and optical power values. A wavelength calibration algorithm should be implemented and tested. It would be very interesting to calibrate the self-built OSA and compare it to a commercial one.

Due to the high success of this type of project we offer in the meantime other topics. Additionally we started the work on a wireless weather station which is modularly set up and therefore expandable to any functional range.

In the middle future we intend to switch the whole lab course from fixed experiments to project work to provide an optimal education for our engineers.

Acknowledgments

First of all I want to thank all the highly motivated and competent students who carried out the project work. They made this new type of lab experiments a success. I also thank my colleagues for the fruitful discussions when creating and optimizing this type of project work.

Abstract—**The idea of this paper consists of developing a new methodology based on a complex system that will be analyzed and programmed by several groups of students that must work openly and cooperatively to achieve a final global result. For this purpose, a personal digital assistant developed as an open hardware called OpenMoko has been selected. The paper details the experience of working with this system and highlights the main obtained benefits.**

Keywords-systemic methodology; cooperative projects; open hardware; lab learning;

I. SUMMARY

Cooperative learning (CL) is a successful teaching strategy based on the constructivist theory of learning in which small teams, each with students of different levels of ability, use a variety of learning activities to improve their understanding of a subject [1], [2]. Usually, learners are divided into different groups so that they can discuss and share their work with each other during the learning process to increase the efficiency and quality of their learning. One of the main benefits of cooperative learning is that learners can improve their ability in the subject and learn to adjust their interpersonal relationships through interactions with other group members [3]. In cooperative learning situations there is a positive interdependence among students' goal attainments; students perceive that they can reach their learning goals if and only if the other students in the learning group also reach their goals [4]. Cooperative learning must be distinguished from group work. Although cooperative learning does employ groups (actually teams), group work is not necessarily cooperative learning. The main differences of Cooperative Learning (CL) respect to small-group discussions and group projects typically used in Higher Education are the selection of group members on the basis of predetermined criteria which have been deliberately designed to potentiate the positive effects of small group learning, the continuity of group interaction, the interdependence among group members, the explicit attention to the development of social skills, and the role of instructor as a facilitator [5].

On the other hand, project based learning (PBL) is an educational teaching and learning methodology that has been actively used for some time now. Project-based learning is grounded in general theories of knowledge such as situated learning [6], which states that knowledge must be presented in an authentic context, using settings and applications that would normally involve that knowledge, and includes social interaction and collaboration to solve complex problems [7], [8]. When compared to traditional lecture-based or teacher-centered engineering curriculum, the PBL model appears to inspire a higher degree of involvement in study activity [9]. In this case, PBL should not be confused with problem-based learning. The main difference is that in project-based learning, students mainly apply previously acquired knowledge and the production of some final product is the central focus of the assignment. By contrast, problem-based learning students have not previously received formal instruction in the necessary background material and the solution process is more important than the final product [10], [11].

This paper proposes the combination of both concepts in an electronic lab subject using a complex system over which groups of students can develop partial works. An open hardware project called OpenMoko has been chosen as the complex system in which both learning strategies are developed. Openmoko™ is a project dedicated to delivering mobile phones with an open source software stack. The Openmoko stack, which includes a full X server, allows users and developers to transform mobile hardware platforms into unique products. The license under which is released gives developers and users freedom to cosmetically customize their device or radically remix it.

II. METHODOLOGY DESCRIPTION

The proposed project consists of building an application for an Openmoko phone able to connect to a beacon (implemented in a PC) which provides information pages through a Bluetooth link. These pages are very simple and can contain texts, menus and sounds. Due to the complexity of the project, four subgroups were created:

- Subgroup 1: Bluetooth. The objective of this subproject consists of managing a Bluetooth link between OpenMoko and the Pc beacon.
- Subgroup 2: Graphic Interface (QT). This subproject consists of working with the QT framework to develop a graphic interface.

- Subgroup 3: Audio Interface. Mplayer software is used to play both local files as well as the audio information transmitted by the beacon.
- Subgroup 4: Accelerometer. The embedded accelerometer is used to recognize some movements and perform some actions depending on the detected movements.

The global project is specified in detail. Consequently, each subproject must develop its own tasks but taking into account the activities and interfaces with the rest of subprojects working with the OpenMoko system.

In the first few sessions the teacher explains some introductory lessons about the GNU/Linux operating system, the Openmoko platform and the development tools. In order to facilitate the work both inside and outside the classroom, the teacher created an image of a GNU/Linux distribution with the toolchain installed so that the students could use it by simply installing an open source virtualization platform. In this way students can work in their own PCs with the same environment without having to change their O.S. or spend time installing the toolchain and setting up the environment.

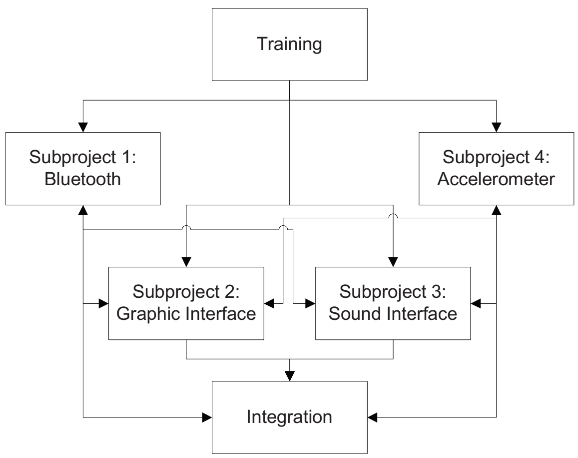

Figure 1. Stages of the methodology and subprojects relationships.

The following sessions were dedicated to the project's development and they were divided in three stages, Figure 1:

- Stage 1: Training. In this stage students must study the technologies and tools related with their subproject, and they must perform small test programs.
- Stage 2: Modular design and specifications. First, the particular specifications of each subprojects are defined, working in a coordinated manner with the rest of groups. Necessities are analyzed and specifications are agreed to guarantee the compatibility of the modular developments performed by each group. Second, each individual project is launched and developed.
- Stage 3: Integration. All the individual projects are joined together, making the necessary corrections to achieve the required main functionality.

During the development of individual subprojects, the first minutes of each class were devoted to follow-up reviews. Then, the self-learning of the group and the utilization of previous knowledge and skills of each group member are promoted.

III. RESULTS

The obtained results by each subgroup are next detailed:

Subgroup 1: Bluetooth. The students managed to establish a connection between the Openmoko phone and a computer by using Bluetooth's SDP profile and RFCOMM protocol. The SDP profile was used to publish the specific service so that the devices belonging to the system can connect between them without bothering devices that do not belong to the system. For the data transfers, the students used the RFCOMM protocol, since it provides a serial-like link. They also designed a specific application layer protocol intended to be run on top of RFCOMM, Figure 2. This way they can send easily simple files describing the data that should be displayed on the Openmoko terminal.

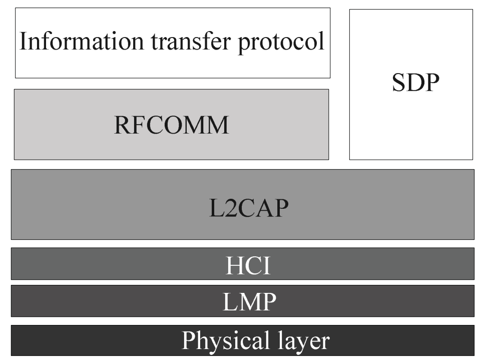

Figure 2. Protocols of the Bluetooth link.

Subgroup 2: Graphic interface. The progress of this task was slower than others due to some problems the students had to face, but finally they managed to build simple windows on demand, at runtime, using QT as the framework for developing the graphic user interface.

Figure 3. Graphic interface.

Subgroup 3: Audio interface. This subgroup built a basic sound infrastructure based on mplayer that was able to play both local files and streams. This infrastructure is intended to be used together with the Bluetooth module in order to play the incoming streams from the beacon (PC).

The designed sound interface uses the sound infrastructure and certain audio applications that are installed in OpenMoko phones, adapting them to fit our application requirements. These needs are focused basically on playing OGG/Vorbis compressed audio streams which are received through the Bluetooth connection. The group assigned to this subproject managed to create programs that played audio streams by using ALSA and Mplayer. In order to accomplish this, they launched Mplayer in command mode and created a pair of pipes (FIFOs), one for sending the audio stream and the other one for sending commands. The sound interface is able to launch on demand several Mplayer instances running in background simultaneously. They also made some tests to integrate a text-to-speech program (Festival) within the sound interface and managed to generate little audio chunks and compress them in OGG/Vorbis format. This group even defined the API functions necessary to control the interface. They implemented these API functions as a library (libsui.a) which can be linked to any application using the sound interface. The set of functions that control the audio player were implemented as an independent program running in background (suid),, Figure 4.

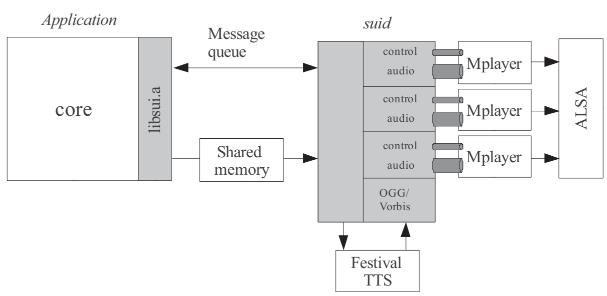

Figure 4. Audio interface scheme.

Subgroup 4: Accelerometer. The students managed to retrieve the accelerometer's data and do a simple post-processing on the data to detect certain movements. In the third stage this events are reported to the main application. This way, the user could change the selected item in a menu by simply moving the phone.

Integration. The previous subprojects have been integrated in a final application where the human machine interface is solved making use of hand movements. Whenever the phone is moved up-down-left-right, the cursor is accordingly moved. This way the final user can visualize incoming information or play incoming audio streaming. The integration stage requires the different subgroups must negotiate common interface specifications.

IV. PEDAGOGICAL EVALUATION AND BENEFITS

To analyze the pedagogical value of the proposed lab learning methodology, we must first corroborate that we are indeed developing the mentioned cooperative and project based learning.

The key pedagogical assumptions of cooperative learning are: (i) knowledge is created as it is shared. Therefore the more students share information the more they learn; (ii) that learner’s have prior knowledge they can contribute to the discussion; (iii) that participation is critical to learning and; (iv) that learners will participate if given optimal conditions [12], [13]. To accomplish these premises, groups must work together and members should solve problems by a process of discussion and interpretation of results. Participation is encouraged because groups should evaluate themselves at the end of the course indicating the degree of involvement of each member. Participation is one of the main antecedents of information sharing [14][15], and knowledge sharing allows the creation of new knowledge through a process of knowledge revealing, knowledge reusing and knowledge recombination. The use of prior knowledge is also promoted with an intentional group formation. Groups are formed trying to merge different students’ profiles in terms of previous knowledge and previous curriculum. Finally, students have available all the technical resources, including documentation, lab equipments, and the complete framework for working with OpenMoko

On the other hand, PBL has also several premised that should be accomplished. Some authors [11], [16] takes a broader approach to defining PBL, offering five criteria that a class project must have in order to be considered an instance of project-based learning. The project must be (a) central to the curriculum, (b) focused on questions or problems that drive learners to encounter and struggle with the central concepts and principles of a discipline, (c) a constructive investigation or goal-directed process that involves inquiry, knowledge building and resolution, (d) conducive to student autonomy, choice, unsupervised work time, and (e) realistic, focusing on authentic challenges where the solutions have the potential to be implemented. All these premises are also considered in the proposed methodology. OpenMoko is an open hardware intended to perform developments directly related with a lab learning activity. The course organization also pursuits a constructive approach, promoting the discussion, the searching of solutions and alternatives, and improving the students autonomy when facing a new and unknown problem. Finally, the integration stage guarantees the result is realistic because it is finally implemented.

The main benefits of CL have been highlighted in [17], where they analyze 120 studies to compare the relative advantages of cooperative, competitive, and individualistic learning on individual achievement. The results show that cooperative learning promoted greater achievement than competitive or individualistic learning methods. The research also found that cooperation promoted greater intrinsic motivation to learn, more frequent use of cognitive processes such as re-conceptualization, higher-level reasoning, meta-cognition, cognitive elaboration, and networking, and greater long-term maintenance of the skills learned. At the end of the course, it was checked that students' motivation was improved. They exhibit a high degree of involvement if their tasks. In particular, the integration stage was valued as the most exciting and interesting phase of the project development.

The main benefits of project based learning are listed below:

- Students develop skills and competences like collaboration, project planning, decision taking, communication and time management.
- The learning process is linked with real life, and this issue contributes to improve knowledge and skills as students are more involved with the project.
- Development of collaborations skills to build new knowledge. Student must share ideas, and then discuss and negotiate solutions.

The work with OpenMoko is clearly linked with the field of mobile phones applications. The use of Bluetooth and accelerometers are linked with emergent technologies and students feel strongly motivated for this kind of tasks. The course organization as subprojects integrated in a global big project makes necessary not only the collaboration between group member but also the discussions and negotiations between groups themselves.

V. CONCLUSIONS

This main novelty of this paper is the integration of cooperative and project based learning in an open platform like OpenMoko. The course has been designed to consider both learning methodologies and to take advantages of their benefits. The obtained feedback signals the integration stage and the link with real life as the most interesting issues covered by this course.

An Experience of a Multidisciplinary Activity in a Biomedical Engineering Master Degree

Jordi Colomer, *Student Member*, *IEEE*, Pere Miribel-Català, *Member, IEEE*
Electronics Department, Universitat de Barcelona
Instrumentaion and Communications Systems Lab. SIC
Barcelona, Spain
{jcolomer,pmiribel}@el.ub.es

Abstract- **Training Biomedical Engineers presents major challenges because of the different backgrounds they are coming from. These activities should stimulate the student's professional skills and, in the particular case of a Master Degree, this is even more complicated. It represents a higher educational level where students should increase and improve their ability to solve problems related to very different areas such as the engineering and biomedical. The Biomedical Master Degree shared between the *Universitat Politecnica de Catalunya* and the *Universitat de Barcelona* has students coming with extremely different backgrounds, from the medical or biological to the engineering profile. Taking into account this situation, we have developed a *4-days multidisciplinary charge activity* in a particular course of Biomedical Devices. It is focused on the amperometric sensors and in the conception and application of biopotentiostat amplifiers. Regardless the student's profile the activity is focused in such a way that everyone has to work actively in the experience. This paper presents a proposal based on co-operative learning strategy and the feedback that students give to the learning process as a first approach for future improvements.**

Index terms: Biomedical Engineering Education, Workgroup teaching, Analog electronics teaching.

I. Introduction

The Bologna process in the European Union (EU) has been defining, since 1999, a new conception of the Credit measurement [1-3]. This European treaty that should be concluded in 2010 is the configuration of the European Higher Education Area. It brought a reformation in all the European Countries involved, in order to establish qualification comparability criteria for all the higher education institutions in Europe.

This new credit, defined by the European Credit Transfer System (ECTS) must be a measurement of the full student's work [4-6]. This conception imposes a more practical approach in the learning process, and it is of particular interest in technological disciplines where technical practices are essential for a complete learning. This was one of the main reasons to develop this activity, as a different approach to classical laboratory experiences. In the case of a Master degree in Biomedical Engineering, in the University of Barcelona [7], is even more important taking into account that the profile of the students covers several areas, and the conception of the curricular courses is a key point for their professional's future.

This Master degree is conceived with 120 ECTS credits which are distributed in 4 semesters.

As it was mentioned before, due to that this Master degree is cursed by students of different degrees, like Biology, Biochemistry, Pharmacy, Medicine, Veterinary, Ontology, Electrical, Electronics, Mechanical, Biomedical Engineering, Physics, and Chemistry, the students should follow different schedules depending on their previous knowledge. Students coming from Biological and/or Biomedical area can just overcome 60 credits to obtain their master degree. On the other hand, students coming with engineering, physics, and chemistry backgrounds must complete 5 ECTS extra credits.

In this paper is presented the conception of a specific experience in the course of Biomedical Devices, designed to an optional subject in the curricular formation of the students.

II. Background and Interest of the Activity.

The particular problem we have encountered has been how design an activity that allows students with different profiles work together ***actively*** in the lab, and an initial cooperative work has been followed. Interesting approaches have been presented in [8-9].

The key aspect is the design of one activity that allows to put to work in the same laboratory students as heterogeneous as we have found, being a completely new experience for teachers and also for students.

For this course, the theory is designed to cover several topics to understand, design and work with basic biomedical devices. Firstly, there is an introduction to the measurement systems, focused on devices and instrumentation for measurements of temperature, pressure and flow. Also there is a basic explanation of different types of sensors and biosensors such calorimetric, potentiometric, amperometric, optical biosensors, immunosensors and bio-optoelectronics, and to finish the students learn concepts of Electrochemical techniques, like voltammetry and Electrochemical Impedance Spectroscopy [11-13].

In particular, in the field of sensors and biosensors, the introduction to the concept of Potentiostat Amplifiers, and their applications with biosensors, has been used to design such activity for students that either have an electrical engineering profile or for those who are coming from other areas and could have a weak background in electronics.

Different objectives are pursued in the design of the experience. One is the development of an integrative laboratory that promotes inquiry, relevance, and hands-on experience for students with different profiles [14]. We do not want groups where just only some students work actively in the lab, depending on the type of activity. The scope of the activity is that everyone work and participate actively. In this experience the students must applied their skills in math, science and engineering. The key aspects of the ABET EC 2000 criteria have been followed [15]. The students take measurements and interpret their results.

This experience is based on a traditional master class, but it is just one more element in the process. Thanks to the activities in the classroom and the laboratory, some other aspects are reinforced, like the communication and team work between the students, working in a multidisciplinary team, and a more hands-on approach to learning is developed [16-18].

An important aspect is the cost of the laboratories for the biomedical engineering education. The Biomedical Devices lab is organized in teams of two or three students, in ten full equipped tables with standard instrumentation equipment. In our case, a portable low-cost potentiostat amplifier has been designed for each table. In the classroom some commercial biopotentiostat amplifiers are presented, from different commercial suppliers, like a high performance amplifier from TekNet Electronics [19], or an educational potentiostat like the Voltalab 06 [20]. These equipments are quite expensive to be placed at each table. Through the designed equipment students have an approach to this type of equipments at a low cost for the University. These kinds of equipments are compared with our discrete amplifier at the end of the sessions. The discussion arises in terms of the trade-off between their performances and cost, where the commercial ones are much more expensive than our low-cost PCB design, (30 USA$ vs. more than 3000 USA$ for each commercial device and worktable). Following these approach we can also incorporate in our laboratory an experience to provide students with hands-on, real-world application.

The presented activity, that is centered in a cyclic voltammetry, is designed in order to work different aspects related to the students activities (ECTS credit transfer), and to work specific objectives in the course, which are the interest to present the feasibility to carry out electrochemical experiments controlled by a PC, and make noticeable how works the instrumentation used to interface the electronics with the experience.

III. DESIGN OF THE ACTIVITY

The activity is focused on the presentation of the potentiostat amplifier and its use to control a cyclic voltammetry. There are different techniques to define a Cyclic voltammetry [21-23]. In our case, it is an electrochemical technique based on a triangular scan of the potential of the working electrode. As the potential of the working electrode is scanned in one direction, any electroactive species in the sample will undergo reduction or oxidation (depending on the direction of the scan). As soon as the direction of the potential scan is reversed, the species will undergo the opposite reaction (oxidation or reduction, respectively). These electrochemical reactions give rise to redox currents, which are recorded as a function of potential. The current-potential graph is the cyclic voltammogram, which gives quantitative and qualitative chemical information.

The selected biopotentiostat setup uses a three electrodes sensors configuration [24-26] which are a) the working electrode (WE), which serves as a surface on where the electrochemical reaction takes place; b) the reference electrode (RE), used to measure the potential at the WE, and c) the counter electrode (CE), which supplies the needed current required for the electrochemical reaction at the WE.This amplifier controls the voltage between the WE and RE electrodes to a control input voltage (Vin). In order to keep this condition the current at the RE electrode should be ideally zero and no current should flow through it.

The potentiostat amplifier design has a very low-cost structure which is depicted in Fig.1. This structure is based on four operational amplifiers (Opamp) and two resistors. OP4 is the transimpedance amplifier, which defines the virtual ground voltage of the WE electrode and provides current-to-voltage conversion. The key characteristics of the transimpedance amplifier, in terms of its input impedance, very low input leakage current and offset voltage, are some of the elements that the students must work in the activity, working their thinking critical skills**.** The gain in theI/V conversion is defined by an external resistor. OP3 is used to ensure minimal current flows through the RE electrode. It senses the voltage difference between the RE and WE electrodes, that is measured between the RE voltage and the virtual ground. This difference is used by OP2 and compares this voltage with the desired Vin voltage, changing the voltage at the CE electrode and defining a current trough the cell in such a way that the voltage difference between the RE and WE electrodes follows the defined Vin signal that polarizes the sensitive cell.

The activity is divided into four different parts, which are programmed in two weeks, as is represented in Fig.2, where are also indicated the inputs for the student's evaluation. The total work for the students is estimated to be around 10h, which are equivalent to 5/6 ECTS, for this activity. Five of these hours represent practical work done by the students in the faculty, and the remainder of the hours represents their individual or group work out of the classroom and the laboratory. It is important to emphasize that the students can contact their supervisors/teachers by e-mail for tutorship if needed.

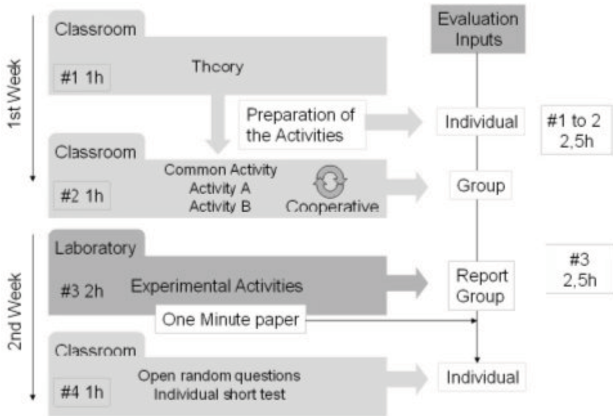

Fig.2: Schedule of the activities.

Team groups are formed by two classmates at least, where both are coming from different study areas but at least one of them should have engineering background. Ideally, a team of three members is preferred.

A work in the classroom is planned to present the circuit and experience, which is the first part of the program. The concepts of the potentiostat amplifier and the sensor are introduced in this section. The second class is devoted to a *cooperative task*.

In order to develop the work in the lab the students must prepare a theoretical previous work, which is developed here. This work is focused into three main activities, as a previous lab work, which programmed in terms of the student's profile.

This common activity for all the students is divided in two categories A and B. Activity A is oriented to students with an engineering background (A Student), and Activity B for the rest of them (B Student).

These activities must be read and prepared by the students before the class time. The common activity is based on the visual analysis and identification of the components used in the design of the potentiostat amplifier, of the designed PCB, which is depicted in Fig.3.

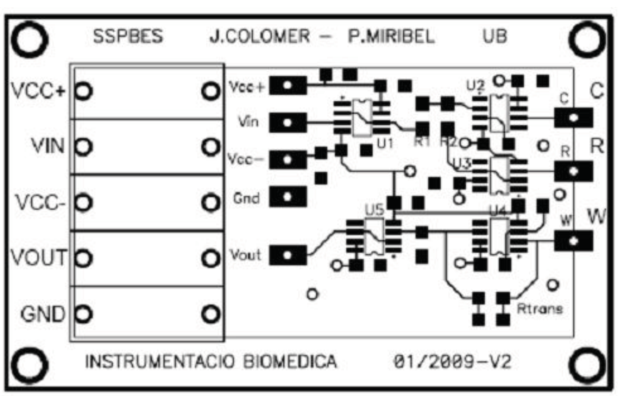

Fig.3: PCB representation of the biopotentiostat amplifier.

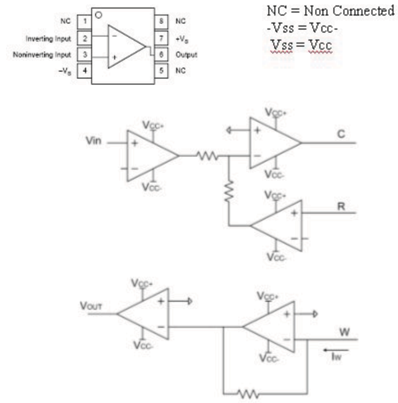

Fig.4: Caption of the exercise.

They must identify the different amplifiers that define the potentiostat amplifier, and find out the connections between the different elements, Fig.4. Following this technique all the students have a first contact with the PCB implementation before their experimental activities in the laboratory. The scheduled time for these activities, two hours, are more focused to run the different programmed measurements. This will make better time in the lab.

Activity A is focused to find out the mathematical expression that describes the relationship between the Working (W) and the Reference (R) electrodes with the input signal (Vin).

Also, for the students with an electric engineering profile, some more specific activities are programmed, and are used in order that they explain to their classmates the main reasons to select one amplifiers, and no others, for this design. The selected operational amplifier is the OPA 656 from Texas Instruments [27], which presents good parameters in terms of input impedance and offset voltage. They are requested to search the datasheet of this amplifier and compare it with some other amplifiers with worst and better characteristics like the LM741, LM725, LF411 and OPA124.

Fig.5: The instructor works with one group defining the CV measurement using Labview © interface of the programmed CV.

Activity B is focused to find out the sensor that has been used. The students only have the reference of the supplier (BVT Technologies) [28]. They must find its datasheet and identify the electrodes and their characteristics, and also will work the principles of the chemistry redox.The second part of the practical work is developed also in the classroom (second day), to work in a cooperative way. Previous activities concerning to each class are delivered, individually, to the teacher before the class, using the e-learning Moodle resources or e-mail. These are essential tasks for the individual evaluation of the students. Also, the students must indicate an approach to the time needed for them to complete the activities, which are estimated by us, around 2 hours and a half. Thanks to this work, out of the faculty, we are placing the students to prepare these activities before the work in group. If one of them fails, the whole qualification fails in the cooperative stage.

Following a three-step interview methodology [29-31], they must discuss the common activity and work on it together, the electronic background student (A student) should explain to the other students (B Student) its activity, in a basic academic language to be well understood for the rest of the group, and the B students introduce their research of the sensors to the A students. By the end of the class they should deliver a common report of the activity. Without this work finished and delivered to the professor before the laboratory activity, they can not go ahead with the activity, which is translated to a negative qualification.In the lab, part three, they proceed with the experimental measurements which are indicated in the student's laboratory manual. These activities are carried out during the second week. Work in the lab promotes interaction between students and the -laboratory equipments, with groups up to 20 members. In Fig.5 the instructor is working with one group, while they are taking a CV measures using LabView© interface.

During this session they are focused on the experimental part of the activity. The students work with a LabView©

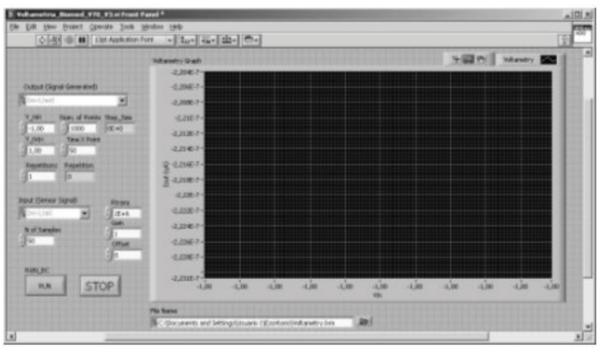

Fig.6: Interface of the programmed CV using Labview.

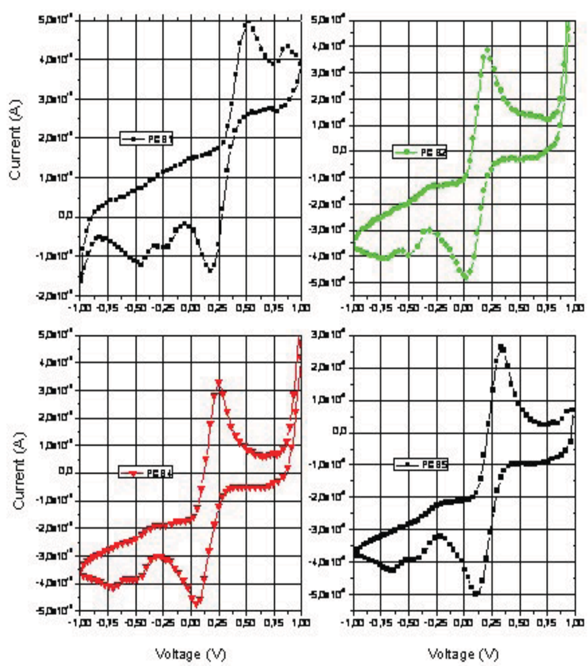

Fig.7: Different measurements programmed CV using Labview by the students.

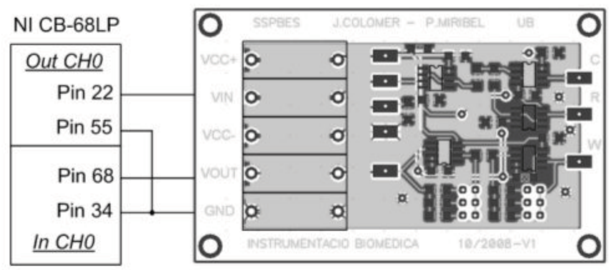

Fig.8: Interface connections between the PCB and the acquisition board.

Fig.9: Introduction review at the beginning of the lab session.

interface used to program and obtain the Cyclic voltammogram response (CV), defining the maximum (V_max), and minimum (V_min) voltage levels, time acquisition, in terms of the numbers of points (Num.of.Points), and the defined time of measurement for each point (TimeXpoint), Fig 6. The number of iterations for each CV can be defined (Repetitions) as well. They learn how the electronics are used to control the electrochemical reaction, basis of the electrochemistry. The CV, in terms of the current vs. the cycle voltage is depicted online in the panel, and the results can be browsed for their analysis, as shown in Fig.7. In the student's laboratory manual is described the right way that must be followed to bias the circuit, and the channels interface with the acquisition board, from National Instruments© (PCI-6014), as it is depicted in Fig.8. The instructor presents an introduction at the beginning of the session, Fig.9. Then, the students must prepare a report based on their measurements and some final questions. Reports are programmed to be presented to the professor before the next class, one week later. Also, the students must indicate the time needed by them to complete the report, which is also estimated around 2 hours and a half. At the end of the lab experience the monitor asks for a one minute paper [30]. That is a traditional technique followed in cooperative learning, and it is used in our case as a feedback measurement on where is the student's understanding of the material. Questions like: What was the most important or useful thing you learned today? Which three important questions do you still have? In the next class, the professor asks to the students following different strategies based on the feedback process: open random questions or short individual written examination. Also half of the class is used to solve the main student's doubts

IV. FEEDBACK FROM THE ACTIVITY

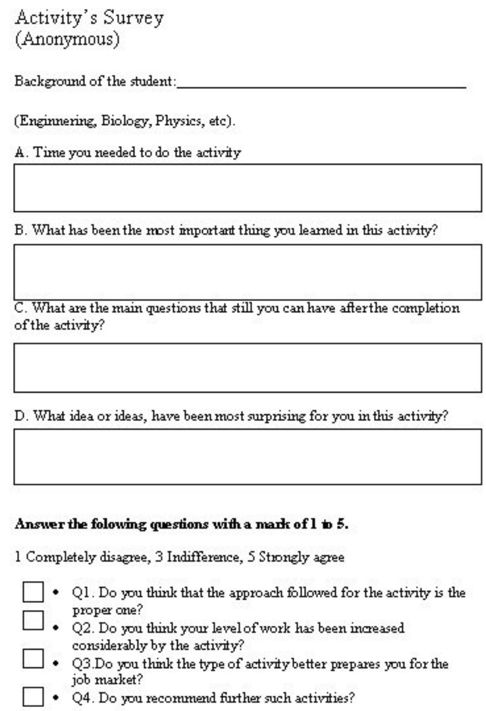
An interesting study has been also carried out between the students, which are not very keen on this type of activity. For this academic course we had 22 students, divided in four groups, as is indicated below in this section.

Figure 10 presents the survey used to know the opinion of the students about this activity. During this first experience we asked to them about their feeling about cooperative learning. From these surveys among them, we have analyzed their opinion and views on the full activity. These questionnaires are adapted from [33]. By using a defined scale, from 1(never) to 5(always), or 1 (strongly disagree) to 5 (completely agree), we have recollected the strengths and weaknesses of the activity.

In order to analyze these inputs, the curricular background of the students is required in the form.

The study was divided into four main groups depending on the background of students: Electrical & Electronics Engineering (7), Computer Engineering (4), Mechanical Engineering (2), Physics (4), Chemistry and Biology-Medicine (5). All students remark the interesting fact to know how they can relate the experience of a chemical reaction with the use of electronics' instrumentation for experiences that are the basis of spectroscopy.

Basically, the students with an electric and electronics engineering profile have an excellent comprehension of the involved electronics, and they focus their main interest in the experience, according to surveys, to the use of electronics in the functioning of the electrochemical experience. They highlight the fact that a potentiostat amplifier can be used in the measurement of chemical reaction and its biological applications. Their main concerns are related with the chemistry in the experience as it could be expected.



Activity's Survey
(Anonymous)

Background of the student:________________

(Engineering, Biology, Physics, etc).

A. Time you needed to do the activity

B. What has been the most important thing you learned in this activity?

C. What are the main questions that still you can have after the completion of the activity?

D. What idea or ideas, have been most surprising for you in this activity?

Answer the folowing questions with a mark of 1 to 5.

1 Completely disagree, 3 Indifference, 5 Strongly agree

- Q1. Do you think that the approach followed for the activity is the proper one?
- Q2. Do you think your level of work has been increased considerably by the activity?
- Q3.Do you think the type of activity better prepares you for the job market?
- Q4. Do you recommend further such activities?

Fig.10: Survey's form.

In the case of the rest of engineers, and for students with a degree in Physics, they have some difficulties with the electronics but they can cope with them with success. They have the same difficulties with chemistry linked with the laboratory experience.

As examples, these are some interesting answers of the students.

From question B of the survey: *What has been the most important thing you have learned in this activity*, they responded: "The use of chemical sensors, which I had never seen one, and I had no idea how they were and how they could be used, and thanks to the experience I have a first approximation.", by an Electrical and Electronic Engineer.
"I learned a visual and practical use of an electrochemical instrument", by a Mechanical Engineer.

For question C, *What are the main questions that still you can have after the completion of the activity?*, they say "My main doubt is related to the electronics", by a biologist. This answer is common in the group of chemistry, biology and Medicine students.
"My main problems were when I has to analyse the electronics", by a Physicits.
"The voltammogram response is a bit difficult for me to understand", by a Mechanical Engineer, very similar with comments by other students with an engineering brackground: "I do not understand very well the measured curve", by a Computer Engineer.

For question D, *What idea, or ideas, has/have been most suprising for you in this activity?,* the say: “The fact that an electric current is generated by a redox reaction and it is converted to a voltage that can be measured and processed.” by a Computer Engineer.

“The use of the electronics with the chemistry and sensors in the field of the introduced application and its use”, by a biologist student.

“It is for me the most surprising and new idea that I have learn from this experience that you would be able to measure biological concentrations using electronics”, by a Computer Engineer.

“The current detection by the electronics which is produced by the redox reaction”, by a Physicist.

“The application of electronics in biomedicine in general seems very important.” by an Electrical and Electronics Engingeer.

There are also some comments which are very grateful for the lab professors, like: “The attitude and involvement of teachers surprised me positively”, which is a great reward for teachers. In terms of the proposed experience, in general, and especially for the majority of students with a deficiency in training in electronics, the method has a high score, as it is shown for the different groups for question Q1, Fig.11.

What has been a great surprise is the average of indifference in terms of the work load for the students, question Q2. We expected a general sense in terms of an increase in the hours needed for the experience to be completed by the students.

Question Q3, designed to check the practical impact of it, in terms of a real job training approach, we have very different answers. In the particular case of the mechanical engineer’s profile, they mark this question with an average of “2”, which is a “disagree” opinion. Computer Engineering students and Biology-Chemistry and Medicine students have a good perception of this activity as a nice preparation for a real job.

Finally, question Q4 indicates a good perception of the students with this type of activity, which indicates a success in terms of the implementation of this kind of co-operative activity in this particular field.

The ECTS work of this activity represents 1/6 of the total activities of the students in this subject. Our first estimation was planned to be a total average of 10 hours. Thanks to the feedback collected from the students the real average time is around 12h.

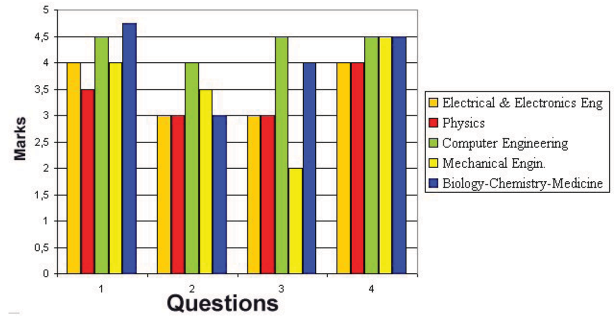


Fig.11: Mark’s report for survey questions Q1 to Q4.

V. CONCLUSIONS AND FUTURE WORK

This activity has been conceived to provide students with real hands-on experience. The focus of the activity was achieved for all students, regardless of their profile. They worked actively in the activity, having a good understanding of the experience, difficulties in more detailed aspects, but with success in the entire experience.
The students are introduced to one type of sensors and they work with the electronics involved in the design of a potentiostat amplifier, in its basic architecture. In this way they are introduced to commercial solutions but working in a design based on discrete components they are able to have an approach to its architecture. Also, in terms of cost it is more economic to have this discrete PCB for each working group that a commercial one. In this activity they work different clue aspects like the application of previous knowledge, the ability to work in multidisciplinary teams, communicate their results, etc ...

Teachers have noticed how all the students have understood the experience and they worked actively on it, particularly students with very weak foundation in electronics have been able to work with the track and understand the experience. No typical passive roles in the labs were present, which was one of the main concerns taking into account the diversity of the students.

Next year we would like to change the followed approach to increase the interaction between the students. The students with and engineering background will work just the sensors and chemical aspects of the activity, and the rest of student will work in the electronics. Then, they will work following a three-step interview methodology. In this case we expect a better interaction. The students will correct their classmates within the fields they have a better understanding and background.

It is also our purpose define new modules of experiences, like the Electrochemical Impedance Spectroscopy (EIS), and the use of lock-in amplifiers in the characterization of sensors and in the measurement of Electro Chemical Impedance Spectroscopy.

More in-depth analysis of the student's ECTS charge and comparative analysis of the qualification of the students following this kind of activity or traditional approaches will be presented in future works.

ACKNOWLEDGMENT

Abstract— **In this work, we present a complete set of undergraduate microwave and RF laboratory experiences, that have been designed to improve the students competences on the high-frequency design, analysis and characterization. The developed courses include one-port and two-port circuits' measurement and characterization with the current most used instruments: vector network analyzers, spectrum analyzers, noise figure analyzers and power-meters. The computer-aided design has not been overlooked: a *design-optimization-fabrication-measurement* process is proposed to improve the students' global vision of the subjects.**

Keywords-microwave circuits; antenna design; low-profile laboratory; computer-aided design and simulation; microstrip lines.

I. INTRODUCTION

Last decade has been characterized in education of electrical engineering for an overwhelming development of web-based software and/or CAD programs for low-cost simulations of technological phenomena [1,2]. Two positive consequences have been derived from this fact: firstly, budgets devoted to the acquisition of new laboratory equipment could be reduced -especially in recent engineering campuses-; and, secondly, subjects related to computer engineering have increased their presence in electric engineering syllabus. But also negative facts have appeared as drawbacks: on one hand, a high percentage of graduate students are not able to translate all the theoretical knowledge to real-world and, on the other hand, the academic formation in specialized areas of electrical engineering, such as high-frequency and microwaves, has decreased. This paper presents the development and adjustment of a low-profile laboratory for teaching high-frequency and microwave techniques in Electrical Engineering. As it was pointed-out in [3], special attention has to be paid to these laboratories, according to both the high cost of the electronic equipment and difficulties to achieve realistic designs and high-precision at these frequency ranges.

The high-frequency laboratory has to be useful for several courses of the Telecommunication and Electrical Engineering degree, all of them in the undergraduate last two semesters (the students are assumed to have a consistent knowledge of electromagnetic theory and analogical circuits and systems). The first of the courses to be taken is a basic introduction to microwave theory and techniques, including passive and active circuits design, as long as scattering (*S*) parameters analysis and measurement. Parallel to this subject, a second course is related to antenna theory, design and characterization, including radio-wave propagation theory. Finally, an advanced course on microwave circuit design, including circuit components of wireless transducers such as low-noise amplifiers (LNA), oscillators and mixers is also developed.

This paper is organized as follows. After this brief introduction, the two sets of experiences that have been developed for the laboratories are introduced in Sections II (microwave courses) and III (antennas and propagation course), respectively. Section IV discusses the competences that the students should develop after following the combined three proposed courses, and presents the main conclusions of this work.

II. MICROWAVE LABORATORY EXPERIENCES

The first three explained experiences (*II.A* to *II.C*) are oriented to the study of different characterization techniques and the involved instruments, while the last two ones (*II.D* and *II.E*) are useful to the microwave engineering process.

A. Two-port S Parameters Characterization with VNAs

One of the main parts of any elementary course on microwave circuits theory and design is the study of the *S* parameters [4], which overcome the problems that arise when applying the usual low-frequency characterization parameters (i. e., *Z*, *Y* or *H* parameters) to the microwave frequency range, where the voltage and current strongly depends on the reference position of the access transmission line. *S* parameters are based on power and phase measurements, which are measurable using standard coherent reception techniques. The students of Telecommunication and Electrical Engineering are used to these techniques and thus are able to fully understand the *S* parameters measurement.

In the laboratory, students learn how to use a *Vectorial Network Analyzer* (*VNA*), which is the most used instrument to characterize high-frequency circuits from a few *kHz* to over 100 GHz. To do so, it is essential to deal with two-port calibration techniques. Therefore, the students have to study and validate some of these techniques (such as *TOSM* – Thru/Open/Short/Match or *TRL* – *Thru/Reflect/Line*).

During the first of the courses developed on the microwave subject, the students characterize two-port passive networks,

This work has been partially supported by the University of Granada via Project PID-08-180.

and study their properties taking into account the scattering parameters theory. In the second course, active devices (microwave amplifiers) are characterized using the *VNA*: the dependence of *S* parameters on the polarization is studied, and stability analyses are performed.

B. Microwave Characterization with Spectrum Analyzers

The use of *VNA* to characterize two-port or, in general, multiport circuits, is usually restricted to linear applications, as this equipment is based on the measurement of the circuit behavior at a single frequency, which is swept to perform broadband characterization.

However, this involves that non-linear effects, such as harmonic appearance or intermodulation products, are not observable without specific modules or instruments that, in most cases, are quite expensive [5].

One of the possible alternatives is the development of home-made control software to perform non-linear measurement with *VNAs*. However, a simpler approach is to make use of a high-frequency signal generator and a spectrum analyzer, each of them connected to one of the ports of the device under test (*DUT*). In this way, the power at the input and output planes is known. This technique, apart from allowing the students to learn how to use both instruments, gives them the idea of the basis of the *VNA*, as they measure a magnitude proportional to the transmission *S* coefficient. Moreover, the necessity of a calibration tool will arise in a natural way, since the students identify the frequency-varying probe loss (here, low quality probes and connectors are used to enhance this fact).

C. Noise Measurement and Characterization

Noise is a fundamental parameter on telecommunication systems, but undergraduate students do not usually have the opportunity to handle with real noise measurements. This is the reason why a *noise figure analyzer* has been included in the high-frequency laboratory.

During the second course on high-frequency circuits, the student has the opportunity to measure real circuits noise figure, including passive and active devices, and comparing the results with those expected from the theory.

D. CAD Design of High-Frequency Passive and Active Circuits

The main objective of this work is to show a set of experiences that allow the students to have a comprehensive formation on high-frequency design and characterization. In this context, we do think that computer-aided design is extremely useful for circuit design and optimization and therefore should be considered in any high frequency laboratory.

There are several commercial tools able to simulate RF and microwave circuits. Most of them allow the integration of 3D or 2.5D electromagnetic simulations within block system design, where simple models for each circuit part are used. Common examples of this kind of packages are *Agilent Advanced Design System* (*ADS*) [6], *AWR Corp. Microwave Office* [7] or *Ansoft Designer* [8]. However, their correct use calls for an intense training that is not achievable in a one semester course. Moreover, only some of these codes are available in student versions, and these versions are usually truncated so that most of their functionality is missing.

As the solution of the Maxwell equations via numerical methods is necessary in the antenna design and optimization process, the CAD-aided design in the microwave laboratory has been centered on the model-based simulation of planar transmission lines. One good code based on transmission line models is *PUFF* [9]. This code was developed in the last 80's and it has been used for more than one decade in the academic environment. Its main advantages over the professional tools are:

1. It is more intuitive, as it allows the students to *see* the circuit they are simulating, in contrast to other model-based simulators.
2. Implemented models are simple but enough accurate for an introductory course.
3. It is a low-cost tool, in contrast with most of the commercial codes.

Following its example, we have developed *MWSim* [10], a model-based simulator. Its main differences with the *PUFF* code are: *i)* an updated to current standards graphic user interface, *ii)* a larger variety of microstrip models, performing more accurate results and allowing the comparison with other commercial tools, *iii)* an input/output format fully compatible with standard *Touchstone* (which allows the use of embedding and de-embedding techniques with VNA measurements and with electromagnetic simulators) and *iv)* it includes the possibility of exporting files into *Gerber* format [11]. The last option is of special importance as the students are able to export the geometry file of the designs and fabricate them using automatic milling machines, which is the objective of the experience IIE.

The students of the advanced course are encouraged to work with this tool and also with evaluation/student versions of commercial tools in order to compare the obtained results. With these comparisons, a twofold objective is tackled. First, the students get a better understanding and critical assessment on the models validity. And second, the use of the evaluation versions of commercial tools might be useful in their future professional life.

E. Microwave Passive Device Fabrication and Characterization

The engineering process in the designed laboratory does not stop on the design, simulation and optimization steps. In order to give the students the opportunity to build their prototypes, and characterize them by using the techniques they have already studied in experiences *II.A* to *II.C*, they are allowed to export the geometry of their designs into standard Gerber files, which can be fabricated using a milling machine. Thus, the laboratory has been equipped with the *LPKF* Protomat S62.

As the objective of the exercise is not to obtain professional prototypes, but to provide the students a general overview of the design to fabrication and characterization process, these designs are fabricated on Double-Sided Standard FR4 PCBs, which are quite cheap and allow well-working designs up to a few GHz [12]. Moreover, in this range of frequencies high-frequency milling tools are not necessary, and therefore the milling process becomes cheaper.

Fig. 2 shows a microstrip circuit (branch-line coupler) that was simulated with *MWSim*, exported to Gerber and fabricated using the milling machine. Although the objective of this paper is not to introduce the results of the comparison between measurements and simulated data, it is worth to say that a very good agreement is usually found between them [10]. From a didactic point of view, this helps the students to understand how the abstract concepts they theoretically study can be translated into practical circuits, which they can fabricate and measure.

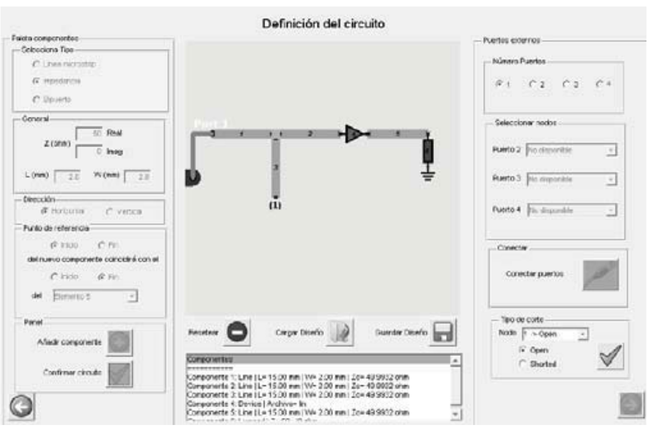

Figure 1. MWSim simulator: front-end user interface.

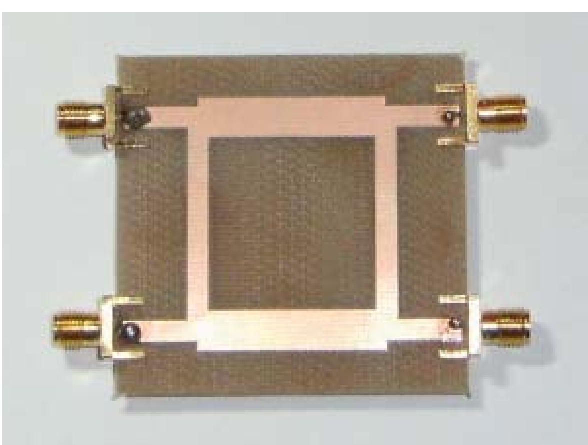

Figure 2. Microstrip circuit (branch-line copuler) designed with *MWSim* and fabricated with a milling machine using a double-side PCB and low-frequency mill tools.

III. ANTENNAS AND PROPAGATION EXPERIENCES

Experiences in this field are strongly related with those from Section II. Most of the experiments are performed in parallel with those described in Sections *II.A*, *II.B* and *II.D*, although more emphasis is made in the measurement and validation of one-port devices. Further, radiowave propagation and derivation of antenna parameters, and in some way the CAD design of antenna, constitute the new set of practical knowledge acquired by the students in this subject.

A. High-frequency Laboratory Equipment for One-port Measurements

Experiments related to this objective are focused in the use of the *Vectorial Network Analyzer* in one-port mode as well as the use of a *Spectrum Analyzer* with internal tracking generator as Scalar Network Analyzer. Additional efforts are made in this stage to perform measurements of the time-domain impulsive response of the antennas, as an alternative way to characterize the broadband and ultrawideband devices, matter of hot interest in the industry industry in applications related to both goniometry and impulsive radar fields [13]. Figure III shows a picture of the control panel of home-made software based on *LABVIEW* [14] and designed for time-domain characterization purposes.

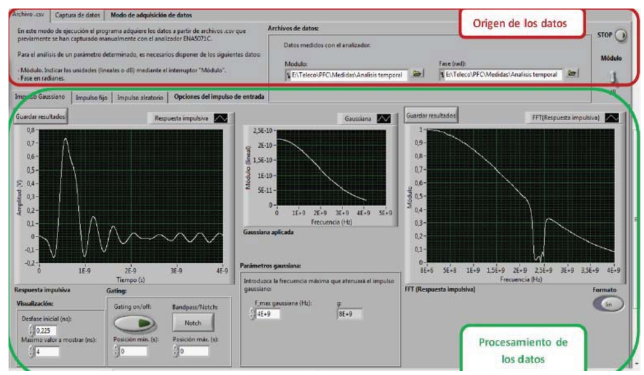

Figure 3. Software tool for the measurement of time-domain impulsive responses.

B. Practical Measurements of Antenna Parameters and Propagation Effects

Simple transmit/receive configurations can illustrate basic effects -mainly associated to antenna properties and radiowave propagation- which are involved in real-world wireless communications. Most of the available educational kits at affordable prices are devoted to this purpose, being the dimension of the laboratory a critical parameter in this choice. In our case a commercial X-Band antenna kit was chosen, being able to illustrate the effects in a real anechoic chamber related with the positioning and calibration of the system.

C. Mesurements of In-site Radiowave Spectrum

Acting as a complementary experience to *III.B*, the students should be set to perform in-site electromagnetic radiation measurements. Then, the first step is to guide them into the identification of radiowave signals for a specific place, which is done not only by looking at specific ranges of electromagnetic spectra, e. g. WiFI 802.11 emissions, but also by consulting the public information provided by Spanish Government related to the allowance of the emissions for the different TV and radiochannels [15]. Once done, they further compare measurements by using calibrated professional equipment for radiowave measurements and radioelectrical planning, and by using a set-up of laboratory equipment for non-calibrated measurements of radio and microwave spectra – basically a log-periodic array of antennas connected to a spectrum analyzer. Excellent agreement is achieved for identification purposes, but some considerations about the level of the received signals are arisen from the use of non-calibrated equipment.

D. CAD of High Frequency Wireless Communications

This experience presents different alternatives to the computer-aided design of antennas. Rather than focus in aspects related to particular software, these experiences are oriented to show the theoretical basis of commercial packages [16], and the limitations presented for carrying out the designs to prototypes. Hence, special attention is paid to the physical geometry of the antenna as a major factor for the choice between the high-number of CAD for antenna design, and some time is devoted to the limited number of wireless and radiopropagation tools available in the market.

E. Fabrication and Measurement of Antennas

As a final step, the manufacturing of planar and microstrip antennas, as well as the measurement of their radiation parameters, can be made by employing high-frequency milling machine and SMD tools, starting from CAD student's simulations. This stage is understood as a final evaluation of the maturity of the student, and lead to results as shown in Figure 4.

Figure 4. Example of a 2.4 GHz patch antenna.

IV. Discussion and Conclusions

The experiences that have been presented in Sections II and III have been developed during various semesters, and a continuous effort is being made to provide the students the best possible education in the subjects related to microwave and radiofrequency guided and wireless communications. Working together, efforts have been summed to have a laboratory as functional as possible.

The laboratory contains a couple of two-port VNAs, with their corresponding calibration kits and RF probes, six couples of microwave generators and spectrum analyzers, a noise figure analyzer, a milling machine, and a PC for every student.

With this equipment, during two semesters, the students are able to work in the laboratory under an expert supervision. These are the main abilities they acquire during this period:

1. Operation of specific high-frequency equipment. Specifically, they learn how to use the VNAs to characterize both multiport circuits and monoport ones (antenna), including the appropriate calibration techniques for each of them.
2. Simulation of microwave guided and wireless circuits, including both commercial and home-made simulators, and making use of both electromagnetic simulation schemes and model-based tools.
3. In-depth knowledge of the full “design to characterization” RF engineering process, including the simulation, optimization and fabrication steps.

Acknowledgment

F. G. Ruiz, M. F. Pantoja and S. G. García would like to thank Prof. Rafael Gómez and Prof. Amelia Rubio Bretones for their help in the development of antenna experiences. F. G. Ruiz and N. Rodríguez would also like to thank the rest of the members from the PID-08-180 project. Finally, the collaboration of D. Coronado, F. M. Gaitán, M. Calmaestra and J. Puertas is also acknowledged.

***Abstract*—Remote laboratories are the natural solution in order to perform real experimentation under e-learning tools. Nevertheless these tools are the result of the research developed by the universities to cover their own needs without having in consideration the deployment of this technology by other institutions. This paper presents a hw prototype for a Remote Lab for microcontrollers that tries to solve these problems contributing new possibilities from the commercial and professional point of view.**

Remote laboratory; e-learning platform; microcontrollers

I. Introduction

The advantages offered by e-learning platforms have caused important changes in education. However certain technical studies require the use of laboratories where develop real experiments with a greater didactic capacity than simulators [1].

Nowadays, the use of Remote Laboratories in universities is extending widely. A Remote Lab is a combination of hardware and software which allows a student to complete lab assignments remotely, e.g. from his home, just as if she was present in a laboratory. The student remotely controls the devices in the laboratory through a web interface, and monitors the outputs resulted from her interaction through a WebCam, a data file or using other electronic measuring instruments like oscilloscope or multimeter.

II. Actual Scenario

Since the end of the 20th century, Remote Labs fill a very active research field in e-learning, and during the last five years the number of universities working on new Remote Labs has been multiplied. However, most of these new solutions do not match a professional level.

The fact that very few projects have been exported to other universities is just a proof of this statement. The most remarkable examples of this would be the VISIR Project [2] (BTH-Sweden) and the iLabs (MIT – USA) [3]. Another proof is that there is no market of commercial Remote Laboratories, neither a company supporting them, except National Instruments (NI).

The technical reasons behind this lack of professional or commercial projects in remote experimentation are the deficiencies of the software and hardware underneath.

From the point of view of the software, many Remote Labs have been developed without matching even minimum requirements. For instance, in a research asking 10 researchers in remote experimentation (MIT, BTH, EPFL, etc.) what features were more important for the development of a Remote Lab, the preferred ones were those related with software aspects (security, cross-platform, supported web browsers, etc.) instead of those related with hardware aspects (frequency, accuracy, etc.).

This shortage can only be addressed by designing the Remote Laboratory focusing appropriately on the software design and technologies used –as in the WebLab-Deusto Project using Web 2.0 technologies [4] (U.Deusto, Spain)–, or designing the Remote Laboratory on top of a LMS (Moodle, .LRN, Sakai, etc.) that will provide many transversal aspects of any Remote Laboratory.

On the other side, from the hardware viewpoint, the biggest problem is that the experiment is not autonomous, so part of its basic functionality is tightly coupled to the software side. It is usually difficult to isolate the hardware from the software providing the experiment, so it is not possible to unstuck the hardware side of the project and deploy it on other platform (such as an LMS) easily.

The users of a Remote Lab are the teachers and the students, and also the university. So a Remote Lab must be focused on teachers and students. Usually the teachers' requirements are forgotten by the researchers (because they usually will be the teachers). The teachers need a tool easy to install, to use, to manage, etc., more or less as Moodle is for them. The question is, are the Remote Labs easy to deploy? The answer is no, attending to the lack of deployed or commercialized Remote Laboratories.

Imagine that a high school want to install a Remote Laboratory, is it possible? Not today

The authors would like to acknowledge to the Spanish Science and Innovation Ministry for the support in the project TIN2008-06083-C03/TSI "s-Labs – Integración de Servicios Abiertos para Laboratorios Remotos y Virtuales Distribuidos"

III. Previous Approximation

Due to the scenario described in the previous paragraph, during 2008 the Faculty of Engineering of the University of Deusto developed a Remote Laboratory in order to achieve two targets: get a low cost and easy to install platform [5].

After analyzing the architectures adopted in most known Remote Laboratories we come to the conclusion that all of them were based on a robust server (or more of one in some cases) entrusted of carrying out the tasks of interaction with the experiment and with the user.

The software installed in the server, designed generally in proportion to the particular needs of the developer university, impedes the deployment of the Remote Laboratory in other infrastructures and increases the cost of the final system. Therefore it is logical to think that eliminating the server of the architecture obtains a solution easier to install and certainly more economic.

Advances experienced by 8 bits microcontrollers during the last years allows to have low cost microservers where implement the tasks carried out previously by the computers. The selected microcontroller was the PIC18F97J60 launched by Microchip®, which includes an Ethernet controller inside as well as an incredible performance and diversity of resources to be a microcontroller of 8 bits.

Specifically, the WebLab-DEUSTO-PIC V0.1 is based on a system that implements two PIC18F97J60 microcontrollers that play different roles: Experiment and Server. The first one will run the program uploaded by the student, whereas the second one, the microserver, will allow the client to interact with the experiment: Upload the file to test, passwords control, inputs/outputs, etc. The microcontroller entrusted to execute the program created by the student is programmed with a bootloader, that is able to allocate in the program memory and execute a hex file received by tftp protocol. (“Fig. 1”)

Figure 1. WebLab-DEUSTO-PIC v0.1 prototype

Student connects to the microserver using any web browser, log in with a password and once he is authorized he just can select the file that contains the program to test and upload it to the Remote Laboratory through a simple web page.

The file then is sent through simple tftp protocol to the microcontroller in charge of the experiment, which interrupts the execution of the previously loaded program when the reception of an UDP packet is detected, and the resident bootloader loads new hexadecimal file in the program memory of the microcontroller. Then new program is executed by the microcontroller until it is replaced with other one by the same or other student. The student that uploads a file is automatically redirected to other web page (“Fig. 2”), where he can experiment changing values of the inputs and monitoring the resultant outputs.

The employment of microservers contributes to the system two clear advantages:

- The cost of the complete system is lower than 200€.
- Being both cards, experiment and microserver compatible with the DHCP protocol, the installation of the system in any infrastructure is so simple as to power both cards and to connect them to the Ethernet network being accessible from moment the cards acquire IP addresses. This is what we name a Plug&Play installation.

In the other hand, the limitations imposed by the microservers determine certain functional aspects of the Remote Laboratory:

- The limited performance of the selected microcontroller generates problems in moments of concurrent access.
- Tasks of management (administration of the users' queue, authentication, etc.) meet limited by the protocols included in the TCP/IP stack implemented by the microcontroller manufacturer.
- Being impossible to use a Webcam the monitoring of the outputs takes place across a web page losing realism in the development of the experiment.
- The resultant Remote Laboratory is not extensible to other laboratories further tan microcontrollers (CPLD, FPGA, etc.).
- It turns out to be very complicated to integrate the laboratory inside any e-learning platform.

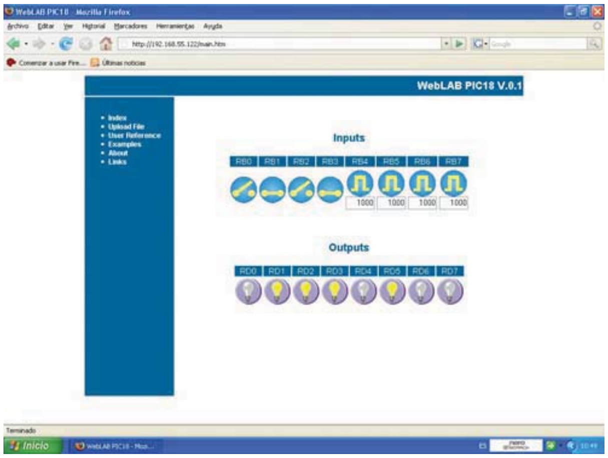

Figure 2. Web page for interacting with the experiment

Figure 3. WebLAB-DEUSTO-PIC V2.0

IV. Proposed Solution

In the Faculty of Engineering of the University of Deusto play the role of users and developers of Remote Laboratories. This double point of view has allowed us to assure us on the one hand of the enormous didactic capacity of these tools as of the difficulty of its design and development as well as of the integration in an existing infrastructure like it can be the network and educative process of one university or school. This difficulty practically limits the use of Remote Laboratories to institutions with capacity for the research: universities. For this motive we have overturned our efforts in the design of a platform looking for a massive implantation in diverse educational centers on the basis of three fundaments:

- The Remote Laboratory must be a stable system. In order that the teacher considers the Remote Laboratory as any other didactic tool it must cause the minimal problems. In many occasions, the Remote Laboratories never pass from the state of prototype and the hardware is capable to external aspects like that a wire is disconnected because it hasn't a definitive connector or that the Webcam goes out of focus on not having been properly anchored. For these reasons the Remote Laboratory must have a professional appearance and the whole interaction between the teacher and the system must be to user´s level making independent the tasks of developer and teacher completely. ("Fig. 3")
- The Remote Laboratory must be adaptable. The deployment of the system does not have to provoke a substantial change in the system of learning. It must adapt to the E-Learning platforms used by every educational center joining as one more resource inside it. Compatibility with Moodle, .LRN, Sakai or other learning platforms must be implemented.
- The Remote Laboratory must be extensible. Although it´s been designed for teaching PIC microcontrollers, the architecture must support any other laboratory as other microcontrollers (Atmel, Freescale, etc.), DSP, CPLD, FPGA or any other programmable device.

V. Architecture Of WebLab-DEUSTO-PIC v2.0

In order to achieve that the laboratory is extensible it has divided in the following parts: ("Fig. 4")

A. *Experiment board*

This board contains a microcontroller PIC18F97J60 on which the student will program the developed project. In this system the programming is carried out across the Ethernet network through a bootloader that receives the content to program in the memory of the microcontroller by tftp protocol. Being independent of the inputs and outputs it can be replaced for other including other device as a CPLD, a FPGA or p. e. an Atmel µcontroller. Although it is convenient, in order to facilitate the assembling, it is not necessary to program the device through a TCP/IP protocol being possible to access to the USB ports of the server.

B. *Inputs board*

This board allows the student to manipulate the signals received by the experiment board. This board is also based in a PIC18F97J60 that receives from the interactive web page, through POST commands, the orders to set/reset digital inputs, change the value of analog inputs, receive serial data through UART port or any other kind of signal according to the nature of the experiment.

C. *Outputs board*

This board allows the student to watch, through the Internet camera, the outputs of the experiment. It can be designed customized for the experiment including most appropriate output peripherals. In WebLab-DEUSTO-PIC V2.0 it includes next elements:

- Two alphanumeric 2x16 LCD, one for experiment with the proper LCD and other one to visualize the information sent across the UART port.
- 8 LEDs directly connected to port B to manipulate digital outputs.

- 8 LEDs connected through an I^2C port expander (MCP23008) to experiment with Inter-Integrate Circuit Bus.
- 8 LEDs connected through a SPI port expander (MCP23S08) to experiment with Serial Peripheral Interface Bus.
- Futaba continuous rotation servo connected through a driver to experiment with PWM.

D. DCS-5220 wireless motorized pan/tilt network camera

Internet camera is placed over the outputs board allowing the student to watch the behavior of the experiment. Due to the size of the Outputs Card, it is convenient that the student can manage the camera focusing the part of the board involved in his own experiment. Interactive web page includes a control to move the camera.

E. Fit-pc2 server

The last advances in low format computers allow to arrange a powerful computer with small dimensions and low cost. New Intel Athom based computers make the employment of microservers slightly efficient being able to acquire robust servers, compatible with operating systems like Windows 7® or Linux, that facilitate the development and the integration of the Remote Laboratory with similar dimensions and price. In WebLab-DEUSTO-PIC V2.0 a fit-pc2 (“Fig. 4”) by Compulab has been incorporated to arrange all the management tasks needed by the experiment. Characteristics of this device are mentioned in “*Table I”*. Functions to be done by this computer depend on the operational mode selected as is explained later.

TABLE I. FIT-PC2 SPECIFICATIONS

Features	
CPU	Intel Atom Z530 1.6GHz
Chipset	Intel US15W SCH
Memory	1GB DDR2-533 on-board
Storage	160Gb 2.5″ SATA HDD
Display	Intel GMA500 graphics acceleration DVI Digital output up to 1920 x 1200
Networking	1000 BaseT Ethernet 802.11g WLAN
USB	6 USB 2.0 High Speed ports
IR	Programmable consumer IR receiver
Mechanical and Environmental	
Dimensions	101 x 115 x 27 mm
Case	100% aluminum die cast body
Weight	370 grams / 13 ounces – including hard disk
Power Consumption	6W at low CPU load <7W at 1080p H.264 playback 8W at full CPU load <1W at standby

Figure 4. Low format computer “fit-pc2”

F. 5 Port Fast Ethernet Switch

To simplify the connection of all the elements with Ethernet connectivity to the network of the infrastructure the system has internally a Switch that interconnects them offering an only one RJ45 connector for its installation

G. Power Supply

25W Switching Power Supply, 5V/2,5A and 12V/1A Dual Output Voltage. Other output voltages and output models needed from other experiments are available with the same dimensions.

To decouple the hardware from the software allows to perform several experiments of different nature changing only two boards involved in the experiment: *Experiment board*, including one containing selected device and the logic to program it and *Outputs board* selecting the proper output peripherals for the experiment. (“Fig. 5”)

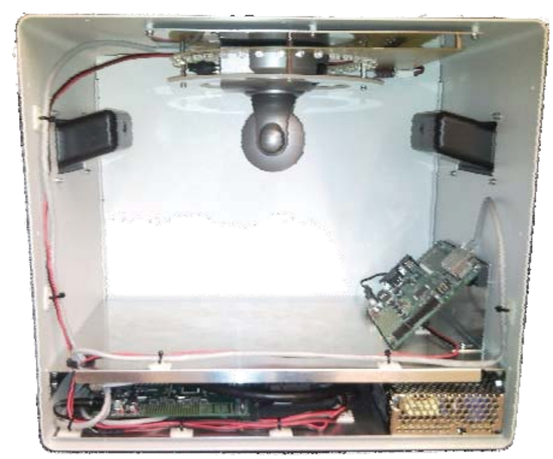

Figure 5. Transversal section of WebLAB-DEUSTO PIC V2.0

VI. FUNCTIONAL CHARACTERISTICS OF WEBLAB-DEUSTO-PIC V2.0

To facilitate the deployment of this Remote Laboratory adjusting to the needs of any educational center the WebLab-DEUSTO-PIC V2.0 can work according to 4 different operational modes:

- ***Plug&Play Operational mode:*** This is the stand alone mode. None other element is required to perform the experiment. The inside computer realizes all administrative tasks: user authentication, user´s queue management and log files generation so as the tasks related with the experiment: program the experiment board with the user hexadecimal file, serve the interactive web page and order to the inputs board all changes demanded by the user. "Fig. 6" shows a snapshot of the interactive web page working in this operational mode. Taking advantage of the high performance provided for fit-pc2 included WebLab-DEUSTO-PIC V2.0 provides a completely autonomous Remote Laboratory with a high degree of integration on the part of the student.

- ***Integrated on WebLab-DEUSTO platform:*** The award-winning WebLab-Deusto project provides a web-based, experiment-agnostic, scalable software infrastructure which permits the University of Deusto to offer several laboratories to its students through the internet [6]. This platform is the result of years of research and provides perfect functionality for the development of remote experiments. The architecture is based in a central server in charge of all the management tasks and a microserver per experiment giving support to the communication with the specific hardware. Microserver task are implemented on the fit-pc2 simplifying integration with the platform. Concurrent similar experiments are allowed reducing significantly waiting times of the students, one of the constraints in the use of Remote Laboratory in the same way that happens in on site ones. (“Fig. 7”)

Figure 6. WebLab-DEUSTO-PIC v2.0 interactive web page.

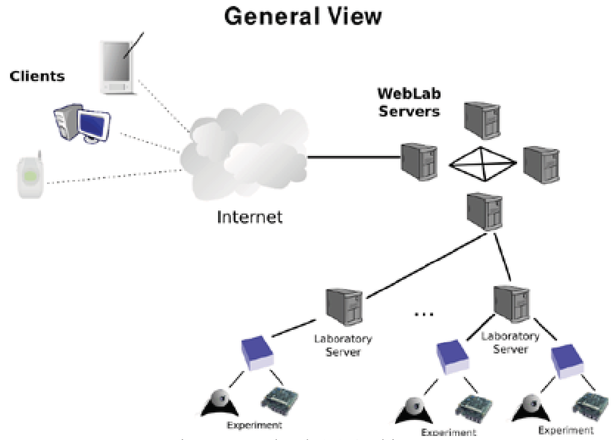

Figure 7. WebLab 3.0 Architecture

- ***Integrated in a learning platform:*** Employment of learning management systems (LMS) gains acceptance amongst educational institutions and their students. Integrate a Remote Laboratory on the institutional platform as one more resource offered improves the satisfaction obtained by the student simplifying the task of the teacher. WebLab-DEUSTO-PIC v2.0 is in process of being integrated on Moodle. A proper integration must allow include an experiment as if it were more available activity such as a questionnaire. Tasks of user authentication, storage of files uploaded by students and user´s queue management must tu be performed by Moodle while the tasks of the experiment shall run on the fit-pc2. Due to the large number and diversity of learning platforms is difficult implement a solution for various systems, but the use of standards and the experience acquired with Moodle must simplify the integration on other LMS as .LRN or Sakai [7].

- ***Ready for xLAB integration:*** The University of Deusto is actively involved in developing the new platform for Remote Laboratories “xLab” in collaboration with the Massachusetts Institute of Technology (MIT) pretending that the WebLab-DEUSTO-PIC v2.0 is one of the first laboratories offered under the same [8].

Regardless of the operational mode chosen, the hardware installation process is simple. All elements included: the outputs board, the inputs board, the experiment board, and internet camera support an announce protocol that provides access to their IP addresses in a simple manner. When the WebLab-DEUSTO-PIC v2.0 is plugged on the institutional network, the inside computer detects each device connected to the lab network and saves in one xml file the IP addresses assigned to each device. Simply configure the inside computer to access the full experiment.

In addition in any operational mode the process of interaction is the same:

- The authorized student generates a binary file using preferred development environment (for example MPLAB IDE). The process of editing and assembling the program is intentionally removed from the laboratory allowing the student to use desired development tool and programming language in each moment
- Student connects to the Remote Lab waiting for his or her turn in case other students are using the lab. System manages user´s queue trying to minimize waiting periods.
- When the student takes control of the lab via a web page selects the file to program the PIC microcontroller included in the experiment board. The file is sent through tftp protocol using the bootloader included preprogrammed in the microcontroller. The functionality of the bootloader is easy, after a reset the program waits 5 seconds to receive a binary file through tftp. If within that period, file is not received bootloader runs the last program stored, however if it receives a file compatible with the microcontroller, content is stored in program memory and bootloader launches the execution of the new program. The system should cause a reset in the experiment board before sending the file tftp. The reset is generated by the inputs board when receives a RESET POST command from the system.
- Automatically, after PIC is programmed system opens the interactive web page that allows the user to check the operation of the program. For 60 seconds (obviously timeout is configurable according with the experiment), the student can modify the value of the inputs from this web as seen on "Fig. 6" and monitor the result through the internet camera focusing the outputs board. Currently the interactive page allows control of 5 digital inputs whose value can be set or reset, three digital inputs that are activated during a period specified in milliseconds, two analog inputs whose value is selected through a list and allows the sending of a string through the asynchronous serial port (UART) by means of a text field.
- After this time, student is automatically asked to be relocated on the bottom of the user´s queue.

VII. Deployment of the WebLab-DEUSTO-PIC v2.0 on a Subject

Since the development of Remote Laboratory WebLab-DEUSTO-PIC v2.0 has been delayed until early November 2009 his employment in a real subject was not conducted until the second semester of course 2009-2010. The first course that will use this resource is "Digital Electronic Systems" belonging to the second year of the degree in Telecommunication Engineering in the Faculty of Engineering, University of Deusto.

This experience will determine the satisfaction of the students and teacher as a result of using the system. The teacher of the selected course has not participated in developing the system beyond the requirements analysis.

Based on the results obtained in this pilot, from the next academic year WebLab- DEUSTO -PIC v2.0 will be deployed on other subjects of the same nature.

VIII. Conclusions and future

Main contributions of the presented WebLab-DEUSTO-PIC are focused in improving three fundamental characteristics in a remote laboratory: stability, adaptability and extensibility. The employment of the system in a real subject during the second semester of the course 2009-2010 will serve to measure the improvement with regard to other remote laboratories used previously.

In the near future work will be focussed on next objectives:

- Integrate the system in learning platforms type Moodle.
- Implement more units to study the improvement in student satisfaction having several similar laboratories concurrently with the consequent decrease in waiting times.
- Integrate new devices (DSP, CPLD, etc.) over the designed platform.

fgarofan@xtec.cat

Abstract— **iLabRS is a remote laboratory developed in Telecom BCN, the Telecom and Electronics Engineering School of the UPC with the key participation of a Secondary Education Technology teacher. Students and teachers can access to real experiments in the electronics and physics areas using a web browser. The remote experiments have been designed to partially cover the technology curriculum in the last two high school years with a triple goal: (1) to enrich the set of laboratory experiences available in High Schools, (2) to provide a clear example of the possibilities of internet-based technologies and (3) to promote the interaction between University and Secondary Education. Currently, there are 13 different experiments available. A pilot evaluation experience was carried out, in collaboration with 7 High Schools and around 100 students participating. In the experience assessment, the students gave a mark of 3.8/5 and the teachers of 4.4/5.**

Keywords- Remote laboratory; Secondary Education; Student engagement.

I. Introduction

Engineering studies, and more specifically, Information and Communication Technologies (ICT) related higher education studies have suffered a decrease in the incoming students from Secondary Education in the last years. Several initiatives are being carried out, mainly in the western countries, to promote the technological and engineering vocations. In ETSETB-Telecom BCN, the Telecom and Electronics Engineering School of Universitat Politècnica de Catalunya (UPC), placed in Barcelona, an existing modular remote laboratory platform [1] has been adapted to provide remote access to real experiments to Secondary Education students, as a way to increase their technological knowledge and skills but also to promote the interaction between the Secondary Education students and teachers and the University.

Remote laboratories are usually developed to enhance the conventional educational experiences and to optimize the use of resources [2], [3]. Leaving aside virtual laboratories based only on simulation, there is a considerable amount of remote laboratories that provide real-time access to real instruments. There are educational research lines devoted to the study of this topic [4]. Most of the remote labs for engineering education are in control [5],[6],[7] and electronics or circuit theory [8],[9],[10] areas. A good review of developments in the systems engineering area can be found in [11]. The aim of remote laboratories could be to provide complementary learning tools but also to provide facilities to access to big or singular equipments [12] or even to fully implement the laboratory activities [13]. Two literature reviews can be found in [14] and [15].

Almost all remote laboratories which have been reported have been designed and implemented to be used in the University frame. Meanwhile, Primary and secondary school students and teachers have access to a vast amount of internet-based resources. In our knowledge, almost all of them are virtual demonstrators, which are usually based on Java applets or flash animations, and very few of them are based on remote laboratories with real experiments [16], [17].

The remote laboratory described in this communication was initially designed to fulfill the needs of an advanced course in Electronics Engineering. However, it has been adapted to provide formative activities to Secondary School students. It has been possible thanks to the collaboration between the Telecom BCN staff, which includes our faculties, granted students and the IT staff, and Francesc Garófano, a Secondary Education teacher that spent a full sabbatical year in the development of both technical and didactical aspects of the remote laboratory.

In this communication we will mainly describe the non reported pilot experience that was carried out in 2008 with seven High Schools, involving around 100 students.

Nowadays, work is focused on developing new experiments, building more replicas of existing experiments and designing a complete software application to manage access to resources in terms of organization, security and accessibility.

II. Remote laboratory

iLabRS has been built over our custom modular platform [1] to develop remote laboratories in the instrumentation and sensors field. It is based on a main board that one of its functionalities is to provide a custom acquisition system around an Ethernet-capable microcontroller. The specific experiment circuit boards (10x10 cm) are connected to the corresponding main board in a sandwich structure (Figure 1).

Figure 1. A main board with the experiment board 2 connected on its top. It implements a configurable linear power supply.

The main board has a single 5V input power supply and provides +/- 5V to the daughter board. The connection between both cards also include 4 A/D and D/A channels, 8 I/O bits and a selectable serial bus (SPI/I2C). iLabRS structure consists of several main boards, each of them with its own IP address, connected into a LAN through a switch with a dedicated server. This server is in charge of running the NI - LabView programs which implement the user interface and control. Teachers or students can perform experiments using a web browser to access to the iLabRS web site (http://ilabrs.etsetb.upc.edu), which contains didactic materials for each experiment and also the url to the LabView remote panel (Figure 2) which gives the control of the experiment.

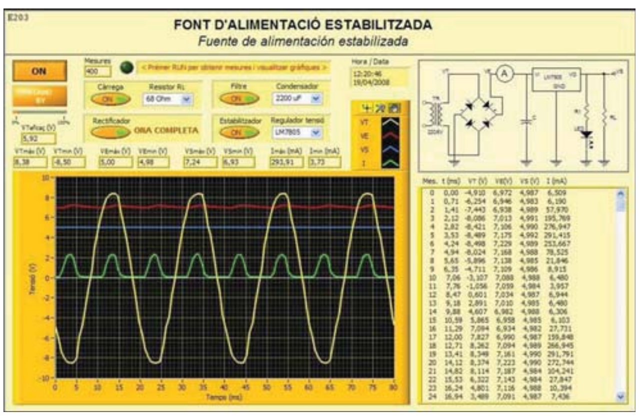

Figure 2. Remote panel corresponding to an experiment which deals with a regulated power supply. The students can see the schematic with the voltage and current symbols and read their instantaneous and time series. Several parameters (filter capacitor, load resistor) can be changed and the circuit configuration (half/full wave rectifier, insert regulator) can be selected.

At this time, up to 13 remote experiments corresponding to the Technology curricula of the two last High School years can be performed. Figure 3 shows the 10 boards that implement these experiments. There are three boards that can implement several experiments each one, and which are replicated three times. Experiments have been replicated because usually in High Schools all the students are moved to the computer room to perform a guided session by the teacher around one or two remote experiments while in the university courses are mainly used by the individual students from their homes. An additional board (left of the figure 3) implements a singular experiment (strain - stress measurement). The currently available experiments list is the following:

- Board 1: I/V characteristic curve of a resistor, silicon diode, germanium diode, LED and zener diode, all of them both in direct and inverse polarization. The experiment consists of performing a voltage sweep from -5V to 5V through a resistor. Also includes a capacitor's charge and discharge process and time constant RC concept.
- Board 2: Basic linear power supply circuit. Components are a full/half wave diode rectifier, capacitor filter and a linear voltage regulator. Activities involve voltage and current measurements for different load resistor and filter capacitor values to determine ripple, linear regulator drop-out,..
- Board 3: Implements a basic transistor circuit characterization. It is possible to measure input and output characteristics, load line, operating point and gain. Input and output circuit resistors and voltages can be changed at any time and the device under test also can be switched between a signal and a power transistor.
- Board 4: Strain-stress characteristic of a polymer sample. The experiment controls a linear stepper motor and measures the output signal of a displacement and a force sensor. The motor can be operated manually or set in an automatic mode to obtain the up and down strain-stress characteristics of the sample. Proposed students activities consist of determining force constant using Hooke's law and determining hystheresis among others.

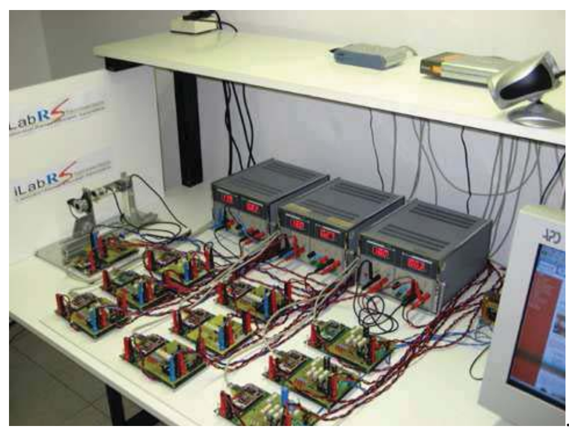

Figure 3. Remote laboratory current set of boards. It includes 10 main boards and 3 replica of 3 different experiment boards performing 12 different experiments on basic electronics plus a singular one (left) which measures the strain-stress characteristic of a polymer sample.

Once a given experiment is selected in the web page, the user gets the remote panel on his computer and takes the control of the LabView application (Vi, Virtual instrument) associated to this specific replica of the experiment. At the beginning, the Vi configures the board to select the circuit by switching relays which is transparent to the user. Then, the user selects the parameter values and circuit configuration (e.g. in the regulated power supply circuit, the filter capacitor and load resistor can be changed between three values each, and the circuit configuration (half/full wave rectifier, regulator inserted or not) can be selected). The main circuit node's signals are depicted in the schematic included in the panel, which can be monitored in three ways: instantaneous value, time series and graphical representation. In the first view of the panel, all signals are represented together. The individual signals can be seen more detailed (autoscaled) by scrolling the panel.

The didactic experiment guides include several documents: the experiment background review, the panel's user manual, the suggested set-up and a set of questions that student should answer using the obtained results. Usually, the student should paste these data to spreadsheet program to perform calculations (e.g. power from voltage and current, determination of slopes, etc.). At the end of the didactic guide, there is a set of additional questions.

III. PILOT EXPERIENCE

Seven High Schools from around Catalonia were selected and their Technology teachers were contacted. The amount of students of their Technology subjects in the two last years of High School was around 100. All of them were invited to visit the physical laboratory that supports the remote experiments in a specific Telecom BCN School Open Doors day. This was a good activity, useful not only to increase the feeling of reality of the remote lab but also to show the students the School laboratories and facilities and even the research activities. During the last term of year 2008, they performed classes based on the remote lab, mainly using two modalities: taking the whole group to the computer room and carrying out the experiences described in the didactic guides or using the experiments as demonstrators in the classroom using a projector (Figure 4).

Figure 4. Students using the remote lab as demonstrator in the classroom in their High School

Not all the High Schools performed all the experiments, but they were asked to present the reports they made to a contest. The first, second and third winners received an award consisting in a technological gadget.

At the end of the term, the teachers and students were asked to fill a survey through a web page. The survey contained eight questions with a quantitative answer (1-low to 5-high) and five questions with an open, written answer. Table I shows the marks given by the first 8 questions. The experience was well valued, mainly by the teaching staff, as it could be expected.

TABLE I. RESULTS OF THE SURVEY

#	Question	Std.	Teach.
1	Ease of use	3,4	4,3
2	Appreciation of the experiments	3,7	4,3
3	Appreciation of the documentation	3,8	4,5
4	Is this resource useful to improve the experimental learning?	4,0	4,5
5	Appreciation of the remote lab as an innovative resource	4,0	4,5
6	Perspectives of future	4,0	4,5
7	Personal satisfaction	3,6	4,5
8	Global appreciation of the remote lab	3,9	4,5
	Average	3,8	4,45

Concerning the qualitative answer questions, their responses were grouped by similarity. The most representatives are the following:

Q1. Which is the aspect that you consider more positive and practical of the remote lab?

- Being able to work in teams in a different way than usual.
- Being able to see the graphical results in real time during the class.
- The feeling that what you are simulating is really there and the fact that is not virtual, nor calculations.

Q2. Which is the aspect that you consider more negative and less effective of the remote lab?

- The limitation of a single simultaneous user in some experiments.
- The fact that the pilot experience has been performed at a point in the course which was not the most suitable.
- The limitation of getting only a limited set of values of a few variables.

Q3. Which aspects can be improved?

- An increase in the number if simultaneous users.
- The experiments should have a higher number of parameters to be changed.

- The aesthetical aspects of the panels, the availability of the lab, the extent of the documentation.

Q4. Suggest please new experiments:

- Digital electronics and experiments on other technological fields (mechanics, hydraulics, robotics, magnetism…).
- Experiments with continuous changes in the parameter values, i.e. not only a few discrete values for the resistors.
- Measurement of voltages and currents in more complex DC circuits. AC and transient measurements in RLC circuits.

Q5. Global comments:

- The experience has been positive both for the students and teachers. It has improved the student's attitude.
- It has helped to reinforce the theoretical explanations.
- The experience is innovative and should be improved and augmented in the future

IV. Current work

Several tasks have been carried out this last year and a lot more are under development. The whole laboratory was moved to a more suitable location and the software was transferred to a new and more powerful server. An IP camera is connected in order to have a visual confirmation of the experiences, even when the only mobile part is the strain-stress experiment. At the beginning of year 2009, the lab received a grant from the Catalan government, together with other experiences that should increase the scientific and technologic vocations. Thanks to that, new experiments are being developed: a robotic arm whose movements can be programmed in real time or following a sequence, an hexapod robot based on shape memory alloy (*Stiquito*), an experiment to measure the efficiency of different lamps, an experiment to visualize the spectra of different light sources, … Also more replicas (5) of the existing experiments are being built. Given that users can hold the panel's control for several minutes but in fact the real usage of the hardware resource is short (usually of around 10s periods), we are developing "virtual replicas", which allow sharing a given board between several panels, using concurrence and event control.

More complete software it is under design to manage the secure access and the resource organization for large groups. It also includes a resource booking tool to allow teachers to book a full set of experiments for a given slot of time. In addition, there is a control layer which manages the dynamic creation of remote panels under demand and the dynamic assignment of hardware boards to these panels. At this time, iLabRS is currently working and several High Schools are using it. A second promotion campaign will be carried out in January 2010, when the current improvements are planned to be finished, tested and validated.

V. Conclusions

An existing, modular platform to build remote laboratories at the Telecom BCN Engineering School has been used to implement a remote laboratory oriented to Secondary School Technology subjects. The main aim was to increase their technological knowledge and skills but also to promote the interaction between the Secondary Education students and teachers and the University. Thirteen different experiments were implemented and a pilot test was carried out with around 100 students from 7 High Schools. The results have allowed us to face a second phase, with improvements in both the experiments and the control software. The users' evaluation of the experience was clearly satisfactory.

Acknowledgment

Francesc Garófano has devoted a sabbatical year paid by the Education Department of Generalitat de Catalunya to develop this project. The second phase of the project has a grant from EnginyCAT project, SOC-FSE. The authors wish to acknowledge all people that have worked in this project and the teachers and students who have taken part in the pilot experience.

Abstract—**The present work describes the implementation of a new remote lab, SecondLab, that allows students to control a microbot from Second Life. SecondLab works over WebLab-Deusto, the remote lab of the University of Deusto, giving the students the chance to work with real experiments from a social 3D-based immersive environment. This approach places the remote lab closer to the students, trying this way to increase their motivation to study science and engineering.**

Remote experimentation; Second Life; e-Learning

I. Introduction

The new learning trends suggest both entertainment and highly immersive environments as a way to achieve an effective learning process. In particular, socialware and game-like implementations are presented as attention-captive solutions applied to virtual education [1]. The recently published research from the Massachusetts Institute of Technology focused on Physics experiments is a commendable example on this direction [2].

The present work follows this line proposing a tool that can contribute to solve the current decrease of enrollments in scientific and engineering-related degrees. To achieve this purpose, SecondLab takes advantage of the technical possibilities of remote labs and the increase of popularity of social immersive environments among teenagers.

The present paper is structured in two main sections. Section II first shows an overview of the projects involved in the design, while Section III describes the implemented solution from a technical point of view. The research finishes in Section IV with the conclusions and future plans.

II. Background Components

The aim of this project is to offer an attractive electronic experiment to be used from a virtual 3D environment, taking advantage of other projects with different well-defined goals. Pursuing this aim, the research has basically involved an integration effort. The three components which SecondLab is based on are WebLab-Deusto, Second Life and the SecBot microbot (see Fig. 1).

The authors would like to acknowledge to the Spanish Science and Innovation Ministry for the support in the project TIN2008-06083-C03/TSI "s-Labs – Integración de Servicios Abiertos para Laboratorios Remotos y Virtuales Distribuidos" and to the Regional Government of the Basque Country for the support in the project SAIOTEK S-PE08FD03.

Figure 1: The three background components

A. *WebLab-Deusto*

WebLab-Deusto [3] is the remote lab of the University of Deusto, which makes possible to offer real experiments to a certain group of users through any computer network, such as Internet.

This remote lab has been used since February 2005 by the students of the University of Deusto as an essential tool for their practice works in four different engineering-related subjects.

WebLab-Deusto provides a distributed software architecture (see Fig. 2) that makes easy to integrate new experiments inside, so every experiment served this way automatically takes advantage of all the common features implemented by WebLab-Deusto:

- *Authentication*. WebLab-Deusto offers an extensible authentication system that currently supports three ways to verify the user credentials: username and password stored in a MySQL database, authentication through a remote LDAP server and trusted authentication based on the IP address of the client that is trying to log in.

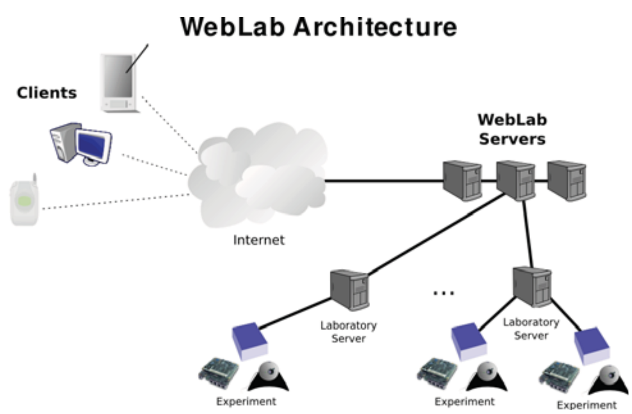

Figure 2: WebLab-Deusto architecture

- *Reservations*. WebLab-Deusto offers a generic reservation system that makes possible to reserve any available experiment for a non-scheduled period of time (i.e: 200 seconds), which is defined as a parametrizable experiment-dependant property.
- *Queue management*. WebLab-Deusto manages different reservation queues for the different available experiments, making the experiments themselves completely unaware of the users that are trying to use them.
- *Scalability*. The WebLab-Deusto architecture is horizontally scalable since more hardware can be added to improve not just the performance but also the availability of the remotely served experiments. The more experiment hardware devices of the same type are added, the more users will be able to use the same experiment simultaneously.
- *Security*. The WebLab-Deusto distributed architecture keeps in isolation the experiment-dependant hardware and software, so any problem related to a wrong use of the experiment will never put the whole remote lab at risk. Besides that, this same architecture considers the Login server separate from the others, so the most sensitive information (usernames and passwords) could not be accessed in case of eventual security attacks (see Fig. 3).
- *Deployment*. The WebLab-Deusto deployment system makes easy and flexible to configure the distributed network map in which all the servers and experiments are involved. Every WebLab-Deusto server can be configured with an easy-readable .xml file to declare the protocols which it will be communicated through, being five different ones available up to now: XML-RPC, Python-dependant SOAP messages, TCP sockets, UNIX sockets and “Direct” (direct method calls inside the same program instance).
- *Logging*. Everything that may happen during the use of the remote lab can be logged at different risk levels. The amount of events to log is up to the WebLab-Deusto administrator.

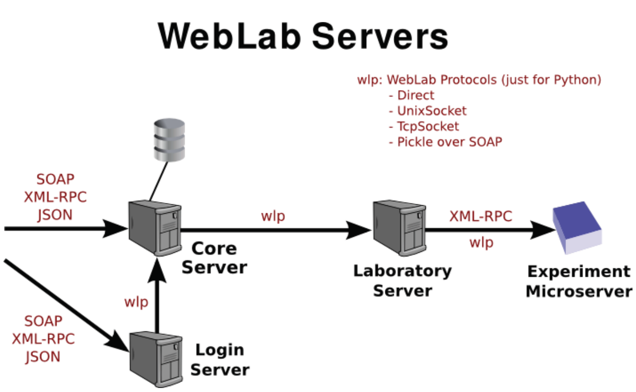

Figure 3: WebLab-Deusto servers

- *Administration*. As a common feature that every remote lab requires, WebLab-Deusto offers administration tools that make easy both to monitor who is currently using the remote lab as well as to add, edit or remove users, permissions and experiments.

B. *Second Life*

Second Life [4] is an end-user MMOW (Massive Multiplayer Online Worlds) software developed by Linden Lab since 1999. It provides a 3D environment where people can create their own customized avatar (a virtual representation of a person) and interact with other people. Its goal is to offer a real-world-like platform with the same physic laws, rules of conduct and opportunities (to get a job, to buy things…) that everybody has in the real life.

The most remarkable feature of Second Life is that there are no established goals for its users. Due to this, the platform has been mainly used in an entertainment way, but during the last few years it has also been used as an educational tool [5].

Second Life consists on two main software components: the private server farms at Linden Lab and the free-software client. The servers manage the business logic and the persistence tier, so the client is just responsible for rendering the 3D world and notifying the servers all the events carried out by the user. Therefore, developing software in Second Life entails both designing 3D graphics as well as programming server-side software.

C. *SecBot*

SecBot is an auto-programable microbot specifically designed for this project. Despite that, SecBot can be considered as a background component, since any other experiment could have been offered in SecondLab instead (from a technical point of view) and the microbot itself could also be used in a different context.

The reasons for choosing a microbot as the experiment offered in SecondLab are both educational and technical. The educational reason points to the attractiveness of the experiment for young students, which works in the direction of promoting entertainment while learning. The technical reason is related to the state-of-the-art in auto-programmable microcontroller memories. Now it’s possible to create an autonomous microbot with the capability of programming its own instructions memory, so it can completely change its behavior in run-time. This is exactly the feature required to design the autonomous remotely-programmable microbot desired for the educational aims of the project.

This customized microbot, called SecBot, has been built over the *Robot Sumo Terminator S300230* from SuperRobótica [6], a commercial mechanical structure commonly used in the fighting modality of robotics competitions. As a first prototype version, SecBot offers the student the following components:

- 1x PIC18F4520 microcontroller from Microchip [7]
- 1x MD22 engine controller circuit from Devantech [8]
- 1x GP2D12 infrared sensor from Sharp [9]

III. SECONDLAB

SecondLab merges all the previous components in order to create a remote lab that allows students to program a microbot from Second Life. The best way to understand how SecondLab works from the student point of view is looking at the “happy path” scenario, described by the following steps:

1. Write a C program with the instructions that the microbot shall follow.
2. Compile the .c file to obtain the assembler .hex version of the program.
3. Open Second Life and log in with the avatar’s name, surname and password.
4. Travel to SecondLab by typing “SecondLab” in the search tool.
5. Enter the laboratory with the avatar (see Fig. 4) and press the big green START button.
6. Upload the .hex program (see Fig. 5).
7. Wait until the screen in front shows the microbot working under the programmed orders (see Fig. 6).
8. Press the big red STOP button and leave the laboratory.

A. Architecture

Since SecondLab takes advantage of the previously described background components, its architecture is completely determined by them. In particular, WebLab-Deusto determines the global architecture, as it is the real remote lab underneath.

The WebLab-Deusto architecture follows an experiment-agnostic approach [10]; that is, it makes all its features completely independent of the specific requirements of the remotely-served experiments. Thus, integrating a new experiment in WebLab-Deusto becomes as simple as developing two components: a microserver at the very end of the server side (capable of interacting with the microbot), and a web-client module at the highest layer of the provided web-

Figure 4: The SecondLab entrance

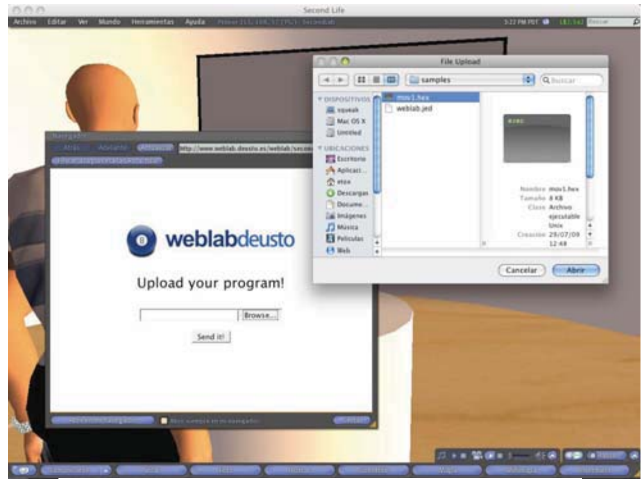

Figure 5: Uploading the program

client application (presentation layer). Since the client platform had to be Second Life in this project, the most remarkable challenge became making Second Life work as a WebLab-Deusto client. Figure 7 shows the interaction among all these components.

A third smaller component, Web-uploader, had to be developed too in order to solve a certain Second Life technical limitation that will be explained later.

B. Microserver

The function of a WebLab-Deusto microserver is to communicate the experiment-agnostic set of WebLab-Deusto servers with the final hardware of the experiment (the SecBot microbot in this project). The only requirement established by WebLab-Deusto to develop a microserver is to implement the following interface (neutral language):

- test_me(value)
- start_experiment()
- send_file_to_device(file, file_info)
- send_command_to_device(command)
- dispose()

This interface can be implemented in any of the following supported protocols:

- Direct (function calls from/to the same process)
- Pickle over UNIX Sockets (Python dependent)
- Pickle over Internet Sockets (Python dependent)
- Pickle over SOAP (Python dependent)
- XML-RPC (language independent)

As figure 7 shows, the microserver in this project had not just to translate the messages received from WebLab-Deusto to the microbot, but also to manage with two different communication protocols: Bluetooth and any other from the

Figure 6: Watching the microbot working

five above. For this reason, a high-level and well-communicated language as Visual Basic .NET was chosen to develop this component. Therefore, XML-RPC was the only possibility to implement the listening interface.

C. *Client*

As previously explained, the most significant challenge in this project was to make Second Life work as a WebLab-Deusto client. Since Second Life provides a generic world where people can live and build their lifes, it also provides technical features so developers can program the created objects and buildings with certain behaviors.

Several steps must be followed to develop a custom piece of virtual world in Second Life. Building is not allowed for free, so buying a plot of land is the first step in order not to lose the work; secondly, every desired object must be graphically designed (buildings, items, textures…) using the 3D model editor provided by Second Life; and lastly, as many programmed behavior as wanted can be added to the world thanks to the scripting language created by Linden Lab (*LSL, Linden Scripting Language*). Every object in the world can be linked with many LSL scripts, which will be executed when the different programmed events happen in the virtual world (e.g.: an avatar touches a certain object).

From this scenario, developing a WebLab-Deusto client in Second Life entailed two big steps: designing a graphical 3D laboratory where the students could go with their avatars and communicating this laboratory with the remote lab so it could work exactly as a valid WebLab-Deusto client. Since the graphical task involves a creative work, the technical challenge was programming a communication layer under the conditions of a limited language like LSL.

The WebLab-Deusto architecture presents the server side as a webservice with the following public interface facade (neutral language):

- login(username, password)
- login_based_on_client_address(username, address)
- get_user_information(session)
- list_experiments(session)
- reserve_experiment(session, experiment)
- get_reservation_status(session)
- send_file(session, file, file_info)
- send_command(session, command)
- poll(session)
- finished_experiment(session)
- logout(session)

This facade can be called using any of the three following format protocols:

- SOAP
- XML-RPC
- JSON

Second Life offers both XML-RPC and the underlying HTTP protocols; however, the provided XML-RPC support is too limited to be used with a minimally complex service (only one integer and one string values can be retrieved at a time). Therefore, an XML-RPC layer has been manually implemented in LSL so the provided HTTP service is definitely used to communicate Second Life with WebLab-Deusto. This developed XML-RPC layer is limited to the specific use done in this project, so it cannot be considered a generic XML-RPC library for LSL. Although the original design considered it, the technical memory restrictions found in Second Life (64 KB/script including bytecode, stack and heap) made impossible that desirable approach.

Finally, as figure 7 shows, the communication between Second Life and the webcam that points to the microbot is done through the RTSP streaming protocol, thanks to the easy-to-use RTSP client support offered by Second Life, which only requires to specify the URL where the streaming is received from. The network camera used in SecondLab is the D-link DCS-5220, although any IP-based webcam with RTSP support could be used.

D. *Web-uploader*

The web-uploader server module covers a Second Life limitation. The LSL programming API does not offer any user interface component to allow the user to select a file from its computer. This shortage becomes a critical issue in a project

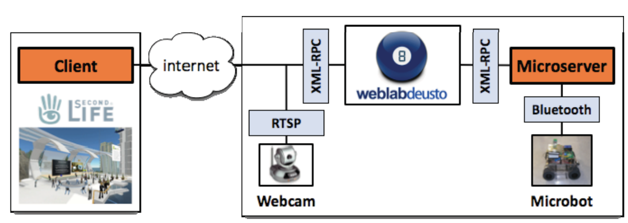

Figure 7: Architecture of SecondLab

like SecondLab, where sending a file from the student's computer is the main action in the interaction scenario.

This module takes advantage of the most flexible utility offered by the LSL programming API, which is a function that shows an embedded web browser with the specified URL loaded. The solution has been developed like a set of two server-side Python scripts. The first one offers a traditional HTML form with a *file* field that allows the user to choose a file from its hard drive (see Fig. 5). As figure 8 shows, when the submit button is pressed, this script sends a HTTP POST request to the second one, which really sends the selected file to WebLab-Deusto and notifies Second Life that the file has been sent, so the web browser can be closed and the user can be told to look at the virtual screen in front.

IV. CONCLUSIONS AND FUTURE WORK

SecondLab proves that it is possible to mix virtual environments with real experimentation in a first approach (prototype version). However, it also proves that developing a remote lab for end-users under Second Life is not recommended due to its serious technical limitations:

1. *Limited scripting language*. The Linden Scripting Language is not comparable with any modern programming language. Its most remarkable handicap is the limited support offered for data types, which makes impossible to manage minimally complex data structures in memory. Suffice it to say that LSL does not offer basic structures (struct in C) or dictionaries, being a very limited (non-nestable) list the most complex structure supported.
2. *Few User Interface components*. Second Life was not designed as a real development environment but as a platform where average-users could create buildings and interact with other avatars through simple question-answer dialogs. Therefore, the LSL programmer can only get input data from the user by two simple UI components: a dialog window with customizable answer-buttons (llDialog) and a text box where the user can write characters (llTextBox). As already explained, sending the user's .hex file in SecondLab had to be implemented using the embedded browser provided by Second Life in a quite unorthodox way (see Fig. 8).
3. *Memory restrictions*. Every LSL script is only provided with 64 KB of total memory (bytecode, stack and heap included) at the Linden Lab servers. Having tested during the development of this project that 1000 lines of LSL source code consume approximately 55-60 KB of memory, this restriction becomes a significant problem that makes Second Life a really limited environment where almost none ambitious project can be developed at. However, Linden Lab also enables to set up a personal server and connect it to their grid, so the environment restrictions imposed by the Linden Lab service might be avoided. Although SecondLab has not been deployed this way (since renting a land was enough for a prototype), this other approach may solve the memory limitations.
4. *Lack of high-level communication protocols*. As already said, although according to the documentation LSL offers both XML-RPC and HTTP as communication protocols, the provided XML-RPC support is too limited to be used with a minimally complex service. Therefore, HTTP becomes the only well-supported communication protocol, so any higher-level one must be manually implemented (as done with XML-RPC in this project).

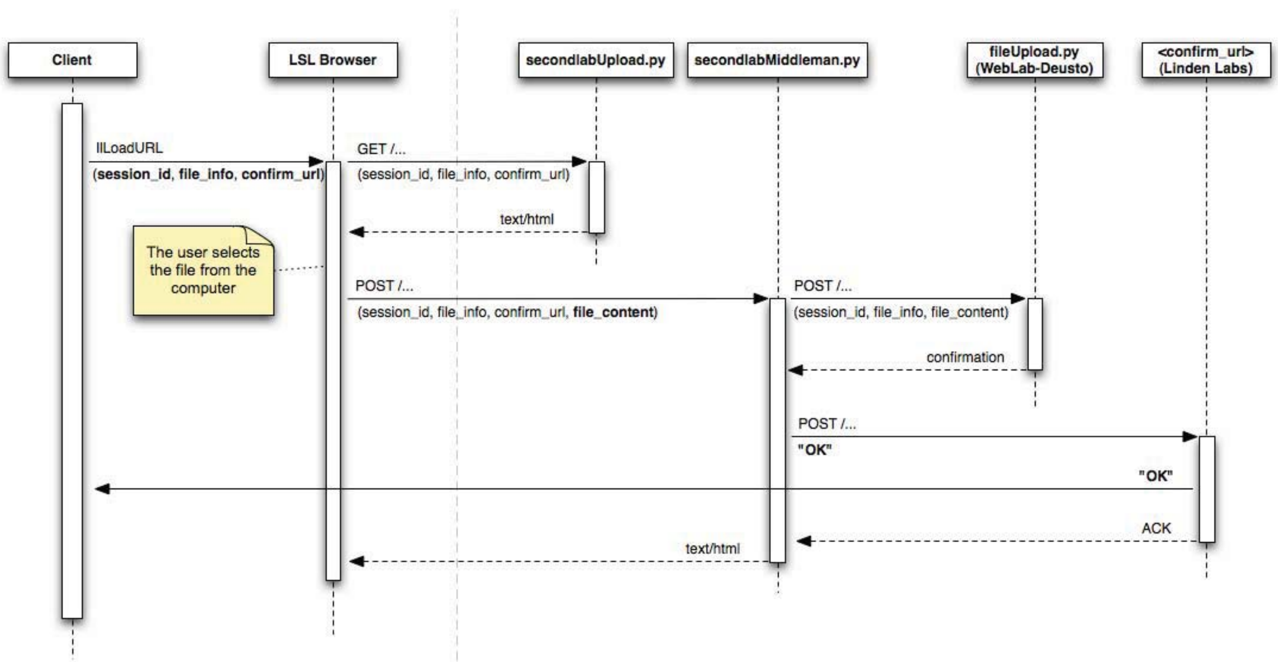

Figure 8: The web-uploader sequence

According to these limitations, a production-ready 3D-based remote lab for end-users should consider the idea of choosing a different 3D environment, such as Wonderland [11] or OpenSimulator [12].

After getting around of the current Second Life issues, future plans for this project consider technical improvements both in the software and hardware sides.

The main software improvement will extend the functionality of the remote lab (based on Second Life or any other 3D environment) to offer two real microbots for two students at the same time, so different kinds of competitions may take part remotely in order to increase the students motivation.

In addition, the next SecBot version will rely on an auto-rechargeable battery system, so the microbot will be completely autonomous. This mechanism will be based on a circular customized ring. The walls of this ring will be filled with two conductor strips connected to the power supply, so as the microbot stops being used it can move forward and stay attached to any wall charging its battery.

J. Irurzun is a Computer Engineer by the University of Deusto, Bilbao 2009. He is Research Intern at the WebLab-Deusto Research Group and MSc student in Development and Integration of Software Solutions at the University of Deusto. (e-mail: irurzun@deusto.es).

I. Angulo is with the University of Deusto in the Dpt. of Industrial Electronics, Control Engineering, and Computers Architecture of the Faculty of Engineering. He is the lead hardware designer and developer of WebLab-Deusto. (e-mail: ignacio.angulo@deusto.es).

P. Orduña, is a Computer Engineer by the University of Deusto, Bilbao 2007. Nowadays he is Research Assistant at the Ambient Intelligence department of DeustoTech - Tecnológico Fundación Deusto, and PhD student at the University of Deusto; his research is focused on Remote Laboratories. He is the lead software designer and developer of WebLab-Deusto. (e-mail: pablo.orduna@deusto.es).

J. Ruiz-de-Garibay, is a Computer Engineer by the University of Deusto, Bilbao 2003. Nowadays he is Research Associate at the Ambient Intelligence department of DeustoTech - Tecnológico Fundación Deusto, and PhD student at the University of Deusto; his research is focused on Remote Laboratories based on Robotics. (e-mail: jonathan.garibay@deusto.es).

U. Hernández is with the University of Deusto in the Telecommunications Department at the Faculty of Engineering. He is developer of the research group on web-based laboratories and he is in charge of the Remote Labs based on instruments control. He is involved too in the deployment in University of Deusto of the VISIR project leaded by the Blekinge Institute of Technology (Ronneby, Sweeden). (e-mail: unai.hernandez@deusto.es).

M. Castro, Electrical and Computer Engineering educator in the Spanish University for Distance Education (UNED), has an industrial engineering degree from the ETSII (Industrial Engineering School) of the Madrid Polytechnic University (UPM) and a doctoral engineering degree from the same University. He received the Extraordinary Doctoral Award in the UPM and the Viesgo 1988 Award to the Doctoral Thesis improving the Scientific Research about the Industrial Process Electricity Application. He works as researcher, coordinator and director in different projects, ranging from solar system and advanced microprocessor system simulation to telematics and distance learning systems, acting now as and senior technical director. He is now with the UNED (Spanish University for Distance Education) as Professor in the Electronics Technology subject inside the Electrical and Computer Engineering Department as well as he is Director of the Department. (e-mail: mcastro@ieec.uned.es).

E. Sancristobal is a Computer Science Engineer by the Salamanca Pontifical University (UPS), Madrid 2002, has a Technical Engineering degree in computer networks (UPS), Madrid 1998. He finished his Doctoral Studies in Electronics Technology by the Electrical and Computer Engineering Department from the Spanish University for Distance Education (UNED), Madrid 2005. He worked for the University Distance Education Institute (IUED). Nowadays is working for the Computer Science Service Centre of the Spanish University for Distance Education (UNED) and is an associate professor Electrical and Computer Engineering Department from UNED. Abstract— **This short paper presents a new hardware system that lets develop labs of Digital Electronics. The system is focused on the verification of logic functions, so teachers can create new experiments only changing the problem proposed, within the range of input variables and output functions that system supports. The students have to solve the problems finding and simplifying the functions. Then, they must implement the results in the proposed system.**

Keywords - logic design; laboratories; practice assesment

I. Introduction

This paper shows how an experiment about realization of logic functions using logic gates can be performed with a flexible, computer based hardware. This system is initially designed for used in remote labs, but can also be used “in-situ” for normal labs.

This work is a demonstrative part of the Project S-Labs “Open services integration for distributed, reusable and secure remote and virtual laboratories”, sponsored by Spanish Ministry of Education and Science. The main objective of this Project is to integrate technologies for learning theoretical and practical using any Learning Management System (LMS) [1].

The proposed system has several characteristics that make it different from other existing remote laboratories.

First, the experiments can be performed using the services offered by the LMS used by any University involved in this project. Then this remote laboratory will be a new resource, like other material published in Digital Electronics Courses over the LMS’s. With this feature we don’t need to create again the basic services that a remote laboratory uses, like administration, content packaging, etc., because they are included in all LMS.

For teachers, has the advantage of being able to share the laboratory between different departments or Universities, with little investment and, of course, a sharing policy. Then the system can be fully productive.

For students, the main advantage is the use of the familiar environment provided by the LMS, so make remote practice becomes easier.

On the other hand, the second important feature is that the system allows the realization of logic functions without restrictions, so you can perform many different practices. With few changes you can prepare different experiments for different groups of students, or you can change the remote practice from one course to another, avoiding that student’s lab results could be passed on to “next year” students [2].

In the following paragraphs of this paper will be listed the objectives to be achieved with this laboratory and the physical description for the elements of the system.

II. Objectives

The main objectives of this work are:

- Get flexible and reusable systems for remote labs.

  The laboratory proposed is very flexible: the professors of different courses can implement different practices even at the same time. Also the system can be used for other kind of practices, for example to check a given logic function or to study maxi- and miniterns.

- Enhance the students’ skills in logic design.

  With this tool the students can test any function they obtain in the problems that the professor proposes. They can test their solutions in real hardware with real results, instead of simulations.

- Enable the students to control the experiment.

  There are remote labs that are like “black box” for the students. We try to show them all the process involved in the experiment, and avoid any component that can be difficult to understand for beginners in Digital Electronics.

- Get an adequate use for the remote labs.

  If the equipment needed for the remote lab is used only by one group of students in a University, the ratio between material and personal cost and use of laboratory is poor, because it will be used only one or two weeks a year. Sharing the lab between several courses and Universities will increase this ratio.

- Get a cost reduction in remote labs.

  The equipment needed for a remote lab can be expensive [3]. In this approach, we use elements that can be achieved at an affordable price.

III. Description of the System

To achieve the objectives listed below, we are developing a hardware set and the computer programs needed for the control of the hardware. The system is an evolution of another one developed to teach practices "in situ" [4]. The system is a useful tool for the students, which have the opportunity to experiment with digital circuits outside of the laboratory. In the following paragraphs we explain the hardware components and the software programs needed to build this new laboratory system.

A. Hardware set

The physical system has four main parts. In Fig. 1 you have a block diagram of the whole platform:

- A computer.

  The main tasks for the computer are the control of the correct performance of practices and the lab server. It receives the logic function to be performed, set up the function board which will be described in the next paragraph and sends back the functions results.

  The computer selected for this purpose has special specifications. Thus, being a computer that will operate 24 hours a day must have reduced power consumption. On the other hand, a small and low-cost computer will be the better option.

  We have chosen for this remote lab a mini-ITX mainboard [5]. The Mini-ITX form factor (just 17 cm x 17 cm) is designed to fit in the mounting points of a standard ATX board, enabling to use a standard case to fit all the system components. The Mini-ITX embedded boards are used on a variety of applications: in-vehicle computers, digital kiosk and advertisement, Network Attached Storage (NAS), etc. The main features of these boards are: X86 architecture, low power consumption, rich integration (LAN 10/100, USB, Serial, ATA, SATA, PCI connections, etc.). For our purposes, the most important are the consumption and the USB and PCI connectivity. We used a fan less VIA EPIA 6000 board with a Compact Flash based Solid State hard disk for storage, giving a reliable and cost effective platform without mechanical parts.

- The function board.

  This is the circuit that performs the logic functions. It's based on LSI integrated circuits, and its main parts are an AND gate array followed by an OR gate array, with programmable connections between the two arrays, and also between inputs and the AND array. The state of the switching matrix is stored in a memory builded with shift registers that control directly the switches. Fig. 2 shows the diagram for this board. This configuration for a circuit that performance logic functions is intuitive, because is like the wire diagram that students can write. We prefer this more complex approach instead of the use of a field programmable gate array (FPGA) because the FPGA is like a "black box" for the student, and its more complicate layout probably will be inaccessible for beginners. In addition, the use of FPGA forces students to make programs that probably needs more knowledge of digital electronics that they have. With this circuit you can generate a modest performance: up to 4 functions of 4 variables each, sufficient for the most of the practices.

- A digital acquisition board.

  This board has two different tasks. First, the card programs the logic functions to be performed in the function board, putting into the memory the switch configuration. Second, several of his digital lines enters the values of the variables into the function board and others read the generated functions and send the results to the computer.

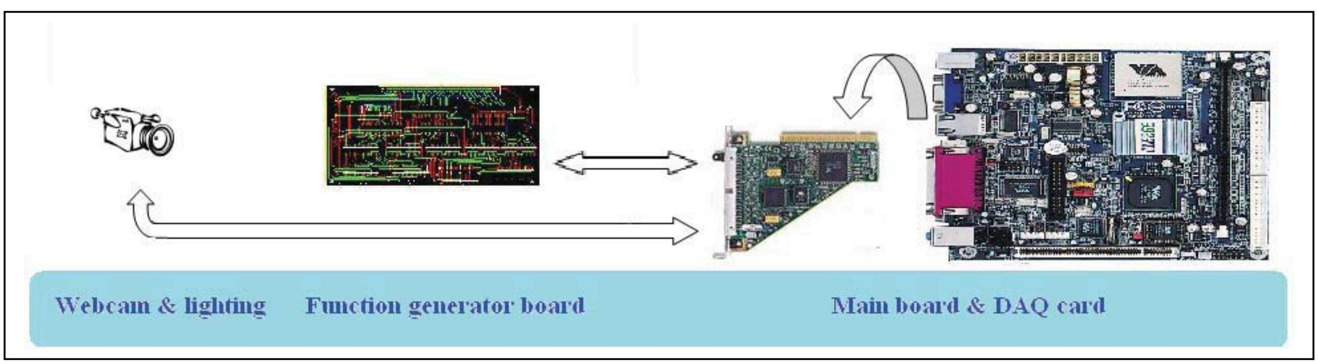

Figure 1. Block diagram for the hardware.

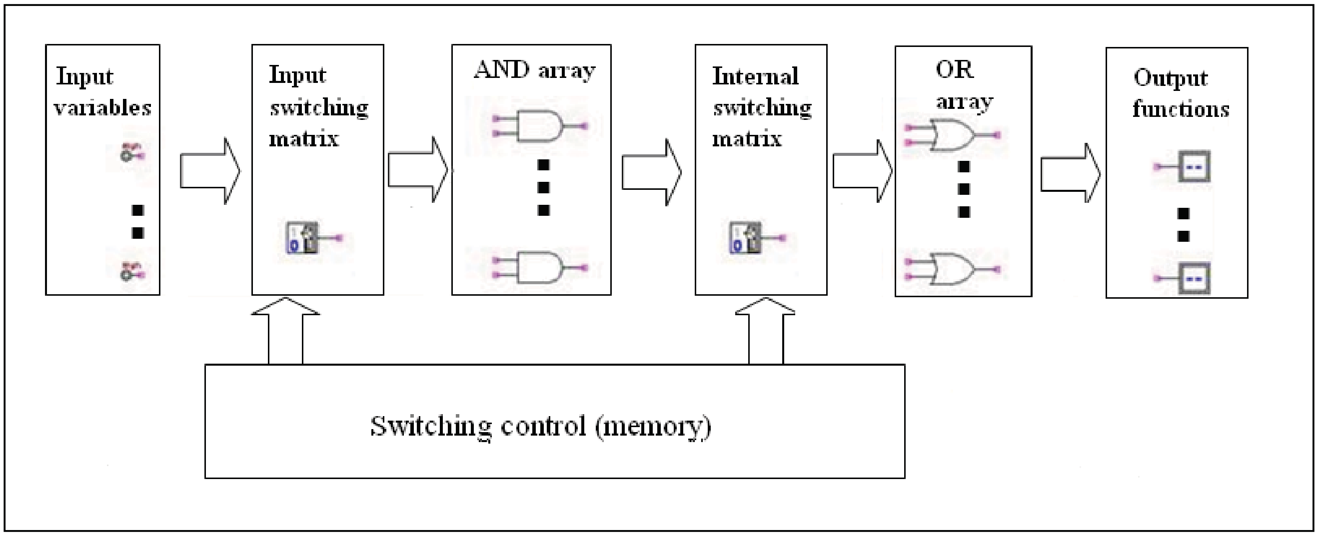

Figure 2. Block diagram for the function generator card .

For this prototype we have chosen a NI-PCI-6503 acquisition board from National Instruments [6]. This is an acquisition card with 24 digital input/output lines organized in three 8 bit ports, and PCI connection to the computer. The board is in the basic range for this manufacturer, and its price is low compared with other solutions. For our purposes, one port is used as output and sets up the four variable values, other port is set up as input and his four lower bits reads the functions results and in the last one several bits are set up as output to put the switch values into the memory and others act as inputs for handshaking.

- A webcam.

The webcam is used to receive visual feedback from the function generator circuit. The circuit has LEDs for inputs and outputs. A view of the circuit lets the students check out the state of the variables and functions. There are no moving parts in the circuit, and the changes on the LEDs state are slow, so a rate of one frame per second is enough for our purposes. The webcam have extra illumination with LED lighting that only goes on when an experiment is running.

All these elements are housed in a desktop PC case, so that the laboratory is a compact set well isolated from ambient light interference and possible mishandling. Figure 3 is a set of pictures of this prototype.

B. Software

If we want to run this lab in a remote way, we need two software applications. This paper is really focused on the hardware, but it is necessary to point out some aspects of the software.

The server software application is now under first stage of development. The main tasks of this software are:

- Receive the functions to be performed. The format used for the functions representation is a vector containing all the variables and its opposite, e.g. A and $\overline{A}$, being $\overline{A}$ =NOT (A). If a position have a

Figure 3. Photographs of the prototype.

"1", the variable is present, if have a "0" not. An example could be the following function:

$$F = B\overline{C} + A\overline{B}C + \overline{A}D \quad (1)$$

That can be represented as:

$$F(ABCD\overline{A}\overline{B}\overline{C}\,\overline{D}) = 01000010$$
$$10100100 \quad (2)$$
$$00011000$$

- Program the switches. The software takes the vector representation, like the example shows in (2), and programs the switching matrix according to the function. Every value of an element of the vector is an input switch, and the number of elements of the vector determines how many internal switch will be closed.
- Put input values on the variables. Once the functions are programmed, the user can select one input variables combination to be sent to the function, and the software will put these values in the function generator card inputs.
- Take output values of the functions. The acquisition card reads the results from the functions implemented in the function generator card and sends to the user for verification.
- Makes the truth table. If it is desired, the software can build the truth table for the functions.

This software has been developed in Labview environment [7] [8]. This developed software kit allows an easy communication with the DAQ card, and has been used in older similar projects [4].

The software can add new features to improve the system, or even to change its functionality. For example, with a new version of software we can transform the remote laboratory in an "in situ" laboratory. With this example version, the students could build the switch matrix by themselves selecting in a schematic view of the function generator board the state of all the switches.

On the other hand, the remote laboratory needs to be connected to one or several LMS to be useful for students. This feature can be achieved if we define, design and develop a middleware capable of communicating an E-learning platform with the laboratory, as shown in Fig. 4. The LMS environments arise as distributed systems and must operate in real time processing of data from heterogeneous systems, databases, directory services and applications, and integrate with other environments. To be able to integrate all these pieces is necessary an universal medium, neutral with regard to the platform, to describe, transport and transform data between distributed systems: XML. Using XML as a standard representation would develop multiple types of interfaces based on other technologies such as AJAX or dotNET that have interactive components lighter burden in terms of their own Java applets.

IV. AN EXAMPLE OF USE

With the system proposed, the students can check their knowledge for solving problems that involve digital logic. The professors will put on one or several LMS's courses problems about logic design. When a student access to the LMS's course, there will be two links, at least, along with other LMS services (chats, forums, contents of course, etc.). When the students click on the first link a proposed problem will be shown in a frame of an LMS. Then he will have to find the relationships between variables and functions and to obtain the corresponding truth tables. Finally, he will have to simplify the

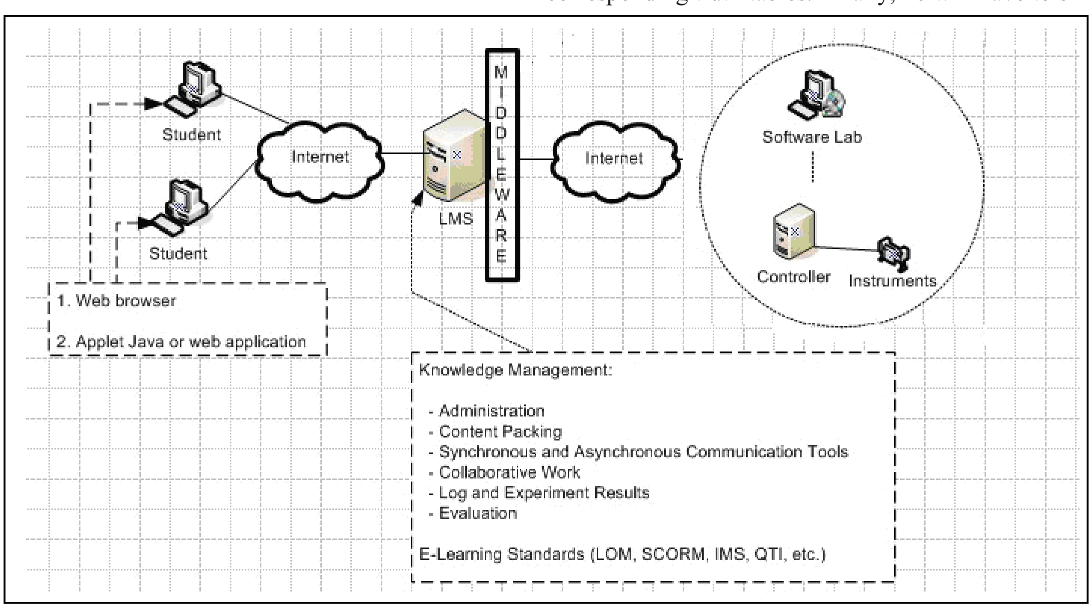

Figure 4. Integration of LMS with remote laboratories.

functions using any method (e.g. K-maps). Once the problem is done by the student, he goes back to the second link and the student can enter the remote laboratory through LMS`s course and intro the functions obtained. A comparison between the truth tables obtained and the ones offered by the remote laboratory will be the final result of the experiment. The log file of the sessions helps the professors to evaluate the student skills. It important to say that the students beside of working with the problem and the remote lab, he can use the services offered by LMS as chats forums, etc.

V. CONCLUSIONS

A remote laboratory developed to check digital functions has been presented. At this moment, only hardware is on an advanced step, therefore not been possible to obtain results of its application in a group of students.

The main features of this approach are:

- It's a laboratory designed for use inside any LMS.
- It's a low cost, low power consumption system.
- Simplify the implementation of truth tables.
- It's very versatile.
- It can be used "in situ" only with a new software development.
- It's open to future developments.

VI. ACKNOWLEDGMENTS

This work has been developed inside the framework of the S-Labs ("Open services integration for distributed, reusable and secure remote and virtual laboratories") Project, supported by the Spanish National Plan for R&D (2008 – 2011) of the Science Ministry. Our thanks to all the people involved in this Project.

The authors would like to thank the help of the students who have worked in the early stages of design, especially Fernando Ortiz Benito and Jesús María Gutiérrez Calzada, and those who have tested the system and provided critical feedback on their performance.

Also we would like to acknowledge the help of the UPM and the UNED for the publication and attendance to the conference.

Abstract— **This paper presents a work in progress related to the knowledge and competence management techniques applicable in an electronic systems engineering company. It also discusses the role of the university-industry collaboration in the knowledge management process.**

Keywords: knowledge management; engineering education; professional profiling, electronic systems engineering.

I. INTRODUCTION

In this paper we describe a work in progress related to the systematization and organization of competence and knowledge management processes in a small electronics engineering company. This work is promoted by an electronics engineering and consultancy company and conducted in collaboration with the Electronics and Telecommunication Department of the University of the Basque Country. The basic objective of the work is the development of a preliminary analysis that could serve as the basis of a collaborative proposal for a project to be presented in the framework of the regional R&D and innovation initiatives.

II. ELECTRONICS SYSTEMS ENGINEERING

A. Ubiquity of Electronics

Electronics systems are penetrating all possible aspects of human life, and are being used to improve them. Companies seeking to add value to their products are often driven towards the integration of embedded electronics, transforming traditional devices into more adaptive and useful ones.

In the medical field, electronics systems are not restricted to hospitals; they can also help patients, disabled, elderly and dependent people outside medical facilities.

Modern forms of mass transport system, such as trains, airplanes and cars, use embedded electronics technology to increase safety and performance. In the automotive sector, for example, the share of electronic components in the total value of a passenger vehicle is currently estimated at about 25%, with an expected increase to 33-40% in 2010 and up to 50% thereafter [1].

Electronics is an enabling technology for many sectors and fields of application. The existence of a local electronics industry is widely considered to be an essential contributor to prosperity and growth. This is not only due to the scale of market for electronics products, but also to the radical effect that the application of electronics has on the competitiveness of other sectors of the economy. In the Basque Country (Spain), the Association of Industries for Electronic and Information Technologies (GAIA), comprising more than 190 companies, has structured its 2009-2012 strategic plan with horizontal branches (Electronics and communication technologies) crossing three main vertical sectors of application: energy, transport and health [2].

In addition, we cannot overlook the impact of globalization. Offshoring and outsourcing are spreading globally in all economic sectors, but are especially prevalent in electronics, where even R&D activities are being outsourced. Electronic systems must often be assembled from COTS (Commercial off the Shelf) electronic subsystems and components, which may be manufactured half way around the world. But, at the same time, system integration is becoming more complex and involved. One of the big challenges in electronics systems engineering is to manage the complexity and reliability of the development, operation, and maintenance of embedded electronics systems [3].

B. The role of an electronic systems engineering and consultancy company

While companies operating in various sectors consider electronics as an essential technology, in most cases they view it as a means, not an end, in their business strategy. The rapid evolution of technology and the variety of skills and techniques required for a successful application of electronics in their products is driving them to consider outsourcing of engineering as an optimal solution. Even electronics-related companies follow this trend. One can find a UPS manufacturer that sees its real product not as equipment but as the "power availability at the point of service", and therefore, focuses its strategy in setting the specifications and analysis of the application, outsourcing its development and manufacturing.

Other companies have undergone a rapid shift towards electronics technology. Consider, for example, a wheelchair manufacturer, moving from pure mechanical products towards electric wheelchairs that include power electronics, motor control and battery chargers, and, in addition, intelligent navigation and communication aids.

Distributors of electronics components and subsystems are trying to add value to the supply chain. They can offer the range of components needed for a complete solution, from board level components to enclosures, modules and powerful COTS subsystems. They can provide their customers with sporadic technical support through field application engineers. University departments and technological centres should concentrate their resources in research and basic development. None of these actors is orientated towards engineering or consultancy in complex and high workload projects involving demanding quality and deadline objectives.

An electronics engineering consulting company is the link which fills the gap between the end user needs and the available technological solutions (Fig. 1). It uses knowledge as its raw-material (research results and education from universities, internal R&D and collaborative projects with universities and technological centres) or as a semi-finished product (components, subsystems, tools and technologies produced by specialized companies all over the world, or even free software and hardware projects and communities) and generates applied knowledge as its output. Its role is to process and internally manage this knowledge and apply it properly in its clients' projects. To meet its clients' requirements it is essential to use the right type of knowledge, at the right moment in time, and with the right intensity, in every task and during every stage of the project.

The electronics system engineering process follows an iterative loop from the requirements definition, to functional and structural design. The same process is applied in a top-down approach to every subsystem, module or component.

In a typical electronics systems project, a broad range of competences and skills may be required. Managing competencies of the people who need to perform specific tasks or jobs in a project can crucial to the success or failure of the project.

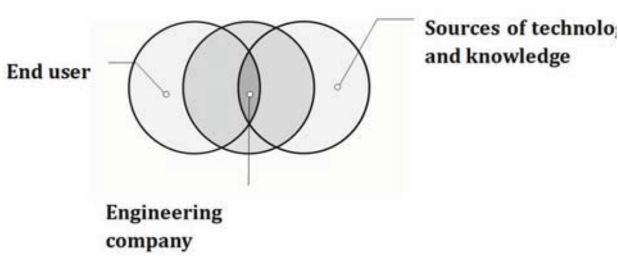

Figure 1. The role of an electronic systems engineering company

III. Professional Profiling based on Competency and Competence management.

In this section we differentiate between competence (the specific level of knowledge, skills, experience, etc. necessary to carry out a defined function) and competency (the description of the knowledge, skills, experience, etc. necessary to carry out a defined function).

Competency and competence management is the process of identifying, classifying and analyzing competencies, and managing competences of the people working in a project. This process must be the basics of professional profiling, selection, hiring, career development, training and evaluation. Core competencies are those key competencies that all members of the organization must master, along with the vision and mission of the company. There is also a distinction between soft and hard competencies (the latter being equivalent to knowledge, skills, and abilities or KSA). In current management and education literature, the structure and management of core and soft competencies has received considerable attention. But, for a small engineering company, the more specific and hard competencies are as much as important as the soft or core ones. This perception is in line with studies that confirm that specific technical competence is the most valued characteristic of an engineer [5]. Our attention will be focused on the structure and management of those hard competencies in the electronics systems engineering.

This work in progress is fundamentally devoted to classification and parameterization. From a static point of view it is a try to establish taxonomy, covering the spectra of skills and knowledge of interest, with fine grain definition, analyzing detailed and very specific skills.

As an example of static classification requirements, it can be mentioned the case of single board computers (SBC) related skills. The static competencies classification must include from the fundamentals of computer architecture to the most specialized and detailed skills, such as the ones related to very specific form factor standards.

From the dynamic point of view, the skills and competences should evolve to adapt to market and client needs. The classification should include parameters to allow analysis of the dynamics, predicting the need for taking actions in order to control the evolution.

Some other examples can be considered to see the importance of this dynamic consideration. In fewer than ten years, a specialist in power supply and power converter design, has had to evolve from a profile involving important design related skills towards a new profile involving specification, selection and verification of converter modules, designed and manufactured by OEM suppliers. Now the engineer has to focus on the study and analysis of standards applicable to the sector. The new profile would be more systems engineering oriented. The impact of offshoring with its cost reductions and standardization of power converter modules has greatly reduced the need or advantage of home-made designs.

As a second example, the case of a microcontroller specialist can be considered. From development with small 8- o 16-bit microcontrollers, programming in assembler or C language, the engineer has had to move towards development with SBCs based on powerful ARM or x86 embedded processors, running RTOS (real time operating systems) or embedded Linux. The new professional needs now to be knowledgeable about driver development and the integration of applications combining compiled and scripted languages, network services, etc

Being able to predict those changes and quickly conforming to them is critical for a small engineering company, which must adapt with agility to new market circumstances and customers, sometimes in very demanding sectors, such as transport or energy.

Our work is currently focused on the development of a software platform for skills and competencies classification. The classification follows a tree structure, with fundamental branches (analogue and power electronics, digital, computer science, communications and networks etc.) split into more specific and specialized branches so that the classification of competencies related to projects and sectors of current interest is prioritized (Fig. 2).

There is also a need to decide the parameterization of every skill related field. Regarding the competence level, classic classifications based on Bloom's taxonomy or the Anderson variant, competence levels of Dreyfus professors [6], and previous experiences [4][9], like the ones applied in clinical practice[7][8] are being considered.

The static tree classification with competence levels has to be graphically analyzable, yielding at a glance the specialization profile for a professional, a team or project requirements. The dynamic parameterization must be also easily analyzable, both for forecasting and for assessment of professional recycling programs. A spectral representation similar to the that used in engineering and physics, indicating the difference between "low frequency" skills (those fundamental skills that are very permanent and are only slowly renewed) and "high frequency" skills (those achieving obsolescence quickly or that have to be acquired and renewed frequently) is proposed.

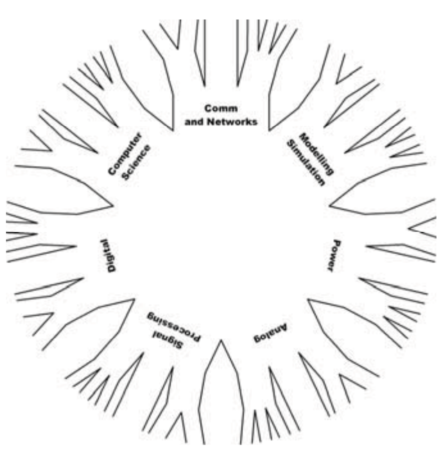

Figure 2. The competency tree

IV. Knowledge Management

The approach to knowledge management (KM) is from the eclectic point of view of engineers approaching any management fad [10][11]. KM has raised strong interest in the business community, but perhaps some managers are thinking about KM as the magic solution that will allow a company to keep engineer's brains after they leave. For us, an important aspect of KM is that the effectiveness of an engineer performance, key of any success, depends on the proper delegation of intellectual tasks and authority to knowledgeable and empowered professionals [15].

Nevertheless, for a company dealing with complex and multidisciplinary projects, the handling of data, information, and their processed forms cannot be disregarded. From that point of view the definition of KM as the systematic and explicit management of knowledge-related activities [12][13][14] can be easily shared. It can also be agreed that a KM strategy must pursue a direct connection between an organization's intellectual assets, both explicit and tacit, and positive company results.

The analysis is based on some well-accepted definitions such, as the Ackoff pyramid [17] and the associated transformation process [16] that can be schematized as:

- The raw material is data
- Understanding of relationships in data gives information.
- Understanding of patterns in information gives knowledge.
- Understanding principles in knowledge gives wisdom

It is also relevant to pay attention to the identification of the opposite terms: absence or false data, misinformation and non-knowledge [18]. Most failures in critical systems, even causing loss of human life, can be attributed to misinformation or non-knowledge. Fail tolerant system design must take into account the flow of data, information and knowledge and establish procedures to avoid failures.

The new information is transformed into knowledge by means of internal processes of association. As in a complex state machine, new knowledge depends on input (information) as much as on the previous knowledge. This transformation is executed by human minds, individually, or by means of some collaborative interchange of ideas and thinking [12]. The transformation of knowledge in wisdom is the realm of pure human intelligence. At the present time we have a started the systematization of the basic actions [12]:

- Collection of data, maintaining daily record of data related to task and jobs.
- Processing of data in order to obtain information, and make the information available.
- Individual and collective processing of information to generate tacit knowledge.
- Try to make tacit knowledge explicit by socialization

The process should be effective and simple. Internally, as a tool, we are using a collaborative intranet that includes task management software, document repository, version control, wikis and forums.

For company-university collaboration we are analyzing a process based on the systematic accumulation of data, information and pre-processed knowledge that can be conveyed from company to university. Professors at the university can complete the process to synthesize new knowledge by using generalization and conceptualization. The new knowledge is conveyed back to the company and, in some cases, others possible recipients, such as students, by means of courses, papers or reports.

An example can illustrate this process. In recent years there has been a rapid transition in standards related to communication between CPU and peripherals in SBCs. A migration from parallel buses such as ISA or IDE towards high speed serial buses such as PCI-Express, SATA, or USB has taken place. A company can obtain initial knowledge of these new technologies by processing information from manufacturers and standardization bodies, and can also gain some experience in specific applications, involving both hardware and software design. Involvement of academia would undoubtedly be beneficial in this process. A university department can approach the study of high-speed serial buses from a broader perspective, and can even assign the subject in end-of-term projects or thesis. The work in progress is oriented towards the systematization of this kind of process, establishing systematic means of collaboration. More theoretical subjects such as application of formal methods in specification and validation of systems, model based engineering, reliability and fault tolerance, etc. can benefit of this industry-university interchange of ideas.

V. Conclusions and Future Work

The viability of an electronics system engineering company depends directly on the competitive quality and application of its knowledge assets. Realistic and effective management of those assets is an unavoidable strategic activity. University-industry collaboration is a mutually beneficial way of closing the knowledge of loop, conveying structured knowledge from academia to industry and experience in the opposite way, from the professional field to academia.

As a future work we are proposing a research project, devoted to analysis of techniques and processes applicable in competence and knowledge management. Other interested partners can join in the effort. The involvement of the Spanish University for Distance Education (UNED), with its ability to provide education and training to active professionals, would be very valuable.

Abstract - **Research activity is an integral part of the study process and it is to be noted that many of the research programmes are very important for the industry and economy of Latvia.**

Keywords - Scientific project management, doctoral study innovation, research and development

I. INTRODUCTION

Creative, effective and prestige – these are the three words that describe the scientific and research strategy of our University. Our goal is to stimulate and improve the development of all forms of human intelligence – from nature and social sciences to the high technologies.

Riga Technical University (RTU) is open to world-wide co-operation in scientific research and in education for sustainable development of knowledge based society. It provides general information on different fundamental and applied research projects carried out in our academic and research units. It also gives the names of our academic staff members as well as institutions involved in particular research areas. RTU plays critical role in technology development in Latvia. A lot of technological research, innovations and engineering activities in Latvia are completed by RTU graduates, RTU staff, but at the same time research organisations, that results in technological development in Latvia. RTU education structure allows pupils from schools to get all possible education in technological areas in the same place. Studies in RTU mostly is State financial supported, it is opportunity for everybody to make also scientific research and get PhD.

Doctoral studies play an important role in the new scientific staff education and attracting. The existing research facilities allow make scientific research, especially in scope of PhD. The main daily research work done by PhD students, mainly in technology development, results of these researches are often patented in Latvia. Nowadays RTU offers 23 doctoral study programs that provide doctor degree in engineering sciences, architecture, chemistry and economics. Every year hundreds of new students start their PhD's. The changes of student's amount in all programs are shown in figure 1.

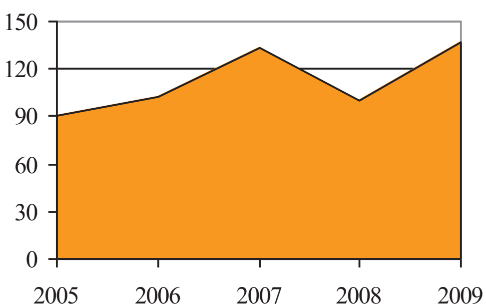

Fig.1. Doctoral students enrolment
(2005-2009 years)

II. DESCRIPTION OF EDUCATION STRUCTURE

There are about 500 doctoral students in RTU. The number of students in all programs is shown in figure 2 [3]. As a basic research force the doctoral students of RTU are employed in RTU as scientific assistants or researchers, according to qualification.

The RTU strategic priority is to archive 30% incomes of budget from scientific projects, involving in this way PhD students in regular research work, is important for RTU sustainable development.

The year 2008 budget of RTU was 62 Mil. EUR, but incomes from other scientific projects was just 2%. This means that the efficiency of usage scientific personal and equipment has potential to growth up in nearest future. The increasing of financial efficiency in RTU needs application of special methods, dissemination of scientific projects results and attracting new researchers is critical priority for RTU as a scientific institution. The main financial targets increased incoming finances from scientific research by 28 % next 5 years. According new scientific research it is important to have an infrastructure and, of course researchers.

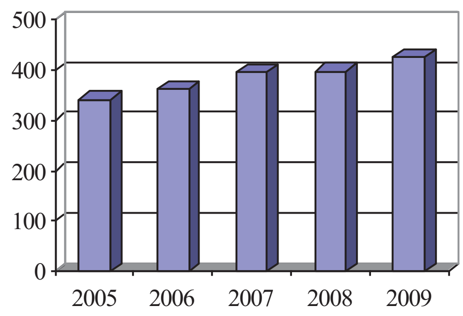

Fig.2. The dynamics of Doctoral students in RTU (2005-2009 years)

During two last years in RTU the common project control instruments and procedures were introduced. In figure 3 the fragment of formal project control tool is shown. In administrative structure of RTU also the special strategic department was introduced, with main responsibility to have formal control project documentation and other formalities, to keep in touch all formal project management cycle. However this control instrument and all departments could only control existing activities, but do not attract new scientific force to reach the target amount of projects. These procedures are not suitable to check scientific quality of project deliverables.

Fig. 3. The fragment of project control e –tool

To control of project deliverables scientific quality is project manager responsibility, and control procedures are different almost in each case, this issue is discussed in contract signature time.

To attract new researchers in scientific project development the such issue like free choice subject for PhD course students was introduced. The other issue is publication of project results in university newspaper "Jaunais inzenieris".

The main scientific cooperation in RTU is ongoing cooperation with industry partners from Latvia. That's way special RTU support programme was introduced. The amount of application on annual support for research in RTU this year was 34 projects, this amount shows active cooperation amount between RTU scientists and other companies. To attract young people in scientific research the special criteria as involving master students and doctoral students was introduced. To increase this active cooperation the attraction of new scientist is important, and in fact last few years main human resources in research are doctoral students.

The main measure of effectiveness of scientific research is amount of patents and trademarks. The patent and trade mark application amount are shown at figure 4.

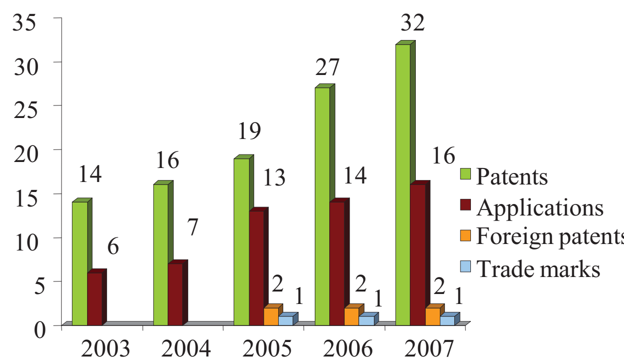

Fig. 4. The dynamics of patent application, foreign patents and trade marks

Most of the experimental works in laboratories were made by doctoral students.

III. Scientific Project Management Course Introduction

The doctoral students mainly become main researchers in RTU, so it is important to educate doctoral students, in time of doctoral studies and involve them into financially successful research.

There are doctoral programs, in which study subjects are divided into three blocks of basic subjects: compulsory subjects, subjects of obligatory choice and free choice. Within the time of three years for full time studies the subjects of free choice are considerably developed: „Management of scientific projects", „Intellectual Property Protection" and „Planning of experiments", pedagogy and other subjects are also accessible for the students of all RTU programs and from other Universities. During the study time the main is allocated for research and writing thesis. Every year the centralized assessment of doctoral student progress in research and studies is realised. The head of RTU Doctoral study department or deputy head of RTU Doctoral study department are present at these doctoral students progress meetings, so if the control of progress of research of the studies is centralised.

The development of doctoral studies in RTU deals with three main problems: financing, development of good relationship with industry, national and international partners. The course “Scientific project management“ was introduced in 2007, and still this course structure is under development. In 2006 the lecture note was written by professor I. Rankis and senior researcher N. Kunicina, so theoretical part of the course is written, but there are many practical and methodological issues to apply knowledge of project management into real scientific project preparation.

Each scientific investigation made by doctoral student is controlled by doctoral department of Riga Technical University, and scientific stuff in the Faculty or Institute. The course “Scientific project management“ helps doctoral students to structure their research, and to imagine all the process from the beginning of the research to commercialized result. Before this course it was not clear for students how to achieve market with their research results, because there was no structured information about scientific project management in Riga Technical University.

The main student’s response was that the information about project management and scientific product commercialization makes research more attractive and motivates doctoral students not only to get scientific, but also commercial applicable result after doctoral studies.

The product life cycle could be considered within two main parts: project and product management (see figure 5). The project stage requires financial investments and could be realised by scientific institution. Scientific project development technology could be separated in such project management stages: idea evaluation, research stage, conception stage, and realization and introduction stages. In introduction stage scientific institution should work together with a market company, which has bought product licence, or in other way has rights to commercialised product.

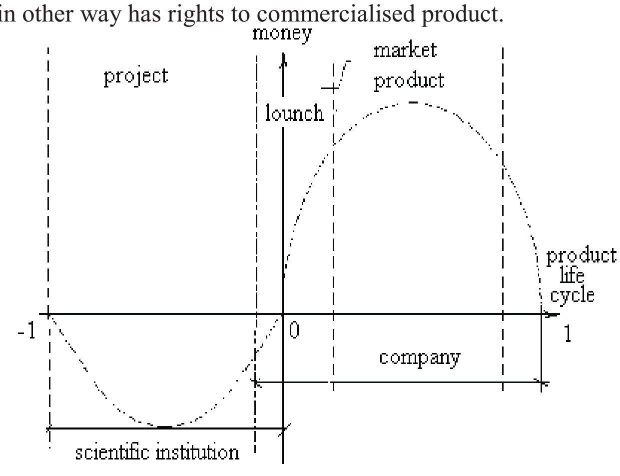

Fig. 5. Successful innovation commercialization cycle

Figure 5. presents a development cycle of a successful scientific investigation from the very beginning of the project till the final commercial application of the product. This diagram is used in “Scientific project management course” for schematic visualisation among product development and life time on market among time and finances.

Product management is divided in four stages: market introduction stage, growth stage, mature stage, saturation and decline stage. Market product management should be made by market company, and in case, if in product in mature stage will need some innovation, the scientific institution can made technical innovation, which could prolong product time in market.

Innovation is a very wide term that includes investigational, financial, market organization as well as a lot of other measures. Innovation development process is presented in figure 6 [2].

Innovations are connected with new technologies and implementation of the products with the help of scientific methods, i.e. scientific projects and their management. The scientific projects that are connected with new technologies and products implementation are considered to be applied by the researches.

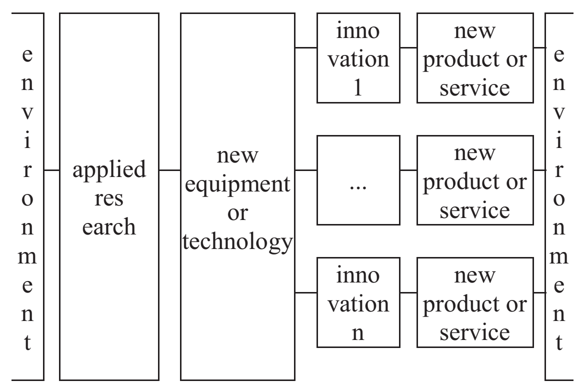

Fig. 6. Innovation development process

The innovative idea commercialization process is difficult for doctoral students. There are stereotypes and non structured knowledge that they have at the beginning of course. At the end of course they become skilled young researchers with structured knowledge about ways and possibilities to realize commercialisation of their research results [1].

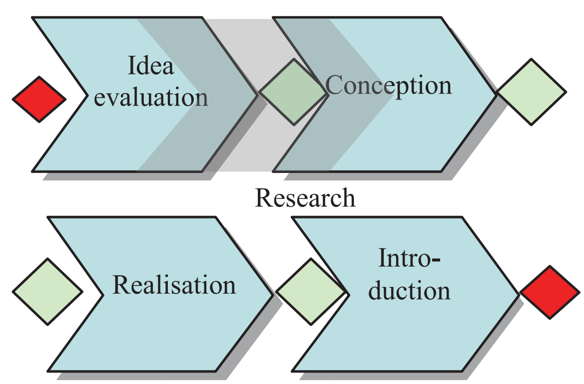

Fig. 7. Project realisation stages - development process and decision-making points

Project management is divided in four stages: idea evaluation, conception, realisation, introduction, and one additional research stage, which is actual for scientific research projects (figure 7).

Idea

Evaluation - Context

- Takes place when the idea has been defined and its strategic fit has been evaluated. Product development project begins

Objectives

- Product development activities aligned with strategic goals
- Ensure that core offering and customer needs and earning logic are defined, there are a basic understanding of market potential & competitive situation
- Ensure that technical feasibility has been reviewed
- The goals, milestones and desired outcome of the product development activities

Research

Context

- Takes place between idea evaluation or concept phases.

Objectives

- Development technology, product or methodology, to fulfil clients' requirements in a new way.

Concept development & evaluation

Context

- Takes place when the concept has been defined and evaluated against standardised concept description and evaluation template
- Implementation begins from this decision point

Objectives

- Ensure that value proposition is defined and core offering is tested by customer survey
- Ensure that the project has a business case and the solution is technically and legally feasible
- Ensure that implementation phase has relevant project plan
- In context of research projects in concept phase is important to ensure intelligent property of authors – make patent application, publishing scientific results, taking part in scientific conferences.

Offer development and launch planning (realization)

Context

- Takes place when the new product is ready to launch
- The market launch of the product is after this decision making point

Objectives

- Ensure that value proposition and business case are valid
- Ensure that the product is technically ready for launch
- Ensure that there are no open regulatory or legal issues
- Ensure that there is a relevant product launch plan

Introduction (Launch)

Context

- Takes place after launch has been carried out and evaluated to launch plan and business case

Objectives

- Ensure that market launch is evaluated and needed modifications are done
- Ensure that ongoing monitoring of product is planned and implemented
- Ensure that the product development project is evaluated

The knowledge structuring for doctoral students is one of three critical components to start scientific project, based on scientific research in doctoral studies. The other components is scientific research, with possibility to gate such final product, with ability to sell it on real market, mainly it should be new device, material or computerised program. The research results should not be too theoretical. The last component is ability of young scientist to work in risk condition.

IV. Finansial support

The supports of daily activities of doctoral students are grateful role for European Structural founds projects.

Since 31 of July 2009 doctoral study support project "Support of RTU doctoral study" Nr.2009/0144/1DP/1.1.2.1.2/09/IPIA/VIAA/005 has being realized. The European Union directly supports it in the frames of European social found financed projects. This is aim stupendous for doctoral students. In working programme annex 1.1.2.1.2. sub activity "Support for doctoral study programme". The activity in this project was started by organising competitions for doctoral students, and persons, who develop doctoral thesis (there is a special support for graduated students, who completes doctoral course, and who are going to defend doctoral thesis). Project realization duration is 76 month till September of 2015.

Aim of project is to increase of PhD defends amount, which will create and introduce in production new products, with high additional value, technological innovations. Doctoral research mainly is a base of new products development with high additional value. In this project frame approximately 300 persons will receive support. For scholars that is also a support of their scientific conference attendance and for supervisors.

During four years more than 360 RTU doctoral students and young doctors obtained grant and financial support for the purchasing of materials, visiting conferences, seminars, exchanging experience etc. Using also doctoral support financial resources doctoral students have a great possibility to cover doctoral and research activities and involve them themselves in scientific cooperation projects.

The Scientific project management course introduction in doctoral studies in Riga Technical University gives doctoral students structured knowledge in scientific project, in possibilities to apply projects at international level.

In natural figures, if the budget of RTU is 62 mil. Euro, the incomes from scientific projects should be 18 mil. euro per year. It seems, that target financing income from one researcher is 50 000 euro, or 550 000 euro per one scientific institute per year.

The main ways to have such financially successful researches are to evaluate scientific institution ability and skills of each researcher and show them possibility to achieve financial results in scientific teams.

Doctoral student's course scientific project management course is divided in two parts theoretical part and applied. Theoretical part allows to structured basic knowledge's about scientific project management, but practical application allows to student write formal application for scientific project tender.

The practical part for students is free choice topic. The experience since 2007 year is positive, but slow. The first students in the course as final paper presented their scientific research and novelty of scientific research, formalised in special way. The scientific projects scope, aim and work packages were formalised mainly in those projects. Next year the students have had prepared proposal for RTU scientific research projects, it was scientific project description with budget calculation, but this project total budget was not bigger then 20 000 euro. This year students prepare scientific project proposals in all three levels; there were students, which prepare projects with total budget more then 300 000 euro.

The introduction of course "Scientific project management" was successful, there was enough structured study material, hand book and competent teaching stuff. The results of implementation of this study course is not enough financially successful, it means, that knowledge's is just one of three components and it is not enough to start new projects. The motivation and ongoing support is important for starting new projects.

The other components is scientific research, was ability to sell final product on real market and the last component - ability of young scientist to work in risk condition.

The ability to develop and sell research final product on real market is mainly competence of scientific adviser head of structural unit - scientific institution. In particular in frame of European social found financed project „Development of doctor program and its quality in Riga Technical University", agreement Nr.2005/0132/VPD1/ESF/PIAA/04/APK/3.2.3.2/0050/0007 was introduced also other two important free choice study subjects „Intellectual Property Protection" and „Planning of experiments", this studies subjects helps students to formalised and finished their research results and make the market ready results of their research. Also additional infrastructure features was made for doctorants during this project. During the project „Development of doctor program and its quality in Riga Technical University" three teaching aids for the free choice subjects were developed, synopses of lectures were prepared, the thesis subjects has been developed with the aim to give an opportunity for young scientists to start first research projects within the doctor course, and to obtain scientific contacts and possibilities, consolidate RTU as a scientific institution enhancing from the research and investigations. The doctoral students who do not plan to continue the research can choose any subject of free choice from the register of subjects.

Using the seminar rooms (that were equipped during the project „Development of doctor program and its quality in Riga Technical University") provided also the use of the equipment within the project "Improvement of doctor studies effectiveness with the use of distance education" examining a lot of technical possibilities, purchased equipment: computers, notebooks, cameras, microphones, the opportunity to connect ten users into net was reached, that is useful for the doctor students individual tutorials and scientific work as well.

V. RESULTS OF THE PROJECTS AND FURTHER DEVELOPMENT

Third part to attracting doctoral student to take part in scientific research is knowledge in possibilities to apply projects at international level. The doctoral students during practical training have to know how to make qualitative project proposal and hove to apply for international founding projects. The main possibilities is to take part in COST, EUREKA (EUROSTARS), seventh framework programmes or other projects. The usage of some structural funds, which are managed in Latvia is also actual. The information about programme aims, structure, application procedure, samples of successful and not successful applications, this is the way how to motivate doctoral student to make his/her first application. Students realised, that they really could take a part in such projects, even that they haven't knowledge's about this projects and financing possibilities before they took part in this course.

The situation in Latvia, when research capability of small country is limited the cooperation with other international partners is critical to increase efficiency and financial incomes from research activities in RTU. The partner searching sometimes is not so simple, and the existing relation of scientific advisers is not enough for preparation of successful proposal at international level. In this time the Erasmus exchange program, European Cooperation in Science and Technology (COST) actions or any other direct cooperation programs are critical. The is possibility to find partners in conferences or from scientific societies, but this ways are not so efficient, as direct cooperation during research in common projects.

The experience in network of excellence was also positive just few years ago. The research activities of Institute of Electrical Engineering and Industrial Electronics of Riga Technical University L. Ribickis, A. Levchenkovs, N. Kunicina, Y. Chaiko, A. Ziravecka, V. Brazhis who took part in European rail research Network of excellence (NoE) FP-6 PLT – 506513 was created proposals in such topics: Operation and System Performance; Rolling Stock; Product Qualification Methods; Safety and Security; Environment and Energy Efficiency. Project proposal „SAFCORS: Safe and Cross-operable Rolling Stock" with 20 participants from 12 European countries for FP7 2nd call Area: Sustainable Surface Transport FP7-SST-2008-RTD-1 was appled.

The EUREKA project development now is very actual, because the is ongoing European Regional found project proposal frame "Business and innovations" 2.1.1.2.activity

"Support for the international co-operation of the projects in science and technologies, this financial resource allows to reimburse project proposal preparation expenses and it is chance for new researchers to get founding for future work in RTU as researchers. Unfortunately now work in EUREKA projects is not frequent, because of shortness of financial resources in Latvian budget, for example cooperation in EUREKA project Hybrid Modular Home Media Equipment was not efficient, because project team have to move activities, waiting till new year for financing and all this troubles negatively influence project realisation.

The partners search and project preparation for seventh framework projects are efficient just in particular cases. There is national contact point, which is responsible to support project preparation. The RTU awarded young scientist of 2008 Dr.sc.ing. Kaspars Kalnins during scientific project management course is specially invited to have a practical seminar and help student's to prepare the seventh frame work project proposal in efficient way. The annual competition for the award young scientists was introduced in 2006 with the aim to enhance scientific research in RTU, to involve young scientists in research activities and to evaluate the results of the scientific research work of RTU scientists.

The motivation of doctoral students is organised in all levels directly and not directly, as an example internal RTU projects financing scheme and evaluation criteria. The criteria to apply for research financing includes such quantitative criteria as published monographs, students books, articles, presentation of research results in international scientific conferences. As well the ready to market of final product - patents.

The improvement of the doctoral study program and technical equipment at RTU is long term investment politics in economics' sustainability. The sustainable development depends also on the availability of equipment, which meets modern technological requirements. The main priority in the research staff training in RTU is development of doctoral studies in high-technology research-intensive fields. Many financial possibilities, which we have during the last years allows using of more modern scientific equipment for experiments.

There is a good practice during recent years - support innovation commercializing, based on State financing, CONNECT network, and university – enterprises collaboration agreements. The education by involving the doctoral students in the research is still under development, but in some divisions we could see, that it really works. The subjects that are interested for a lot of doctoral students are prepared in web based format, using new equipment, which was bought in last four years. Implementation of the doctoral studies base facilitates the use of website environment for training purposes and for communication among doctoral students and contacts with cooperation partners in other countries. Development of doctoral studies at RTU promotes the development of human resources and helps to improve the situation on the enterprises developing the ideas ready for commercialization.

VI. Conclusions

Doctor studies play an important role in the training of scientific staff for sustainable development of Latvian economics. The application of project based learning approach in doctoral studies is main instrument to reach acceptable level of industry in Latvia. The analysis of case study of IEEI, which is a leader in RTU in project-based learning application shows, that such strategy application could increase the financial resources of institution more than two times. Research projects in the field of power electronics and electrical engineering. The annual scientific report informs on the main branches of the research activities, contact information of the staff, scientific results and the present scientific infrastructure. Special attention is devoted to the Doctoral students who will provide the development of science in future as the basic workforce.

The course helps doctoral students to structure they research, and to imagine process from the beginning of the research to commercialization. The main response was that the course research more sustainable and motivates doctoral student's also commercial applicable result after doctor studies.

The main motive force of knowledge based economy is innovative activity, which promotes the use of the newest science and technology achievements. Innovative activities promote the participation of professionally qualified experts in commercial activities and increasing demand of research work in universities and research institutions. The final results of innovation are products which are able to make competition in world market and services with high added value. Result provides important increase rate of gross domestic product, more work places for qualified specialists, which can promote economical growth, social welfare and country up growth.

Acknowledgment

The authors are grateful to European Commission, that have partially supported apart of the work described in the paper, under scope of project „Support to the development of doctoral studies at Riga Technical University", agreement of implementation no. 2009/0144/1DP/1.1.2.1.2/09/IPIA/VIAA /005.

Introduction to Electronics as a Minor Subject

Marco Winzker
Hochschule Bonn-Rhein-Sieg,
University of Applied Sciences
Sankt Augustin, Germany
marco.winzker@h-brs.de

Abstract — **Technical knowledge should not be limited to computer scientists and engineers. Also people outside these professions should have a basic understanding of technical concepts, trends and challenges. This paper describes a module of electronics for technical journalists and shows that electronics can be successfully communicated finding a balance between simplification and accuracy.**

Keywords – electronics, technological literacy, life-long learning, educational methods

I. Introduction

Technology has a major impact on today's life. Electronic circuits help us through the day, starting in the alarm clock that wakes us in the morning and the radio that gives us the news during breakfast. And the electronics in a smoke detector guards us during the night.

Below the surface, the advancement of electronics has a significant impact on society and economy. Looking at society first, a number of current developments are consequences from new technology. This can be illustrated with the MP3 coding and the internet. These two technologies enable an easy sharing of music with programs like Napster. The music industry objected and copyright laws were changed in a number of countries. So, technological advancement led to a major change in legislation.

Figure 1. Camera for video surveilance

Another example are closed-circuit television (CCTV) systems for surveying public areas (Fig. 1). While already in use, the increasing computing power will lead to new applications like automatic detection of "suspicious" behaviour or tracking of persons through a city. Here society needs to discuss, whether those systems are a valuable help for the protection against crime and terrorism or a threat to the privacy of citizens.

Looking at the economic impact, electronics is a key technology that enables other products. A modern car is only competitive with an anti-lock braking system and electronic stability control. Car manufacturers without access to those systems will not be able to sell their products.

The same applies to other product categories. A washing machine in the higher market segment certainly has a more stable mechanical body and more powerful motor compared to a budget washing machine. Nevertheless, a customer paying the higher price for the advanced machine also expects a sophisticated appearance, e.g. a small display giving the remaining runtime. Such electronics costs little but are required to sell the expensive machine.

This impact of electronics on our lives and the economy however is contrasted by a lack of interest in society as a whole. People outside engineering and computer science are often unaware of the role modern electronics plays. This lack of communication and understanding between two important groups in society, the scientists and the literary intellectuals, has been described in the influential 1959 talk of C.P. Snow "The Two Cultures" [1].

There are a number of reasons why we, the engineers and computer scientists, should try to change this situation. If we want appreciation or remuneration for our work, we need people to understand what we do and where our work has an impact. Furthermore, visibility of our profession draws prospective students. And we also want to interact with society and discuss the risks and benefits of new technologies.

Such a basic understanding of engineering and science is termed technological literacy and has been proposed in [2], [3], [4]. Individual courses are described in [5], [6] and a comparison of different approaches teaching technological literacy is given in [7].

Many of the described courses cover the broad subject area of physics and technology. Other dwell on systematic procedures in engineering by programming exercises. The course described here specifically focuses on electronics, which is a subset of technology, but a significant subset.

The paper reflects teaching electronics as a minor subject and gives experience based on a course held for technical journalists. The same approach could be used for students studying economy, law or political science.

II. Educational Objectives

While for every course its objectives should be defined, this is especially important when teaching a broad topic in limited time. Also a balance must be found between simplification and accuracy. For the course of electronics as a minor the following educational objectives were defined.

The students shall,

- be able to explain basic terms and components in the field of electronics,
- know the main tasks in design and manufacturing of electronic circuits,
- be able to assess new information about trends in electronics.

However, it must be noted that it is no course objective that students shall be able to design electronic circuits themselves. This will not be their task in their aspired professions.

III. Teaching Approach

A. Target Group

The most important recipients to have a basic knowledge about electronics are decision makers, like managers and politicians, as well as knowledge multiplier like journalists. The approach described in this paper covers a module of electronics for technical journalists, held at the Bonn-Rhein-Sieg University of Applied Sciences. The course has been held for five years with about 60 students each year. A similar course can be used in other degree courses and is offered as continuous education.

The teaching approach has to consider a heterogeneous group of students, both in respect of previous knowledge and interest. Graduates and students of the described study courses are normally quite familiar with applications of electronics, such as computers, mobile devices and automotive electronics. However, they often do not realize the technology behind the product.

B. General Teaching Approach

Looking at the complete field of electronics, students could consider it too broad to be covered in just one module. The first task of the instructor is therefore to structure the contents in smaller topics [8], [9]. Each topic corresponds more or less to a teaching block of 90 minutes.

The individual topics serve several purposes. Besides structuring the complete course, they help motivating students, because for every teaching block they are told the relevance and impact of "today's topic". This is important, as the motivation of students for a minor subject can be limited.

Also each topic provides a new entry for students who have missed the last lecture or could not keep up. Consequently it is possible to give some more in-depth lecturing for each topic, as students who do not fully comprehend more advanced concepts have the chance of catching up with the begin of a new topic at the next lecture.

C. Structure of Topics

Teaching time for the module are six lectures and six seminars, each having 90 minutes. The seminar also contains small lab exercises.

The complete subject has been structured into the following six topics, each approximately taking 90 minutes lecture [8].

1) Introduction, Basics

This topic motivates the course by discussing the impact on society and economy similar to the argumentation in chapter I of this contribution. Then the basic components like resistors, capacitors, diodes, transistors as well as printed circuit boards are explained. Additional to an introduction to electric circuits some considerations for manufacturing and device selection, such as packages and tolerances are discussed.

If students did not have a previous physics course, also electric charge, voltage and current can be covered. In this case, this topic could be extended to two 90 minute blocks.

2) Analog and Digital Electronics

Signals and circuits of analog and digital electronics are contrasted in this topic. The sine wave as the fundamental analog signal and the concept of calculating with zeros and ones are presented. Basic circuits for rectification and amplification as well as logic gates and flip-flops are introduced.

3) Semiconductors

After having learned about the function of diodes and transistors, this topic looks "under the hood" and explains the p-n junction as the physical effect that is active in diodes and transistors. While this is rather abstract, the complete field of electronics is based on the p-n junction, so it needs to be covered.

Also solar cells are explained which receive high interest from students due to the economic and environmental importance of renewable energy.

4) Design and Manufacturing

People not working as engineers have limited conception about the different steps during a design project but need a certain level of understanding when discussing the development of new products. Tasks like specification, circuit concept, circuit entry and verification are explained. Furthermore, sourcing of components and manufacturing is covered. The topic also looks at the introduction of new products and questions why a product can be a success or fail.

Especially this section is an addition to courses described in literature [7] as it emphasizes the economic impact of technology.

5) Micro- and Nanoelectronics

With the knowledge of semiconductors (topic 3) and electronics design and manufacturing (topic 4) this topic explains integrated circuits, covering technology, design and manufacturing.

Semiconductor memories are also explained and receive good students' interest, as the advancements in this field are apparent, e.g. in the rising memory capacity of USB flash drives.

6) Automotive Electronics and Embedded Systems

These two subjects should not be missing in an electronics course, representing an important application and the integration of electronics in a machine. Again, based on the previously discussed general knowledge of designing electronics some special considerations for embedded systems are explained.

D. Repetition of Important Concepts

Structuring the complete course into topics also allows reiterating basic concepts of electronics. Thus, students get a repeated chance for understanding.

For example, the transistor is discussed in topics 1, 2, 3 and 5. In the "introduction" (1) the basic function of the transistor as a switch and amplifier is explained. In "analog circuits" (2) a simple amplifier is presented. The topic "semiconductors" (3) explains the physics of a transistor and "microelectronics" (5) covers the integration of millions of transistors on a single device. Each time the transistor is discussed, giving stronger students the chance to apply their knowledge and weaker students to ask questions and get another explanation.

IV. SIMPLIFICATION AND ACCURACY

As the target group only needs an overview about electronics and will not themselves design circuits, the lecturer has the right and the duty to simplify the presented information. However, a balance has to be found so that the simplified information is still accurate.

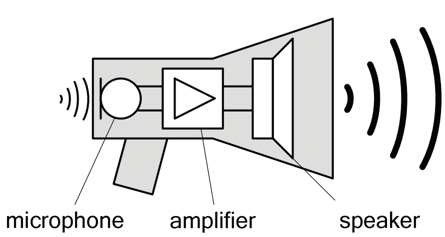

Figure 2. Megaphone as example for an amplifier

A. Transistor as Amplifier and Switch

How such a balance between simplification and accuracy has been established shall be discussed for presenting the function of a transistor. First, the need for an amplifier is illustrated with a megaphone (Fig. 2). The weak input signal shall come from the microphone and the sound is given to a speaker.

Then Fig. 3 shows the simplified function of an amplifier with a transistor. Controlled by the weak input signal the transistor opens the path from the power supply through the speaker. For an electrical engineer, the circuit might seem trivial, but it helps students grasping the concept of an amplifier. By discussing the circuit it becomes clear, that the transistor does not provide energy to the speaker but switches the flow of energy from the power supply through the speaker. Nevertheless, it is explained that a real amplifier, e.g. of a megaphone, has several amplifier stages and some more components like resistors and capacitors.

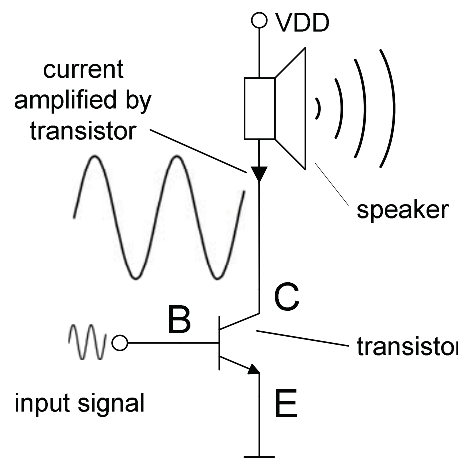

Figure 3. Transistor as an amplifier

Based on the simplified amplifier a real circuit is presented later in the seminar. It is a light sensor where a photoresistor senses brightness and the transistor switches an LED (light-emitting diode) on or off (Fig. 4). It is similar to a street lantern that automatically switches on during darkness. Compared to a real lantern again this circuit is simplified but it is a working circuit.

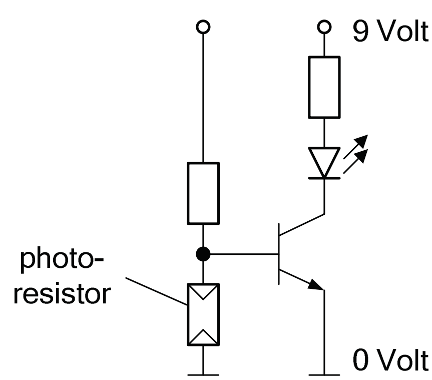

Figure 4. Street lantern with light sensor

During the seminar, the function of the light sensor is explained by discussing the two cases of brightness and darkness. In brightness, the photoresistor pulls the base of the transistor to ground and closes the transistor. In darkness the left resistor pulls the base of the transistor to 9 Volt and opens the transistor, the LED lights.

This explanation is simple enough for non-engineering students to comprehend. The circuit is also soldered on a printed circuit board in a hands-on lab during the seminar. This activity is motivating and gives the students the possibility to personally interact with electronics.

B. *Digital Circuit*

Another small example is used to illustrate the principal function of a digital circuit. A small dice shall be implemented that draws between four possible outcomes.

While a button T is pressed, the circuit switches between four states name A, B, C, D (Fig. 5). These states correspond to the four possible results of the dice. Switching is so fast, that a person pressing the button generates a random state upon release.

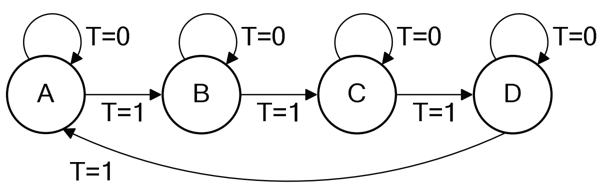

Figure 5. State diagram for simple dice

The circuit is implemented with two flip-flops storing the current state, some gates calculating the next state from the current state and some further gates calculating four outputs A, B, C, D that light LEDs giving the result of the dice (Fig. 6).

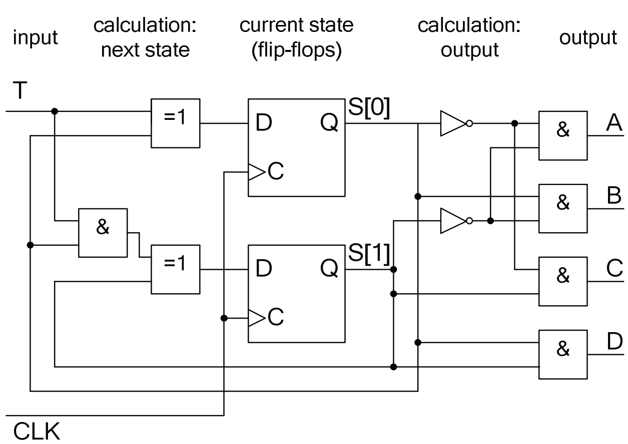

Figure 6. Circuit diagram of simple dice

The circuit is discussed with the students during the seminar and switching from one state to another state is calculated with paper and pen. A real hardware model of the dice has been constructed in a student's project. It shows the digital circuit at work and allows playing with the dice. As an addition a web based simulator is used to further demonstrate the circuit's behaviour [10], [11].

Again it must be noted that the digital circuit is working, but for a real application probably a small microcontroller would be used.

V. APPLICATION EXAMPLES

A. *USB Flash Drive*

Relating electronics to prior knowledge about technical systems is important to involve students in the module content. Also it underlines how the course is linked to topics outside the classroom. For this purpose application examples are used.

As an application example a USB flash drive is used to illustrate design and manufacturing of electronics. It is well suited due to several properties:

- As an everyday item it is well known to students.
- It only contains two integrated circuits with clearly defined tasks plus some small components.
- The product category undergoes rapid technological developments, especially with rising memory capacities.

B. *Specification and Circuit Concept of USB Flash Drive*

Different types of USB flash drives are known to students. They come as a simple mass storage or as an MP3-player with the option to store data. The design can be simple or fashionable. Optional features are a switch for write protection or data encryption.

All these options give the possibility to discuss the economic impact of the product specification with students. Which features are expected by customers? What is the cost impact? At which end of the market will the product be placed?

Based on the specification the circuit concept can be discussed. The block diagram of a USB flash drive (Fig. 7) is fairly easy to understand. A controller communicates via USB with the PC and stores information in a flash memory. Some LEDs are used as a status display.

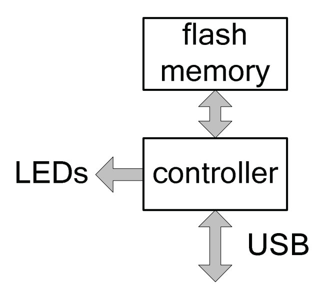

Figure 7. Block diagram of USB flash drive

With the block diagram further considerations for product design can be discussed. Often several controller can be used, some already available, others announced. Which shall be chosen? Should a small display be used instead of simple LEDs? These question will not be answered in the course, but illustrate the decisions engineers are faced during product design.

C. Design and Implementation of USB Flash Drive

Having discussed the block diagram the further steps in circuit design can be presented. Again, the students shall not learn how to perform these design steps but should be aware of the engineering tasks.

Implementation details from a commercial USB flash drive are available in a reference design [12]. This design is used to show students a complete set of engineering and manufacturing data including schematic, layout of the printed-circuit board (Fig. 8) and bill of material. A product photo (Fig. 9) shows the complete product.

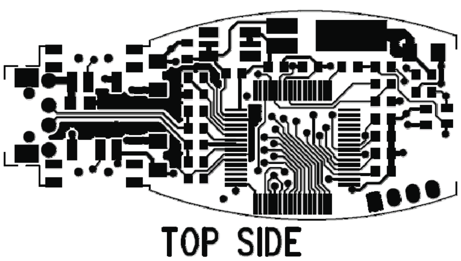

Figure 8. Printed-circuit board layout of USB flash drive [12]

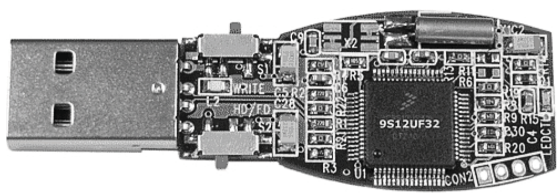

Figure 9. Product photo of USB flash drive [12]

Finally, also start-up of a prototype design is explained using the USB flash drive. In a first step an engineer will address the controller and try to read a device number and switch on/off the LEDs. Only if this works, the flash memory will be put into operation. Students can discuss to what extent parallel work of several engineers is possible and whether it makes sense trying to start-up the memory when the correct function of the controller has not yet been achieved.

D. Role of Application Examples

As discussed in chapter IV simplified examples are used for basic concepts, like transistor functionality or principle function of digital circuits. The application examples use a real design to relate the course to industrial products.

Other application examples use a stopwatch to illustrate programming of an embedded microcontroller [13] and the driver's door of a car to explain use and function of automotive bus systems.

VI. Observations and Evaluation

The experience of five years teaching electronics as a minor subject shall be given as personal impressions during teaching and discussing with students as well as a formal evaluation using a questionnaire.

A. Experience during lectures and seminar

During the course students showed significant differences in their abilities and motivation. Some students are already familiar with electronics, while others are very reluctant to engage with the subject.

This heterogeneity has been anticipated and led to structuring the course into different topics. For the weaker students it has shown to be helpful repeating important concepts several times. Students with previous knowledge were eager to discuss advanced problems.

B. Students' motivation and "weaker students"

Some more thoughts shall be given here about students' motivation and working with weaker students. Of course, every instructor wishes for students with high motivation who follow every word that is said and take the initiative to further dwell into the subject.

However, students' interest in minor subjects is often limited as they focus on the main subject of their studies. Also, they do not invest much time to compensate missing previous knowledge. While this is regrettable from the instructors viewpoint, it is an understandable approach from the students side.

Nevertheless, the experience of teaching an interdisciplinary course as a minor has been and still is very positive. Students with little previous knowledge might not reach a very high level of knowledge but often show a very steep learning curve and reach the educational objectives.

Also they might come up with interesting ideas for applications. For example, during discussing the electronic dice, a student asked whether the dice could be extended to give 20 different values. Such twenty-sided dices are used in role-playing games. So, while the student learned about electronics, the lecturer learned about role-playing games.

C. Formal Evaluation

In addition to discussions during the lab, a formal evaluation has been undertaken, to investigate to what degree students accept complex topics. In one degree program students also attend a hands-on lab and after the written test at the end of the term they were asked to judge three different lab exercises.

- A: "current–voltage characteristic" – This is a typical engineering exercise where the students measure the characteristics of resistors and diodes.
- B: "light sensor" – A very interesting exercise, where students solder a small circuit on a board (as discussed in chapter IV-A and with Fig. 4).

- C: “embedded system” – Here the students should modify C-code to program a stopwatch [13].

For the three exercises students have given marks in two categories. They should indicate whether the exercise helped for understanding the lecture contents and whether they could transfer the knowledge to real life. The value 1 means “excellent” and 5 is “poor”. Evaluating three exercises allows a better assessment of the embedded systems lab.

The results of the evaluation are shown in Fig. 10. A total of 56 students responded. As expected the interesting and entertaining experiment “light sensor” (B) gets a better evaluation than the a bit tedious “current–voltage characteristic” (A). These values are used as reference.

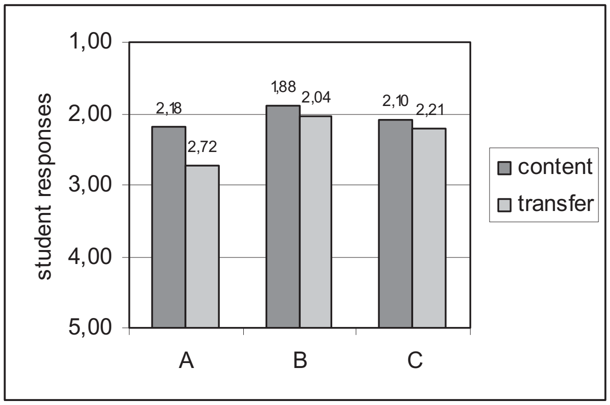

Figure 10. Evaluation of three lab exercises

The relevant result is the evaluation of the “embedded system” exercise (C). Here students without previous programming experience were a bit overchallenged. However the evaluation showed, that they accept small frustrations and give this exercise good ratings.

This becomes especially apparent looking at the different responses for content and transfer to real life. Exercise A (“current–voltage characteristic”) is accepted as giving knowledge for the exam. However, the students do not see much value of this information for their professional life. In contrast, for the “embedded system” exercise (C) students realize that they can transfer the knowledge they gained outside the classroom.

VII. Conclusion

The basic concepts of electronics have been successfully taught as a minor subject to non-engineering students. Key to the lecture is a strong focus on the educational objectives, accepting that students will not design electronics themselves. They rather have to comprehend and assess information about electronics and be able to professionally interact with engineers and computer scientists.

In addition to other technological literacy courses, the economic impact of electronics is emphasized, linking the course content to other subjects. Also this provides the application for the students, as their assessment of technology will be based on economic merit.

Organizing the course into clearly differentiated topics allowed coping with the heterogeneity of students. To students with previous knowledge, more advanced information could be given, while enabling students with little previous knowledge can catch up at the beginning of a new topic. Discussions with the students and the evaluation show that students engaged in the topic and believe they can transfer knowledge from class to real life.

Acknowledgements

The semiconductor manufacturer Freescale allowed the used of extensive information from its USB Thumb Drive Reference Design in the lecture and the textbook which is gratefully acknowledged.

Abstract— **Calls for educational reform emphasize the need for student-centered learning approaches that foster lifelong learning. To be a lifelong learner includes characteristics consistent with those of self-directed learners, such as being curious, motivated, reflective, analytical, persistent, flexible, and independent. Educational research has shown that the building of these aptitudes involves a complex interplay among nearly every aspect of human development. Instructor support of students' self-directed learning (SDL) development relies on understanding and balancing these factors in the classroom. Engineering educators play a critical role in influencing outcomes related to SDL through their design of courses that support students' transitions from controlled to autonomous learning behaviors. This study will examine a variety of engineering courses and pedagogical approaches. Each will be characterized using instructor course information, videotaped classroom observations of instructor-student and student-student interactions, student and instructor responses to surveys, and focus groups. Finally, the students' capacity for SDL will be measured using the Motivated Strategies for Learning Questionnaire. This approach should provide for rich, contextualized descriptions of what instructors and learners do, how instructors and students relate to each other, and how students view their classrooms. This work-in-progress paper will describe our initial work in this multiyear study.**

Keywords-Lifelong learning, Autonomy support, Self-directed learning

I. INTRODUCTION

Calls for educational reform emphasize the need for student-centered learning approaches that aid development of broader skills and attitudes such as a capacity for lifelong learning [1,2,3,4,5]. Engineering educators as well as ABET recognize that students' development of such a capacity is vital for their success in today's global and rapidly changing engineering environment [4,5,6]. However, the current emphasis – particularly in the engineering education community – seems to be on assessing students' lifelong learning abilities, rather than on understanding the relationship between instructor practices and lifelong learning outcomes. To be a lifelong learner includes characteristics consistent with those of self-directed learners, such as being curious, motivated, reflective, analytical, persistent, flexible, and independent.

Designing learning environments and activities that engage students in self-directed learning (SDL) and foster the growth of autonomous individuals, however, is not a simple task. With its introduction of program outcome (i) "a recognition of the need for, and an ability to engage in lifelong learning," as a requirement for all engineering graduates, ABET essentially challenged engineering educators to determine how we may best engage students in SDL (and eventually lifelong learning). To effectively promote SDL, faculty need to be skillful in facilitating pedagogies that engage students in self-direction, be sensitive to and understand student attitudes and behaviors in SDL settings, and be aware of the roles that classroom environments can play in aiding students' SDL development.

The limited existing studies show no significant gains in undergraduate engineering students' capacity for SDL via traditional instruction [7,8]. However, nontraditional instructional practices such as problem-based learning are more explicitly designed to develop student attitudes and skills relevant to SDL, and there is some literature support to suggest that these approaches are more effective at developing self-directed learners [9]. There remains, however, little empirical data on those factors that promote SDL amongst undergraduate engineering students, especially from carefully designed studies using validated instruments. This multiyear investigation seeks to fill that gap by conducting an observational study that examines a range of engineering environments, carefully characterizes instructor practices regarding support of student autonomy, and analyzes the relationship between classroom environments and proxies for lifelong learning such as SDL behaviors and attitudes.

This work is supported by the US National Science Foundation under Grant Nos. EEC-0835884, EEC-0835889, EEC-0835901, and EEC-0835911.

II. BACKGROUND

A. Defining Self-Directed Learning

One of the greatest challenges associated with SDL lies in its definition. Some engineering educators may consider it as a single skill that individuals either have or lack. In reality, the building of SDL aptitude involves a complex interplay among nearly every aspect of human development. Individuals become self-directing through mastery of a broad range of skills, attitudes, and knowledge [10-17]. The education literature includes extensive discussion of the competencies and attitudes of effective self-directed learners [18-21] and descriptions of the many factors that affect student growth in autonomous learning environments. These include cognitive and metacognitive factors [11,22] motivational factors [11,23], behavioral components [24,25] and contextual and social aspects of learning [22,26-30].

Motivational, cognitive, behavioral, and contextual factors are clearly interrelated, and the support of the development of students to become self-directed learners relies on a complex balancing of these factors in the classroom. For example, much is known about the relationship between student self-direction and motivation, and about the importance of fostering positive student attitudes and behaviors for engagement in SDL environments. Autonomy has been shown to increase students' intrinsic motivation, self-efficacy, and perceptions of task value [31-33], and use of cognitive and metacognitive strategies for learning and adaptive motivational strategies [34]. Black and Deci further demonstrated that autonomy-oriented students had higher perceived competence, higher interest and enjoyment, and lower anxiety and grade-focused goals [27]. Zimmerman emphasized that in addition to metacognitive skills, students need a sense of self-efficacy and personal agency for success in self-directed environments [35].

B. Role of Instructor in Self-Directed Learning

Although much of the burden of developing SDL competence falls on students, instructors also play a critical role in effectively promoting individual SDL development both through their instructional choices and their interactions with students. Autonomy support is one such area in which different practices may yield different outcomes. Black and Deci, in their investigation of undergraduate students in organic chemistry, revealed that students' perceived instructor support of autonomy related to improved perceptions of competence, interest and enjoyment, and ability to self-regulate [27]. Opportunities for individual choice, control, authority, and responsibility appear to be important elements in both the academic achievement and the psychological development of students.

Table I, developed by Stefanou et al. [28], provides a framework for characterizing different types of autonomy support that may help develop students' self-directed learning, along with examples of specific instructor strategies. In this framework, Organizational Autonomy Support includes student choices that are primarily related to contextual factors (e.g., selection of team members) and behavioral factors (e.g., managing due dates). Procedural Autonomy Support includes choices related to students' intrinsic motivations (e.g., discussing their wants and displaying individual work), and some opportunities that connect motivational and cognitive strategies (e.g., selection of resources). The Cognitive Autonomy Support describes choices that relate directly to students' mental processes during learning (e.g., self-reflection on errors, consideration of multiple solutions and strategies).

TABLE I. STRATEGIES ASSOCIATED WITH THE DIFFERENT FEATURES OF AUTONOMY SUPPORT

Organizational Autonomy Support	Procedural Autonomy Support	Cognitive Autonomy Support
Students are given opportunities to: • Choose group members • Choose evaluation procedure • Take responsibility for due dates • Help create class policies	Students are given opportunities to: • Choose how competence is demonstrated • Display individual work • Discuss their wants • Choose resources to use	Students are given opportunities to: • Discuss multiple approaches • Find multiple solutions • Justify solutions • Be independent problem solvers • Reevaluate errors • Debate ideas freely • Have less teacher talk time; more teacher listening

Unfortunately, there is little solid empirical data that shows how instructor choices promote or hinder SDL development in undergraduate engineering students. Of the many factors that contribute to the student response in autonomous learning environments, perhaps the least explored are the contextual or environmental factors. In 2000 Paul R. Pintrich noted that "there is a clear need for more descriptive, ethnographic, and observational research on how different features of the context can shape, facilitate, and constrain self-regulated learning [13]. Nearly a decade later, the need remains. Studies have shown that students' positive perceptions of their assigned tasks and instructors' autonomy support can lead to increases in intrinsic motivation, self-regulation, perceived competence, interest, engagement, and academic performance [34,36,37], but the connections between these student perceptions and the instructors' choices in course design and classroom environments remain unclear.

Clearly, there exists an opportunity for researchers to identify approaches, interventions, interactions, and contexts that promote the development of SDL skills in undergraduate students. In particular, there is a need to provide a deeper understanding of the relationship between the types of student autonomy support and the development of SDL competencies. Our study will aid instructors' understanding of how their classroom practices affect a range of student outcomes related to lifelong learning. We expect that variations in ways that instructors support student autonomy will influence students' development as self-directed learners. We aim to gain a clearer understanding of how aspects of course design and implementation relate to student responses and learning outcomes by exploring these questions:

1. In what ways do engineering instructors assist students to become self-directed learners? Are there instructor practices

and behaviors that lead to greater student involvement in and ownership of their own learning?

2. What are students' behavioral and affective responses to different ways autonomy is supported in undergraduate engineering settings?

3. What effect does a sense of autonomy have on students' perceptions of their own learning?

III. Methodology

A variety of different undergraduate engineering course environments will be examined as part of this study. The courses span nearly all academic levels, include both lecture and laboratory settings, and provide a range of pedagogical strategies that emphasize active, collaborative, problem-based learning, and project-based learning. This study focuses on active learning environments since these have provided the most promising results to date for developing students' capacity for self-directed learning.

Although all of the classroom settings may be characterized as "active," the different courses will present recognizable differences in the types and amounts of student choice and control, as well as differences in the classroom environment characterized in terms of student-student and student-faculty interactions in support of student autonomy. As such, these courses provide an opportunity to study the relationships between differences in autonomy support on the development of SDL-related competencies of motivation, student autonomy, and cognitive and metacognitive strategy use. We anticipate the different courses will provide wide variety in the type and level of organizational, procedural and cognitive student autonomy support. The rigorous characterization of the classroom environment with respect to student autonomy support is the first phase of the evaluation component of this project and is the focus of this paper.

A selection of class sessions for each of the instructors will be studied intensively through the lens of autonomy-supportive practices. To do this, syllabi and classroom artifacts in the form of classroom assignments will be collected, selected class sessions will be videotaped, and the instructors will complete a survey that measures personal epistemology. Students will be asked to complete a survey that measures the aspects of motivation, autonomy, and cognitive and metacognitive strategy use that are associated with SDL at the beginning of the semester and again at the end, and students will be videotaped along with their instructor during preselected class sessions. At the completion of the course, the instructors will be interviewed to discuss the choices they made in their course and students will be interviewed to discuss how those choices affected the variables of interest in this study.

IV. Work in Progress

We are in the first year of this three-year study, and are beginning the process of characterizing our various classroom environments. We will report on preliminary findings at the conference. Here we describe the various courses and characterization methods in this first year.

A. Descriptions of Courses

Heat and Mass Transfer is a required course for third year chemical engineering students. It adopts a problem-based learning structure in which students work in teams to solve a variety of open-ended, relevant engineering problems. Students are provided limited organizational autonomy support (they have some influence of team members and due dates) and more significant procedural autonomy support (they have significant influence on the selection of resources and regular opportunities to discuss their wants). In addition, the course incorporates very substantial cognitive autonomy support elements in that students are engaged in regular discussions of multiple approaches and solutions to problems with heavy course emphasis on justifying their solutions and exhibiting independent problem solving strategies.

Circuits is a sophomore-level course for electrical, industrial and mechanical engineering majors. Faculty-student interactions occur primarily during class lecture periods. In a typical class period, the professor prepares notes in PowerPoint which are projected using a TabletPC. The notes are intended to provide the outline and structure for the discussion of the topic, and there are many spaces where students are encouraged to write in their own notes, answers to questions or solutions to problems. Students are often asked questions to be sure that they are following, and they are called on in order going around the room to be sure that everyone is involved. In short, there is a reasonable amount of faculty-student interaction during these times but little student-student interaction during this time.

Most periods of the Circuits course also include at least one activity for which the problem statement is included in the notes along with whatever supporting information is necessary. Students are told to "turn to a helpful neighbor" and work out their solution. Students then work together on the problems while the professor walks around the room and checks in with groups, asks questions or answers questions. During this time, there is a fair amount of faculty-student interaction and student-student interactions within their groups. Finally, there are significant student-student interactions in cooperative-learning homework teams. Three to four students are assigned to each team at the beginning of the semester and each team meets weekly to work on the week's assignment. Team members rotate through various roles on the team and submit one solution set.

Failure Analysis and Prevention is a project-based, upper-level elective course for engineering students. Student development in the course is focused on professional-level competencies and application of self-directed learning skills. By organizing and carrying out self-directed failure investigations of real-world components and systems, and through analysis of published case studies students learn failure analysis by doing failure analysis. The projects emphasize the interdisciplinary nature of failure investigations, and they provide students with the opportunity to select team members and due dates (organizational autonomy), identify resources and express their own goals (procedural autonomy), and select learning strategies, manage class time, align learning with their own goals, and self-assess their project work as well as their development as a team member and lifelong learner (cognitive autonomy). Throughout the projects, the instructor serves as a consultant and a sounding board for students' experimental strategies and data analyses. Some of the class periods are devoted to open-ended discussions and debates of contextual factors that contribute to engineering decision-making. In the first half of the semester, the instructor provides weekly reading assignments and facilitates an in-class discussion of the readings. In the second half of the semester, student teams take responsibility for the selection of readings and facilitation of the in-class discussions.

The final course under study in the first year, Thermodynamics II, is a required course for mechanical engineering students. The course is taught in a lecture format with homework sets, quizzes, and midterm and final exam. It relies on the least amount of formal team work both in and out of class, and opts instead for peer teams formed *ad hoc* during class meetings. The instructor uses active-learning techniques during class, including the use of clickers and "turn-to-your-neighbor and discuss." Outside of class, students are highly encouraged to work in small groups to complete the assignments, but each student is expected to submit a homework, if he or she elects to do so. In addition to active-learning techniques, the instructor makes available partially completed notes, and incorporates some conceptual questions (using the clickers) to get away from focusing only on calculation-based examples. A typical class includes a brief lecture (less than 10 min) and quickly moves to problem solving. The instructor sets up the problem (describing it, providing known values, etc.) and breaks it into small 'chunks' or steps, which is then turned over to the students to solve individually. The students' understanding is then checked using the clickers. When there is some confusion as to the correct answer, students form impromptu two-person teams to discuss the question, and then are retested using the clickers. This procedure is repeated until the problem is completed, at which point a new problem or topic is begun.

B. Evaluation Methodology

A mixed-method approach will be used to examine how instructors support and facilitate student autonomy and other outcomes associated with SDL, such as motivation and cognitive and metacognitive strategy use. The evaluation plan includes:

- Characterizing the learning environment within the chosen engineering courses with respect to support of student autonomy and authority
- Using surveys to collect data on student outcomes relevant to lifelong learning in the diverse classroom environments
- Conducting focus groups with student to develop a deeper understanding of emergent themes in the student responses to instruction in the different course settings
- Conducting semi-structured, open-ended instructor interviews to develop a deeper understanding of the instructors' rationales for instructional decisions with respect to objectives associated with supporting student outcomes associated with lifelong learning

Each of these elements is described in more detail below, and a summary of the evaluation goals and assessment tools is shown in Table II.

1) Characterizing the Learning Environment

The classroom environment will be characterized according to the rubric developed by Stefanou et al. [28], which breaks student autonomy support into the three categories of organizational, procedural and cognitive autonomy support. This characterization of the classroom environments will use instructor course information (e.g., syllabi and assignment descriptions), videotaped classroom observations of instructor-student interactions, student surveys using the Learning Climate Questionnaire (LCQ) [39] and instructor surveys using the Epistemic Beliefs Inventory (EBI) [38]. In addition, student responses to the LCQ survey, focus groups and student dialogue from the videotaped class sessions will be used to gauge students' perceptions of the degree to which the learning environment supported their sense of autonomy. This approach should provide for the creation of rich, contextualized descriptions of what instructors and learners do, how instructors and students relate to each other, and how students view their classroom environments.

2) Assessment of SDL Outcomes

Students' capacity for SDL, defined in terms of motivation, autonomy, and cognitive and metacognitive strategy use will be measured at the start and end of the term using an available validated survey instrument (MSLQ) [40]. This instrument provides the opportunity to correlate differences in relevant outcomes with specific instructor practices and classroom environments. Multivariate analyses of variance will be used to evaluate the effects of time and the independent environmental variables on the multiple dependent variables such as student cognitive strategy use, self-efficacy, and motivation. Causal model or path analysis will be used to build a model that describes how different instructor approaches lead to different student psychological outcomes. This model development will include determination of the correlations between instructor approach and student outcomes, and between and among the dependent variables. Cronbach's α values will be calculated to determine reliability and temporal stability of the quantitative assessment data. Inter-rater reliability estimates will be calculated to determine the degree of rater agreement on the data coded for autonomy support.

Student focus groups and instructor interviews will be used to develop a deeper understanding of emergent themes in the student responses to varying levels of learning autonomy in the different course settings and instructional decision-making. The design of the formal interview protocol will be guided by the classroom observations and survey results, but possible areas of focus include students' and instructors' goal-setting and planning; student monitoring and self-evaluating of learning; instructors′ environmental structuring; self-view as an autonomous learner and instructor; affective responses to choice and control; internalization of learning goals; time and effort management; active help-seeking; and reflections on learning and behaviors.

TABLE II. OVERVIEW OF PROJECT GOALS AND ASSESSMENT TOOLS

Project Goal	Assessment data and Evaluation Tools
Characterize the classroom environment with respect to student autonomy support	• Course information (syllabi and assignments coded for task, procedural or cognitive autonomy support) • Classroom observations (videotaped and analyzed by coding for task, procedural or cognitive autonomy support) • Instructor surveys (Epistemic Beliefs Inventory [38] will be completed and correlations calculated between scores on this instrument and type of autonomy support practiced as determined on the basis of the coded data from videotapes and artifacts) • Student surveys (Learning Climate Questionnaire [39]) • Student statements from videotaped classroom sessions, coded for evidence of statements associated with autonomy beliefs • Instructor interviews recorded and analyzed for reflection on teaching practices that support autonomy • Student focus groups videotaped and analyzed for consistency with observations from videotaped class sessions
Assessment of SDL outcomes	
• Cognitive and metacognitive strategy use	• Student completion of Motivated Strategies for Learning Questionnaire (MSLQ) [40]
• Motivation	• Student completion of MSLQ
• Autonomy	• Student completion of MSLQ
• Behavioral regulatory strategy use	• Student completion of MSLQ

Analyses will involve transcription of all interview data and audio/video recordings; coding of interview transcriptions; and comparison of coded data to frameworks for SDL. Correlation analyses will illuminate the existence and strength of relationships between instruction and a range of outcomes tied to SDL. Based on the proposed assessment tools, we expect to identify correlations between the type and degree of instructor support of student autonomy, authority, and feelings of competence and students' motivation, self-efficacy, self-regulation, perceptions of the environment, and perceptions of lifelong learning competency development.

3) Summary of Evaluation Plan

The mixed qualitative and quantitative approach proposed in this study will enable examination of how the instructors' choices regarding support of student autonomy in courses may affect the classroom climate and ultimately students' development as self-directed learners. The results from the proposed investigation will be a valuable resource for all engineering educators who strive to help their students develop lifelong learning skills and ultimately enable them to be successful in their careers.

Abstract — **this paper describes a method of recognising and assessing learning at Masters Level alongside the monitoring of engineering competence development in the work-place. For successful participants in the programme the outcomes lead to a Masters Degree and recognition as Chartered Engineers in the United Kingdom. It concentrates on the monitoring of professional development and competence assessment through the work of appointed Professional Supervisors.**

Topics: *Area 4: Active Learning, Area 4: Learning Models, Area 4: Pedagogies*
Keywords: *mentoring, workbased, competence, pedagogy, professional*

I. Introduction

In 2008 Kingston University, London initiated a new MSc Professional Engineering program undertaken through work-based learning, in collaboration with the UK engineering regulatory body, the Engineering Council, London.

This paper explains how and why this initiative to develop a new learning model has come about and how it has provided an innovative approach to the mentoring of developing engineers. In particular it concentrates on the theme of competence monitoring and how professional supervisors interact with the engineers who are participating.

The process of providing learning targets is summarized. These develop the necessary knowledge and understanding at Masters Level within individual learning contracts. Also, presented in more detail, is how the competences necessary for Chartered Engineers are monitored and assessed.

The underpinning theory of mentoring we are using is explained together with details of how industrial mentors are brought into the mentoring process alongside professional supervisors appointed by the university. Also explained is the pedagogy of problem-based active learning that we have developed within this program.

The current structure of the role and responsibilities of the professional supervisors is clearly spelt out and explained with details of their activities, training and reporting mechanisms.

The very positive feedback from both employers and students or participants [1] that has been forthcoming is evidenced through the participation of major UK-based and global engineering companies that are impressed by the motivation of their employees; the paper describes how an international support and mentoring strategy is being developed specifically to support participants globally.

Finally, an evaluation is made of the successes and challenges presented by this new program together with an explanation of how interested parties may become involved in it internationally.

II. Background

There is a shortage of registered Chartered Engineers in the UK, yet there are many engineers working successfully within many UK companies who are not registered. Some have the qualifications, experience and competence but have just not applied. However, an even greater number are able, have experience and are potentially very competent but do not possess the qualifications necessary to be registered. Attending a university to gain the necessary Masters degree is financially and socially quite difficult for them, involving, as it must, periods of absence from the work-place. A work-based learning Masters degree in engineering can solve this problem.

Kingston University, London has nearly 10 years experience of running Masters Programmes for professionals in many disciplines entailing the evaluation and assessment of work-based learning (WBL): the Masters by Learning Contract. In Engineering this has developed through the UK Government's Gateways to the professions Project in engineering[2], based at the Engineering Council, London into a nationwide Masters

[1] As the students are mature it is customary to refer to them as participants.
[2] http://www.engineeringgateways.co.uk

degree: the MSc Professional Engineering. Now, several universities[3] in the UK are running programmes based on the Kingston model: the model described in this paper.

The initial stage of the MSc or Entry Gateway consists of a Professional Development Audit in which there are three elements. For each of these, an in-depth analysis is required from the participant in the form of a printable electronic document:

- Evaluative Review (ER) or Reflective *Curriculum Vitae*
- Learning Contract (or Agreement) (LC)
- Competence Demonstration Action Plan (CDAP)

Once these three documents have been assessed as reaching the required standard by the university the participant's enrolment is confirmed and the documents are supplied to the participant's Professional Engineering Institution (PEI). Participants need to become members of the PEI before they can fully enrol on the MSc. The PEIs who initially signed up for the MSc are the:

- Institution of Engineering and Technology (IET)
- Institution of Mechanical Engineers (IMechE)
- Royal Aeronautical Society (RAeS)

Other PEIs are currently joining this group[4].

Each participant works towards seven learning targets (or goals) contained within the LC. The last of these is the Exit Gateway, a reflective summary, which includes a *viva voce* examination and if this is successful, the participant is awarded an MSc Professional Engineering.

The programme normally takes two to three years to complete, during which each participant is advised, monitored and assessed by an Academic Supervisor appointed by the university.

A requirement for registration by a PEI as a Chartered Engineer (CEng) is the attainment of competence as described in the Engineering Council's United Kingdom Standard for Professional Engineering Competence (UK-SPEC) [1]. In this Standard a range of competences is described in depth and these require underpinning knowledge at Masters Level. The MSc Professional Engineering provides this knowledge through WBL. However, the competences themselves require to be demonstrated in the work-place. A university appointed Professional Supervisor monitors and advises the participant and the employer on how the competences are being met and provides reports to the university. Although meeting the competences is not a requirement for the award of the MSc, the PEI is informed of progress and undertakes a Professional Review and Interview (PRI) once the participant has completed the MSc. Successful completion of the PRI results in professional registration as a CEng.

III. Learning Contract and Targets

Learning Targets (or goals) are set during the establishment of the Learning Contract. Each is based on the work the participant is expected to undertake during the programme. These are rated in Credits [2]. 180 M-level Credits are required in the UK for the award of a Masters Degree. 15 of these are awarded for the PDA at the Entry Gateway and 40 for a successful Reflective Summary and *viva voce* examination at the Exit Gateway. The remainder are set for any acceptable Masters level prior learning for which there is evidence and each of the other 5 Targets. These targets are generally set for 10 to 30 credits each and require a deliverable outcome which can be assessed. Examples of such deliverables are:

- Report on a project undertaken
- Technical or Management report
- Presentation to be delivered to a defined audience
- Major computer programme: documented, relevant, complex and demonstrable
- Paper for publication in a learned journal
- Research results and accompanying paper for publication
- Document on Social implications, Sustainability, Ethics or Environmental issues
- Effective and engaging talks or activities provided to school, college or university students

Once these are agreed between the participant and the Academic Supervisor with the acceptance of the PS, the LC is completed.

IV. Competence Monitoring by Professional Supervisors

The main role of the Professional Supervisor (PS) is to ensure that the competence requirements of UK-SPEC are met in as regular a way as possible. Each PS encourages the participant to assess and note the evidence for existing competence. Once the LC has been agreed, he can help the participant to make an assessment of expected competence development over the period of the programme, together with the necessary evidence. At this stage, the CDAP is completed and provided to the university by the participant.

The PS visits the participant on a needs basis and on average makes 4 or 5 visits per year to the work-place. Each visit is about 3 hours long. Starting with the CDAP as a base, the participant's activities and progress towards meeting the competences are his principle concern and he liaises with the employer's staff whenever necessary: the participant's line manager, company mentor and human resources personnel. He also keeps in close touch with the Academic Supervisor in

[3] Kingston University London, the University of Hertfordshire, Northumbria University and Staffordshire University have now been joined by Universities at Aston, Cardiff, Derby, Hull, London South Bank and Teesside

[4] British Computer Society (BCS), Chartered Institution of Building Services Engineers (CIBSE), Institution of Chemical Engineers (IChemE), Institute of Measurement and Control (InstMC), Institute of Physics and Engineering in Medicine (IPEM), Society of Operations Engineers (SOE)

order to harmonise the processes of participants meeting their learning goals and meeting the competence requirements.

Each participant keeps a Professional Development Record of skill sets required and developed in the work-place and of experience gained. This is in order that the participant's evidence of competence can be provided to the PEI on an on-going basis. The PS ensures that this happens by checking the record, asking appropriate questions and making suitable suggestions for future activity. Most PEIs have an on-line monitoring system so that such evidence is available to members of staff and PEI professional advisors on an on-going basis: for example the electronic Monitored Professional Development Scheme (eMPDS) of the IMechE, Career Manager of the IET and the on-line professional development scheme of the RAeS which is run in conjunction with the Engineering and Technology Board.

The Professional Supervisor has the majority of the face to face contact with the participant. Subsequent to each visit to the participant the PS writes a Visit Report about the progress (or lack of it) in closing any competence gaps that the participant has made since the last visit. These Reports are counter checked by a 'Lead' PS who is very familiar with the participant's PEI, and their requirements. Finally these reports are sent to the University to be lodged in the participant's electronic records. Currently Kingston University is trialling new systems with the IET and the IMechE. The reports and any other documents relevant to the participant's progress can be uploaded and stored in a document vault: in the case of IMechE, the eMPDS system. They will therefore be available for the PEI to examine prior to the PRI, to see the progress made.

PSs attend a training conference each year. The first was held in Peterborough at Perkins Engines last year and others are planned for later this year. Its purpose is to review the processes of competence monitoring, mentoring practices and to ensure that all PSs know how matters are progressing at each PEI.

V. The pedagogy of work-based, problem-based and active learning

Work-based learning is only one of a number of terms that have recently become popular to describe newer alternatives to traditional classroom based pedagogies, such as active learning, problem-based learning, action research, etc. Although there is very little agreement amongst educationists as to the meanings of these terms, there is even less agreement as to their effectiveness. Generally the outcomes of research are inconclusive with no significant evidence of these newer approaches being more effective for student learning. However, there is evidence that their use does generate enhanced student engagement; in particular, problem-based learning can improve student ability to retain information longer and develop their enhanced critical thinking and problem solving skills [2].

The work-based learning methods used in the MSc Professional Engineering programme are actually a complex mix of many different methods, and the make up of that mix can vary significantly from one participant to another. Primarily it is a combination of:

- active learning [6], where the participant is positively doing something, and
- problem-based learning where the participant is positively doing problem solving,

Significantly:

- they are doing it in their own work place.
- it is self-directed learning, and
- the participant has the major responsibility for:
    - designing their own learning activities, and
    - ensuring progression.

Another very important facet of the programme is that is a mechanism for:

- lifelong learning,
- widening participation, and
- employer engagement.

The open and flexible nature of the programme allows people to undertake learning at any stage of their life. The accessibility of the programme enables people who otherwise would feel reluctant to engage with higher education, or could not afford to engage, to gain safe and affordable access to it. The programme's learning content is directly related to the employment work place activity and the employer is a direct partner in the learning, thus ensuring the learning is far more likely to meet employers' needs.

The programme has been developed because it will allow many engineers who otherwise could not develop their capabilities to their highest potential to do so in a way that is beneficial to both employers and the wider engineering community more generally. It has not been developed because work-based learning for engineers is a naturally better form of learning than traditional engineering programmes, (although we believe it certainly can be in many situations).

As such we believe it is probably the most appropriate form for most Chartered Engineers, and engineers working at that intellectual and technical level, for the highest level of critical thinking learning and development required as part of their continuing lifelong professional development.

The basic pedagogy for all participants on the programme, whatever the actual mix of their individual learning contract, is that of experiential learning, as first identified by Dewey [3] and then later developed Kolb [4], and widely known as "Kolb's experiential learning cycle", (fig.1).

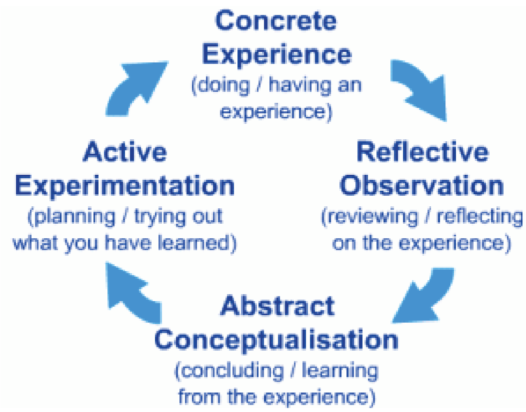

Figure 1

In this, an individual learns by going through four stages of the process:

1. Initially they have a "concrete experience", an interaction or real experience with some aspect of their environment. For our participating engineers this could be the action of implementing a new production line.
2. During or after the experience, the participant engages in "reflective observation" of:
   - what they experience
   - their actions within the experience, and
   - the responses of others to that experience.

   For instance they might try to:
   - analyse why they chose a particular solution to a problem they encountered during the introduction of the new production method,
   - describe what were the drivers of their decision making process,
   - explain how effective the problem solution was that they chose, and
   - ask, how did it impact on each other?
3. The third stage of the learning cycle is "abstract conceptualisation", which involves theory building in which critical thinking skills are developed to evaluate the reflections made about the experience. This for our participants is where the seat of in-depth learning takes place. It is the most challenging, because it requires participants to critically evaluate their existing understanding of engineering theory and practice. It may involve considerable independent study and research of technical theory, in order to be able to justify their actions, or alternatively change or amend their engineering knowledge and understanding to a new position as a result of their experience and independent study.
4. The final stage of the cycle is "active experimentation", where the theory that has been constructed is put to the test, by various means. For our participants this could be by:
   - deconstruction of their new knowledge and understanding into small testable packages,
   - the development of new working processes within their employing organisation for themselves and others, or
   - peer review as part of the MSc programme assessment strategy.

VI. The Role of the Professional Supervisor and the Underpinning Theory of Mentoring Used

The method of mentoring being used by Professional Supervisors is essentially one of assertive empathetic involvement. The closer the PS is to the student's work involvement, aspirations and professionalism the better his understanding of the participant's needs and competence development.

It is generally recognised that this form of mentoring enables:

- knowledge sharing
- working through of professional and personal issues
- improvement and career development
- support for study or research
- provision of a sounding board or critical friend when required

Mentoring [5] is help by one person to another in making significant transitions in knowledge, work or thinking
A mentor is someone who helps another to become what he aspires to be and helps another person through an important transition such as coping with a new situation or in career development.
By providing the means to share the knowledge, experience and advice of the Professional Supervisor, participants who have a keen desire to learn and develop themselves to achieve their goals.

One of the major objectives that the PS tries to achieve as a Mentor is to try and get the participant to 'think' like a Chartered Engineer. By that we mean not being afraid to 'question' an approach to a problem, or a technology suggested as a solution. Also we encourage them to adopt a more 'Strategic' outlook rather than a 'Tactical' approach "because it's always been done that way"!

Company or Industrial mentors are brought into the mentoring process alongside the PSs whenever necessary, whether it is to ensure contact and communication or whether it is to ensure harmony of purpose. It is very important to ensure that management processes within the company are not disturbed, so if there is a need to adjust the programme, then the PS needs to be very careful to put the participant's needs first within the company context.

The learning cycle described above is believed to be very powerful in both engaging engineers in further learning and in building continuing individual learning. However for many engineers, particularly those with many years practical experience it is not a process to which it is easy to take. Successful engineers are very capable in their area of expertise, confident in their understanding of their knowledge base whilst at the same time knowing the boundaries of their expertise, and very goal focused individuals.

It is not generally part of their make up to spend much time "navel gazing", which is how critical reflection is sometimes portrayed. The knowledge and understanding they build up is a mix explicit knowledge, that which is articulated and can we easily communicated, and implicit knowledge, that which is not (perhaps cannot be) articulated but is embedded deep within the engineer's engineering knowledge "know-how". It is often derived from experience where a key element is an ability to successfully apply knowledge gained in one field in an unrelated but similar environment. The accuracy or otherwise of this knowledge is therefore very hard to verify – and it is also hard to change.

In order to build continuous development and learning knowledge mining is required to seek out and incorporate implicit knowledge into explicit knowledge. This can be done concurrently with the "reflective observation and abstract conceptualisation stages of the learning cycle.

The role of the professional supervisor has therefore been constructed around a combination of the need to provide continuing ongoing professional direction to the participant in the progression of their learning contract, but also to engage the participant in critical debate, which challenges the participants' natural thought processes, and forces them to engage in critical reflection. It is this critical reflection which takes the participant through the reflective observation and abstract conceptualisation stages of the learning cycle. The ongoing critical conversation between the participant and professional supervisor is not one in which the learning is carried out by knowledge and understanding being passed from supervisor to participant, but it is a constant to- and fro-ing of ideas, in which engineering knowledge is the focus of the debate, and its value and voracity is subject to exposure and judgement. The professional supervisor is the initial leader of this debate, but in time the roles will be reversed and the participant, by learning from example, will be able to take the lead and start to critically reflect on their own engineering knowledge and hence continually build and develop it through a combination of experience, study and debate. The engineering conversation can then spill out beyond the restricted supervisor participant arena and into the wider employer organisation arena. The participant engineer can then move beyond the phase of individual learner and onto becoming the champion of organisational learning.

The role of the professional supervisor is thus crucial to the success of the whole work-based learning activity. They need to be professional supervisors on two levels:

- to provide the full range of advice and guidance needed by the participant on their journey to professional status,
- to have a very professional approach to their own mentoring activity.

The group of professional supervisors all have to conform to a common approach, and mentoring processes, for their activities, underpinned by a group understanding of the nature and purpose of those activities. This is not a set of processes which can be uplifted from a standard publication on mentoring. This activity and its processes can only be constructed and defined by the professional supervisors currently involved in this MSc Professional Engineering programme. It is a challenging piece of work in itself that is asking of the professional engineers doing the professional supervision to embark on considerable experimentation, reflection and theory building themselves. Progress so far has been very positive, with supervisors having produced working processes, performance and progress monitoring methods and arrangements for mapping academic working tasks against engineering competence standards. Work is ongoing toward a set of materials for the training and development of new professional supervisors, and this paper forms part of our activities to draw in the opinions and knowledge of others who can and would wish to contribute to this development.

VII. PROGRAMME EVALUATION

In order to provide reliable evidence of the effectiveness of this programme an evaluation process has been incorporated into the development project.

Initially prior to the start of the programme and during its development phase a survey was undertaken of engineering graduates who had completed an accredited engineering first degree between 2002 and 2006. The objective of the survey was to investigate the reasons why a very large proportion of engineering graduates did not progress onto professional registration.

The results of this survey [7] were surprising. In regard to furthering engineers learning to Masters Level, there was:

- no perceived deterrent in the additional costs of undertaking further studies, but:
- a lack of awareness of how to develop their knowledge to the requisite level.

In regard to Chartered Engineer registration there was:

- no perceived lack of support from employers, but:
- a lack of understanding as to how to progress.

Now that the programme has been running for two years a further investigation is being undertaken as to how well the programme has met the needs of engineers in these two areas, and to how well it is also meeting the needs of employers in helping them increase the capabilities of their engineers.

Initial feedback statements received so far from both employers and participants have all been positive and encouraging.

A number of case studies of individual participants' programmes which are relevant and illustrative of the initiative have been produced. These are available for distribution.

VIII. Employer Organisations involved

A number of large engineering employers have sent small cohorts of engineers on to the programme to evaluate its potential for helping them meet their forthcoming engineering development needs. The majority of the engineers on the programme are employed within large companies but 25% are employed by small or medium sized enterprises or companies (SMEs). The availability of university-provided professional supervisors is particularly important for those in SMEs because they would be very unlikely to be able to get appropriate mentoring from Chartered Engineers within the company.

The majority of the participating engineers are between 25 and 35 years old. Many of these are qualified with an accredited first degree and are using the programme to speed up their progress to Chartered Engineer status as part of a career development plan.

However a significant minority, 23%, are aged 36 or over. For these engineers:

- the programme provides an opportunity to enhance their own engineering capability and develop additional job satisfaction and personal goal achievement.
- the availability of a highly qualified professional supervisor is of particular importance in enabling them to engage in critical dialogue with a peer who can independently challenge their embedded engineering assumptions.

In total 30% of participants starting the programme have non-traditional entry qualifications. Again for them the availability of a professional supervisor is important in helping them to bridge the divide between their generally practical engineering development and the academic requirements of a Masters Degree learning programme.

IX. International Involvement.

Currently we are in serious discussions with a number of globally based multi-national companies who are very keen to adopt this approach to enable many of their senior engineers, based outside the UK, to become Chartered Engineers through UK PEI's. As these members of staff are based abroad the current ways of supporting them with both the Academic and the Professional Supervisors have to be re-thought.

Thus a new support and mentoring approach is being formulated which will involve enlisting the help of locally based senior engineers, trained by and working on our behalf, giving some Mentoring support and undertaking evaluation for us. This would be supplemented by visits by the PSs twice a year for more intensive and more in-depth reviews with each of the participants. To be cost effective for both us and the Company we would also expect that a minimum of 6-8 participants be enrolled by each overseas-based company, and that they're available in a single location for these twice annual visits. We expect the first of these 'international' participants to be underway early in 2010.

Cooperative work and continuous assessment in an Electronic Systems laboratory course in a Telecommunication Engineering degree

Josep Jordana, Francesc J. Sànchez
Department of Electronic Engineering
Castelldefels School of Technology (EPSC)
Castelldefels. Spain
jordana@eel.upc.edu, francesc.josep.sanchez@upc.edu

Abstract— **Electronic laboratory courses offer the possibility to introduce some specific and transversal skills to the curriculum of the students who follow an engineering degree. This paper examines the methodology and assessment which are applied in the laboratory course of the subject "Electronic Systems" in the second year course in the Telecommunication Engineering degree from the Castelldefels School of Technologyy (Escola Politècnica Superior de Castelldefels, EPSC) at the Universitat Politècnica de Catalunya (UPC). During 14 laboratory weekly sessions of 2 h, students must analyze and design the analog and digital circuitry for an ultrasound-based distance measurement system, by means of several guided practices. Small groups of two or three students worked on a collaborative way, while the teacher acted as a guide to facilitate project comprehension and knowledge acquisition. The experience we describe corresponds to the Spring term of 2009, a period in which this methodology was applied to two small class groups of about 23 and 7 students respectively. This work studies the influence of the initial characteristics of the students and their time devoted to prepare the subject, on their academic performance. The paper finishes with a list of recommendations in order to improve students learning process and course assessment.**

Keywords- *Collaborative work, electronics engineering education, circuit analysis, circuit simulation*

I. INTRODUCTION

It is well known that main general skills that enterprises demand for graduates of engineering programs are: teamwork, creative thinking and communication. To accomplish these requirements class activities must be learner-centred and teachers must become guides in the learning process [1]. The variety of skills that engineering students should master is increasing. There are several pedagogical methods that have been adopted in response to these needs [2]. There is much research showing that students who work cooperatively obtain better results and benefits from their relationships far more than students who do so competitively and individually. Cooperative learning [3] is the instructional use of small groups for students to work together to maximize their learning and that of their peers. Among the advantages of working cooperatively in small groups we can mention that it reinforces learning and improves skills and social relationships. It is a way of making students active cognitively. There are different studies related to the laboratory classes in courses on electronic technology where active learning is promoted [4], [5], [6].

It is very difficult to be objective when assessing laboratory work. In order to tend to give an objective global mark to the students it is very useful to consider applying a varied set of evaluation activities.[7]. Therefore we should use a variety of assignments to measure achievement of student learning [3]. The evaluation of the subject would be continous and it should promote the learning process. The feedback during this process promote competence development.

The present work is focused on: methodology (cooperative work and portfolio) and continuous assessment applied in the laboratory classes of Electronic Systems in the second year course (year 2000 Curriculum) in the Telecommunication Engineering degree from the Castelldefels School of Technology. We try to assess not only the specific course content, but also cross-curricular skills like: effective writing, critical thinking, collaborative work, and information organization. Indeed, these are the basic ideas that we try to convey through the introduction of the student learning portfolio [8]. The correct acquisition of a given competence is demonstrated by doing. For this reason skill assessment must be done through the activities and laboratory assigments students carry out.

II. COURSE ORGANIZATION AND OBJECTIVES

The course Electronic Systems is taught during the first semester of the second year. It consists of 6 credits, 3 credits corresponding to theoretical concepts and 3 credits corresponding to laboratory practices. The dedication of the student's work to the course is about 112 hours, which spread over 14 sessions of 8 h per week, equivalent to about 4,8 ECTS. The course has both a theoretical and a practical component, being laboratory class attendance obligatory. Students perform 2 hours of weekly lectures (classes have a maximum capacity for 45 students) and 2 weekly laboratory practices (laboratories have a maximum capacity for 20 students). This study corresponds to the Spring semester 2009 which has taken into account 30 students, divided in two laboratory-groups of 23 students (Group A) and 7 students (Group B) respectively. This number of students,

This work has been sponsored by the UPC-SLT project: "Consolidation and enhancement of the web of resources of Digital Systems, to support content and language integrated teaching (CLIL) at the EPSC"

corresponding to each group, only depends on the registration procedure carried out during the beginning of the term. Because of the small number of the participants involved in the study it is difficult to generalize the results, but like in other studies with few students useful qualitative conclusions can be obtained [9] [10].

After completing the course, students will be able to:

- Explain the design flow of electronic systems based on microcontrollers: sensors and actuators, conditioning circuits, power supply calculations, SPICE-based simulations, error analysis, assembly language programming, etc.
- Assemble circuits of medium complexity to check their basic knowledge of circuit theory and skills in laboratory instrumentation and prototyping tools.
- Work cooperatively with other students in order to design and assemble an electronic system (an application project integrating a large part of the course content).
- Write technical reports characterizing the behaviour of the electronic system.
- Compare experimental results with simulations and theoretical concepts.

In order to facilitate the student's acquisition of all these specific and cross curricular skills, cooperative work and continuous and formative assessment of student assigments is applied.

A. Cooperative Work

In laboratory classes students are required to work cooperatively in order to increase the communication between group members and reinforce their interdependence. The first day of the class the teacher explains the objectives of the laboratory and the rules that must be followed. These practices are conducted in groups of 2 or 3 people. Although it would be preferable that these groups were heterogeneous [11] they were formed according to their preferences of friendship in order to avoid problems of making meetings outside the laboratory. Each practice group should have a notebook and a portfolio. The laboratory notebook consists of a spiral pad size sheet on which students record all the sequential information (connection diagrams of the assembly, numerical calculations, instructor explanations, etc.) gathered during the laboratory practice. Taking notes in this notebook tries to inculcate the habit of scientific work to the students. The aim of this approach is that they can faithfully reproduce all the practices of the course.

The portfolio contains both students' works and reflections about the way they have learnt in cooperation during the laboratory term. The evaluation criteria are held continuously over the laboratory assigments, thus, the portfolio shows the way the student abilities have changed or improved over time.

Each cooperative group has to understand that individual success will be achieved from group's success; students have to believe that they "sink or swim together" [3], so that each member must ensure that their partner has assimilated the concepts and skills for each practice. During laboratory sessions instructors ask questions to any of the students in the group randomly and the marks are assigned to the whole group. This assessment ensures that students take seriously this learning process and verify that anyone in the group knows how to answer teacher's questions.

Laboratory practices are intended to design the analog and digital circuitry for an ultrasound-based distance measurement system. At the beginning of each session, students, in groups, must show the preliminary study to the teacher, which involves answering a series of theoretical issues relating to the practice implemented in the current session. To ensure a maximum profit from practical laboratory classes it is essential that students undertake this assignment. The teacher highlights in situ the errors that students may have done; they are able to correct them immediately; and as a consequence, the group's final report is improved by this fast feedback.

At the same time, to the development of each laboratory practice, students should complete a simplified report per session of two pages during the last 10 minutes of the session. This report consists of a summary of the major activities performed in each session and contains several basic questions related to the preliminary study and the experimental activities. In addition, the students can add their reflections [9] and questions being raised during the development of laboratory classes. At the beginning of the next session, the teacher delivers the report corrected, which ensures that students analyse the successes and mistakes they have committed.

B. Evaluation Of The Laboratory Classes

The evaluation currently being applied in the EPSC and in many other Schools of the UPC is the formative assessment which consists in carrying out a continuous assessment throughout the course [12]. The teacher-student feedback, introduced by the formative assessment, permits to correct the imbalances that may occur during the course, adapting teaching classes to each situation. For this reason, students and teachers have regular information during the course about the teaching-learning process.

Activities in the laboratory have assigned a weight of 45 % of the global grade. In order to assure formative assessment, the final laboratory grade is based on the following items:

- Two reports (10 %). Written reports were collected in the middle of the term and at the end, corresponding to the analog and digital designs respectively.
- Laboratory work, preliminary studies, reports of each session and portfolio (25 %). It takes into account the functioning of the practice and the answers to questions from the teacher.
- An individual laboratory exam (10 %). This test takes place at midterm, and it is a reference to the teacher to find out if indeed the cooperative learning has been successful, because if so, the members of each group should obtain similar scores.

III. Academic Performance Achieved By Students and Student Time Devoted to the Subject

The academic performance achieved by students is related with the pedagogical methodology applied, but it is also influenced by the past of the students. For this reason, in order to know what type of students attended the laboratory, at the first class of the course the students filled in a survey which consisted of several questions related to: address, previous studies, admission mark to the university, coursed subjects related to electronics, etc.

Analysing the survey of the two laboratory groups we find that most students come from Barcelona or its surroundings. Most of them, 71 %, began their studies in the fall semester 2007, respect the 29 % that began their university studies in the fall semester 2006. Because this subject corresponds to the first semester of the second year, these percentages indicate that most of the students have failed some subjects of their degree for whatever reason and perhaps are not the most brilliant or not the most motivated to study to the expected level.

As we can see in Table I, most of the students come from baccalaureate: 73,3 % respect to 26,7 % who come from professional modules. The percentages are similar in both class groups. In group A the number of students who attend the subject for the first time (47,8 %) is slightly lower than the number of repeating students (52,2 %). However, in group B most of the students (71,4 %) attend the subject for the first time.

TABLE I. Distribution of the students in function of their previous studies and in function of repeaters and non repeaters.

Number of students	Non repeating students	Repeating students	Baccalaureate	Professional Modules
Group A (23)	11 (47,8 %)	12 (52,2 %)	17 (73,9 %)	6 (26,1 %)
Group B (7)	5 (71,4 %)	2 (28,6 %)	5 (71,4 %)	2 (28,6 %)
Total (30)	16 (53,3 %)	14 (46,7 %)	22 (73,3 %)	8 (26,7 %)

In Table II it is interesting to note that the percentage of students that have passed the subject is slightly higher for those that have coursed baccalaureate (68,2 %) than for those that have coursed professional modules (62,5 %). The highest percentage of pass rate is attributed to those students who repeat the subject (71,4 %).

On the other hand, if we center our study on the laboratory exam (done in the 8th week), we can see that these percentages decrease significantly (43,3 %), except in group B where remain the same (Table III). Although both groups have few students, this result confirms that generally, smaller class groups have a higher pass rate than more numerous groups. This can be attributed to the fact that in group B a higher percentage of students attends the subject for the first time. Furthermore, subjective observations made by the teacher showed, in percentage, a higher motivation of laboratory work for students of the group B.

TABLE II. Distribution Of The Students That Have Passed The Subject.

Students that have passed the subject	Non repeating students	Repeating students	Baccalaureate	Professional Modules
Group A (14) (60,1 %)	5 (45,4 %)	9 (75 %)	11 (64,7 %)	3 (50 %)
Group B (6) (85,7 %)	5 (100 %)	1 (50 %)	4 (80 %)	2 (100 %)
Total (20) (66,7 %)	10 (62,5 %)	10 (71,4%)	15 (68,2 %)	5 (62,5 %)

Like in the global pass rate, we observe that baccalaureate students have a slightly higher pass rate than professional modules students, but in this case repeaters and non repeaters obtain very similar results. A possible interpretation could be that the practical exam only consisted on theoretical questions respect to the practices. If it had included some practical exercises using the instrumentation and assembling circuits it is possible that students who came from professional modules would have obtained better results. Time devoted to solve the exam is another aspect to take into account, because more time you lend to students better results they would obtain.

TABLE III. Distribution Of The Students That Have Passed The Laboratory Exam.

Students that have passed the lab-exam	Non repeating students	Repeating students	Baccalaureate	Professional Modules
Group A (7) (30,4 %)	2 (18,2 %)	5 (41,7 %)	6 (35,3 %)	1 (16,7 %)
Group B (6) (85,7 %)	5 (100 %)	1 (50 %)	4 (80 %)	2 (100 %)
Total (13) (43,3 %)	7 (43,8 %)	6 (42,9 %)	10 (45,5 %)	3 (37,5 %)

Another parameter of interest in our study is the distribution of students according to their admission mark to the university (Table IV). After processing the data, we see that most of the students are concentrated in the range of marks between 5 and 7. A number of 25 responses were processed because 5 students didn't inform about their admission mark in the first questionnaire.

TABLE IV. Distribution of the students according to their admission mark to the university.

Number of students	[5,6)	[6,7)	[7,8)	[8,9)
Group A (20)	4 (20 %	11 (55 %)	4 (20 %)	1 (5 %)
Group B (5)	1 (20 %)	3 (60 %)	1 (20 %)	-
Total (25)	5 (20 %)	14 (56 %)	5 (20 %)	1 (4 %)

Tables V and VI show an interesting result: there is no direct relationship between the admission mark and the subject pass-rate. In this sense, we can observe that the pass-rate is higher for those students who entered with the lower admission mark. This result contrasts with the one found in [12], where this correlation was shown to be higher, because the analyzed subject corresponded to the first term of the first year course of the degree.

TABLE V. DISTRIBUTION OF THE STUDENTS WHO HAVE PASSED THE SUBJECT ACCORDING TO THEIR ADMISSION MARK TO THE UNIVERSITY.

Students who have passed the subject	[5,6)	[6,7)	[7,8)	[8,9)
Group A (14)	4 (100 %)	7 (63,6 %)	3 (75 %)	0 (0 %)
Group B (4)	1 (100 %)	2 (66,7 %)	1 (100 %)	-
Total (18)	5 (100 %)	9 (64,3 %)	4 (80 %)	0 (0 %)

TABLE VI. DISTRIBUTION OF THE STUDENTS WHO HAVE PASSED THE LABORATORY EXAM ACCORDING TO THEIR ADMISSION MARK TO THE UNIVERSITY.

Students who have passed the lab-exam	[5,6)	[6,7)	[7,8)	[8,9)
Group A (7)	3 (75 %)	3 (27,3 %)	1 (25 %)	0 (0 %)
Group B (4)	1 (100 %)	2 (66,7 %)	1 (100 %)	-
Total (11)	4 (80 %)	5 (35,71 %)	2 (40 %)	0 (0 %)

Table VII shows the average marks of all items of the continuous assessment of the laboratory work. In addition we present the average marks corresponding to the two theory exams that are done in the midterm and at the end of the course. It can be seen that laboratory work and reports are the items with highest marks and the exams are the items with lowest marks. Students of group B have obtained higher marks than students of the group A on all evaluation items what agrees with instructor observations during the laboratory work. A consequence of this is that students rely on laboratory classes to pass the course, which diminish the pass-rate in exams.

TABLE VII. AVERAGE MARKS OBTAINED IN EACH ITEM OF THE CONTINOUS ASSESSMENT.

Average marks	Group A	Group B
Final mark	4,4	5,3
Reports	6,3	7,5
Laboratory-work	6,4	7,4
Laboratory-exam	2,3	5,9
Theory-exams	2,9	3,8

A possible cause to the low final average mark achieved by the students could be that they didn't spend enough time doing the activities and studying the different topics of the course. For this reason students were asked to evaluate during 8 weeks of the course (randomly selected) how much time they had spent studying for each session (both theory and laboratory classes). The results have been that in average, the students of the group A have employed 3,48 h/week and 3,61 h/week preparing theoretical and laboratory classes respectively. In group B students have spent 3,24 h/week and 4,33 h/week respectively. It should be noted that these times include the activities inside and outside of the class. They have spent more time preparing laboratory practices than studying theoretical ones, what is reflected in the lower marks of theoretical exams. These results are slightly lower to the instructors' previsions of 4 h per week in average.

Fig. 1 shows the relationship between the average of hours per week that each student of the group A devote to the whole subject and the final mark obtained. The time value that appears in the figure is the average of theoretical and laboratory work per week, that approaches 4 h. Fig. 2 corresponds to the time devoted by students of the group B. In both groups, we don't see a direct relation between the pass rate of the students and their time devoted to the subject. The correlation coefficients have a low value: -0,2907 and 0,3345 respectively.

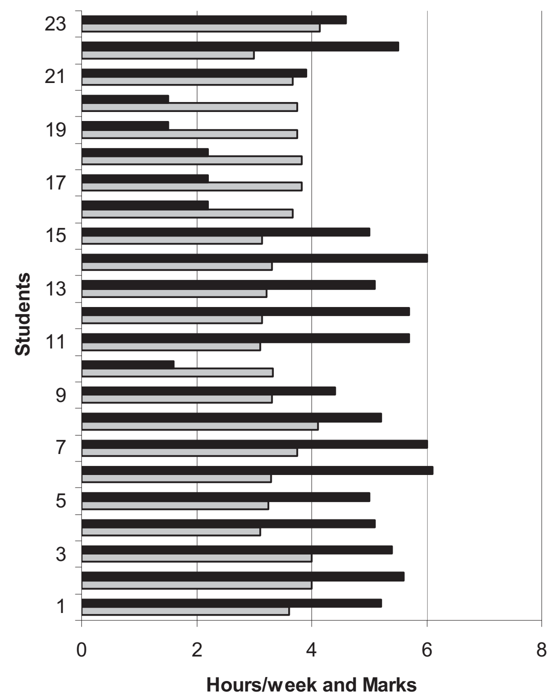

Figure 1. Average time devoted to study the subject (grey) and final mark (black) obtained by each student of Group A.

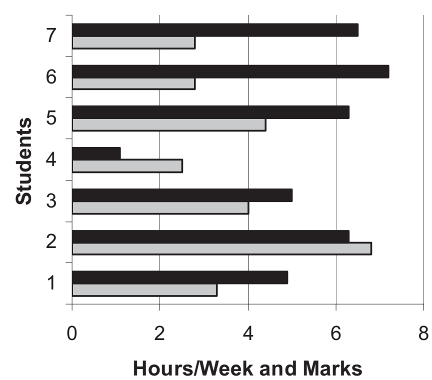

Figure 2. Average time devoted to study the subject (grey) and final mark (black) obtained by each student of Group B.

IV. Final Feedback and Future Improvements

To collect the student's views about the teaching process and to get feedback from them, an adaptation of the Student Experience of Education Questionnaire (SEEQ) was carried out at the end of the course. Around 19 students took part in the survey. In Table VIII we have selected some of the most representative questions we have raised in the two class groups. Students were asked to punctuate each question in a scale from 1 to 5, as: 1. Strongly disagree, 2. Disagree, 3. Neutral, 4. Agree, 5. Strongly agree.

TABLE VIII. SEEQ QUESTIONNAIRE. MOST REPRESENTATIVE QUESTIONS, RELATED TO THE METHODOLOGY APPLIED IN THE COURSE.

Questions	**Group A (16) (70 %)**	**Group B (3) (43 %)**
I have also learned more English, to work cooperatively and make oral presentations	2,94	2,33
The teacher has been dynamic and active during classes of group work and has followed our work	3,88	3,67
Classes have been clear and the explanations have been a good material for understanding the subject	3,94	4,33
Course material was well prepared and has been carefully explained	3,94	3,67
Group work in classes timetable has been useful and well organized	3,87	4,33
The classes of group work that we have organized outside the regular timetable, have been profitable and useful	3,88	4,0
Cooperative working groups have been a good tool to study and learn the subject and share knowledge and ideas	4,06	3,0
Instructot's comments on the corrected work and exams were very helpful	3,69	3,33
The methods of evaluation of this course are fair and appropriate	3,81	3,33
The contents of examinations and other evaluated assignments, correspond to the course contents, in accordance with the emphasis placed on each subject by the teacher	3,69	4,0
The portfolio helped me to organize my study during the course	3,44	4,0
The workload of this course compared with others, has been: very small (1), Small (2) Normal (3) Great (4) Very large (5)	3,56	3,5
I would recommend cooperative learning in other subjects of the grade	3,50	3,0

It can be seen that all items are well punctuated, with average marks of 3,71 in the group A and 3,58 in group B, what indicates that student valuation of this methodology is good.

From the analysis of the results relating to the academic performance and taking into account the feedback received by the students, some improvements that we propose for future laboratory courses are:

- In order to be more objective assessing each student individually it would be useful to give them some written questions, five minutes before the end of each laboratory class. These basic questions could be drawn up in English, because it is an important cross-curricular to be introduced.
- The laboratory exam should include not only theoretical questions but also practical experiments. It would be done at the end of the term instead of the midterm, in order to take into account not only the analog block of the electronic system but also the digital block.
- Although some groups did very well write portfolios, we consider that too little time was reserved to assess the portfolio, because some groups collected the information few days before was presented to the instructor. Students would consider more important its realization if it was graded highly in the assessment process.
- Although the good quality of some written reports collected at the end of the analog block and at the end of the digital block, we have observed some plagiarisms. They could be avoided giving a more detailed writing model to follow, which can be changed from one course to another.
- In order to improve theory exam grades it would be very interesting that laboratory assignments were more related with theory contents and vice versa.
- Students should complete a report about their collaborative work during group meetings done outside the laboratory, in order to reflect about this active learning methodology, when the instructor is not present.

V. Conclusions

This paper has analyzed the ongoing methodology and assessment which have been applied in the laboratory course of the subject "Electronic Systems" in the Telecommunication Engineering degree from the Castelldefels School of Technologyy (EPSC). The experience that we have described corresponds to the Spring term of 2009, a period in which the authors of this work have studied two laboratory groups of about 23 and 7 students respectively.

This work relates the academic performance with the initial characteristics of the students, obtained from the analysis of the responses to a questionnaire that was given to the students the first session of the course. The highest percentage of students who passed the subject occurred in students coming from the baccalaureate or who had repeated the course and no clear correlation between overall academic performance and admission mark to the university was observed.

Students were asked to evaluate how much time they had spent studying for this course. Taking into account the information given by the students and the marks obtained, we conclude that they don't spend enough time preparing the subject. This study also shows that the relationship between the time devoted to prepare the subject (inside and outside the class) and the marks obtained by the students are not correlated. Although there is no direct relationship between time and marks, some students would improve results if they made a more effort.

If instead of applying the continuous assessment, we only took into account exam grades (theoretical and practical), the pass rate would have been lower. Increasing better grades in exams is a challenge for future courses.

Continuous assessment and collaborative work improve the performance of students less prepared, but hinder the emergence of endnotes brilliant, because it is very difficult to get very good grades in all evaluation criteria.

Although academic performance should be improved, most of the students have had a favourable impression of the methodology applied in laboratory classes.

Abstract— **The idea is to conceive an intelligent computing system of decision-making aid, in this context of teaching training, the quantification of the human behaviors is the key to this system's innovation. Seeing that it gives opportunity of measuring the professional acts of the teachers in class. This makes it possible to locate these practices compared to the pedagogical theories, into force and especially compared to the constructive approach. In addition, this system helps to identify the student's styles of learning; therefore it places, at the disposal, information which facilitates to the teachers the adaptation of their pedagogical methods so that the student benefit a maximum assimilation. For what concerns them, the students also profit from an innovating alternative: result of the web based performances analysis in summative evaluation. It is a generated report, for each pupil, automatically at the end of the seizure of the marks stipulating in details their weak points and specifying the adequate remedies in terms of activities to be realized to proceed to reflexive regulations in order to raise their levels of assimilation. An able system, starting from observable behaviors in classrooms and of performances seized remotely via the Web, to quantify in a rational way the cognitive and emotional states of the actors of the context of teaching training. An expert system whose general objectives would be: classifying the profiles of the teachers starting from their professional competences based on their pedagogy, behavior and attitude, classifying the learners' profiles by analyzing their interactions and analyzing their performances in summative evaluations, adapting the resources of the teacher's pedagogical methods in order to have a better coherence with the profiles of identities, the profiles of motivation and the profiles of comprehension of learner.**

Keywords-component; ***Evaluation, statistics, learner profile, teacher profile***

I. INTRODUCTION

The world in which we live witnesses the birth of expert systems which aim to classify and assist with the decision making whose complexity increases with the development of the tools, of the techniques related to decisional data processing. This observation is not limited to technical field but also related to the educational field and more precisely to the diagnosis and the evaluation of the process of teaching training. On the basis of a medical vision, the diagnosis is an activity of identification of the causes of a physical or human system's dysfunction starting from the observation of its revealing symptoms. Frequently, the dysfunctions are diagnosed starting from a whole of associated symptoms named characteristic syndrome. The relevance of the diagnosis is strongly dependant on the complete observability of the device.

We could, also, add that the etymology of the diagnosis term means "knowledge through signs". Therefore, a diagnosis of the profiles of the actors of teaching training can be interpreted as the knowledge of the cognitive state of the actor (teacher and/or learner) of the context through his actions and his reactions at the time of an activity of teaching training.

From there the idea to conceive an intelligent computing system of decision-making aid, in this context, which is a reliable tool in the hands of the secondary education's inspector. A system able to manage the variable characteristics of the learner and the teacher in order to facilitated a reliable decision making of what must be recommended for each whole of circumstances, thus avoiding the recourse to the intuition and subjective and nondescribable decision making in deterministic terms. An able system, starting from observable behaviors in classrooms and of performances seized remotely via the Web, to quantify in a rational way the cognitive and emotional states of the actors of the context of teaching training. An expert system whose general objectives would be: classify the profiles of the teachers starting from their professional competences based on their pedagogy, behavior and attitude. Classify the learners' profiles by analyzing their interactions and analyzing their performances in summative evaluations. Adapt the resources of the teacher's pedagogical methods in order to have a better coherence with the profiles of identities, the profiles of motivation and the profiles of comprehension of learner.

The organizational structure of this expert system is hybrid. Indeed, it is computer software installable on the laptop of the inspector and whose entries are seized, on the one hand, in class by the inspector. He interacts with the system using an interface man machine based on grids of teaching and didactic functions which we will detail later on. On the other hand, the marks of the students' summative evaluations are collected by the remote system starting from a Web site placed at the disposal of the students.

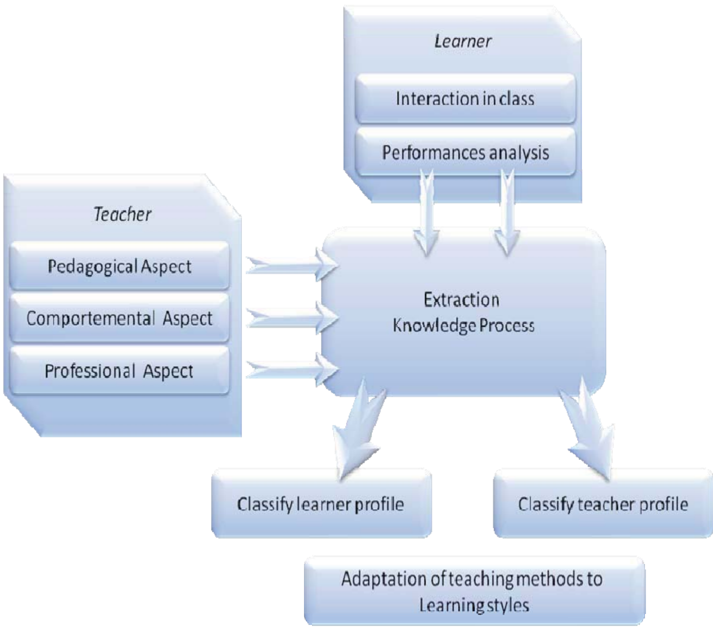

Figure 1

II. DYNAMIC EDUCATIONAL PROCESS OF LEARNING SEQUENCE

In trying to identify the key factors that characterize the various approaches that define the learning, we find that the role of students is essential. In constructing his knowledge that he built himself and who is constructing, acquiring knowledge. This interactive process of teaching and learning is modeled by Marcel Lebrun following five categories.

Figure 2

A. *The steps of a teaching learning sequence*

We began a sequence of teaching-learning by encountering a new situation, a problem suitable for students connected with circumstances known to them, so it presents a real opportunity to gauge their own prior knowledge and skills. And since meaning is given through structure, there is no shortage of ways to provide understanding of the structure to access the significance. This context would be motivating if it leads the student to give a value to the task, it is proposed by identifying the elements, facts, transactions that make sense and meaning. On the other hand, this context has an evocative power and potential for expansion because of its direct contact with reality, experience, applications, and needs: it causes management and control by the student.

The next step illustrates the importance of access and information gathering. Thus, we proceed to harvest information from the context, the views of students and their different representations, resource centers are meeting places, information is contextualized. This is mapping between world and formalism.

The analysis phase is gradually learning to learners to build tools for information retrieval, structuring, comparing, categorizing and confrontation. It means developing the ability to manipulate the world descriptions, relating and manipulating the various form of representation.

The stage of interaction operates the interactive and collaborative learning, emphasizes the importance of factors relating to communication and teamwork, and since action without feedback is unproductive for a learner, we use feedbacks intrinsic versus extrinsic or action in relation to representations, which allows the student to recognize his abilities.

Finally, the production stage that leads to reflection not confined to the goal but as aspect of the whole learning process. It illustrates the importance of personal production, creative activity, the role of self-assessment, promotion of change and reflection "meta" learning how to learn. It is a step of recontextualization in which the student builds something personal.

III. TEACHERS' ACTING PROFILES

The educational relationship is a set of verbal and nonverbal characterizing the act of teaching. These exchanges are affected by teaching methods practiced by the teacher. DeLandsheere and Bayer have classified these exchanges in seven categories, called pedagogical functions that cover the key events of school life. Each educational function is characterized by a set of measurable actions which, once identified, resulting in their existence and sequencing the action plan of the teacher, his rational way to organize a practical rule of advance operations to accomplish. This awareness comes not only from theoretical knowledge but especially from the implementation of this knowledge in the field.

A. Pedagogical assessment

The organizing function that sets the conditions and context in which the act of teaching-learning must be given. Imposition function is for the content of education or starting framework facilitating stimulation. The development function designed by educational and teaching techniques used by teachers to ensure the development of intellectual and psychomotor abilities of the student. The personalization function uses the previous knowledge and representations of student achievements, including his own difficulties. The function of positive and negative evaluation that informs students of the quality of its performance, positive and negative affectivity related to the student personality, eventually, the realization function that characterizes the teaching aids and technical visual, auditory used to channel information to the student to achieve an optimal acquisition of knowledge.

Each measure of verbal and nonverbal teacher’s act must be categorized to the proper pedagogical function; the corresponding time periods must be measured during the course of the activity. An acquisition tool is designed, offering a friendly interface formed by the grid functions and its criteria. A simple click on each criterion detected in the act of teaching that the algorithm accounts for the periods corresponding acts, it collects and makes the combined category. The data collected is stored in a spreadsheet. This algorithm has been validated in advance before its systematic use to ensure its adequacy and accuracy is sufficient.

As a first approach, we opted for the visualization of statistical results in the form of histograms in a plane with two axes representing teaching functions on the horizontal axis and the cumulative final frequency on the vertical axis. This has an

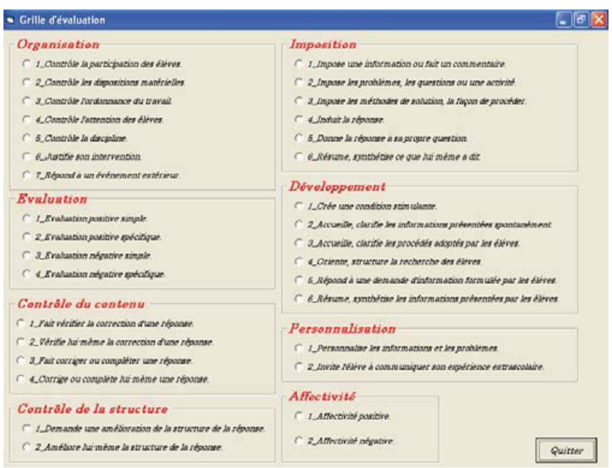

Figure 3

effect not only on visualization of comparative quantities frequencies educational functions between them, but especially between the same functions measured at successive visits.

B. Behavioral assessment

Since the teacher is not perceived by its students solely on the cognitive but also in terms of personality: "we teach what we know with what we are”, it would be appropriate to conduct assessment of attitudes, behaviors and methods of teaching, especially that within his personality, the same order is preserved if we go from what is the most spontaneous to what is more built as finalized and The more organized.

C. Teaching methods

As teachers, the more we know about how our students think and learn, the more successful we will be at helping them realize their educational goals. Teachers are learners too, and we often use teaching methods in our classrooms that complement our own personal learning styles. Our teaching styles may not be effective for our students, who may have learning styles that are very different from our own. There are many ways to assess learning style preferences for our students (and for ourselves): most of these methods rely on the use of diagnostic learning style preference “tests” that are based on one of the learning style models (Myers-Briggs Type Indicator, Kolb’s Learning Style Model, Herrmann Brain Dominance Instrument, Felder-Silverman Learning Style Model).

A teaching method describes the pedagogical means adopted by the teacher to enhance learning and achieve its educational objective. The teacher values over a given time one method than another, at the discretion of the teacher is often a matter of circumstances. To facilitating learning and mediation of knowledge, it is important to review regularly the method of teaching. It is customary to distinguish five teaching methods: expositive, demonstrative, interrogative, discovery and experiential. They can be practiced in a teaching sequence or individually or in small or large groups with the mediation of educational tools.

With transmissive method, the teacher has skills in a structured content and transmit knowledge in the form of presentation, the lecture that leaves little place for interactivity with the learner. In the didactic triangle, this corresponds to the relationship teachers - knowledge where the teacher is an expert of the content, a keeper of truth, which transmits information unambiguously.

The teacher determines a path teaching in demonstrative method: he shows, he makes doing and then make the student to formalize in order to assess the degree of understanding. This method is often used to make the student acquires skills through simple imitation.

Within interrogative method, the student is recognized as having elements of knowledge or representation of content acquisition. Using appropriate questioning, the teacher allows students to construct knowledge by himself or to make connections and make sense of these disparate elements. The student or student group is encouraged to formulate what he knows, what he thinks, what he represents

The teacher creates a scenario, when using an active method, with educational materials that can use trials and errors to learn. He mobilizes the experience of the student or of a group of students to assess the situation and solve the problem with their means. Intracognitif and co-development work between peers is promoted.

Many disciplines or knowledge can be taught but learned by doing with people who can do such as, medicine or art. This knowledge is gained by the student in and by the action in a real project. The teacher encourages the formalization of knowledge by the student who is the real producer of knowledge sharing and re-elaborates it with others. This is what is called experiential method.

IV. STUDENT'S LEARNING STYLES

For any academic training, the learner is implicit target, around which is built a huge process to make him, explicitly, the main actor. It must therefore be identified by our system on different plans and different levels. Beginning with a thorough study of its intelligence and its many facets that make up the dynamics of cognitive development, types of interactions with his teachers, peers, the learning content, technology media in use, and its environment. An environment that must demonstrate its social presence is the result, among other things, of its interactivity and its affectivity. His cognitive presence outcome of the accommodation of its prerequisites with new knowledge and assimilation. Self-regulation and self-evaluation are also identifiable skills in the learner through various indicators which converge, too, with those of his learning style. We consider motivation and attention of the learner in order to be able to "detect" at will during the teaching learning sequence through their determinants in order to maintain an optimal level and maintain it.

Learners are intrinsically different and have different preferred learning styles. Learning styles indicate the way people prefer to "receive" information, they address the learner's preferences for the learning environment and his modality preference. Mc Carthy identifies within his research four student's learning styles. First, innovative learners who are interested in personal meaning of knowledge, they need to have reasons for learning. Reasons that connect new information with personal experience and establish that information's usefulness in daily life. Second, analytic learners who are interested in acquiring facts in order to deepen their understanding of concepts and processes. They learn effectively from lectures and they enjoy independent research, analysis of data, hearing what "the expert" has to say. Third, common sense learners, they are essentially interested in how things work, they want to "get in and try it", they learn effectively with concrete experiential learning activities using manipulative, hands-on tasks, Kinaesthetic experience and so on. Finally, dynamic learners who are interested in self directed discovery, they enjoy simulations, role play and games.

The modalities of those learning styles are subdivided into four categories. Visual verbal learning style in which information is presented visually in a written language format. Visual non verbal style, information is presented visually and in a picture or design format. Students with this modality of learning, benefit from teachers who use visual aids such as film, video, maps and charts. They may have an artistic side that enjoys activities having to do with visual art and design. Students with tactile kinaesthetic learning style learn best when physically engaged in a "hands on" activity. They benefit from laboratory setting where they can manipulate materials to learn new information. Learners with auditory verbal learning style learn best when information is presented auditory in an oral language format, so they interact with others in a listening speaking exchange. They benefit from listening to lecture and participating in group discussions. When trying to remember something, they can often "hear" the way someone told them the information, or the way they previously repeated it loud.

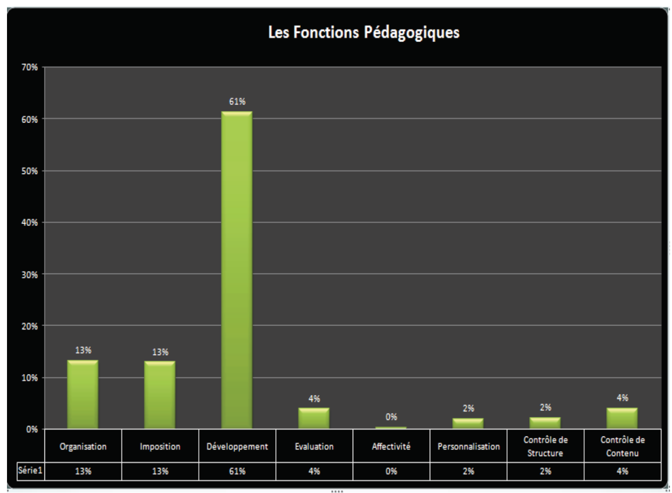

Figure 4

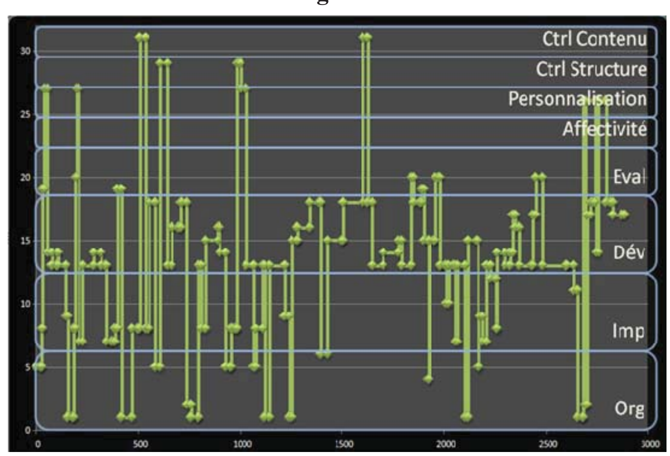

Figure 5

V. Results

The evolution of the teacher's practices in class will decrease school failures enormously and will support a relevant educational insertion. This evolution is the result of the reflexive practices that the professor starts as soon as he has between his hands the static recordings of his professional practices in the forms of histograms. These histograms illustrate the cumulated rates of the teaching pedagogical functions. The teacher can read measurements of his acts and discriminate those which are harmful with any active way. A way with it the teacher plays the part of an organizer, facilitating the access to knowledge which is built by the student in an autonomous motivating style. The teacher can also read the evolution of his practices during the time of the course: it is the dynamic aspect of the recording.

VI. Conclusion

Teachers have experienced a major interest to the various statistics generated at the point where they cheered as soon as the course ended and they often inquire about the meanings of educational functions whose performance is lacking. There is even that in many cases, following a second visit, the development function becomes more dominant than that of imposition. We also note that personalization appears, negative affectivity is substituted with positive one. In some cases, especially for older teachers, they find it difficult to assign the practice of imposition in favor of one that is developed. Despite this, one finds that the development practices evolve without the knowledge of the stagnation of imposition. All teachers visited, old or young, have been manifest in their professional practice developments relating to acts that promote centering on the student in performing their function of teaching learning. Changing teaching practices in the direction of better focus on the pupil, following the identification of their past practices by the evaluation grid used.

One of the challenges which threaten more the educational world and especially the secondary and academic levels is the uninspired pupils. They do not take any interest in what occurs in class and they give up every attempt of fixing to the course of their learning dice the slightest difficulty. The situation is still worsened with the feeling of routine which invades the professor at the time of his practices in class. In this work method and with the instructions of assistance which the expert system generates, the professor and the pupil are in harmony in the classroom. The teacher recognizes his pupil well by adapting his manners to him; the pupil is suitably framed with the feeling of being the Master of the situation who can construct in an autonomous way his knowledge.

Abstract — **In this article, the authors propose an investigation of the learning process of the concepts and of the mathematical relations in the physical chemistry study of the gas, mapping an interdisciplinary teaching approach. The theoretical background of the research is based on the Theory of Meaningful Learning (ML) and on Gowin´s Epistemology trying to relate events, facts and concepts with other elements of knowledge through the "see" heuristic. The research experiments are being conducted with chemistry graduating students at the Universidade Federal de Pelotas in Rio Grande do Sul, during one semester, but it is planned to extend the studies to the engineering courses. The tests to check the subsumers are based on some theoretical questions related to the mathematical concepts already mentioned. Preliminary results of the testing show arithmetic and algebraic disabilities in a percentage of the group, as only 60% of the students answered the tests correctly. Based on the answers analysis contextualized activities are proposed to enrich the mathematics application in chemistry with the objective of favoring the development of the subsumers needed to the comprehension of the PC phenomena studied.**

Keywords- Physical Chemistry, Mathematics, Meaningful Learning, Interdisciplinarity

I. INTRODUCTION

Part of the subjects which composes the specific cycle of the engineering courses and of the chemistry graduation courses need some requirements from the mathematics area (calculus, analytic geometry, linear algebra), as it is the case of physics chemistry. On the other hand, an enormous challenge for the students of these graduation courses is to apply the mathematical concepts that were studied before in an isolated and fragmented manner, in the interpretation of the phenomena related to their area of knowledge.

At Universidade Federal de Pelotas (UFPel) and at Universidade Federal do Rio Grande do Sul (UFRGS), the physics chemistry subject has the characteristic of belonging to the Chemistry filed, but it is also part of the Engineering Courses specifically related to the Chemistry Engineering, Food Engineering and to the Metallurgical Engineering. The aim found in the teaching of this discipline to the Chemistry and/or Chemistry Engineering and to the other engineering courses is that for the first theoretical classes are realized while for the second the classes given are only theoretical. This fact does not allow the complete and adequate contextualization of the mathematical tools causing huge difficulties in their applications.

An optional approach that enriches the practical activities experienced and which has been more present in the graduation courses is related to the use of computer simulation, modeling and virtual reality software among others. The use of computational resources in the education field is related to activities that can potentiate the educational activity and that can add value to the teacher's work as technology and creativity integrate the new format of knowledge transmission. Besides, through the computational activities it is possible to potentiate the cognitive process of the students creating products that put together hypermedia as audio, video, simulations and animations.

In the field of engineering education, we emphasized the research of Zimmer *et al* [1]. Their studies suggest the development of a virtual laboratory of differential and integral calculus in order to contribute for the learning and teaching process in relation to the interest and motivation of students. First, the tutorial software was developed with concepts and definitions capable of solving some differential and integral problems. After, the students presented their works developed in panels during an exposition to the public. Finally, a webpage was created where all the content was organized to be accessible for anyone.

In respect to the teaching of electrical engineering, Vieira Junior & Colvara [12] call the attention to the difficulties that happen due to the huge need of abstraction of the phenomenon studied. This way, they propose the development of some educational software which allows the user to analyze different events of stability in electrical systems.

The authors suggest the use of this software as a helping tool in the teaching process emphasizing the graphics visualization in 3D which allows to put the images and to rotate them showing their view in different perspectives.

Our research tries to comprehend the difficulty of the students through the meaningful learning theory, in relation to mathematical knowledge (subsumers) needed to the study of the gas transformations to propose some software of computational simulation applicable in the physics chemistry subject. The studies were initiated with the realization of a pre-test in order to verify the mathematical knowledge that the students have about: the meaning of an equation, function, its differences and relations, independent and dependent variables, operations about the set of real numbers, quantities directly and inversely proportional and the applicability of mathematics in the chemistry area and, more specifically, in the ideal gas equation in the subject of Physics Chemistry I.

At the same time, interviews with the professors were realized in the Universities mentioned before in this article about the main difficulties found by the students in the applicability of the mathematical concepts. The interviews showed some common difficulties as: in the solving of equations, in the interpretation of inverse quantities, in the representation of functions, among others. One aspect told by the professors is related to the adequacy difficulty of the available graphical software in relation to the aim and needs of the specific subject of Physics Chemistry I.

The initial results of these practical studies indicate the need of developing a graphic simulator for the study of the Ideal Gas Law which will be showed later on this research, after the presentation of the theoretical background. After that the results of the use of the simulator will be presented and discussed and at the end the final considerations will be exposed.

II. TEORETHICAL

The development of the work was based on an investigative study about the learning and teaching process concerned with the Meaningful Learning Theory, its association with Conceptual Maps and the relation between them with Gowin's Epistemology, which are presented below.

A. *Meaningful Learning Theory*

The meaningful learning theory has as its assumption the fact that the student has some knowledge and he can use it as a mean to insert new information into his cognitive structure [5, 9]. According to author [6], the main points of the meaningful learning have as the main actor the student himself who learns when he finds sense in the concept presented and through the conceptual hierarchies which can be understood as the association or combination of new concepts to the ones that already existed before in the cognitive structure.

In the context of this work the concepts about equations and functions acquired by the students will be discussed. From this conceptualization the ideal gas equation will be inserted as the graphical representation of the gas transformations.

The knowledge structures through which the new concepts occur in the meaningful theory [4] sets as subsumers. They act as a support structure to join the new concept forming a new subsumer. The figure below shows this conceptualization.

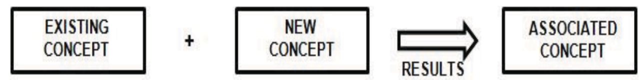

Figure 1. Concepts formation based on the subsumers existency

Source: the authors of this research

The initial process of verifying the meaningful learning consists in the identification of the existence of the subsumers. In this sense, the author [9] suggests the realization of a pre-test to check the existence of the subsumers needed. The pre-test is formed by questions related to the subject which it is intended to be verified and also the level of knowledge that the student has about it.

For the students who do not have subsumers, they are submitted to the advanced organizers, according to the meaningful learning theory. The use of advanced organizers according to author [4] is a way to manipulate the cognitive structure of the student so that he can be able to receive new concepts. The advanced organizers are made of new activities, more elaborated ones so that they can supply the need of the student, affirms the author [9].

B. *Conceptual maps*

In a broad sense, conceptual maps are diagrams that indicate relations between the concepts [11]. The conceptual map establishes the relation among concepts through key words in a non-hierarchical way. The key words can be short linking sentences, verbs, prepositions and also nouns, according to the Figure 2. More specifically, it reflects the conceptual organization of a subject or part of it. In other words, its existence is formed from the conceptual structure of a discipline and it can have two or more dimensions.

Moreira [10] proposes the conceptual maps as useful tools to promote the progressive conceptual differentiation and the integrative reconciliation, concepts present in the meaningful learning theory and he highlights its potential as an evaluation tool over the conceptual knowledge that the student has.

Anastasiou & Alves [8] also suggest the conceptual maps as a strategy of teaching in the classroom. The justification is based on the main thinking operations which allow the interpretation, classification, critics and the organization of conceptual data in a hierarchical manner.

The conceptual maps dimension can be contextualized by classification where dimensional maps tend to present a linear vertical organization giving a broad view of the concepts of a subject. The two dimensional maps, on the contrary, use the vertical and also the horizontality perspective and, therefore, allow a more complete representation of the relations among the concepts of a subject or about a specific aspect.

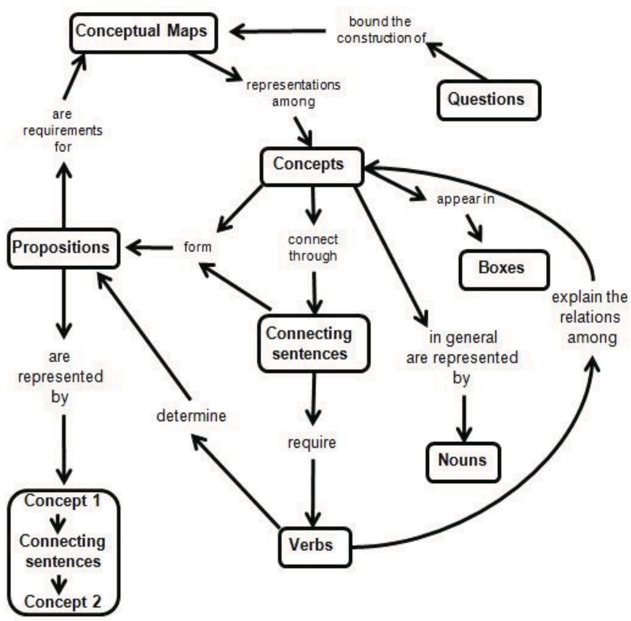

Figure 2. Schematic representation of the relvant aspects of a conceptual map

Source: the authors of this research

In this study, the conceptual maps were used to identify the conceptual domain of the students about the equations and mathematical functions which allowed the evaluation of the level of knowledge of both mathematical concepts. The results showed a simple conceptual map where each student built his own Initial Conceptual Map having as the main point the equation and function from the mathematical point of view. With this, it can be said that the students have different difficulties as to understand the quantities directly and inversely proportional, the meaning of an independent variable, among others.

C. *Gowin's Epistemology*

The scientific investigation process according to author [2] is the construction of meaning structures from basic elements named as events, objects, facts and concepts. The initial idea is from the observation of a specific event or object which occur in a natural way or is even created by the observer, the procedure of research relates specific relations among the observations of the event done, its consequences derived from the studies of the event, the assertions made by the consequences and the concepts, by the definitions used to interpret, analyze in order to get to the explanation of the event or object.

Concepts are defined according to authors [2] and [3] as signs or symbols that describe regularities in events we use to do in an action as thinking, researching, learning, aiming at finding an answer to the observable events. Conceptual systems are sets of definitions logically connected which allow default reasoning as we relate concepts. For author [3] this fact can signify that the event itself occurs naturally or is caused by the observer or the researcher and it can also be understood as the event registration, or yet, the facts are verbal or mathematical assertions, based on the events registrations.

The research process according to Gowin's perspective is a way to generate signification structures connecting concepts, events and facts. Figure 3 shows this connection in a "v" shape matching events in the bottom to concepts and facts on the sides.

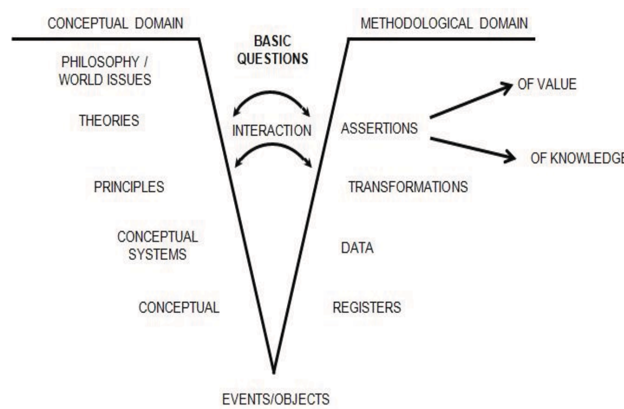

Figure 3. Gowin's epistemology of the 'v'.

Source: Moreira & Buchweitz [10]

The left side refers to concepts and conceptual systems called as conceptual domain of the investigation process where the effective concepts and the conceptual concepts used in the research are situated and generate principles and laws, which also create theories. Value systems, world views and philosophies are related to the theories. In the "v" bottom are the events that happen naturally or that are caused by the researcher in order to obtain registrations through which the phenomena can be studied. Sometimes the phenomenon observed is studied through objects and in this case it can be said that the event is the object itself.

In the case of the knowledge observed in this research that involves mathematics and physics chemistry, the bottom of the 'v' is made of concepts of equations and functions. On the conceptual domain side we have the independent and dependent variables, the quantities directly and inversely proportional, linear and rational function, graphics representation and operations about the set of real numbers. On the other side, on the methodological domain, we have the gas transformations, behavior of an ideal gas, graphical representation with the variables involved in the gas transformation, physics and chemistry analysis and interpretation. The interaction process was realized with the use of the graphical simulator.

The pre-test was constructed in two steps. In a first moment, five theoretical questions were developed about the signified of the content described above, as it can be seen below:

1- What is a mathematical equation?
2- What do you understand as a mathematical function?
3- What is the difference between a function and an equation? Explain it with your own words.
4- Give the definition or explain the meaning of an independent and of a dependent variable.
5- What is the meaning and the purpose of a graphic in mathematics?

In the second step of the pre-test ten questions were created to be answered in an analytical way and eight of them were based on operations involving real numbers and two were described as problems with quantities directly and inversely proportional.

The questions above were answered by twenty students. The result of the first stage showed that most of the students did not answer the five theoretical questions. Two possibilities were raised as possible justifications for this situation:

1º) The students do not understand the concepts;
2º) The students can not express their ideas.

In the second stage of the pre-test ten questions were created to be answered in an analytical way and eight of them were based on operations involving real numbers and two were described as problems with quantities directly and inversely proportional.

Not all the questions in this part were solved by the students. The average of right questions was near 58% (fifty-eight percent) where a higher number was expected.

Through a detailed analysis of the mistakes done, the following were highlighted:

1º) $4/0 = 0$
2º) $2^{-1} = -2$
3º) $3^{1/2}$ = no answer
4º) $x^2 = 36 \Rightarrow x = 6$ (only)
5º) $x^3 = 27 \Rightarrow x = 9$
6º) $\log_2 16 = x \Rightarrow x$ = no answer

In relation to the two problems, part of the students got to the right answer identifying the quantity directly and inversely proportional, but the other part did not get the answer or did not answer the problems. In this last case, among the students that did not do the problems right, most of them chose not to answer the questions.

An initial justification concerning the mistakes of the students is due to the difficulties in understanding or the domain the mathematical conceptualization during his student life, regardless as a high school student or as a graduation one. Another possibility is that the students find difficulties in subjects like calculation because at most cases they need to take the subject more than once. It also reflects in the low number of students enable to take the discipline of Physics Chemistry I.

Relating it to the meaningful learning theory it can be perceived that the students are owners of some subsumers related to some subjects, as an example, operations with numbers. For those who do not have these, they are exposed to new problems with a different focus to avoid the repetition of activities and to put away the possibility of memorization.

Figure 4. Screen from the graphical simulator used to show an isobarican transformation

III. PRE TEST RESULTS

The pre-test with students of two groups of the Physics Chemistry I subject was realized in the beginning of the second term of 2008 and 2009 to verify the existence of subsumers related to the mathematical functions and equations. It was consisted of expository questions and activities to be solved about the math contents needed to the understanding of the ideal gas Law. The results showed that most of the students have difficulties to apply, analyze and interpret the mathematical concepts used in problems applied in the subject in question. It was quite evident that most of them (between 40% and 50%) do not present the subsumers related to the equations and functions for the Ideal Gas Equation.

Based on the initial results, in the second term of 2008 a decision to work in an interdisciplinary way was taken. For that some monitoring activities of the practical classes in the subject were realized by a mathematics professor. During the laboratories classes the Mathematics and Chemistry professors participated in the process realizing the connections between the two areas in a way to highlight the applicability of the math concepts in chemistry.

Interdisciplinary for author [7] is characterized by a group of disciplines, or areas of related knowledge, which aims at achieving the objective established by one or more coordinators of the process. In this specific case of the ideal gas law the common element is the equation which represents the variables involved in the process as a transformation that occurs in an ideal gas.

The results obtained up to the present moment reinforce the assumptions of the meaningful learning theory. Preliminary surveys of the pre-test showed the identification of the specific subsumers which were worked with the development and application of the Simulator causing the development and post preparation of new concepts insertion for the student.

The mathematical conceptualization needed as a requirement for the Physics Chemistry I Subject more specifically related to the ideal gas Law is potentiated with the use of the simulator. In the graphic representation and in the table which related the variables, the student perceives the concepts of the quantities directly and inversely proportional besides checking the difference between independent and dependent variables. Another relevant aspect would be the representation of specific points delimited by values inserted in the Simulator to express a linear function and a rational function.

The simulator allows the comparison between the first and the following representation demanding the reasoning of the student to identify the position of the following graphic as well as of the third and last graphic.

The use of the simulator also helped the student in the improvement of his initial conceptual map due to concepts seen in the mathematics subjects, as the calculations. New relations among the contents were represented and checked creating a new and more elaborated conceptual map. This shows that the students developed the specific subsumers proving domain over the mathematical concepts in their new cognitive structure. In this case, they are capable of receiving new definitions and information according to author [4].

The mathematical background allows the chemistry professor to relate, with the technical conceptualization seen in the subject, the real gases that behave close to reality in the value numerical ranges of the variables involved in the process.

IV. CONCLUSIONS

The activity of identifying the knowledge acquired and of confronting it with its applicability is not an easy task as it demands the group commitment for those who really search the complete domain of the concept presented by the professor. This raises the critical sense in the students and contributes for their future formation.

In the monitoring process of the learning development done in the classroom it was identified that the students have the capacity to recognize and define problems but they have difficulties in finding the solutions and in realizing the analysis as also the interpretation.

The process of use of the simulator was done by the reception learning according to author [6]. It is expected that the simulator can really contribute with the concepts understandings as it allows the realization of comparisons inside the transformation through three kinds of functions represented in the same space where that variation of the number of mols allows a more effective mathematical analysis. Besides, the independent variables selection permits the same inference and also of the variable that assumes a constant value throughout the process.

The initial and final use of conceptual maps, the last to be developed, can show the evolution of the students in the comprehension of the equations and functions concepts as there is a tendency of specifying and of reorganizing the existing relations in the cognitive structure described before, as well as of the increase in the number of related concepts.

It is also perceived that interdisciplinarity can contribute in a way to organize the thinking and to complement the knowledge acquired improving the general view of the concept taught. So we suggest its applicability inside the Physics Chemistry I Subject as well as in other disciplines that allow the association between mathematics and chemistry.

The simulator use will certainly bring other contributions to the research as well as the increase in the new results found up to this moment. It is intended to improve the interface and the functions of it in a way to create new situations that evolve the study of the real gas and also to follow new groups of Physics Chemistry I groups to obtain a comparison between the groups followed now.

It is intended to do future research to supply some aspects that in this research could not be completed and for that a new research is suggested with differentiated instruments in relation to the ones used up to the present moment.

Authoring Environment for E-learning Production Based on Independent XML Formats

Alberto González Téllez
Dept. de Informática de Sistemas y Computadores
Universidad Politécnica de Valencia
46022 Valencia, Spain

Abstract— **E-learning content production has faced the problem of making content independent from authoring applications and delivery platforms. Both aspects are very relevant to the need of keeping learning institutions as much independent as possible from software vendors. Content independence and interoperability is also required to easily share and move e-learning repositories. We propose a user friendly authoring environment based on the independent, open and XML compliant product Docbook; its simple, flexible and well structured markup make it easy to interoperate with other XML languages, particularly those related to e-learning. We are particularly interested in IMS Content Packaging and IMS QTI because they allow importing learning material into our Sakai based learning management system named PoliformaT. Docbook has also a powerful and fully customizable set of XSLT styles sheets that allow high quality web and paper delivery. The user front end is built on the commercial XML editor from XMLmind XXE. The major part of the environment is portable to other XML editors because it relies exclusively on Docbook components. At the moment the proposal presented is much more flexible, usable and productive than the available alternatives.**

E-learning; interoperable formats; XML; IMS; Docbook

I. INTRODUCTION

After being established as a mature technology e-learning has faced the problem of content management in such a way that content be platform and vendor independent. XML originated on the web as a set of standards that provide open and independent data representation and processing, has become the more convenient platform to define interoperable content representation. In spite that these efforts have been more oriented to content packaging (i.e. SCORM and IMS Content Packaging), nowadays there are XML compliant languages that cover the whole range of content types (text, graphics, multimedia, etc). In this way interoperability and standard data processing can be applied to the whole content hierarchy, from individual content items to a whole subject, course or set of courses. In this work we present a learning content authoring environment based on the XML compliant and open product Docbook [1]. The main interesting features of Docbook are its well structured and format independent definition, its total independence from particular software products and vendors, and its complete set of mature and well tested web and paper format generation tools. The simple and well structured Docbook markup simplifies its interoperability with other XML compliant standards, particularly those oriented to import and export e-learning content in learning management systems (LMS) [2].

Docbook has been the framework of choice in other e-learning related works like [3][4][5][6][7]. In [7] we developed our first Docbook customization (TeachdB) aimed to provide content reuse and one-source-multiple-format delivery. In this work we present an extension of this customization oriented to interoperate with IMS Global Consortium Standards [2], particularly IMS Content Packaging (CP) [8] and IMP Question and Test Interoperability (QTI) [9]. The whole publishing process is schematically depicted in figure 1.

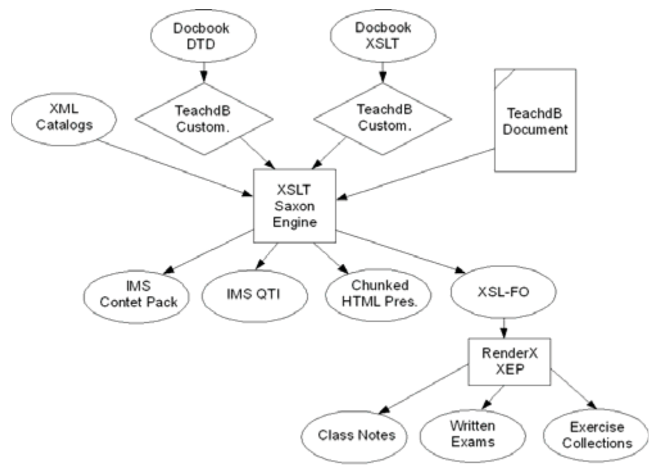

Figure 1. E-learning publishing process based on Docbook.

The ability to easily produce IMS CP and QTI is a key feature for us because our university has based its e-learning support on a Sakai [10] customization named PoliformaT [11] and Sakai uses these two IMS standards to import and export content modules and assessments, respectively. Then our main contribution is the development of a concrete friendly e-learning production tool based on open, independent and XML compliant standards and fitted to Sakai as target LMS. The approach can be applied to other environments like SCORM formats and Moodle LMS [12].

The content of the paper is organized as described next. In section 2 we briefly describe IMS CP and QTI standards. Section 3 is dedicated to summarize our Docbook customization [10] intended to fulfill our requirements. Section 4 contains the main issues involved in the implementation of IMS CP and QTI generation from our Docbook customization. Section 5 describes how authors have to use the environment. It also includes a description of real production examples and some figures about the impact that it had in our teaching experience. Section 6 is devoted to compare our proposal to other available alternatives. Finally some conclusions and future work directions are considered.

II. IMS CP AND QTI STANDARDS

IMS Global Learning Consortium began at 1997 and since then it has published about 20 standards dealing with interoperability for learning systems and learning content and the enterprise integration of these capabilities [2]. In the next two sections we briefly describe the two IMS standards that are relevant for us: IMS Content Packaging and IMS Question and Test Interoperability; both are XML compliant.

A. IMS Content Packaging

As stated in the standard "the IMS Content Packaging provides the functionality to describe and package learning materials, such as an individual course or a collection of courses, into interoperable, distributable packages" [8]; its latest version is 1.1.4.

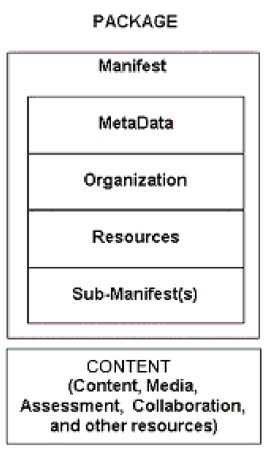

Figure 2. Content Package structure.

As shown in figure 2 a Content Package has two parts: a manifest and a content pool. The manifest corresponds to an XML file, commonly named *imsmanifest.xml*, with a root element <manifest> with the following child elements:

- <metada> is an optional element that describes the package according to IEEE 1484.12.1-2002 standard for Learning Objects Metadata. Other metadata can be included by their corresponding namespace.
- <organizations> is a required element with zero or more <organization> children that describe the structure of content resources.
- <organization> includes a hierarchical composition of <item> elements pointing to content resources by means of unique ids.
- <resources> is a required element that includes the references to all the content resources included in the package by means of a unique id and a sequence of one or more <file> children.
- <manifest> is an optional element that specifies zero or more sub-manifests.

The manifest, schemas and resource files are packed into a compressed file, typically using ZIP format. The manifest and the schemas are located at the root and resources are organized into subfolders.

B. IMS Question and Test Interoperability

IMS Question and Test Interoperability is defined by the standard as "(it) describes a basic structure for the representation of question (item) and test (assessment) data and their corresponding results reports" [9]. The latest version of IMS QTI is 2.1 but at present PoliformaT only supports version 1.2, then this will be our target version.

There are two aspects covered by the standards ASI and Results Reporting, both are totally independent. ASI stands for "Assessment, Section, Item" and it is the component relevant to us because it deals with assessment authoring.

An IMS QTI ASI compliant document is an XML document validated against the schema *ims_qtiasiv1p2.xsd*. Our LMS uses IMS QTI ASI as the format to import and export exams and, among all the compliant structures, it only accepts the following one:

- A root element <questestinterop> with one <assessment> child. In fact only one <assessment> element can be included in an IMS QTI compliant document.
- The <assessment> element includes one <section> child.
- The <section> element includes a sequence of <item> elements. Every item implements an assessment question.
- An <item> element is compounded by three elements:
    - <itemmetadata> describes question features like the type of question.
    - <presentation> includes presentation content like enunciate and response options.
    - <resprocessing> includes the description about the response alternatives (correctness, score, etc).

III. DOCBOOK AUTHORING ENVIRONMENT

The basic Docbook 4 tools are the DTD files and the XSLT stylesheets that produce web and print formats. Both of them are open source and can be obtained from the Docbook site [1].

These basic tools have to be complemented with an authoring frontend and some customizations in order to be productive and fulfill particular application requirements. Either DTD and stylesheets are fully customizable at several levels of complexity [13][14], usually simple customizations will suffice.

In the next two sections we briefly describe our Docbook markup customization and the tools that we have selected to produce and manage documents.

A. TeachdB markup

We have minimized markup customization in order to maintain the maximum compatibility level with Docbook. We have named our customization TeachdB [7].

Our learning/teaching documents are subject themes, lab guides and exams. Subject themes include theory and solved and unsolved exercises. Lab guides include theory briefing, lab activities and exercises. Exams are built reusing exercises from subject themes and lab guides. Exam questions can be open or test type, at the moment we only support multiple choice one answer test questions.

The delivery formats were initially chunked HTML briefings, to be used as class presentations, and PDF to deliver class notes and exercise collections to students in paper format. Lab guides and exams are delivered to students as PDF. The preference of paper format was because we began our Docbook working before PoliformaT started. Even after PoliformaT paper format is still widely used.

From the technical point of view subject themes and lab guide documents use <article> as root element. To distinguish one type of document to another we have made the next Docbook customization:

- *role* attribute of element <article> is restricted to “class” and “lab” values.

An important issue in our customization is exercise management and then the main markup customization part is related to exercises. We implement exercises using <qandaentry> elements. Docbook organizes <qandaentry> elements inside <qandadiv> elements and <qandadiv> elements are grouped into <qandaset> elements. We classify exercises into delivered in class notes, stored in repository and candidates for exam. This is implemented by means of the following customization:

- *role* attribute of element <qandadiv> is restricted to “class”, “repo” and “reserved”.

In Docbook a <qandaentry> element has one <question> child and cero, one or more <answer> children. We have customized <qandaentry> elements in order to be able to:

- Mark an exercise as solved (show the solution) or unsolved (hide the solution).
- Know their last use type and date.
- Implement multiple choice one answer test questions.
- Select a solution pattern or a complete solution depending on the type of document delivered (i.e. exam or exam solution).

The customization consists of:

- *role* attribute of <qandaentry> element is restricted to “example” and “exercise” values.
- Two new attributes *lastusetype* and *lastusedate* are added to <qandaentry>.
- A new element <options> is added to <question> element in order to implement multiple choice questions.
- A new attribute *type* is added to <answer> element, with available values ‘response’ and ‘solution’.

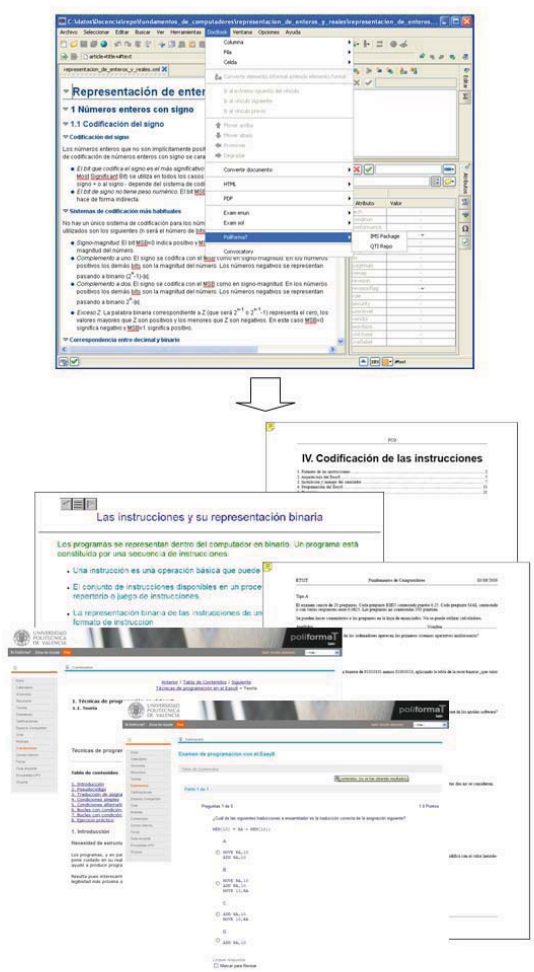

Figure 3. One content source multiple delivery formats.

Written exams are produced using XInclude in order to avoid content duplication and allow content reuse. In this way exams are built by pointing exercises located in subject themes or lab guides. This mechanism has improved noticeably the exams quality in such a way that exams errors are much less probable. Exam document have their own new markup tree described in [7].

The extension to deliver IMS CP and QTI has not imposed any additional markup customization if we limit content to text and still images. However these new formats are able to include interactive elements, like Java applets and multimedia clips, into both module sections and QTI items. So we are considering a customization of Docbook <audioobject> and <videoobject> elements, and the addition of the element <appletobject> at the same level as the former ones. At the moment we simple use standard Docbook <ulink> elements to include these types of materials.

We also plan to extend our QTI item support to fill-in the blanks that will require extending our <qandentry> customization.

Another candidate for customization is metadata, at the moment we do not include metadata inside IMS CP or QTI apart from the general metadata included in PoliformaT templates. Hierarchical elements in Docbook include info children like <articleinfo>, <sectioninfo> and <blockinfo> that can be customized as metadata containers [3].

B. Authoring tools

In order to be productive a user friendly editor has to be selected. XML editors tend to be difficult to use by non experts and this has been an important handicap to XML. Nowadays the situation has changed and there are at least two products that offer a comfortable interface to authors:

- XMLMind XML Editor (XXE) [16].
- oXygen XML Author [17].

XXE was probably the first XML editor oriented from the beginning to authors. We have followed its development and its evolution has been impressive and it certainly offers an easy to use and productive interface. At present XXE is our choice. oXygen has been mainly oriented to XML programmers and recently the Author version has been released. It is an alternative to keep in mind. Both XXE and oXygen XML Author are commercial products but very affordable licenses are available for academic use.

Our Docbook customization can be easily ported to both editors because it mainly deals with Docbook itself. Our first attempt has been to embed it inside XXE.

IV. IMS CP AND QTI PRODUCTION TOOL

After becoming aware of PoliformaT use of IMS CP and QTI formats for importing and exporting courses and assessments we began to extend our production environment [7] to automatically produce these formats from our pool of TeachdB documents. Basically it requires the implementation of some XSLT stylesheets that reuse Docbook XSLT for HTML generation and some simple console scripts. The scripts are platform/tool dependent but XSLT code is portable.

A. IMS CP Generation

Every subject inside PoliformaT has a Content site where content is organized as modules that contain one or more sections. Every section can be a single or chunked HTML page. The content inside Content site can be exported or imported as a whole or module by module using IMS CP.

We use the Content section of our subjects in PoliformaT as a complementary way to publish theory and problem collections. This material is also published as PDF in another subject site named Resources. The added value of HTML is that it allows enriching our learning documents with interactive elements like Java applets, multimedia clips and web links.

We import the subject content in PoliformaT by modules, in such a way that every module corresponds to a subject theme.

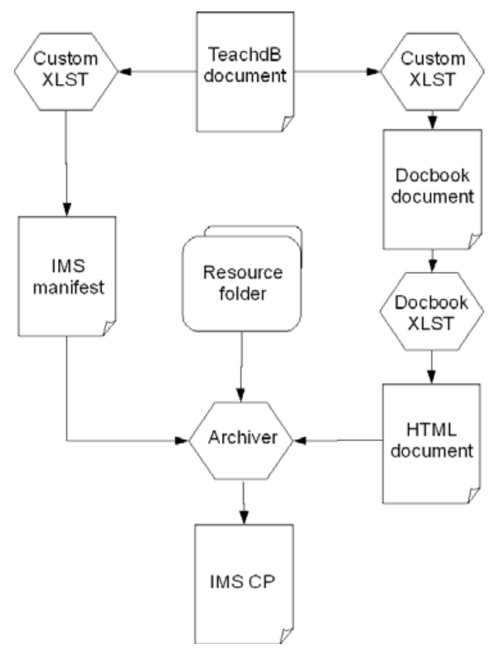

Figure 4. IMS CP generation procedure.

The exercises customization performed in TeachdB allows marking exercises to be solved, unsolved or reserved and then this characterization permits to filter what set of exercises will be published in the Content site or in the Exams site (as we will shown in the next section) and what exercises are reserved to produce written exams.

In order to get from a TeachdB subject theme file the theory and the solved exercises and to pack them into an IMS CP to be imported in PoliformaT we perform the procedure described in figure 4.

We have implemented two XSLT style sheets. One of them produces an intermediate Docbook document from TeachdB in order to use the standard Docbook XLST, properly customized, to produce a single HTML page. The other XLST style sheet produces the manifest document for the content package.

Finally an archiver packs the manifest, the HTML page and the local resources into a ZIP file that will be delivered to PoliformaT.

B. IMS QTI genaration

The implementation of QTI import/export procedure in Sakai 2.4, corresponding to PoliformaT at present time, is rather rudimentary. The automatic importation procedure only accepts a QTI valid file, with some additional restrictions, and any other auxiliary material (figures, graphics, applets, etc) should be uploaded manually to a public folder inside PoliformaT. Considering this situation our QTI assessment generation procedures is depicted in figure 5.

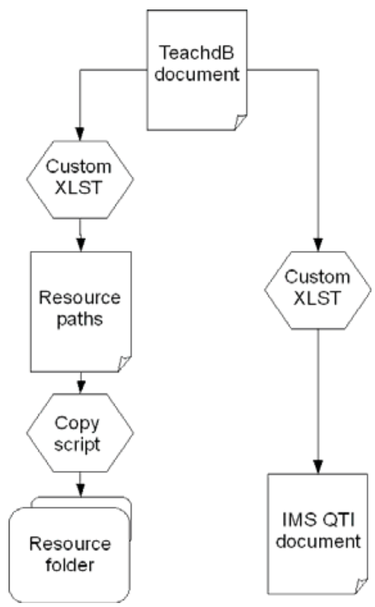

Figure 5. IMS QTI generation procedure.

The custom XSLT that produces the IMS QTI document takes from the TeachdB input file <qandaentry> elements that include an <options> children and that are included inside <qandadiv> elements with *role* attribute set to “class”. The Docbook hierarchical elements are translated to QTI and content markup is converted into HTML by reusing templates from Docbook XSLT. This is implemented by importing the main Docbook HTML style sheet into our QTI producer style sheet.

The other XLST style sheet produces a resource description text file, containing path location for resources (i.e. still images), that is generated by parsing the source TeachdB file. This description file is later read by a copy script that makes a copy on a resource folder of every resource used by the <qandaentry> elements included in the IMS QTI file.

The QTI file is imported in PoliformaT by the import procedure available in the subject Exams section and the resource folder is uploaded by WebDAV to a previously stated public folder inside PoliformaT.

C. XXE Customization

We have implemented inside XXE editor the procedures describe in the two previous sections. XXE has very powerful customization capabilities that allow adapting it to any XML compliant markup offering a friendly editing interface based on CSS [19]. In the professional edition the application menu can be customized with new entries that correspond to XML code able to call external XSLT style sheets and a set of command implemented inside the editor [20].

The customization is performed by including inside a customization folder the DTD for TeachdB, the CSS style sheet to get a friendly editing interface, a set of document templates, the XSLT style sheets that perform format generation and the customization file that integrates all the previous elements. This configuration file is XML compliant according to a schema created by XMLmind specifically to configure XXE. XXE itself has an addon that allows editing configuration file.

The TeachdB customization for XXE Professional Edition, in the state as it is at the time of this writing, can be downloaded from [21]. Figure 6 shows how XXE looks like when the customization is active.

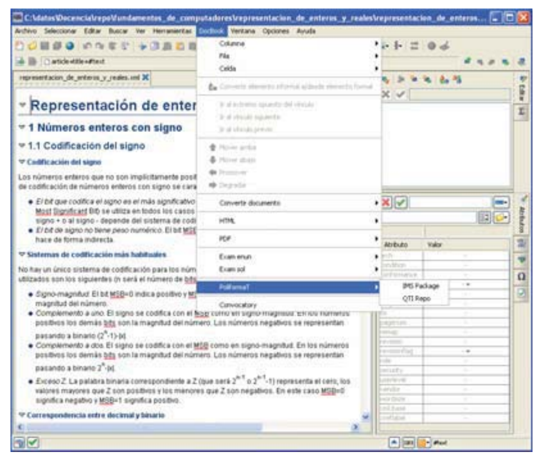

Figure 6. XXE with customized format generation menu entries.

V. ENVIRONMENT USE AND LEARNING IMPACT

We have been using the proposed e-learning production environment since course 2005-06. We have authored three subjects with it, one of them was created just reusing content from the other two by means of XInclude.

A. Environment use

The procedure to produce a subject is to decompose it into modules or themes. Every module is created using the <article> template of TeachdB inside XXE. The content of a module is organized into sections, commonly up to a three level deep section tree. Inside a section the content is organized into <simplesect> elements that are terminal sections in the document tree. A <simplesect> can be seen as a slide and contains an optional title and a sequence of content elements like paragraphs, items lists, tables, images, etc.

Exercises are included inside a <sect> or <simplesect> element using the <qandaset> container. The organization of exercises is explained previously in section III.A. Exercises are authored filling the <question> element with content elements (paragraphs, item lists, tables, images, etc) that define the exercise enunciate. If the exercise is a test question then the last element in <question> has to be one <options> element that defines the multiple choices for the test question. The first item of the <options> element has to be the true answer. When test exercises are imported in PoliformaT they are randomly reordered when students start the exam. After the <question> element we can optionally include one <answer> element with a response template (incomplete tables or images, clues for the solution, etc) and one <answer> element with the complete solution. The attribute *type* of <answer> element distinguishes both cases as we have described in section III.A.

To produce a module to be imported in PoliformaT we select Docbook menu, PoliformaT and IMS Package (figure 6). This produces an imscp.zip that is imported in the Content section of the subject in PoliformaT without any further manual operation.

A similar procedure is followed to produce a QTI exam. We do Docbook, PolformaT and QTI Repo (figure 6) then a qti.xml file is generated that is imported in the subject Exams section in PoliformaT.

A video demo is available at [27] showing the previously describe procedures.

B. *Learning impact figures*

The switch from using presentation slides and exercises collections provided only in PDF format, into our new approach has had a noticeable impact in the learning process. We thing that there are three main reasons for this improvement, first the new IMS Content Package format allows including more active elements like videos and applets.

Then we are able to make use of the new streaming platform PoliTube started in 2007 by our university to deliver learning videos. They can be included in modules by just a PoliTube link or embedding the video using the <embed> HTML element. Another reason is related to QTI as a more dynamic way of publishing exercises, together with the capability of publishing exercises with or without solutions from a single content source. Finally, the procedure to produce written exams automatically by reusing exercises already published and tested has improved quite noticeably the quality of written exams and this is greatly appreciated by students.

Year	p1	p2	np	abs
2005-2006	71	24	89	49
2006-2007	63	17	76	36
2007-2008	61	46	55	28
2008-2009	85	20	39	33

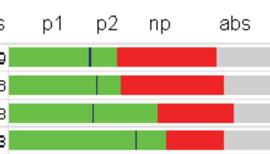

Figure 7. Learning results for a sample subject.

Some figures that measure this improvement in the learning process are shown in figure 7 and in figure 8.

Figure 7 shows how the percentage of passing students has got bigger and bigger and that the contrary stands for the percentage of non passing students. The percentage of absent students is more o less the same.

Figure 8 shows that since the proposed authoring environment is in use (2005) there is a jump of 1.5 points in the mean lecturer opinion pool score (upper line over lower line).

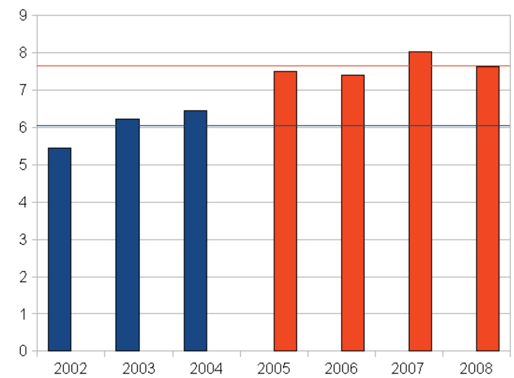

Figure 8. Lecturer opinion pools scores.

VI. COMPARING TO OTHER APPROACHES

The technique that we have presented has to be compared with the following available alternatives:

- Editors embedded in Sakai 2.4.
- Common word processors.
- Specific IMS authoring tools
- E-learning editor eXe.

Sakai 2.4 includes edition tools to produce content modules and assessments [10]. These tools can not be used outside the platform and then their use requires Internet connection which nowadays can still be an inconvenient. The editors are implemented as Java applets and then they suffer from high startup time and lack of functionality compared to common editor applications. Sakai editors neither support good quality printing format.

The previously mentioned shortcomings are not present in commonly used word processors like MS Word and OpenOffice Writer. These editors have another inconvenient, their XML formats are not structured (flat) and very complex, particularly they include a lot of formatting information in their markup [18]. This makes very difficult to implement automatic tools to translate documents to IMS formats, particularly QTI. Our Information Systems Support Department has developed a macro to produce QTI from MS Word documents but it has many restrictions that forces authors to pay a lot of attention in the editing process and limits the type of content in the QTI documents produced. The Open University [22] has also developed an MS Word customization that allows using a custom markup language inside Word in order to facilitate the generation of IMS formats [23]. This markup can be seen as a quite limited Docbook subset. Furthermore, XSLT has to be built from scratch loosing the capability of reusing the powerful and very well tested Docbook XSLT style sheets.

For the present work the more relevant IMS formats specific tools are RELOAD [24] as Content Packaging tool and AQuRate [25] as QTI editor. RELOAD is just an IMS CP editor which means that it is not a content item editor. Content items should be created with other tools and RELOAD allows integrating them into an editable IMS CP.

AQuRate produces QTI 2.1 assessments with a friendly interface and it supports the set of items that we are interested on. However, it lacks from good quality printing generation and we still depend on paper format. AQuRate neither includes at the moment a friendly table editor. Another shortcoming for us is that only the assessment part or our learning content can be produce with AQuRate, then theory content and exercises have to be kept appart. QTI produced with AQuRate generates errors when importing it into PoliformaT, then an additional adaptive transformation must be applied.

Finally eXe editor is an open source project (exelearning.org) that intends to offer a free e-learning oriented content editor that enforces compliance with IMS CP and QTI. The main problem with this tool is that it is not easily customizable, for example it is difficult to get good printing format. The native format is XHTML that is good for the web but really inferior to Docbook in relation to automatic document processing and management.

Our framework built on Docbook has all the benefits of the alternatives mentioned and it avoids their drawbacks. The XML editors we have mentioned, XXE and oXygen Author, are Java applications that are installed locally and do not have functionality restrictions. Docbook markup is well structured and simple, facilitating XML conversion. Furthermore, Dosbook XSLT style sheets allow full control on the production of screen format (HTML) and paper format (PDF). We certainly appreciate this feature and in fact this was one of the main reasons for our initial choice of Docbook. Finally our authoring environment allows producing theory and exercises together which is quite convenient in order to have a consistent content view. When we generate IMS CP and QTI from our customization they match the patter that PoliformaT imports without errors.

VII. Conclusions and Future Work

After having used Docbook extensively as our framework for developing and deploying learning/teaching materials [7][15], we have presented in this work an extension for Docbook interoperation with IMS learning formats in order to easily produce e-learning content that can be automatically imported in our Sakai based LMS platform PoliformaT. Our work is being considered by our Information Systems Department and it received a good appreciation at the September 2008 IMS Quaterly Meeting [26]. A video demonstration of how our tool produces IMS learning formats inside XXE and how these formats are imported into PoliformaT can be seen at [27]. This extension of format delivery from our learning content pool has been fairly easy to implement and it has proven to be very effective, consolidating Docbook as a solid e-learning production tool alternative.

As IMS formats management continue to improve in future Sakai releases we will keep track adapting our environment to the new features. Particularly it is foreseen that Sakai will support IMS Common Cartridge that mixes IMS CP, QTI and other IMS standards into a common standard for e-learning content delivery and interchange.

Docbook is also evolving to version 5, nowadays version 5 is not mature enough to replace version 4 in production but it is worthwhile to consider migration at the right time. Docbook 5 is a complete rewrite of Docbook based on RELAX NG schema validation and includes new features like using XLink as the single linking mechanism, namespaces that allow embedding into Docbook documents other XML makups like MathML and SVG, and easier customization. Porting Docbook 4 documents to Docbook 5 requires little changes that can be automatically performed by simple XLST code.

There are other markup languages that share some of Docbook nice features like DITA. But at the moment we have not found any reason to leave Docbook. If this has to be done in the future the simplicity and good structure of these XML markups make their interoperation easy.

Abstract — **The use of technical articles in scientific and academic scopes is a well-known way to extend new creations and researching jobs throughout the world, mainly as a communication medium of knowledge among educational professionals. Nowadays, with no doubt, the Internet, is the usual way to spread any kind of documentation. Authors send the contents of their publications, based on a typical scheme composed by an abstract for a first understanding of the paper, some names, references and a further content development, using textual descriptions and graphical support elements. These parts of the document are conformed in a unique data unit. However, even the article taking part of the congress edition, the access way to it, is made through the digital media given by the congress. So, only if some congress query media are developed, it's successly possible to access to a certain article information.**

The experience shown in the content of this paper gives a solution to this access problem and bases its development on the information treatment of a congress as digital learning objects. By this way, a technical paper is treated as an information unit which is composed by a data background, essentially the metadata, which are recovered and isolated in every individual documentation.

Once a digital object and its metadata are disposed, congress edition conforms a structured data block, accessible not only in the congress scope but outside it. The use of metadata standards, as IEEE-LOM, let to information being built in digital platforms and repositories to be treated as congress information, as an individual article and even, some of its parts, as reusable digital objects

Keywords- ***learning object; reusable content; metadata; technical article***

I. Introduction

This paper introduces the procedures based on the treatment, classification and organization of the information extracted from technical articles generated in several congresses in the field of Electronics [6]. The project scope has as a primal objective, the extraction of a set of metadata [14], which define every publication in the context of a congress issue, to obtain the information related to the technical and teaching information from the publication content [5], in order to be treated as a digital object by means of its metadata.

The metadata obtained will lead to a set of references associated to every article, whose implementation let the converted digital objects to be treated as reusable learning objects [9]. Subsequently, a data-metadata set will be configured in a files structure, which permits the implementation of some actions as the creation of an homogeneous web site to access them, the dissemination of the structured contents on the Internet through repositories and digital contents platforms [16], and as a final work, to analyze the contents of the information in the congresses to study the resultant information in a tendency studies and organizations relations in Electronics and Teaching fields. To carry out the project actions, the TAEE conference (in Spanish, Applied Technologies for the Electronics Teaching) has been selected because of its increasing track as well as the variety of themes in Electronics scope.

II. The treatment of digital objects

Through the celebration of TAEE conferences since 1994 to 2008, 964 documents have been published. All of them are susceptible to be converted in learning digital objects. It has been necessary to apply individualization actions in every publication in order to maintain a homogeneous appearance, given the different formats of creation and publication, as well as classification methodology to keep the papers in a common context.

Every document has been converted in electronic format and has been deeply analyzed to extract from it every component to be useful in a reusable learning context. These actions have taken in place 4441 additional component digital objects. All of them conform an heterogeneous set, i.e., their types as MIME digital objects has been classified in texts, graphics, data spreadsheets, web pages, photografies, etc. [12]

In a parallel way to the formation of every digital object, main digital objects and component digital objects, it has been performed a file structure to keep them in. The structure is based in the biannual organizations of TAEE meetings. To be placed in the structure, every learning object has been named by means of an ad-hoc unified code system to let every digital object be associated with every metadata file in an homonym way. This code system has been based in a hierarchical system as Decimal System (DS) [17] but modifying the kind of characters given to every name in order to recognize the object belonging to a determined congress, session and order of paper. It can be said that the names codification also offers the first object metadata by itself. When finishing this stage, a files structure is disposed, inside which every digital object and every metadata definition file are placed. [13]

III. DIGITAL OBJECTS METADATA EXTRACTION

To implement the digital objects metadata extraction process it has been required the achievement of a metadata structure appropriated to maintain each of the relevant datum in every article. To do this, two different aspects have been taken into account: the object belonging to a congress context and the property of reusability as learning objects. By that, the IEEE-LOM (*Institute of Electrical and Electronics Engineers – Learning Object Metadata*) metadata standard [1] has been studied to be modified in order to use it in TAEE context. The metadata structure obtained has some similar features, given the use of LOM as a metadata system focused to learning contexts. Other standard are available to perform this action, as Dublin Core (DC) [2], but authors have considered that the standard offers a partial solution to TAEE needs, given it's a common metadata system used in library funds registration, but not having enough focus to educational or learning items. However, if there's a reduced and specific metadata amount per item, both metadata system (LOM and DC) are compatible [4] between them and TAEE system, but this compatibility is compromised if the digital object has to be defined by a greater amount of elements.

In LOM, metadata are grouped in nine main blocks to maintain a hierarchical disposition: *General, Lifecycle, Meta-metadata, Technical, Educational, Rights, Relation, Annotation, Classification.* Each of them defines respectively a metadata clustering in relation to the digital object definition scope. To extend the definition of every metadata group, some qualifiers are additioned to them to offer a complete structured composed by 64 metadata. In table 1, some explanations of LOM main groups are given.

In the case of the TAEE learning object, a new organization in metadata grouping has been made, as shown in Figure 1, in a suitable way according to digital objects information in the conference context.

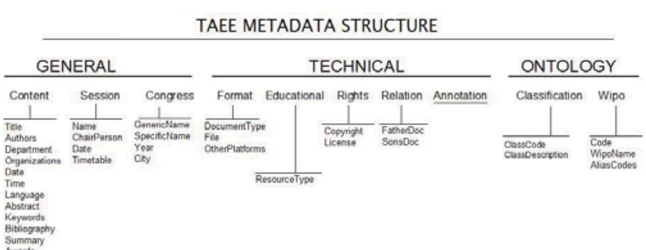

Figure 1. TAEE metadata structure

The metadata structure, therefore, offers in a first instance a division in three main blocks: *General, Technical* and *Ontology*. The first one, *General*, attends to those metadata that identify the digital object in global conference features, such as the object contents, the session and the event, establishing the nature of every document.

In the *Content* subgroup, the involved metadata are defined as "*Title*", "*Authors*", "*Departament*"and "*Organization*" to define the denomination and responsible organization; in addition, "*Date*" and "*Time*" has been created to define the exposure features in the session and congress limitations. The metadata "*Language*" let to know the language used in the paper, using the standard ISO 639:1998. "*Abstract*" and "*Keywords*" are available in the way the original texts have been written and with the information they keep it's possible to approach to the content of the full document. Other metadata as "*bibliography*", "*summary*" and "*awards*" complete the block.

The second metadata block "*Technical"* provides technical matters in relation to the original format of the document, its denomination and definition as a digital file (as done in the codification process), the kind of learning object, the owner's licenses and rights and the relation between main objects and its dependent components.

The last block "*Ontology*" is mainly based in a TAEE-specific-purpose subject structure as an electronics classification method, TAEE ontology, and it has been implemented in "*Classification*" metadata. TAEE Ontology has been created to match every subject to one or more classification families, by means of which a thematic definition can be made in the areas of electronics and teaching. In addition, it has been incorporated WIPO codes as a supplementary way of ontology, using the information given by WIPO (World Industrial Property Organization) which uses it to classify every granted patent or industrial model.

TABLE I. MAIN CATEGORIES IN LOM METADATA STRUCTURE

Group Name	Description
General	Descriptive general information of a learning object as an unit
LifeCycle	Features related with the learning object life and present state and those entities who has taken part in the creation, edition or evolution as authors, editors, etc.
Meta-metadata	Information about the creation of the learning object metadata.
Technical	Learning object requirements and technical features
Education	Conditions, properties and needs which cover the learning resource in an educational context.
Rights	Using conditions related with copyright and licenses for the resource use.
Relation	Types of relation between the learning object and others.
Annotation	Commentaries about learning uses of the digital object.
Classification	Subject description and ontologies family belongings with the specification of the Ontology used.

In the metadata structure, it's permitted the use of multiple values in metadata fields. This is contrary to [2] Dublin Core or LOM standards recommendations but it's justified, due a more compact database. To distinguish every elemental data, a kind of "*flag*", determined by a separation character as ";", has been used in the multiple value fields. So every value can be differentiated. In a further process, the elemental values can be disaggregated by means of the execution of a specific-purpose text treatment software, which reads every multiple value, extracts every elemental value and keep it in reference with the code number given to the belonging document.

In order to maintain the links between the metadata, the database evolutes to a multiple relation tables, in which the main table sustain the total amount of data indexed by a key field (the code of the document) and every complementary table offers a partial group of metadata linked by the same key field. Examples of these complementary tables are the Authors table, the bibliography table, the organizations table, etc.

The metadata extraction process has used, as a means of containment, several related tables from a created "ad-hoc" ODBC means database, in which each field is a container element of everyone of the metadata, whether multiple or single type.

IV. THE CONVERSION OF TEXTS INTO METADATA FILE ELEMENTS

To carry out the conversion of metadata placed in the database to the respective metadata files associated with digital objects, a software tool has been created for generating XML files [3]. The methodology, as well as their functional features, responds to an open schema, which is exportable and adaptable to other systems for metadata creation.

As a first approach to the process of creating XML metadata files, the application that has carried out this work, named the Shuttle [10], has got the tables contents as data source to keep all the organized metadata in the database, providing a open starting solution to any type of process because the Shuttle is universally adapted to any database by means of a multiple configuration definition, regardless of their size and whatever their structure.

Basically, the Shuttle program will open the database, connect to the table where metadata are contained and extract the field values in every record. As a means of data output, the values are sequentially inserted in an XML template file, where each metadata accommodation are equipped with a denomination composed by a label and a decoy as a lure, available for the recognition of the tag where the metadatum has to be inserted.

Successively, after replacing the lure with the metadatum and after filling all the places the Shuttle closes the XML file, giving to it the same name as the digital object reference, which is really recorded in the field "*File*". To illustrate the general process of operation, a block diagram has been shown in Figure 2 where the Shuttle data flow operation is defined.

To diversify the applications and uses of the metadata contained in database beyond TAEE frontiers, such as repositories or digital platforms, it has been thought the implementation of a complementary function in the Shuttle to perform XML files under IEEE-LOM standard. The functionality doesn't vary, with an exception: the treatment of the multiple data fields. It's recommended by IEEE-LOM the use of single-data fields, so then the cited complementary function has to implement a new procedure just only with the multiple-recorded metadata.

In the case of moving multiple data, given it's not permitted, they can't be extracted from the main table fields. It's necessary to switch the input data to the complementary database tables. As a simple solution, it's has been decided to give this function to the templates. Instead of doing a one-way data direction between the Shuttle and the template, it has been inserted some specific procedures in the templates, so then every time the Shuttle tries to insert a multiple metadata content in a single field, the template make an interruption to switch to the respective single-data content table. Then, this table is the only data source during this partial procedure.

The performance of this data flow double implementation generate XML file with both coexisting single-data and converted multiple-to-single data.

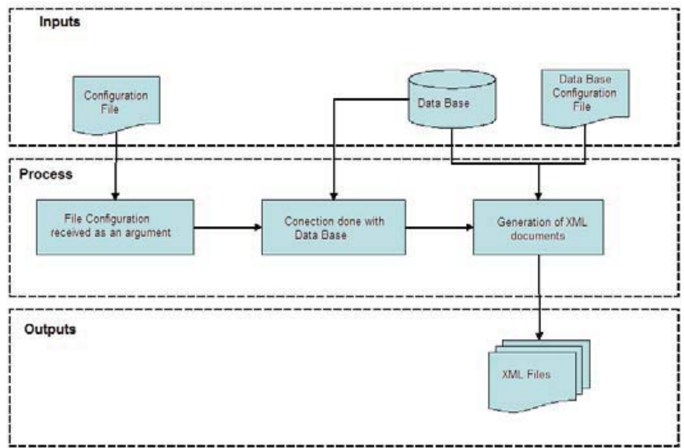

Figure 2. Block diagram of the operation of the application Shuttle

The execution of the Shuttle application has been implemented for the generation of 964 XML files that comprise the main learning objects, having made 34 metadata insertions per document. In various tests carried out under these conditions, it has been obtained an average running time of 2 minutes and 2 seconds, which means that a XML document has been created in 126.56 milliseconds average. In a subsequent set of tests, the same operations have been conducted on 4441 metadata files from the additional components.

Under similar conditions, the average running time has been 7 minutes and 55 seconds, giving a period of 107.96 milliseconds per XML file. This divergence between time values is due to latency and delay times outside the program execution. Applying linearization calculations in the Shuttle application behavior, it has been determined a performance average delay time of 6.03 seconds for each set of 1000 generations and an estimated average time of 101.52 milliseconds per XML file.

V. THE APPLICATIONS DERIVED FROM THE FILE STRUCTURE

The achievement of the processes set up to this point, a files structure of objects and associated metadata has been obtained. It can be said that at this point, the first goal of unification, standardization and labeling of TAEE documentation has been overcome, giving way to the second phase consisting of the dissemination of contents. It has, therefore, been necessary to create a file structure that can be adapted to both consequential actions: the creation of a Web that contains the information hosted on TAEE metadata and digital objects themselves and secondly, the bulk of the structure in institutional repositories and educational platforms.

To perform the first action on the Web site creation, and given the number of objects to handle, it has been taken the decision to create a specific Java software, which from the data contained in the database, will be able to generate static web pages to host the metadata and lead the user to each of the digital objects. The production process has led to an amount of web pages, one per congress, which provides information not only general but structured according to congressional sessions as divisions of every congress. Thus, by navigation through the site, it’s possible to access in a few steps to both digital object as well as the defining tab of each learning object.

Figure 3 shows a representation of the different actions performed by the application made for automatic generation of pages, on which insertion of formats and attributes has been later applied.

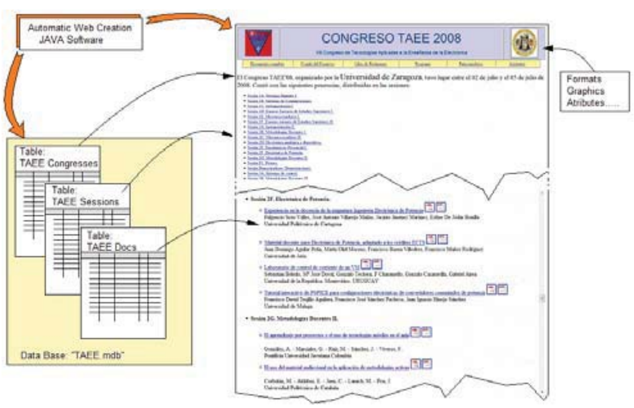

Figure 3. Website of congress and actions of its formation

In this figure 3, it can be seen that accessing the metadata central database, different page sections have been put as the header information, the list of sessions equipped with navigation and internal links, the list of documents that compose the session with the author information, the publication date and the figures which let to access to the digital object (PDF) and to a digital object form created as a result of the application of an XSL transformation exerted on each XML document. The implementation of the XSL transformation over XML files results in an XHTML page.

In order to spread the digital objects furthermore, a process of dissemination of digital objects from TAEE has been carried out through institutional repositories. Due to the amount of objects, a kind of bulk has been performed in our university's institutional repository, eSpacio-UNED [15], located in the web site http://e-spacio.uned.es as a means for the storage and distribution of digital objects, using open protocols like OAI-PMH [11]. The integration of the resulting objects has generated in the environment of the repository a number of elements making up every digital object structure. Thus, the components associated with the digital object are: a component of LOM metadata, a component of Dublin Core metadata derived from the LOM description, a component linked to the URL of the digital object itself and a component of the relationship of that object to other TAEE objects. This means that every digital object will have an own configuration collection, whose handling and visualization is possible by assigning a persistent URL to every one of the components of the object and the object itself. This allows the access to both learning object and its components, not only from the environment of the repository, but so foreign to it. By "*foreign*", it’s meant to be incorporated into the elements likely to be found by the searching engines available on the web as Google.

To improve the access to objects, like through TAEE web, it has been developed an user interface to access TAEE data located in the repository. In that interface, XML data has been used as site backbone. By means of “*adhoc*” style sheets transformation and cascade style sheets, it has been possible to conclude the interface attending to the repository philosophy. An illustration of user interface homepage has been shown in figure 4.

Figure 4. Main page from TAEE interface in the institutional repository in UNED

To access into the repository and have a view to the contents, it can be reached through the site http://espacio.uned.es:8080/fedora/get/taee:Congreso/demo:Collection/view . From the main page, the navigation links can redirect the user to any content in a specific congress, as well as, to invoke a query by means of a searching tool to find any TAEE object. As an alternative, the eSpacio-UNED list of services can be used, so in TAEE limits as in any other kind of object in any other collection.

VI. Analysis Developed in Relation of Metadata and TAEE Digital Objects

By using the data obtained throughout the described phases in this paper, a study and subsequent analysis of metadata [7] has been carried out, in order to get statistics to highlight various aspects. In the horizon of the analysis, it can be found the performance and TAEE usefulness as a meeting place for organizations focused on researching and teaching electronics. Therefore, the issues arised by the analysis can be describe as:

a.- General aspects related to conferences organization, regarding proposed themes, number of presentations and reports, etc,

b.- An study of the thematic issue in TAEE, focusing it on two fronts, the analysis and use of ontology inside TAEE and the analysis of the keywords in documents,

c.- Temporary changes in subjects from three viewpoints: thematic evolution over time, abandonment of different obsolete topics and emergence of new themes and issues with the use of new devices, techniques, methodologies, etc,

d.- Study of participating authors and organizations and their relationships to each other, deepening their relationship with common themes, the degree of collaboration between them, and so on.

Therefore from the analysis of the suggested points, the main objective of the works is achieved by means of a detailed knowledge of the data generated from TAEE reusable learning objects. This analysis is related to a meta-analysis [8] made together this project as a comprehensive study of the contents with the purpose, additional statistical analysis, identification of the path along TAEE conferences, but mainly specializing in a relationships study among participating organizations. Thus, among the obtained outcomes, it was found some organizations which serve as connecting node between gateways of knowledge, so as other ones have been identified as organizations which operate as islands or terminals. This central organizations are the most prolific and matches with those who have taken part of some TAEE organizing committees.

In a first approach to the subjects treated in TAEE, a general study has been made of the digital objects dedication, using the TAEE ontology, using the data extracted from the themes in every TAEE publication. A general data distribution can be observed in figure 5, where a circular graphic has been exposed to define the dedication of publication in nine main blocks. Each sector in the graphic represents the total amount of papers in relation to every subject.

From figure 5 picture, a first interpretation from data can be extracted: there are two main thematical blocks in which, at least, are grouped the 66% of the whole documentation. These blocks are Learning Software Tools and Educational Topics. The remaining ontology families has a much lower ontological resulting dedication value, with the exception of the family that brings together analog, digital, communications and energy systems.

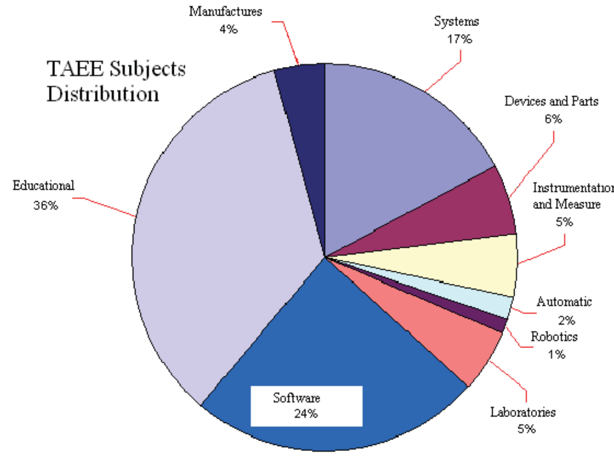

Figure 5. Thematical distribution about TAEE presented papers

Generalizing in TAEE subjects by a triple-block grouping, i.e., clusters which define thematic dedication in Technical, Educational and Software blocks, it's observed an almost exactly division in overall numbers. Using this division, it can be done an evolutionary study over time. This has been shown in figure 6.

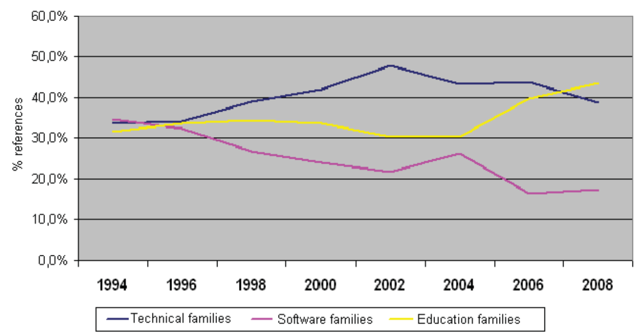

Figure 6. Temporal evolution of thematic division in TAEE

In that figure, it can be observed a similar beginning dedication in 1994 congress. Every one of the thematic blocks evolutes in a different way through time. In the first track, between the 1994 and 2000 meetings, the Technical branch has an increasing behaviour, driven primarily by publications with reference to digital systems and laboratory utilities. The Educational branch maintains the numbers of editions, mainly related to learning methodologies and learning based in practises. In a third place, Software family, tends to decrease about ten points, despite the growth in the use of related Internet tools.

Since 2002 conference, there's a new scenario and it can be observed an oscillating behaviour in the dedication of papers subjects. A growing tendency starts in relation to learning subjects, mainly driven by changes in legislation and education management system, which requires an adjustment in the departments organization in order to create adapted materials in new learning environments. On the other hand, in families dedicated to learning software and technical systems there is a downward trend. The final situation after the conclusion of the last meeting in 2008 leaves asymmetrical figures from the first congress in 1994. In the last conference, the rough division in the dedication is subject to 40% respectively for the families of teaching and technical systems, while reducing the dedication of the family of software tools slightly below 20%.

To access to further conclusions and data, the authors encourage to those interested in deepening reading the complete information from the annalysis, which is available in the Electrical and Computer Engineering Department Web site in UNED.

VII. CONCLUSION

The content of this document offers the work done on the processing of information generated at TAEE congresses. The general objectives consist in the creation of a unified and structured information environment from the documentation generated in TAEE. XML files have been created in connection with every digital object extracted from the general documentation, and it has been used in further utilities. These utilities have been defined as ways for disseminating TAEE information and documentation. In a first instance, it has been developed a common Web environment, in which TAEE services and links have been centralized and which sustain searching tools that favors the thematic consultation of the documentation.

To spread TAEE documentation beyond its frontiers, it has been necessary to make an adaptation of TAEE information to metadata standards in order of promoting online presence through hosting on documentation in repositories. This documentation hosted in educational platforms permits the creation of taylor-made courses, by means of TAEE objects converted in reusable objects.

In a parallel way, it also has been studied the performance of TAEE through its conferences by means of a content analysis of its digital objects through which it's likely to identify the path TAEE has taken, the relations between the organizations and agencies who has taken part of TAEE, as a social network and the methods and procedures carried out in greater profusion in the field of education.

The achievement of the objectives aims TAEE to enhance as Internet social network by adopting the measures applied to documentation and adaptation to the appropriate standard formats. Thus, it aims to provide the public and interested academic, the digital learning handled, allowing the reuse of materials generated as a source of knowledge.

ACKNOWLEDGMENT

VIRTUAL ANALOG AND DIGITAL COMMUNICATIONS LABORATORY: LAVICAD

On line interactive tool for learning communications systems

Margarita Cabrera Bean, Albert Mestres Sugrañes, Carlos Vargas Berzosa, Francisco Vargas Berzosa
ETSETB, Dept. de Teoria del Senyal I Comunicacions
UPC Universitat Politècnica de Catalunya
Contact e-mail: marga.cabrera@upc.edu

***Abstract*— The virtual analog and digital communications laboratory LaViCAD has been designed at the UPC and it results a useful tool to verify different communication systems performance and also signal processing techniques, subjects given in courses typically included in the curriculum of any electrical engineering degree. LaViCAD tool has become a flexible, sustainable and on-line freely offered educational platform and it can be updated whenever new content is required. At pedagogical level, the use of a virtual laboratory facilitates the learning of certain matters, acting as a connection between the theoretical contents of a communications system course and their practical understanding and experimentation. Furthermore, LAVICAD provides resources for professors to organize different teaching activities in their courses. These activities can be used in different environments as for instance in a classroom given in the context of a full attendance course or in a homework activity at a distance learning course.**

The aim of this paper is two-fold: On one hand to describe the main technical features that make LAVICAD an original fully re-usable and reprogrammable tool in signal processing and communication systems courses. On the other hand to show some preliminary academic results obtained with the use of LAVICAD verifying how it improves the level of success.

Keywords-component; Virtual Laboratory, e-learning, re-usability, User friendly environment, Web-based labs.

I. INTRODUCTION

Some theoretical concepts and definitions in a communication system course contain a high level mathematical background. Sometimes the students must develop long paragraphs of mathematical formulas in order to demonstrate a theoretical result. In general, in a basic communication system course the student is faced for the first time to topics that are classified as very difficult by the students. As opposite, when they experiment in an instrumental laboratory, they can verify some implementation errors and misalignments that are inherent to hardware or real time software applications. In this context a graphical and interactive simulator tool can help them to understand better the differences and the similarities between a theoretical result and a real experiment. An accurate designed application tool available to verify a great diversity of communications systems and subsystems can become a powerful and useful learning help. The key idea of the use of LAVICAD consists in its functionality as a bridge from theory to Lab experiments. This idea is shown in Figure 1.

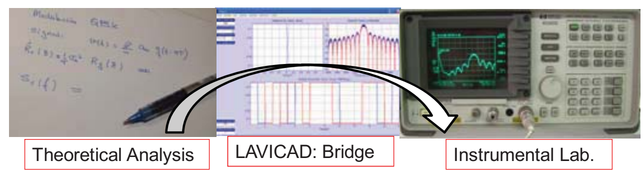

Figure 1. Key Idea: LAVICAD as bridge from theory to practice.

In the last years, the use of virtual labs has spread the engineering education environment with some innovative teaching techniques. Some experiences applied to signal processing and communication system have been presented in [4], [5] and [6]. With LAVICAD, two main advantages are fulfilled. On the one hand the reusability feature to generate whatever new exercise is proposed by the teacher, on the other hand some of the LaViCAD experiments are freely offered in an educational moodle based platform: comweb.upc.edu. The user can access and execute locally without any other software requirement than the JVM (Java Virtual Machine).

The simulation tool LAVICAD has been created to serve in the learning process of the most important basic topics and the most popular advanced topics integrated in a second-year graduate-level course in electrical engineering. The great variety of situations, flexibility and possibilities of emulating the different and not always predictable practical effects in a real laboratory, make of this virtual laboratory a powerful tool that faces the student to problems with different difficulty levels. This tool also constitutes a challenge for educators, who can consider it as a complement or as a substitution of a real and experimental laboratory.

From a user point of view, LAVICAD is formed by an on-line set of four generic and basic communications systems (Digital Modulation, Analog Modulation, etc..) and two popular communications system physical links systems (WiFi and the digital video broadcasting DVD for digital terrestrial television) . Consequently, up the date there are six LAVICAD Link Level Simulators (LLS) currently working.

At technological level, all the programmed LLS share a common and structural Java architecture. In order to create a new LLS, a general reprogrammable platform or “container” was designed and programmed at the LAVICAD starting time.

Paper Outline — after an introductory section, a description of the laboratory tool programming process is presented in section II. In section III we present three cases of use for three kinds of learning activity with different degrees of user interactivity. Section IV is dedicated to explain as the use of some LaViCAD systems in a theoretical and practical communications course has improved the academic scores. Finally, some conclusions are presented in section V.

II. Laboratory Tool Design

This section is dedicated to explain the main design guidelines for the LAVICAD tool.

A. Program Structure

To understand the structure design of the LAVICAD tool it is necessary to take in mind how a communication system works. A typical communication system functional diagram is composed by a set of basic elements sorted from first to last. Each basic element represents a step. An input signal is processed sequentially through all the steps to produce an output signal. Typically the input signal is produced by an information source and the output signal is registered at a destination terminal. The general pattern for a general communication system is shown in Figure 2. In the figure each step is characterized as a closed box. The input signal to each step (box) is the output signal from the previous step (box).

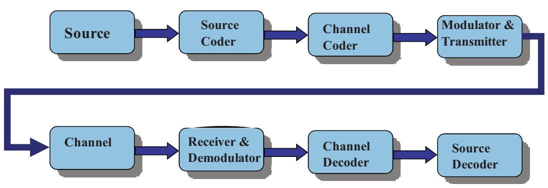

Figure 2. General Communication System functional diagram.

Each one of the experiments that integrate the LAVICAD tool represents a System Link Level Simulator (LLS). All of them admit the pattern shown in Figure 2. Each LLS emulates a different communication system or a subsystem. Depending on the process to be executed on the signal, each step is configured by means of a configuration parameter set and each step produces a set of numerical and graphical results.

Each step represents a single simplified subsystem and illustrates a part of the complete LLS. It processes the signal resulting from the previous step. The signal process is developed attending some configuration parameters. The new processed signal is analyzed in order to present the screen different graphical and numerical results and it is transmitted to the next stage.

Summarizing, there is a set of sequential actions that are developed with each step or stage:

- Acquire the signal from the previous step: Input Signal for the present step.
- Acquire the configuration parameters for the present step. These configuration parameters are introduced by the user by means of a user friendly interface window.
- Process the input signal in order to obtain the output signal.
- Analyze the output signal and present numerical and graphical results.
- Deliver the output signal to the next step or stage.

As additional features, in each one of the stages it is allowed to exchange both the input signal and the output signal with extern stored signals.

As it can be concluded, there is a high degree of repetition when programming the different LLS, and furthermore when programming the different steps included in a LLS. In order to take profit of these features, the LAVICAD tool has been programmed following a model defined at the project startup and described in section II.B.

B. The functional structure of a Communication System

LaViCAD is composed by two different parts: a development container platform and a set of differentiated LLS.

The generic container structure is represented in Figure 3.

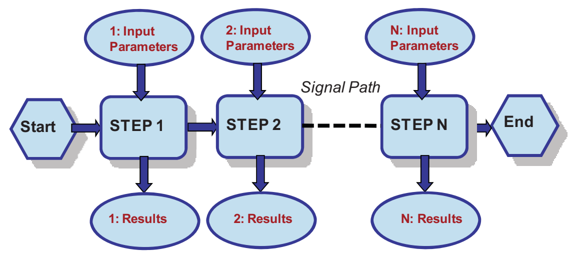

Figure 3. Container Structure.

The container platform is a Java software package that contains the guidelines and associated Java files to program the graphic interface, the variables shared between the different steps that form a LLS and the multiple menus included in each step to interact with the user. A "Container Program" has been designed to integrate all the necessary packages for actions that are sequentially executed. The application has been programmed using the Java programming language. As Java is an object-oriented programming language, the container program includes all the classes, objects and libraries necessary to execute the repetitive actions.

When a new LLS is generated it is compiled with the container platform. It has been fully documented and it is useful for those interested in creating new communications systems simulators.

When programming a new LLS, the following two phases must be followed before the compilation process:

- Phase 1: To accurately design what the new LLS must represent: Number of stages, input configuration parameters, signal processing for each one of the stage input signals and output results including numerical and graphical ones.
- Phase 2: To program all the functionalities designed in the previous phase, using, among others, the Java classes corresponding to the program container.

The set of LLS currently programmed in LAVICAD is formed by six completed LLS and two more in construction.

This work has been supported by Catalan Government Generalitat de Catalunya: AGAUR: 2007MQD and by UPC: Support for teaching innovation projects 2007.

C. User Interface.

From the user point of view, each completed LLS is friendly accessible from our project website [10]. When the user accesses a LLS, the main window presents him the set of sequential steps to be executed like in Figure 4. In turn, each of these steps gives access to a new interface. On this interface window the user can set up different configuration parameters, and view a wide range of results, like in Figure 5. An option provides the user with the possibility of exchanging signals with those obtained when performing a similar experiment in a different platform or just from a different LaViCAD LLS.

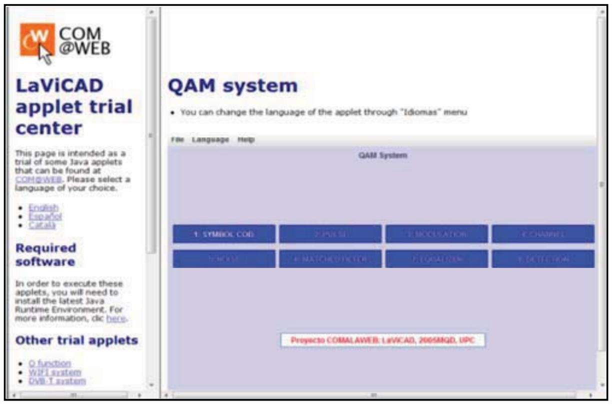

Figure 4. QAM LLS main user window.

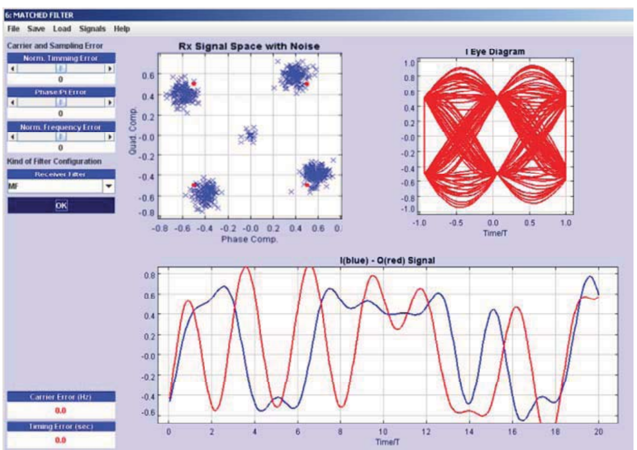

Figure 5. QAM LLS single step user window.

D. Completed Comunication Systems Simulators.

All LLS generated to date can be classified in two types: The academic ones and the diffusion ones. The academic set is used as an important support in a basic course learning process. In this case, a LLS represents a generic simple system and the steps are configured to illustrate some mathematical properties without particularizing any standardized system. They contain the fundamental basis of a certain subject in the area. They are commonly used by the students to complement a theoretical development exercise. The diffusion set has been selected to incentive the students and other occasional users with daily life popular communication applications. They are commonly used by teachers to show examples at the end of each subject that overview the scope of the initial objectives with the aim of motivate the students to enhance and expand their background knowledge on the area.

Some of the Academic LLS currently available within the application LAVICAD are:

- QAM Modulator: This system supports baseband and passband formats, RRC and rectangular pulseshape, AWGN selective frequency channel, matched filter and displaying effects produced by different kind of synchronism errors, FIR equalization and theoretical and measured Bit Error and Symbol Error rates.

- AM-FM Modulator: This system departs from an information source signal generated as a digital modulation, an audio signal or as a single sinusoid. The channel is modeled as AWGN and the demodulation can be coherent demodulation or envelope detection. There is the option to simulate non linear effects on the received signal. At the end of each stage all the signals can be displayed and the user can listen to the baseband signals.

- Channel Convolutional Codification: The main features are convolutional codes with the potential for puncturing, AWGN frequency selective channel, and soft and hard Viterbi decoding. At the last step different error measures are displayed in order to evaluate the improved performance with the use of a convolutional code.

Some of the Diffusion LLS currently available LAVICAD are:

- WiFi system, estandard 802.11g, (Physical Level): This LLS has been designed following the recommendations given by the Wireless LAN Medium Access Control (MAC) and Physical Layer (PHY) specifications document [8]. This communication system is the basis of the WiFi connections between an access point and different terminals. It is widely used to give network access to PC terminals, laptops, PDAs, mobile phones, etc. It has been chosen for its simulation within the project LAVICAD because it is one of the most popularly used today and the population of university students is acutely very aware of this fact.

- Digital Terrestrial Television based on the DVB European standard, ETSI EN 300 744 (Physical Level): [7] Framing Structure, channel coding and modulation for digital terrestrial television. This is the TV broadcast system operating currently in Spain. It still coexists with the analogue system, but just until 2010th. Of course its popularity is undisputed.

Other LLS are currently integrating in LAVICAD but we don't describe here to not extend a lot this description.

III. Cases Of Use

The general and wide range of possibilities to be used in a learning activity offered by LAVICAD is highlighted in this section by describing three different exercises. Each one of them has been devised to be used in a different context, involving inside and outside classroom sessions and depending of the proposed activity is given in a fundamental basis course or I an application course with different degrees of interactivity levels.

A. *Acompanying a theoretical development exercise.*

This activity can be proposed for the teacher in a fundamental communication system course in order their students begin to work with spectral density issues.

By LAVICAD the user can emulate most of proposed exercises in a textbook, as for instance [1], [2] or [3]. Through the QAM LLS some exercises proposed by the author in [1] can be studied. Let's solve exercise 8.7, part 1 in page 563. The statement of the problem can be summarized as:

Problem Statement:

Consider a four-phase PSK (QPSK) signal that is represented by the equivalent lowpass signal.

$$v(t) = \sum_n a_n g(t - nT) \quad (1)$$

In (1) a_n takes on one of the four possible values $\frac{\pm 1 \pm j}{\sqrt{2}}$ with equal probability. The sequence of information symbols $\{a_n\}$ is statistically independent.

Determine and sketch the power-spectral density of $v(t)$ when $g(t) = \begin{cases} A & 0 \le t \le T \\ 0 & \text{otherwise} \end{cases}$

Theoretical Solution: The student faced to previous analysis proposal, must obtain, after some calculus that the demanded spectral-density equals:

$$A^2 \left(\frac{\sin \pi fT}{\pi fT} \right)^2 \quad (2)$$

Practical Solution: Setting adequately the QAM parameters set from the first step to the third step, the theoretical and the real spectrum for a generated random symbol sequence can be sketched as in Figure 6.

B. *Accompanying a laboratory experiment.*

A utility of interest and wide acceptance among students is the real-time comparison of results obtained in an instrumental laboratory with the use of LaViCAD. It is of great pedagogical interest to compare the different functions measured in practice, with the functions explained in a lecture session.

The use of LAVICAD in a laboratory session can serve as a complement during the experiment execution or as a previous mandatory homework to prepare the laboratory session.

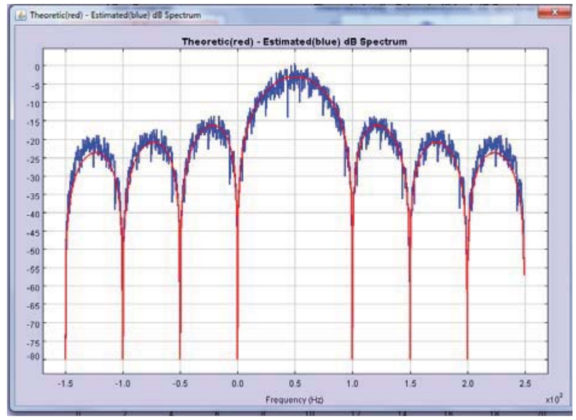

Figure 6. QAM Spectrum for the Exercise proposed in III.A.

Let's assume that in a digital modulation practice (QPSK) it is mandatory to visualize the spectral-density on a spectrum analyzer screen. The students are faced simultaneously to the theoretical spectral density generated by LAVICAD and to the measured real one, presented on the spectrum analyzer screen. They realize of the imperfections and alignments errors obtained in practice and develop their critical thinking skill oriented to analyze what causes the alignment errors.

Figure 7. Use of LAVICAD acompanying an instrumental laboratory practice. LAVICAD is being executed at he computer whose screen can be seen on the table.

C. *Use of LAVICAD in a project.*

LAVICAD can also be used in a more complex activity integrated in a project based learning course with a multidisciplinary range of areas. With the activities described in III. A and III.B the user interaction with the simulator is limited to introduce in each step the setting parameters and watch the results, and the setting parameters must be previously calculated from the exercise proposed by the teacher. The third use we propose in this section consists on the implementation of a new system or a new step. Some kinds of activity are identified and ordered from low difficulty degree to high:

- To form a new communication system by combining two or more generated LLS. In this case, the user can introduce as input signal to a LLS step the output signal obtained from a different step. Depending on the new communication system to be verified, the user must design and select the different steps to be combined in the new system.
- To modify a single step in a generated LLS.
- To add a new step to a generated LLS.
- To design and program a new LLS using the LAVICAD container application in the compilation process.

The proposed activities are helpful in a process to train the students in some general skills, as engineering problem solving, quality awareness and self learning.

IV. Preliminary Academic Results

The use of LAVICAD based learning activities has been implemented in two different courses: the course of “Communications I” and the course of "Communications Laboratory I". These courses are among the current ones in the second and third year of our studies. An introduction to digital and analogue modulations is given in “Communications I”. "Communications Laboratory I" is dedicated to develop experiments based on the theory given in “Communications I”.

In a 45 students group (2008 spring semester) “Comunications I” course, two mandatory theoretical exercises were proposed by the teacher to the students. The qualification of these two exercises represented a 5 percent of the final course score. The teacher proposed the students to use some LAVICAD LLS in order to complement the exercise development, like the learning activity described in III.A, but the use of LAVICAD was not mandatory. Two weeks later than the second activity delivery term ended there was a midterm exam to evaluate the skills of two subjects included in the course program and partially related to the proposed exercises. The qualification of this exam represented a 20 percent of the final course score. The success levels of the course are shown in table I.

TABLE I. Avaluation Results with the use of LAVICAD in the course of Comunications I

	Number of students	Midterm exam approval percentage	Final Score approval percentage
Use of LAVICAD	31	25 (80%)	20 (64%)
No use of LAVICAD	14	5 (36%)	6 (43%)
	45	30 (67%)	26 (58%)

The third row in the table shows as the success level is highly correlated with the use of LAVICAD to complement the theoretical developments

Authors are aware of the sample size is small in this preliminary startup, but after that semester, the use of LAVICAD activities has been introduced from time to time with some student groups and they have always produced results similar to those shown in the table.

The laboratory course program ("Communications Laboratory I") is composed by five subjects or experimental works dedicated to analog and digital communications. The use of LAVICAD is mandatory for all the students as an accompanying activity of the two last subjects.

With the new European higher education adaptation process startup, the contents and methodologies of both courses will be integrated in a new course, entitled “Fundamental of Communication Systems”. This course will start on February 2011 at the Escola Tècnica Superior d’Enginyeria de Telecomunicació de Barcelona - ETSETB, UPC .

V. Conclusions

The integration of the LAVICAD tool in the daily teaching activities of fundamental and laboratory communication system courses is becoming a useful resource in order to provide students with some typical engineering education skills. The tool is composed by a set of web access simulators (LLS) that can be applied to a wide range of academic or practical exercises. The use of the “Container Program” to generate new LLS results a very low consuming effort process. As a limit of use of LAVICAD there is a memory resource restriction that cannot be exceeded. This is a JVM feature and the upper limit depends on each user computer or laptop.

There are currently several e-learning tools available for academic purposes, but few of them regarding signal processing and communication systems courses. This represents one of the innovative points of this paper and can be considered as an add value of LAVICAD.

From preliminary LAVICAD experiences it can be concluded that final scores have increased when some LAVICAD based teaching activities are proposed in the course. As last conclusion, authors can assure that the student satisfaction level has also increased. This statement was deduced as a consequence of spontaneous successful students comments addressed to the teachers and referencing the LAVICAD based activities and as a consequence of the increasing number of queries presented by the students at the teacher’s office hours.

The challenge of introducing LAVICAD based activities in a communication system course consumes a great amount of teacher time and teacher effort. With the EHEA startup some new teaching uses must be renovated. In our course each teaching activity must be designed to cover some generic skills and dome specific skills and this is one of the most effort demanding features to be considered in a LAVICAD based activity design.

Acknowledgment

LAVICAD has been awarded the first National Edition of final degree thesis (Proyecto fin de carrera) by Sun Microsystems in Madrid Spain, 2008 [9].

Authors are thankful to the anonymous reviewers for their constructive comments.

Open educational resources (OER) inspire teaching and learning

Bruno Wenk
Institute of Information and Communications Technologies
University of Applied Sciences, HTW Chur
Chur, Switzerland
bruno.wenk@ieee.org

Abstract—**Open educational resources (OER) can significantly reduce the time required to prepare lectures. The prerequisites are that a desired resource can be found quickly and that its adequacy for the intended purpose can be estimated easily. Eventually, the resource should also be suitable for modification. In the first part we outline the requirements for the sourcing, storing, retrieval and exchange of open educational resources considering technical and legal aspects. In the second part we present a case study focusing on the user level perspective. We describe the searching for a particular OER (an online Moodle tutorial), the analysis of the resource found, its modification and the publishing of the modified resource on a repository.**

Keywords-open educational resources; repositories; metadata; learning objects; learning design frameworks; open access; community of practice;

I. INTRODUCTION

Imagine the following situation: A university teacher is preparing his next week's lecture. The topic is the visualization of multivariate data with scatter plots and parallel coordinate plots. He has already held this lecture one year ago. His memo of that lecture indicates that the students had some difficulties with the sketching of a parallel coordinate plot. Our teacher would like to improve his lecture with elements that involve students directly and actively in the learning process, thereby promoting understanding by doing. He has some instructive simulations in mind, exercises, perhaps an assignment. However, our teacher has neither the time nor the budget to develop the required material. Certainly, hundreds of teachers all over the world must have the same or similar needs. Probably, one or more persons have already developed an easy to use software the students could experiment with in order to better understand the use of parallel coordinate plots for the analysis of multivariate data. Let us suppose that a free Microsoft Excel add-in would satisfy the needs of our teacher. How can he find this software? In case he finds it[1], how can he quickly compile an accompanying worksheet for the students?

[1] Such an MS-Excel add-in would be Visulab® - Interactive data visualisation in Microsoft Excel (http://www.inf.ethz.ch/personal/hinterbe/Visulab/)

The amount of work to develop educational resources (e.g. documents, graphics, images, videos, laboratory exercises, compatible learning units) is high. Moreover, all these resources have to be maintained and to be developed further as technologies or curricula change. Unlike scientists, teachers are all too often "lone fighters". They do not have many opportunities to discuss their lectures and materials with colleagues, to exchange ideas or even to develop materials in a team.

This is where open educational resources (OER) come into play. OER can help teachers to reduce their amount of work for the preparation of the lectures. Open educational resources can be modified to suit the specific didactical needs of a lecture and the "producers" and "consumers" can contact each other in order to discuss modifications and extensions to existing OER.

II. WHAT ARE OPEN EDUCATIONAL RESOURCES?

The OER movement aims to break down barriers – such as teaching material locked up behind passwords within proprietary systems or filed in personal drawers – and enable sharing content freely [1].

The *openness* of OER refers to [2]:

- The freedom to use the work and enjoy the benefits of using it.
- The freedom to study the work and to apply knowledge acquired from it.
- The freedom to make and redistribute copies, in whole or in part, of the information or expression.
- The freedom to make changes and improvements, and to distribute derivative works.

Educational means that the material is produced for use in formal educational settings, although open educational resources can well be used for informal or non-formal learning outside formal educational settings [1].

Open educational resources are digitized materials offered freely and openly for educators, students and self-learners to use and reuse for teaching, learning and research [1]. An open educational resource can be:

- *Learning content* (e.g. courses, modules, learning objects, exercises, references to collections and archives).
- *Software* (e.g. development tools, tools for organizing content, simulation tools)
- *Hardware* (e.g. electronics prototyping platforms such as Arduino [3]).
- *An implementation resource* (e.g. creative common licenses, best practice design principles).
- *An interoperability standard* (e.g. the sharable content object reference model SCORM [4], the IMS content packaging specification [5]).
- *Media* (e.g. images, audio recordings, videos).

III. Institutional and National Repositories

In order to be accessible from all over the world, open educational resources must be made available on servers connected to the internet, so-called repositories. Repositories can be provided by universities, libraries, communities, national bodies or other institutions. An exemplary collection of open e-learning content repositories can be found on the website of the Open eLearning Content Observatory Services OLCOS [6].

OER repositories must comply with standards. Otherwise, only local searches on the distinct servers can reveal the "hidden treasures". The repositories must exchange the descriptions (metadata) of the educational resources stored in their databases. In this way, searching on a specific repository yields the list of relevant records from all the connected repositories. The exchange of the metadata records is accomplished by means of the open archives initiative protocol for metadata harvesting OAI-PMH [7].

A central access to all OER repositories would simplify the task of searching for a needed resource. Such a central access already exists: The OAIster® database [8]. OAIster boasts more than 23 million records representing digital resources (digitized books and journal articles, digital text, audio files, video files, photographic images, data sets with statistical information, theses and research papers) from more than 1,100 contributors. OAIster records are freely available through WorldCat [9], the world's largest network of library content and services.

Figure 1. Search box providing access to WorldCat from within the OAIster website.

OAIster is intended to be a collection of open access resources. Open access resources are primarily library resources. Nevertheless, OER repositories incorporating the standardized OAI-PMH harvesting protocol could deliver their metadata to the OAIster database and thus make open educational resources accessible through a "single-point-of-search". The resources on existing repositories that do not support OAI-PMH cannot be retrieved through searches initiated on a repository supporting the OAI-PMH harvesting protocol. What should be done with such repositories? Their technical infrastructure could be upgraded with a suitable implementation of the OAI-PMH, provided that the metadata are already present or newly entered. Alternatively, the resources could be transferred to a repository supporting the OAI-PMH. In any case, new repositories should be based on the aforementioned standards.

Furthermore, all OER repositories should internally provide their metadata in a format that allows search engines such as google, yahoo or cuil to index them. In this way, teachers, students and self-learners can find open educational resources by using their preferred search engine.

IV. Metadata and Formats

If we want to find open educational resources on other repositories than the one we are logged in, our repository must provide access to the metadata of the resources on the other repositories. As depicted above, this is done through metadata harvesting. In other words, we do not have access to the full text of those resources. And when we think of multimedia resources such as images, audio or video, it is obvious that we need metadata in order to be able to find appropriate content. Which metadata standard is suitable?

The Dublin Core metadata standard or a subset of it is a candidate for the description of open educational resources [10]. In the OAIster database, for instance, the simple Dublin Core metadata format is used. The Dublin Core provides general fields such as <title>, <creator>, <description> and <language> as well as fields specifically useful for educational resources (e.g. <audience>, <instructionalMethod>, <educationLevel>). With respect to complex educational resources such as courses or modules, there are important fields missing. For instance, no metadata fields exist for the specification of "educational objectives" or "typical learning time".

```

  <dc:title>Algebra</dc:title>
  <dc:subject>mathematics</dc:subject>
  <dc:date>2008-04-23</dc:date>
  <dc:language>EN</dc:language>
  <dc:description>
     An Introduction to Algebra
  </dc:description>
</rdf:Description>
```

Figure 2. Dublin Core metadata example (extract).

Another candidate for the description of open educational resources is the IMS metadata specification which is now aligned to the IEEE Standard for Learning Object Metadata (LOM) [11] [12]. The IMS Global Learning Consortium has specified these "data about data" in order to make the process of finding and using a learning resource more efficient. With the fields provided by the IMS / LOM metadata specification a learning resource can be described in more detail than it can be done with the elements of the Dublin Core.

Discussions with practitioners indicate that either metadata format will not be used extensively by teachers because of a significant lack of time to fill in the fields accordingly [13]. Eventually, the use of folksonomies (collaborative tagging) could improve the situation [14]. An author only provides a minimal set of descriptive fields with the educational resource when she or he publishes it on the repository. Users add appropriate tags when they find the resource. The more tags are added with time, the more relevant the results of a search for an OER will become.

```

   American History. It has a portrait
   photograph and links to further resources.
educational.language = en-US
classification.keyword = architecture, chicago
school, modernist, prarie
```

Figure 3. IMS metadata example (extract).

The reuse of open educational resources further depends on reusable document formats. Material created on a Macintosh must be usable on a MS-Windows computer as well. The following formats can be recommended for reusable documents:

- Plain text: Unicode
- Images: TIFF (Tagged Image File Format)
- Audio: MP3 (MPEG-1, Layer 3)
- Video: MPEG-4

The Portable Document Format (PDF) is widely used for documents incorporating text, graphics images and even audio and video. A PDF-document can be read on every computer system, but it cannot be modified. Thus, PDF is not a suitable format for reusable learning objects. Open Office documents should be used instead.

What about HTML? HTML pages can be modified. It is relatively easy to add or remove content and to change the layout (as long as cascading style sheets are used to style the pages). Using a free Web authoring tool (e.g. KompoZer), the pages and styles can be modified even without a sound knowledge of HTML [15]. If the HTML pages and style sheets along with the images and further media should be packaged into a SCORM or IMS content package that could be imported into a learning management system, a so-called manifest file would be needed. Although the manifest is a text file written in XML, it is not easy to hand-code it. In this case, an appropriate authoring framework could be used, e.g. the ReCourse Learning Design Editor [16].

Complex educational resources such as courses and modules could be authored in XML. XML has several advantages:

- The sources are text files and can be written and modified using a simple text editor.
- XML is also the basis for the manifest file.
- Using XSL (eXtensible Stylesheet Language) transformations, the resources can be produced and published in different formats, such as HTML, SCORM, or PDF.
- The XML sources can also be written and modified using open source authoring frameworks, e.g. the Firedocs eLesson Markup Language (eLML) Editor [17].

Unfortunately, the eLesson Markup Language is not a standardized language. Educational resources written in a different XML-based learning design language cannot be edited with the Firedocs eLML editor, and vice versa.

V. Reuse of Educational Resources

Before they can be reused, open educational resources must be found. (We talk about reuse because we defined OER as materials produced for use in formal educational settings. Thus, the publication of the resources on repositories allows their reuse.) We already discussed the respective prerequisites (repositories, metadata exchange, search engine indexing, reusable document formats).

Anyway, who is interested in reusing educational resources? The intention of open educational resources is the reuse by other teachers. The promise is that the teachers can significantly reduce the time required to prepare lectures. The resulting variety of materials (and didactical concepts) also stimulates students. However, according to [18] only 15.3% of the users of MIT open course ware content are educators. 31.4% are students and 48.2% are self-learners. Why do only few educators reuse open educational resources?

The granularity of the resources could be a reason. It could be harder to integrate resources with coarse granularity (e.g. complete courses) into ones lectures. An expressive graphic or a table with significant data can be reused more easily than a complete online course or the recording of a two-hours lecture. The findings of [17], however, indicate that resources with fine granularity (e.g. images) are not reused more often than resources with coarse granularity. The determining factor for reuse with respect to granularity seems to be the *reuse context*. Resources with a slightly lower granularity than the object that has to be developed are easier to integrate than resources with much finer granularity. For the development of a course, for instance, the integration of a complete lesson is more convenient than the reuse of a single image.

Several teachers do not often reuse open educational resources because of technical barriers (e.g. no access to the repository, wrong document format). The most important obstacle is the difficulty to find the needed resources. This is mainly due to the lack of appropriate metadata. Eventually, a teacher, who is searching for a video with experiments regarding the psychology of human perception, really finds one. The duration of the video is 47 minutes and there are no descriptions of the individual scenes and no specifications of their beginnings and endings. The teacher does not have time to inspect the whole video and resigns the reuse of that resource.

First of all, teachers must make their own resources available. Otherwise, the OER movement will not be successful. Many teachers express certain reserves towards the publication of their own material. Some of them fear the criticism of the colleagues. Others complain that it would not be fair to freely reuse their material which they have worked very hard for. Some teachers worry about the time required and the cost of obtaining permission for using assets in their material (mainly graphics and images, audio and video content) for which a third party owns the copyright. On the other hand, teachers get personal satisfaction when they make their materials publicly available. They gain reputation. Authors of open content would like being personally rewarded through workplan, promotion, awards etc. for the use of their material and being acknowledged as the creator, especially when the resource is adapted or changed [1]. In any case, teachers must be encouraged to supply their materials and the institutions must setup the accompanying measures in order to support the authors of open content.

VI. CASE STUDY

At the University of Applied Sciences *HTW Chur* we currently use Claroline (Classroom Online) as learning management system [20]. In autumn 2010 we will introduce Moodle for the first-year students in the master program in information science [21]. The students enrolled in the further programs (business administration, tourism, civil engineering, electrical and electronics engineering, and media engineering) will follow in 2011. The faculty involved in the master program in information science has to become acquainted with the basic concepts and the efficient handling of Moodle's functions before the beginning of the new academic year in September 2010. During the first week of the fall semester, the students have to learn how to work with the Moodle platform. The respective introductory courses have to be repeated every year. Therefore, a blended learning course would be adequate. With two face-to-face lessons we could shortly summarize the concepts of Moodle and the peculiarities of the configuration at the *HTW Chur*. We could go through an exercise so that the participants could get to know the relevant functions. Consequently, the exercise would be different for the faculty and the students. Afterwards, an online course for the faculty and another one for the students could give them the opportunity to further study the effective use of Moodle for teaching and learning. The online course would also allow the faculty and students to have a look at individual topics at anytime whatsoever and to become acquainted with them on own accord.

The planning and realization of such an online course is both, time-consuming and costly. However, Moodle is widely used at universities all over the world. Thus, we expected that at least one adequate Moodle online tutorial would be available as an open educational resource.

A. *Finding resources*

The prerequisites were that the language of the educational content was German and that the online course was suitable for the training of both teaching staff and first-year students, or that the content should at leat be suitable for modification. Thus, we first searched the Swiss national learning object repository SWITCHcollection [22]. Unfortunately, we did not find a Moodle tutorial there. SWITCHcollection is a relatively new repository and does not yet contain many resources. In a second step we used the phrases "open educational resource" and "online tutorial" to search for pages in german with google. The search yielded 3 hits only! We changed the phrase search into a separated keyword search ("open educational resource online tutorial") and found at the first place among 15'300 pages the Moodle online tutorial on the web site of the institute for research in open, distance, and e-learning (IFeL) at Brig, Switzerland [23].

B. *Analyzing the resource*

The Moodle tutorial is hosted on the Moodle server of the institute IFeL. It is freely accessible over the web and the learners also get a free user account in order to work on the exercises and assignments.

Figure 4. Online Moodle tutorial (introductory page)

The tutorial comprises eight modules: Basic concepts, course configuration, content distribution, communication with students, collaboration, exercises & assignments, reflections, user administration. The intended audience is the faculty. Although the Moodle tutorial has not been published on a repository yet, its sources are available under the creative commons licenses BY (attribution) and SA (share alike) on the corresponding website. (The authors intend to publish the Moodle tutorial on SWITCHcollection in due time.) We downloaded the sources and inspected them. Unexpectedly, there was also a tutorial for students included in the download package.

Does this resource suit our needs?

- The language of the educational content is German.
- There are two different tutorials, one for the faculty and the other for students as intended audience.
- The modules of the tutorials follow an intelligible didactical concept. The front page of every module lists concisely formulated objectives and the approximate time needed to complete the module. The content is structured according to the ECLASS model [24]. An ECLASS module is partitioned into five (eventually six) sections: Explain (overview), clarify (requirements, recommendations), look (review examples or samples), act (practice what has being taught), share (student interaction), self evaluate/ submit (self-evaluation and submission of completed work); eventually, a summary concludes the module.

Figure 5. The ECLASS model (modified).

The tutorials come up to our expectations. Metadata would have been desirable in order to get a quick glance at the objectives and the overall time needed to complete the tutorials. These metadata should be added to the resource when transferring it to the SWITCHcollection repository.

C. Modifying the resource

The tutorials have been developed on the basis of eLML, the e-Lesson Markup Language [25]. The sources are written in XML and can be modified with any ordinary text editor. Structure, content and form of the tutorials are separated from each other. Using XSL transformations, the content can be published either as HTML pages, as SCORM-compatible content package or even as a PDF document. Besides the XML sources, the download package also contains the HTML derivatives.

We already had some experiences with learning resources based on eLML, but we were unsure whether or not the modifications of the eLML sources of the Moodle tutorials could be modified easily. We wanted to know more about it and contacted one of the authors. This was possible because the e-mail addresses of the team members who developed the tutorials were published on the entry page. The discussion with that person revealed the pitfalls of the eLML technology. At least one member of the development team must be a technician who is familiar with the eclipse development framework. Otherwise, the modifications of the sources (content, cascading style sheets, XSL-transformations etc.) would be rather complicated.

```

          Grundaufbau und Basiseinstellungen
          </link></item>
          <item><link targetLesson="moodle2">
          Organisation und Administration
          </link></item>
      </list>
      <paragraph title="Aufbau">Das Tutorial ...
      </paragraph>
   </clarify>
</learningObject>
```

Figure 6. eLML source text (extract).

We had three options to proceed:

- The faculty could use the existing online tutorial hosted on the Moodle server of the institute IFeL. We would provide additional material with explanations of the specifics of our own Moodle configuration. The tutorial modules for the students could be published on our own web server.
- We could modify the existing HTML pages of both tutorials and publish them on our own web server.
- We could plunge into the technical details of eLML and the eclipse framework and modify the XML sources and XSL transformations according to our specific needs.

We decided not to alter the XML sources but to modify the HTML derivatives and publish both tutorials on our own web server. In this way, we do not need to modify the XSL transformations which would be needed to generate the HTML pages from the XML sources. Modifying the HTML pages is the easier approach but its drawback is that our modifications cannot be directly fed back into the original.

What were the modifications to be carried out?

- There were some typing errors on various pages of the tutorial. Correcting them was easy.
- The layout should reflect the corporate design of our university. Thus, the cascading style sheets had to be modified accordingly.
- The entry page of the tutorial should summarize the content and let the users select the faculty part or the students' part. It had to be designed from scratch.

- A presentation of the didactical concepts that can be supported through the configuration of a Moodle course is missing. It has yet to be developed.

To modify the HTML pages and the cascading style sheets was quite easy. However, to understand the structure of the pages and the navigation mechanisms was cumbersome. We had to inspect every single file and to sketch the relations between the HTML files and the style sheets in order to find the position for a particular modification. A concise documentation of that structure and the individual files would have been very useful.

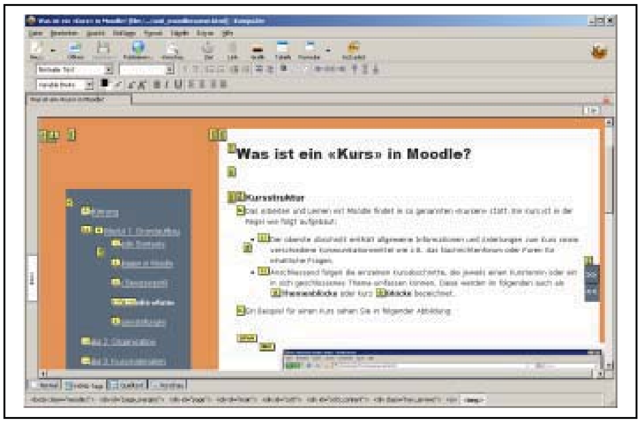

Figure 7. Modification of an HTML page using the free web authoring tool KompoZer [24].

Figure 8. New Moodle tutorial entry page.

D. *Publishing the new resource*

In order to give our work back to the community, we have to publish it on an institutional or other repository. We decided to publish our open educational resources on the SWITCHcollection repository.

The publication of an educational resource should be as easy as the download of a resource from the repository. Thus, we implemented the harvesting interface between our learning management system Claroline and the SWITCHcollection repository. Our faculty can transfer resources from Claroline with the “click on a button” [26]. It is most convenient to package the content (e.g. the HTML pages and stylesheets) along with the metadata file and the documentation into a zip-archive. Alternatively, the resources could be arranged in a SCORM or an IMS content package. In this way, only a single file has to be transferred to the repository. Before transferring the resource, a metadata form must be filled in. It is most important to precisely describe the resource in detail. Otherwise, it would be difficult to find it in the repository as the individual contents of a zip-archive, a SCORM, or an IMS package cannot be found by the repository’s search engine.

The SWITCHcollection development group is working on the refinement of the metadata fields and the definition of their meanings. We are contributing to this work because meaningful metadata are crucial for the enduring success of open educational resources.

VII. CONCLUSIONS

In order to be found and widely reused, open educational resources must include three elements: The content itself, appropriate metadata, and a documentation (at least a sketch) that points out the structure of the resource from a didactical and a technical point of view. The resources must be published on servers that comply with open access standards (such as the Open Archives Initiative Protocol for Metadata Harvesting) and include Web 2.0 functionalities (such as comments). Educational institutions must support their faculty in the production and publication of open educational resources and last but not least the establishment of a community of practice would be of great value within and amongst institutions.

Abstract— **This work presents an approach to the education in sensors, targeted to future engineers that relies on using educational sensors. An analysis of major issues on sensor education is carried out and two types of didactic, capacitive and low cost sensors are presented, which allow the student to easily under-stand the physical principle of the measurement, as well as to evaluate other sensor features like repeatability, sensitivity and measurement uncertainty. To this aim, some capacitive sensors have been developed to measure levels of oil and water in the laboratories. In the academic year 2006-07, the Laboratory of Sensors and Signal Conditioning of the Electronic Technology Department of the University of Vigo started using those sensors experimentally. During 2007-08 and 2008-09, a methodology based on these didactic sensors, combined with signal conditioning circuits and simulations in Pspice, has been launched. Then, a signal conditioning circuit is assembled and the information displayed on a PC monitor, connected by a data acquisition system. Furthermore, this paper includes the efficiency evaluation results of the proposed methodology, obtained from student surveys.**

Keywords-capacitance transducers; circuit simulation; learning systems; level measurement.

I. Introduction

The instrumentation and measurement topics in the engineering education present big difficulties to the learning methodology, the economic cost of the materials and equipments, and the time spent in the laboratory sessions. Thanks to the advances in microelectronics in the last years, the data acquisition systems became the most economic part, with better features and easier to use by the students [1]-[3].

Advances have been outstanding in sensors as well, thus achieving more intelligence, precision and functionality. Nevertheless, from a didactical viewpoint they are still expensive, barely didactic and difficult to assemble in robust scale models. This leads the teaching staff in charge of sensors and signal conditioning laboratories, to make continuous efforts to ease the study of sensors. Therefore, a major objective of the Electronic Technology Department of the University of Vigo is developing low cost didactic sensors and signal conditioning circuits, friendly to use by the students and to teach the physic principles of sensors [5], [6].

This work presents a group of capacitive sensors fabricated from common recycled materials, familiar to the students. In particular, there are two types of capacitive sensors for the level measurement:

- Flat capacitors constructed with a Compact Disc (CD) box, to which the capacitor plates are attached. The plates are made of aluminum covered with laminated plastic.
- Cylindrical capacitor made off two different pieces of copper pipe, constructed in a coaxial way.

In order to be handled in the laboratory, the flat sensors have been placed in already available scale models, even though they can be easily mounted in low cost homemade scale models with a simple container to hold the capacitor. These sensors will permit the measurement of water level. The cylindrical capacitor has been assembled in a homemade scale mod-el to measure the oil level. The students have characterized four different sensors and implemented two simple signal-conditioning circuits of first order, one active and the other one passive. The next section describes the implemented sensors and their characterization according to the teaching methodology followed.

II. Characterization of the Sensors Developed

The changes of a physical variable, in this case the liquid level, causes variations in the dielectric, such that when the level is zero the dielectric is air (ε_{air}), but for a certain level h of liquid, a portion of the dielectric is still air but the rest is liquid, whose level will be measured. Thus, the changes in the dielectric cause changes of capacity for this type of sensors. The capacity also depends on the capacitor area and the distance between the plates (Ec. 1).

$$C = \varepsilon_0 \cdot \varepsilon_r \frac{A}{d} = \varepsilon \frac{A}{d} \qquad (1)$$

A. Level measurement with flat capacitors

This type of capacitor is constructed with a CD box, whose interior sides are attached to the plates. These are made of aluminum covered with laminated plastic. Several prototypes have been developed; Fig. 1 shows an image of one of them and Fig. 2 another one, whose plates are formed by three triangles. The plates are cut out and only two little "wings" are left for external connections. Thus, the capacitors consist of two parallel plates separated a certain distance "d" given by the type of CD box used, which can be normal (d~5 mm) o narrow sized (d~2 mm).

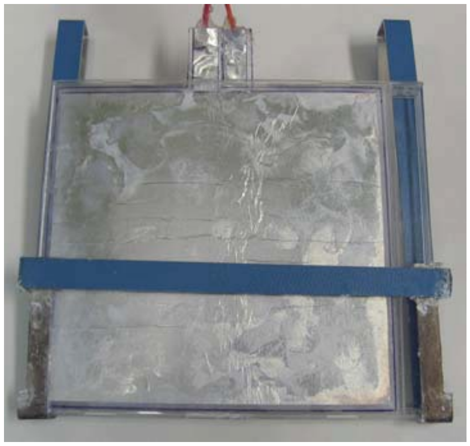

Figure 1. Normal flat capacitive sensor based on a CD box.

Figure 2. Flat capacitive sensor of triangles based on a CD box.

In order to analyze the sensor operation, the portion of the plates with air as dielectric is considered in parallel with the one dipped, according to the level of liquid that is being measured (Fig. 3). Since capacitances in parallel are additive, the general expression (2) is obtained from (1). The expression demonstrates that the sensor characteristic curve is linear, so the response does not have to be linearised in this case.

$$C_{Total} \cong C_{aire} + C_{liquido} = \varepsilon_{liquido} \cdot \frac{a \cdot h}{d} + \varepsilon_{aire} \frac{a \cdot (b-h)}{d} = \\ = \frac{a}{d} \cdot \left[h \cdot \left(\varepsilon_{liquido} - \varepsilon_{aire}\right) + \varepsilon_{aire} \cdot b\right] \quad (2)$$

In the sensor of Fig. 2 the capacitor plates consist of three triangles each one, which present characteristic curves of second order (3) for the capacitors C_1, C_2 y C_3 (Fig. 4), so the students will take into account this non-linearity.

$$C_1 = C_3 = \frac{a}{4 \cdot d} \cdot \left[h^2 \cdot \frac{\varepsilon_{liquido} - \varepsilon_{aire}}{b} + \varepsilon_{aire} \cdot b\right] \quad (3)$$

$$C_2 = \frac{a}{2 \cdot d} \cdot \left[\frac{(b-h)^2}{b} \cdot \left(\varepsilon_{aire} - \varepsilon_{liquido}\right) + \varepsilon_{liquido} \cdot b\right] \quad (4)$$

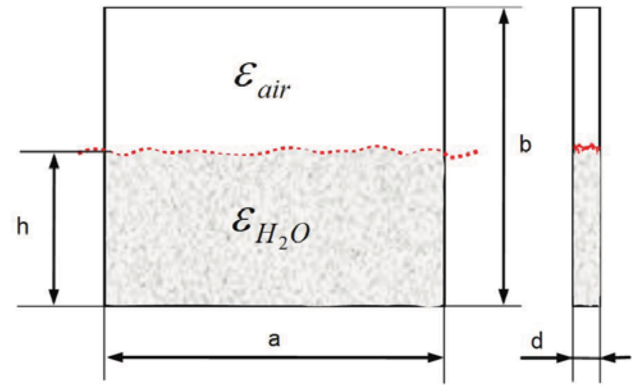

Figure 3. Top and side view of a flat capacitive sensor.

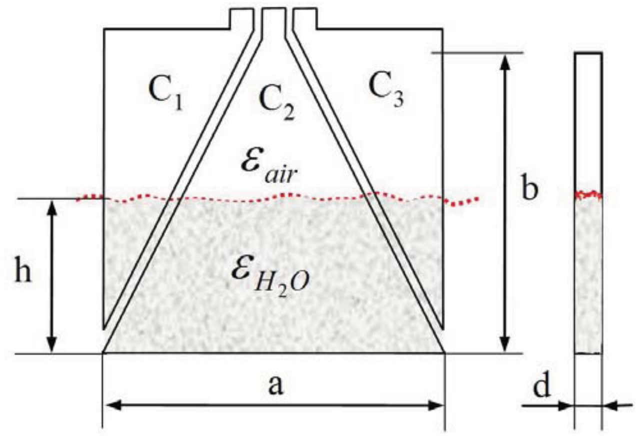

Figure 4. Top and side view of the triangular capacitive sensors.

In order to obtain the characteristic curve for the flat sensor of Fig. 1, it is placed vertically into a water container. At first, the capacitor is completely dry, that is, the dielectric is air with no humidity in the plates. Under these conditions, the water level starts to rise and thus the sensor presents the curve of Fig. 5. In this graphic, when the sensor reaches saturation and the level starts to reduce, it can be observed how the capacity grows as the plates stay damp. This behavior will not occur in the next filling and emptying cycles since the capacitor is always damp. Figure 6 shows the average of data taken during the level rising and lowering processes, which are repeated 5 times. The last two curves allow to obtain the trend ones of Fig. 7 that show a repeatability of 23 pF, which in turn means a total average margin of 1.5% over the full scale. Finally, figure 8 shows the total average characteristic of the sensor, from which the height of water is given by (5) as a function of the capacity.

$$h = 0.0791 \cdot C(pF) - 4.383 \quad (\pm 0.56) \text{ mm} \quad (5)$$

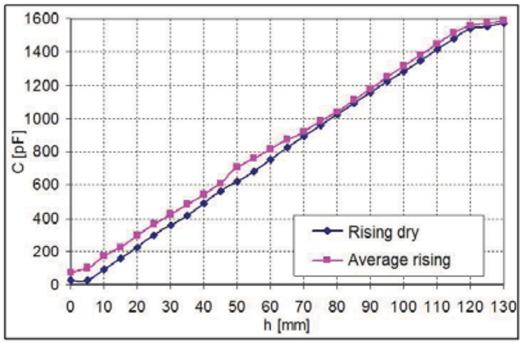

Figure 5. Response of the flat sensor of Fig. 1when initially dry.

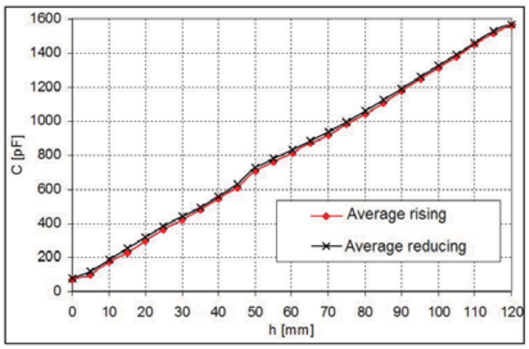

Figure 6. Response of the flat sensor of Fig. 1 with rising and lowering level after several measurement cycles.

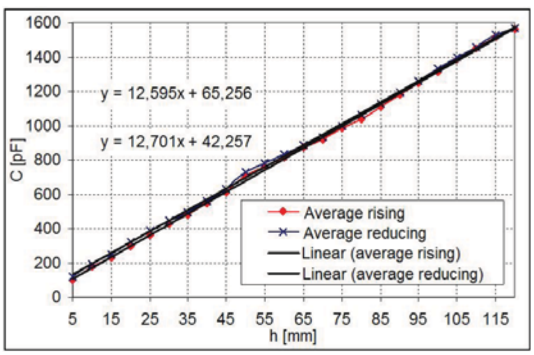

Figure 7. Trend lines for the sensor of Fig. 1 with rising and lowering level.

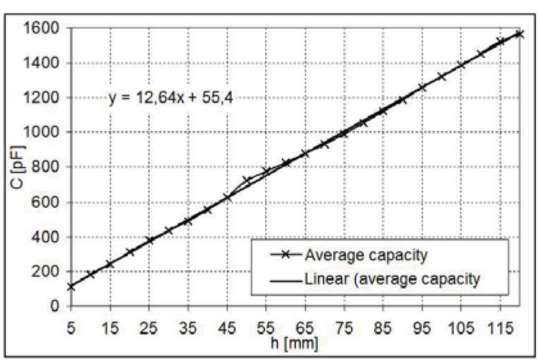

Figure 8. Total average curve and trend line for the sensor of Fig. 1.

B. Level uncertainty in flat capacitors

To calculate the uncertainty, the following parameters will be taken into account:

- The typical deviation, which is obtained after repeating the experiment five times.
- The capacity measuring resolution (1 pF).
- The length measuring resolution (1 mm).
- The following assumptions are also taken into account:
- The uncertainty introduced by the instruments has a uniform distribution.
- There is no correlation among the causes of uncertainty, that is, the SSR (Square Sum Root) method will be used to evaluate the total error.

The average typical deviation (σ) of the measurements is 9.2 pF and, in order to have a confidence margin (supposing the statistical distribution of the measurements a normal distribution) over 95%, it is assumed a value of twice the typical deviation (that is, 18.4 pF), which means an error of 1.22%. The errors introduced by the instruments are 0.04% in the capacity and 0.46% in the length measurement. According (5), the errors in capacity measurement lead to level errors, amplifying them by the curve slope, that is, 0.0791. Therefore, the total uncertainty in the level measurement will be caused by the following uncertainties:

- Uncertainty introduced in the level measurement (0.46%).
- Uncertainty introduced in the capacity measurement (0.0031%).
- Uncertainty introduced by the staff that made the measurements (0.096%).

The total uncertainty derives from these data and, according to the method utilized, it can be:

- Worst-case method. All the uncertainties are added, that is, 0.5591%.
- SSR method. They are squared added:

$$\sqrt{0.46^2 + 0.0031^2 + 0.096^2} = 0.469\%$$

C. Level measurement with cylindrical capacitor

The cylindrical capacitive sensor consists of two coaxial copper tubes, shown in Fig. 9, of 17 and 27 mm respectively. The theoretical sensor response, which is linear, is given by (6). Fig. 10 shows an image of the sensor assembling, which is about 12 cm long, inside a test tube with oil whose level will be measured. The sensor hangs from the wires connected to the capacitor plate that allow the sensor to rise and descend and thus measuring the height fluctuations of the cylinder submerged in the fluid. Sunflower oil is the fluid used in the laboratory sessions due to its low cost, for it is simple to obtain and has relatively low viscosity.

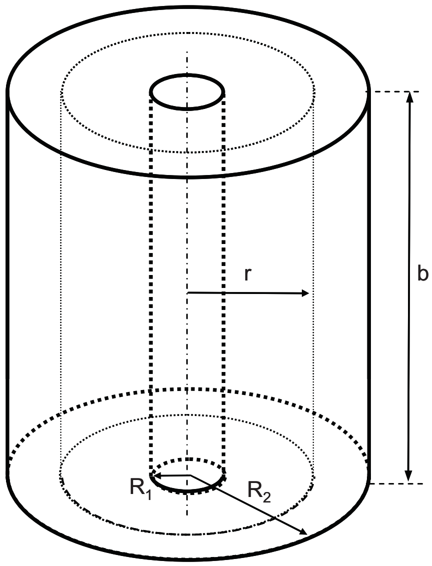

Figure 9. Cylindrical capacitor.

$$C \cong \frac{2 \cdot \pi}{\ln \frac{R_2}{R_1}} \cdot \left[h \cdot \left(\varepsilon_{liquido} - \varepsilon_{aire}\right) + b \cdot \varepsilon_{aire}\right] \quad (6)$$

Fig. 11 shows the results of the measurements made to characterize the sensor and, from Fig. 12, it can be deduced the characteristic equation (7).

$$h = 3.0506 \cdot C(pF) - 104.081 \ \ (\pm 3.54) \text{ mm} \quad (7)$$

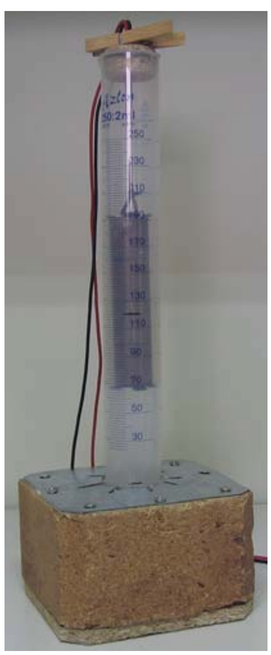

Figure 10. Photograph of the cylindrical sensor.

D. Measurement uncertainty with cylindrical capacitor

In the same way as the flat capacitors, the uncertainty is obtained for (7), which is based on applying the SSR method to the following uncertainties (8):

- Uncertainty introduced in the level measurement (0.58%).
- Uncertainty introduced in the capacity measurement (2.623%).
- Uncertainty introduced by the staff that made the measurements (2.25%).

$$\sqrt{0.58^2 + 2.623^2 + 2.25^2} = 3.54\% \quad (8)$$

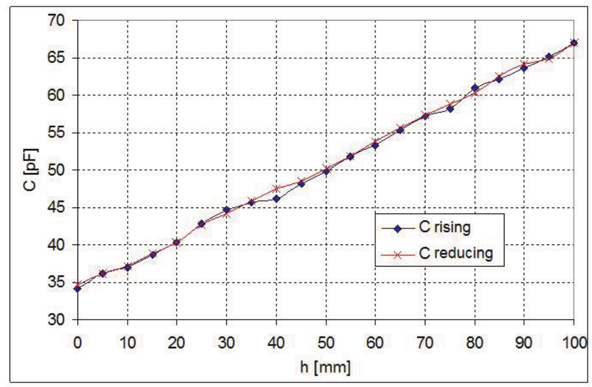

Figure 11. Response of the cylindrical sensor to level rising and lowering.

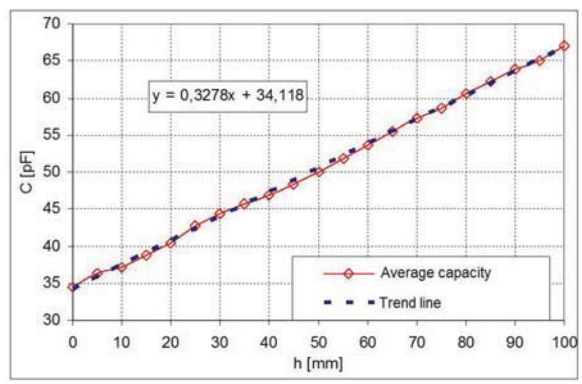

Figure 12. Total average curve and trend line of the cylindrical sensor.

III. TEACHING METHODOLOGY

The abovementioned sensors are currently utilized in the laboratory sessions of the sensor subjects given by the Electronic Technology Department of the University of Vigo. Undergraduate students of several degrees are trained in those laboratories. Among them, the degrees given by the Telecommunication Engineering and Industrial Engineering faculties stand out. This section explains the methodology followed in the subject "Laboratory of Sensors and Signal Conditioning", included in the fifth academic year of the Telecommunication Engineering degree. This subject, whose academic load is 6 credits, is given in the second term and previously, its theoretical counterpart “Sensors and Signal Conditional” is given in the first term with an academic load of 6 credits as well.

The subject is aimed at:

- Showing the student the working principle of the capacitive sensors.
- Familiarizing the student with the basics of measurement, i.e., repeatability, sensitivity, dead zone, saturation and uncertainty [7].
- Designing a complete system for signal conditioning and liquid level display in a container.

In order to achieve these objectives, the following tasks are carried out:

- Simulation of the sensor and signal conditioning circuit with PSpice [8].
- Design and assemble of the signal conditioning circuit (to be connected to a level sensor), that will be placed on a scale model.
- Acquisition of the sensor response by means of a data acquisition system (DAS), for later storage and display on a PC screen [1].

This subject has an academic load of 4 hours per week and the student devotes two sessions to carry out the work related to capacitive sensors, that is, 8 hours as a whole. In addition, the student must do, as previous homework, the design and simulation before attending the laboratory session, where they characterize the sensor, assemble the signal conditioning circuit and see the results on a PC screen.

IV. EVALUATION OF LEARNING

To assess the quality of the sensor education methodology and whether the students consider it appropriate, a survey has been elaborated and delivered to them. To this aim, the subject “Laboratory of Sensors and Signal Conditioning”, of 5th academic year of Telecommunication Engineering degree has been selected. The survey comprises 25 questions, including 16 regarding the student theoretical education in capacitive sensors, their characteristics, how to assess parameters like repeatability, sensitivity, hysteresis, linearity, uncertainty, etc. and 8 regarding the methodology followed. This one is based on low cost didactic sensors and the design of the signal conditioning system with the aid of simulation tools to finally assemble and connect to a PC.

The evaluation is carried out by the abovementioned survey, which is delivered twice to the students. The first 16 questions are delivered at the beginning of the laboratory sessions and once again at the end. The purpose of the survey is to assess how these laboratory sessions help the student acquire knowledge and understand the target concepts, which have been mentioned in the sections above. The other 8 questions are related to the interest the student has on the educational sensor applications, on the combination of design and simulation for the complete development of a measurement system and, in summary, on the methodology followed.

The surveys have been carried out during the last two academic years with a group of 8 students during 2007-08 and 19 during 2008-09. Table 1 shows the results obtained regarding sensor education and, particularly, their characterization and quantification of technical parameters.

TABLE I. RESULTS OBTAINED FROM THE SURVEYS

Academic year 07-08						
Students	8					
Questions about sensors	Total number of questions			128		
	Before			After		
	Correct Answers	Incorrect Answers	DK/NA	Correct Answers	Incorrect Answers	DK/NA
	32	62	11	87	41	0
Academic year 08-09						
Students	19					
Questions about sensors	Total number of questions			304		
	Before			After		
	Correct Answers	Incorrect Answers	DK/NA	Correct Answers	Incorrect Answers	DK/NA
	82	208	14	216	88	0

The results of Table 1 show that, with this methodology, the student acquire an important knowledge on the usage and characterization of a capacitive sensor, as well as the quantification of the technical parameters like sensitivity, uncertainty, hysteresis, etc. In the academic year 2007-08, the percentage of correct answers rose from 25 to 68% between the first and the second survey, while the DK/NA answers descended from 7 to 0%. In the academic year 2008-09 the percentage of correct answers rose from 27 to 71% between the first and the second survey, while the DK/NA answers descended from 5 to 0%.

Moreover, 8 questions were added regarding the methodology followed. This means 64 answers for the academic year 2007-08 and 152 for 2008-09. Those questions were related to the usage of simulation tools for sensors and signal conditioning circuits and the usage of educational sensors in the laboratory. The results show that 100% of the students consider the methodology very adequate for their education in this subject.

V. THE SUBJECT IN THE NEW EHEA

The European Higher Education Area (EHEA) establishes an education system based on competences and on the active role the students will have in their own learning process. Concerning sensor education, the student will acquire the following competences:

1) Specific competences:

a) Ability to specify and handle electronic instrumentation and measurement systems

2) Common competences:

a) Basic knowledge of computational tools for engineering applications.

b) Ability to use computational programs to support the development and usage of electronic applications.

c) Knowledge of basic subjects and technologies, which allow them to learn the new methods and technologies and provide them with a great versatility to adapt to the new scenarios.

d) Ability to solve problems with initiative, decision-making, creativity, and to communicate and convey knowledge, experiences and skillfulness, assuming the ethic and professional responsibility of a Telecommuni-cation Engineer.

e) Knowledge to carry out measurements, calculations, as-sessments, studies, reports, planning and similar in the sphere of activity of telecommunications.

This subject in particular presents a methodology to ease the student education, which is based upon their own work and appropriate usage of the material available, comprising didactical sensors, simulation tools and electronic components.

In summary, we strongly believe that this methodology absolutely fits in the new approach emerging from the EHEA, which is currently ongoing in all Spanish universities.

VI. CONCLUSIONS

The usage of educational sensors allows the student to see, in an easy and effective way, the operation of the primary measurement element, along with checking the sensor operation in the laboratory. Furthermore, their simplicity has contributed to unveil the sensor operation, which is often seen as a black box. It must be highlighted the benefits of the experiences carried out on studying the sensor technical characteristics like repeat-ability, sensitivity, dead zone, saturation and measurement uncertainty.

On the other hand, this methodology follows the European Higher Education Area (EHEA) and the results of the student surveys leads us to believe on its utility for the student education in sensor engineering.

Abstract— **This gesture recognizer, developed by students in a third-year microprocessor-based laboratory course, takes Wii remote (Wiimote) as an input device to estimate the movements of the user and to compare the detected trajectory with the previously learnt movements, in order to carry out the associated actions. Such a cheap state-of-the-art wireless user interface is very attractive for the students and can be used in many interactive applications, from robotics to virtual reality and multimedia presentations. By combining commercially-available hardware, pattern-matching techniques and programming skills, we are able to foster students' interest on developing innovative potentially-marketable systems. This freeware project, implemented as a configurable publicly-available library, can be adapted to the needs of any course or student. In our laboratory this open-source DLL is used for remotely controlling a robot (based on an open-hardware Arduino platform), using a PC and the Wiimote, although the DLL can be integrated in any C, C++, Java or C# project. A GUI application (based on a Model-View-Presenter paradigm) is also provided and can be used as a template for new applications or just for debugging purposes. Although the developed application only uses data from the accelerometers, data from the infrared camera and buttons of the Wiimote is also available.**

I. INTRODUCTION

Project Based Learning (PBL) is a systematic teaching method that engages students in learning both theoretical knowledge and practical skills through an extended inquiry process structured around complex, authentic questions and carefully designed products and tasks [1]. The 21st century information and knowledge economy is shaping the way in which colleges and universities are preparing undergraduate and graduate students with knowledge skills and abilities throughout the world. PBL is becoming one of the most important educational approaches to help faculty improve student learning process and there are many examples of its successful application in university courses [2] [3]. In university teaching it has been applied to a wide variety of disciplines from business to science [4] [5]; but most applications have been in engineering courses [6] [7]. Compared to traditional teaching, PBL technique reveals a higher degree of learning [8] [9]. PBL allows increasing students' involvement in the learning process, obtaining better results in terms of the theoretical knowledge and practical skills students are able to acquire.

In our PBL laboratory course LSED, students must face a State-of-the-art project based on a commercial Wiimote interface and R&D and innovation pattern-classification techniques.

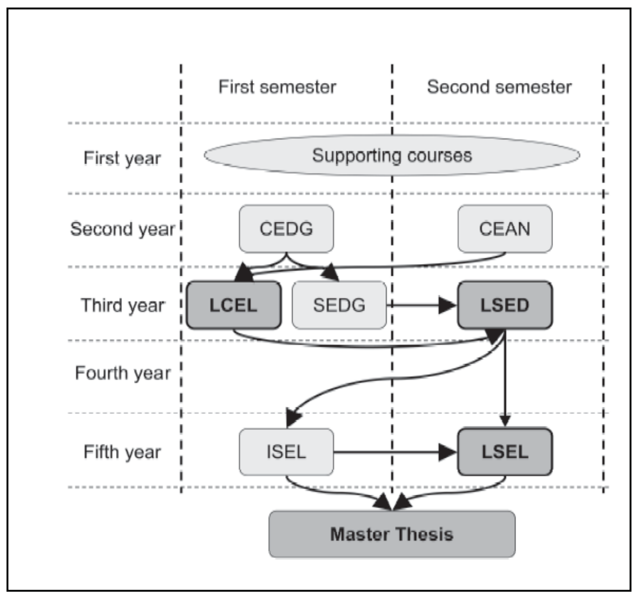

Figure 1. Structure of the curriculm on Electronics.

The paper is organized as follows: Section II describes the laboratory course in the context of the curriculum structure. The implementation of the system is described in the following sections. First the required pattern-recognition algorithms are explained; afterwards hardware and software requirements are outlined. Finally the conclusions of the proposal are drawn.

This work was supported in part by UPM under innovation projects

II. Course Description: LSED

In the literature, many curriculum initiatives used PBL as their main learning strategy [4]. In some cases, PBL is enhanced using multiple case-studies or using several mini-projects for improving assessment [5]. In LSED case, students must develop a multidisciplinary supervised project.

The curriculum scheme can be seen on Figure 1. CEDG, CEAN, SEDG and ISEL are theoretical courses while LCEL, LSED and LSEL are project-based ones. The arrows show the dependencies between subjects from a theoretical point of view.

A. Theoretical courses

The three theoretical courses before LSED are problem-oriented and examination-based, with a great emphasis on analysis issues, albeit the evaluation is mainly based on the analysis of a simplified system.

CEDG (Digital Electronic Circuits) and CEAN (Analog Electronic Circuits) introduce the fundamentals of both digital and analog circuits, both in the second year (3rd and 4th semester). The gesture recognizer described in this paper can control a hardware system that can be analyzed by means of the fundamentals provided in these courses. An example (a robotic system) is described in section VI.

In SEDG (Digital Systems Based on a Microcontroller): students learn the fundamentals for programming a microcontroller-based system: inner structure, programming issues, timing resources, exception handling and peripherals (such as universal asynchronous receiver/transmitter or analog-to-digital converters). The emphasis is put on system-level programming.

After LSED, one theoretical course is left (ISEL, Electronics Systems Engineering), focused on advanced embedded systems, operating systems and real-time issues.

B. Project-Based courses

The design of electronic systems must deal with decisions in several axes:

- HW versus SW design (or co-design).
- Life cycle process: analysis, design, implementation, and testing iterations.

To involve student in dealing with all these aspects more than one semester is needed. PBL courses must be coordinated to get complementary learning objectives covering the whole life cycle and all hardware/software aspects.

In these courses, the teaching approach is based on multidisciplinary PBL, using electronics to create systems to solve problems in signal processing, communication or control areas. Students must design, build, test, and document a complete system (hardware or software or both of them) with emphasis on creativity (innovative solutions), realism (in terms of cost) and professionalism (evaluating factors such as technical writing quality and oral communication capabilities).

LCEL (Electronics Circuits Laboratory) is the PBL course that precedes LSED, focused on the design and implementation of analog and digital electronic circuits from a set of technical specifications.

LSED (Microprocessor-based Laboratory), in the first semester of the third year, students must develop an electronic system mostly based on programmable devices. The system always includes a real-time component (in the proposed Wiimote system, data from the device must be obtained and processed in an interrupt service routine), making the debugging of the system more complex and thus the development of the whole prototype more challenging.

After LSED, only one optional PBL laboratory remains: LSEL (Laboratory of Electronics Systems Engineering), focused on a software/hardware balance, reusing previously-implemented modules when implementing a fully-functional prototype. Programming is not a critical issue and the emphasis is on high-level programming and student-defined specifications.

C. Master's Thesis.

Finally, every student must complete a Master's thesis individually in order to get the Telecommunication Engineering degree. At this point, students coming from LSEL are very well prepared to take on a Master's thesis involved in one of the research and development lines developed in the Department of Electronic Engineering.

Similar to LSEL, the Master's thesis focuses on both SW and HW aspects and considers all the steps in the life cycle of the development of an electronic system.

The main difference with respect to LSEL is that Master's theses are developed individually: The student has to analyze, design, and implement the system architecture, controlling the functionality of all the modules. First of all, the student has to design a detailed testing plan, which is one of the main targets in this level of the curriculum. As a result of the Master's thesis, the student develops a quasi-professional system, generally involved in a research and development project that is being completed by the instructors with a company or a government institution.

III. Wiimote Data Sampling and End-Pointing

A sample of data received from a Wiimote is shown in Figure 6. Three different regions are shown in Figure 3.

Region 1 corresponds to a situation when no intended Wiimote movement is being made, just random movement or electronic noise is received. In this region 1, the received values vary between zero and the first threshold (green line). If an intended movement is carried out, the data values pass through an intermediate region 2, a transition area between "no detected movement" and "a movement clearly detected" (labeled in the diagram with a 2). The system detects the beginning of the movement when the data values overpass a second threshold for a brief period of time. Then, collected data is identified as a specific gesture (region 3) until data return to a noisy situation which is reached after a contiguous sequence of samples are detected below the first threshold (final region 1).

This end-pointing algorithm is implemented as a software finite state machine as shown in Figure 2.

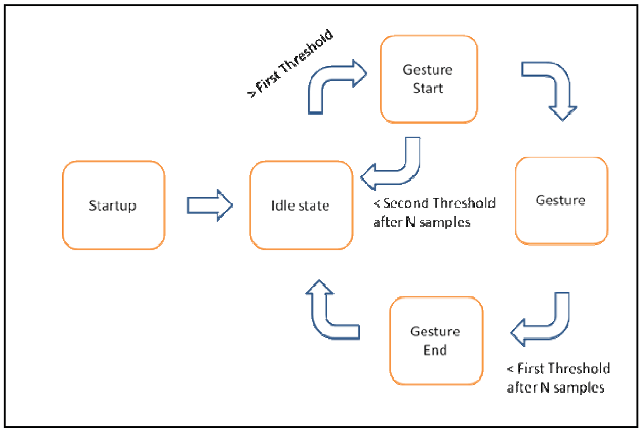

Figure 2. Finite state automaton of the gesture recognition system

The first state is Startup, which calibrates the system in order to take into account electronic noise and working conditions when establishing the values of the thresholds. This way, the system can automatically adapt to the user that is using our recognition software at that specific moment in a specific environment.

After this calibration, the Idle state starts; Wiimote data is sampled for later comparison and to know if any activity has occurred above our first threshold. If first threshold is exceeded and the system does not exceed the second one after several samples, a false alarm has occurred, no gesture should be saved and the system must go to the previous state again.

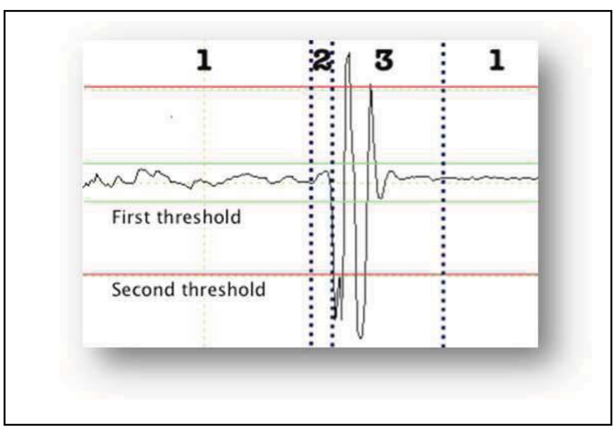

Figure 3. One-axis acceleration data when a movement is performed

If the second threshold is surpassed, a new gesture is actually being made, so the system starts to save all the data received from the Wiimote unit, until data below the first threshold is received. This involves that a new “no movement or noisy situation” has started and the movement has already finished.

IV. Gesture Recognizer System Description

In order to identify the gestures we need to have previously-collected data to compare with. That is way the recognizer works, in two modes: training mode and recognition mode.

During the training phase, end-pointed movement data is serialized and saved as an XML file. This file is used in the recognition phase to compare the new data received from the Wiimote with every movement previously saved by means of the Dynamic Time Wrapping method (DTW), very popular in the design and implementation of speech recognizers for low-end mobile phones.

This DTW algorithm is able to compare two sequences of multidimensional data (such as the three-axis acceleration data from the Wiimote) to each other, even if the length of the sequences is not the same. In order to carry out the comparison, the standard DTW algorithm allows insertions and deletions in one of the sequences (although penalizing these operations when computing the distance between the sequences) as shown in Figure 5. Although normalizing the data of the sequences (such as subtracting the average value of the sequence to each of the samples) is a usual preprocessing technique (before comparison), good gesture recognition rates have been achieved without any normalization and using a linear scale and an Euclidean distance (for other signals such as speech, it is usual to use the log-energy of the signal when computing the distance, although for acceleration data, a linear approach is completely appropriate).

V. DLL and GUI Development

The Wiimote-based gesture recognizer DLL was designed using C# Programming language on the .Net 2.0 Framework [10] [11], using a Visual Studio Express 2008 (free Student Edition) to develop the architecture, as this Integrated Development Environment is quite intuitive and easy to start working with.

Programming with this language was easy and quick thanks to MSDN Library also [14], freely available on the Internet, which collects all the documentation of the .Net Framework in a similar effective way as Java does. Thanks to the MONO development project [15], the project can be extended to other platforms based on Mac OS X or Unix systems. As future work, the team of students is in charge of extending .Net Framework to both Operating Systems.

In LSED laboratory the generated open-source DLL is used for remotely controlling a robot (based on an open-hardware Arduino platform), using a PC and the Wiimote, although the DLL can be easily integrated in any other C, C++, Java or C# project.

VI. Hardware Demonstrator

To demonstrate the capabilities of the gesture recognition system, students decided to show DLL’s functionality by controlling a small basic robot based on an Arduino Duemilanova board [16]. This board is based on Atmega328 with 16KB to 32KB of Flash memory and clock speed of 16 MHz. Its physical structure was made from various recycled plastic parts taken from old or broken devices (Figure 4.).

The main feature of this system is offering a fully open-source-based hardware platform. The available development kit is completely free and all the reference related to its programming tips can be found on Internet. The main advantage when programming an Arduino board is the use of a high-level language, very similar to C: all the libraries needed are already included in the development kit.

Figure 4. The robotic platform controled by the gesture recogniser

For demonstration purposes, students established a serial communication directly to the robot, so they could send the processed data from the recognition software in order to control the robot at will. In this case they simply recovered the data sent through the serial line and with the recovered command from the data they made the robot react in a certain way (to move forward or backwards or to turn on the left or on the right).

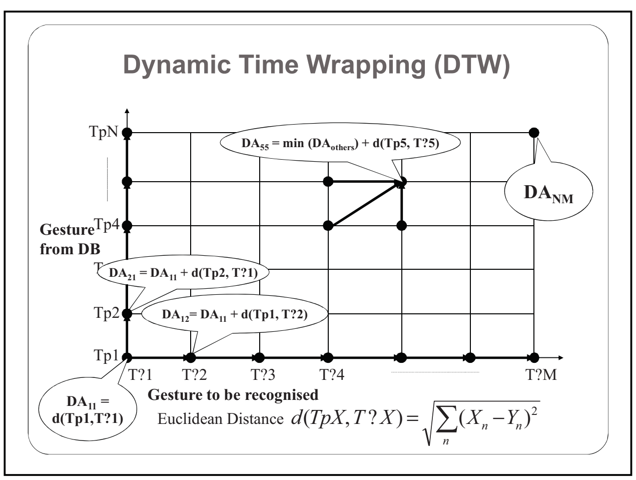

Figure 5. Graphical procedure of Dynamic Time Warping

VII. CONCLUSIONS

A new engaging project has been proposed, designed, implemented and tested for a PBL course on microprocessors. The use of cheap wireless game-oriented commercial hardware, open-source software and hardware and pattern-matching techniques is very attractive and has already engaged several teams of students during the last two years in a third-year microprocessor-based laboratory course. This freeware project is able to foster students' interest on developing innovative potentially-marketable systems.

The gesture recognizer estimates the movements of the user's Wiimote and by comparing the detected trajectory with the previously learnt movements, is able to carry out the associated actions in interactive applications (from robotics to virtual reality and multimedia presentations). Implemented as a configurable publicly-available library, it can be adapted to the needs of any course or student. In LSED laboratory at UPM, this open-source DLL is used for remotely-controlling a robot using a PC and a Wiimote. The developed DLL can be integrated in any C, C++, Java or C# project and a GUI application is also provided as a template for new applications or just for debugging purposes. Although the developed application only takes data from the accelerometers, data from the infrared camera and the Wiimote buttons is also available.

From a personal point of view, on behalf from the authors; the development of this kind of project based on the PBL methodology has been a quite profiting experience for both the students and the professor, although working with a different development environment and platform can imply an extra effort for the people involved, due to the fact that learning how to handle the different required tools takes time.

On the other hand, conducting an innovative and different project has increased people's awareness for this type of approaches. With this type of methodology we are capable of reaching others students and professors related with similar projects.

After this second-year experience, next year we can offer a standardized project to most of the students in the LSED laboratory course. There is a video demonstration at http://www.youtube.com/watch?v=joo3G3BejwY.

ACKNOWLEDGMENT

Authors thank J. Macías, R. San Segundo and all the members of the Departmento de Ingeniería Electrónica and the GRIDS innovation group at ETSIT-UPM, for their continuous effort to offer high-quality education to the students and for all their fruitful comments and suggestions that made this work possible. Authors also thank the IEEE Spanish Student Branch members at UPM for their support and also UPM innovation project "Implantación y evaluación de la metodología docente asociada a una plataforma no presencial de diseño electrónico orientada al autoaprendizaje" for partially financing this work.

Deptartment of Electronic Engineering
Lunghwa University of Science and Technology,
No. 300, Sec. 1, Wanshou Rd., Touyuan county, Taiwan
suhu@mail.lhu.edu.tw

Abstract—**The widespread use of robots in many areas makes the fundamental understanding of them a necessity for many electronic system design engineers. Therefore, to effectively speed up the learning process, the applications of learning-by-doing hands-on laboratory to help students get acquainted with the design and implementation of robots is inevitable. Lunghwa University has teamed up with local microcontroller manufacturers to redesign course contents, to host free workshops supported by the Ministry of Education, and to hold national contests for intelligent mobile robots. The devised low cost educational robot kits and multimedia lecture notes not only reinforce the hands-on laboratory exercises, but also help motivate students to learn actively the intelligent mobile robots.**

Keywords- mobile robots, hands-on laboratory

I. Introduction

Robots are attracting more and more people's attention recently, especially when Sony and iRobot announced the biped humanoid QRIO robot and Roomba vacuum cleaning robot, respectively. Robots are mechatronic engineering products, capable of acting autonomously in various physical environments. The widespread use of robots in many areas makes the fundamental understanding of them a necessity for many electronic system design engineers. Unfortunately, learning the design philosophy of robots is interesting but difficult, because it includes many areas of knowledge, e.g., the mechanics and electronics, linear and nonlinear vehicle control theory, and firmware programming of microcontrollers, etc. Teaching the autonomous mobile robot design course is a challenging undertaking because one can not assume that all students enrolled in the class have solid prerequisite knowledge in so many areas. It is noted by Heer *et al* [1] that introducing a platform for learning™ robotics courses enhances students' sense of community, innovation capabilities, and troubleshooting skills. The students could experience first-hand the fun associated with robots while gaining a sense of accomplishment. Therefore, to effectively inspire students' interest and motivate them to participate actively in the learning process, the application of hands-on laboratory which leads to an interesting robot to help students learn the design and implementation skills of robots is inevitable.

Heer *et al* [1] propose a low cost and easy to control Tekbots platform for hands-on freshman and even senior level robotic exercises. The Tekbots platform is simple and good for motivating the students, but it may not be used to experience more advanced firmware implementations, control, signal processing, and path planning algorithms. Kuc *et al* [2] used Javascript simulations to make students familiar with what robots can do to interact with environments. The students can develop their own logic circuit designs to program a robot for tasks of increasing complexity. Once the designs are verified in simulations, they can be downloaded to the robot and control the robot in an actual environment. Although students can check quickly whether their ideas work or not for tasks, this approach limits what students can learn in the hands-on exercises because the robot brain is a combinational logic circuit. To make the learning platform more fun and versatile, Lunghwa University of Science and Technology has teamed up with local microcontroller companies (see figure 1) to design low cost line following robots and micromouse, and the corresponding multimedia lecture notes. These companies support not only free samples of microcontrollers, integrated design environments (IDEs), but also free workshops and technical support in this project. By using a similar idea to that described by Hussmann *et al* [3] to inspire students' interest furthermore, the team also works together to hold contests for these mobile robots. The contests and free workshops for university and vocational high school students are also supported by the Ministry of Education. It should be noted that the contest[4] did attract many students and teachers. More than 200 teams compete with each other for the championships of fastest line following robots and micromouse this year.

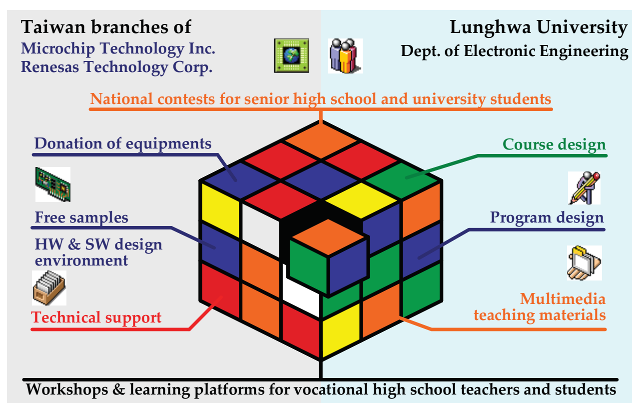

Fig. 1 The joint effort between Lunghwa University of Science and Technology and microcontroller manufacturers

II. Joint Efforts on Developing Learning Platforms

Learning by doing is a very effective idea for students to acquire knowledge, if they are well motivated. It is found that students will be willing to do tedious research work to solve practical problems when these problems are related to an interesting, and competitive contest [3]. Racing contests of line following robots and micromouse are such examples [4-5]. This is why Lunghwa University of Science and Technology wants to team up with local microcontroller companies to design low cost line following robots and micromice, and to hold jointly the corresponding contests. The followings are brief descriptions of the devised mobile robots.

A. Line following robots

Line-following robots are self operating robots that move along a line on the floor. Recently, the Fortune Institute of Technology had held 6 times of line following robot racing contests to encourage students from technological and vocational education system in Taiwan to show their creativity and techniques. It is a very successful contest not only because of the high prize, but also in attracting senior high school students to join the contest. The Taiwan micromouse and intelligent robot contest even include the line following robot racing contest as one of its major events this year [4].

The rules [4-5] allow contestants to memorize where straight lines and curve turns are along the track by providing prompts every time the curvature of the track changes. Figure 2 shows the 4th generation learning platform for line following robots of the joint effort. The idea [6] of using analog outputs of reflective optical sensors to estimate accurately the line position is applied in this prototype of learning platform. To calculate precisely the distance that the robot moves and lower down the cost, home-made encoders are installed onto two DC motors. The resolution is about 0.5mm/pulse. Two dsPIC microcontrollers are used in this configuration. One is for collecting the encoder pulse information for two dc servo motors, and the other is in charge of reading the reflective optical sensor outputs, calibrating these outputs, estimating the line position, and controlling the run speed and orientation of the robot. It is capable of running at speed more than 2m/sec. The robot costs about $ 150 USD. Two-third of the money is for the maxon DC motors due to its high performance and small size.

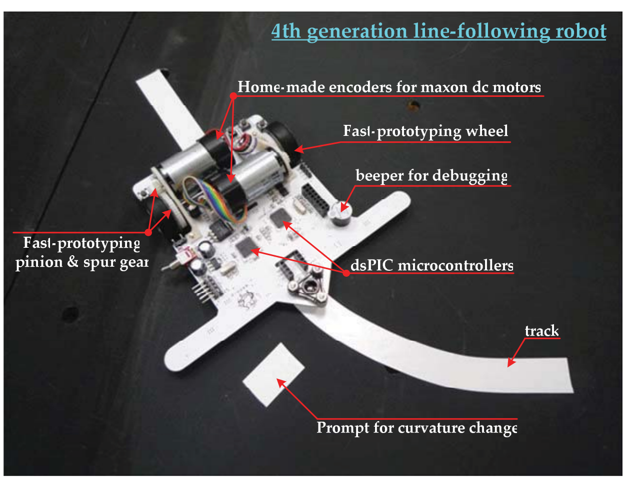

Fig. 2 A sample learning platform for line-following robots

B. Micromouse

Micromouse contests are for miniature autonomous robots to compete for the title of best speed and intelligence in solving a maze and finding the goal. Over the years, the micromouse contest became one of the few student competitions among engineering schools around the world. After all these years of development, the micromouse has made a great improvement in both maze-solving algorithms, and motion control implementation in the international competitions. This is partly due to the fast development of microcontrollers and sensors, which not only shrinks the hardware circuits, but also makes detect the environment conditions and motion control of the micromouse easier and execute the algorithms faster. These contests are still very popular to engineering students in UK [7], USA [8], Japan [5], Singapore [9], and Taiwan [4], because the micromouse project is helpful and fun for students to learn and integrate multidisciplinary knowledge. The micromouse is also a very good example for learning embedded control systems.

Figure 3 shows the 4th generation learning platform for micromouse contests of the joint effort. Local industries also contribute to make the maze court, the post, and the wall. The cost for the maze is about 30% of the price found on the Internet [10]. The functions of the two micro-controllers installed on the micromouse in figure 3 are basically the same as those for the line following robot in figure 2. Therefore, students familiar with controlling the line following robot in figure 2 can easily switch to this micromouse learning platform.

The differences between the micromouse and the line following robot that make the micromouse a more advanced project for intelligent mobile robots are threefold. They are 1) a maze-solving algorithm which should be integrated with the motion control algorithm, 2) various maze wall configurations should be taken into account in the motion control algorithm such that the micromouse won't hit the maze wall, 3) a gyro sensor should be used because the centrifugal force is large at high speed.

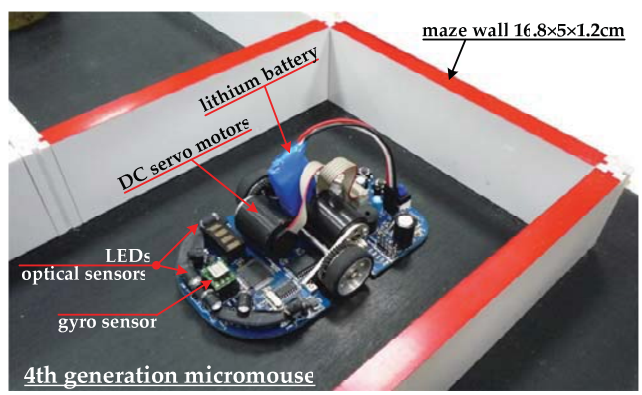

Fig. 3 A sample learning platform for micromouse contests

III. PROBLEMS STUDENTS CAN LEARN TO SOLVE IN THE LEARNING PLATFORMS

The followings are brief descriptions of some problems students may face in making their own line following robot and micromouse projects.

A. Mechanical Design of robots

Students that enrolled in department of electronic engineering in general do not have the opportunity to design their own mechanical systems. When students want to make their own line following robot or micromouse faster, they have to take into consideration the power, torque, and top speed ratings of their DC motors, the grip force between tyre and the ground, and the height of the center of gravity. These things are all related to the mobility of the robot. This motivates the students to learn computer aided software to help them design and verify their own mechanical structures before construction. Figure 4 shows such examples for mechanical designs of stepper motor and dc servo motor micromice. Although these are only simple structures and won't take students too much time to learn to design their own, they do bring a lot of fun to students in designing their own robots.

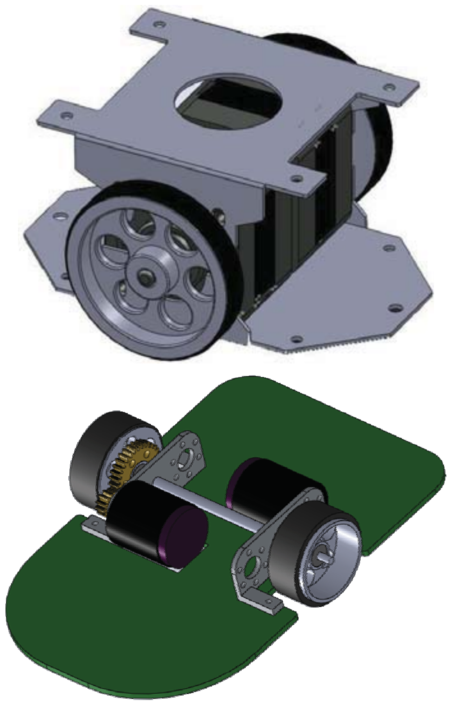

Fig. 4 Example student designs of mechanical structures for micromice

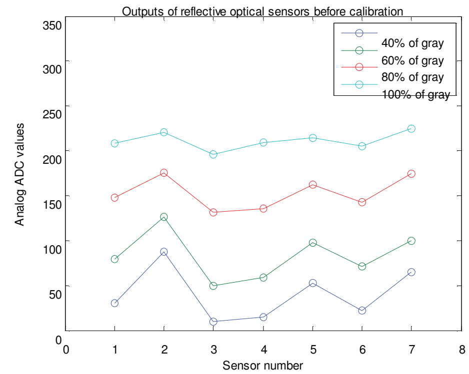
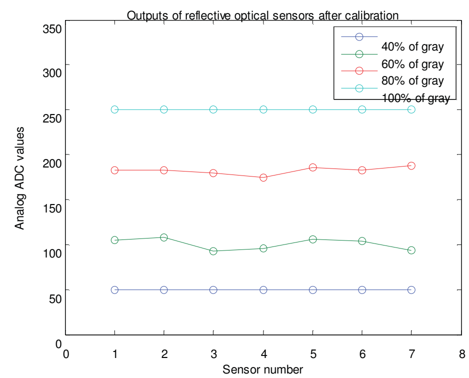
B. Calibration of Optical Sensor Outputs and line detection

To detect the line in the racing track, most people use two or more reflective optical sensors[11]. Unfortunately, this approach works fine only at low speed. Chan [6] uses analog output voltages from reflective optical sensors and digital PD control algorithms, such that the line following robot can run faster than 80cm/sec. Before students can use the analog sensor outputs to estimate line positions, each output should be calibrated to give almost the same level of voltage under the same working condition. This is due to the variations of optical sensor characteristics, even though their part numbers are the same. It can be seen in figure 5a that the output values of different reflective optical sensors vary a lot even if they are under the same working condition. Figure 5b shows the results after the software calibration procedure [12] is applied.



(a)



(b)

Fig. 5 The reflective optical sensor outputs for different gray scale (a) before and (b) after calibration

After the calibration procedure is finished, it is ready to calculate the line position based on those adjusted analog output values from the corresponding reflective optical sensor circuits. Students can use various interpolation techniques or the way of find the "center of mass" [14] to do it. It is important at this part for students to figure out a way to verify how accurate their estimation algorithm is.

Suppose that the coordinate of the 7 reflective optical sensors are x_0, x_1, x_2, x_3, x_4, x_5, x_6, respectively, and the corresponding analog output values are y_0, y_1, y_2, y_3, y_4, y_5, y_6, which is shown in figure 7. The estimated line position can then be calculated by the following weighted average formula:

$$x = \frac{\sum_{i=0}^{7} x_i y_i}{\sum_{i=0}^{7} y_i} = \frac{3(y_6 - y_0) + 2(y_5 - y_1) + (y_4 - y_2)}{\sum_{i=0}^{7} y_i}, \quad (1)$$

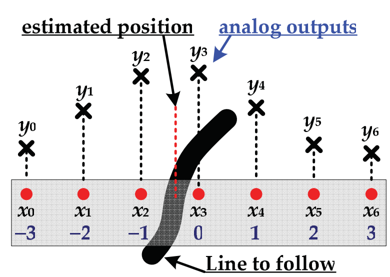


Figure 6 The line detection algorithm via weighted average

Figure 7 shows the experimental results by using the "center of mass" approach.

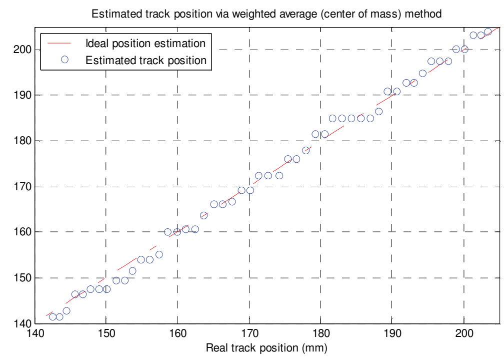

Figure 7 The experimental verification of the center of mass line detection algorithm

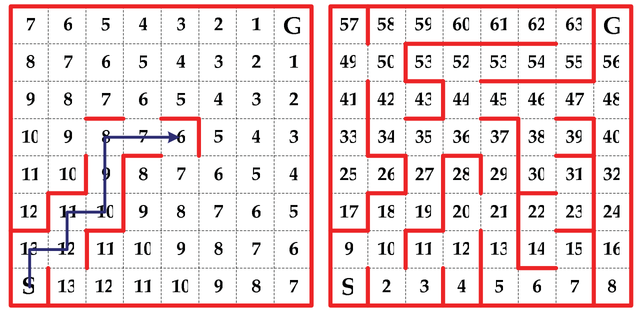
C. Maze solving algorithms

To solve a maze and plan a shortest path from the start point to the goal, the micromouse has to search and memorize the environment first, and then find the shortest path based on some optimization approaches. The simplest method available to a micromouse is some variation on the flood-fill or Bellman algorithm [15-16]. The idea is to start at the goal square and fill the maze with values which represent the distance from each square in the maze to the start or goal square. When the flooding reaches the goal, or start square, the algorithm can then be stopped. The micromouse could follow the values downhill or uphill to the goal square. Take the 8×8 maze shown in figure 8a as an example. The number at each square in the maze in figure 8b is the index for the square stored in the array. At first, the micromouse does not know any information about the maze configuration, except the start square. The first iteration of the flood algorithm then gives the result shown in figure 8a, if the distance value is to the goal square. The micromouse then tries to follow the values downhill to the goal square. Since the distance value to the goal square of the start square is '14', the micromouse will try to move itself to a square whose distance value is '13'. Because the square no. 2 is blocked by a maze wall, the micromouse goes from the start square to the square no. 9. The process goes on and on until the micromouse reaches the square no. 37 whose distance value is '6' as shown in figure 1a, because the micromouse can not find a way to go to squares whose distance value is '5'. Under this condition, the flood algorithm should be executed once again. The distance values in that array would be updated according to the updated maze wall information shown in figure 8a. By using the procedure described above, the goal square would be found at last.

A more advanced flood algorithm should take not only the distance between the start square and the goal square into account, but also the movement of 'going straight' or 'turning'. In other words, the time for the micromouse to move from one square to another should also be considered in an advanced flood algorithm. It is because the weight transfer effect [18] would make the micromouse skid if it makes turns too fast. Therefore the speed of the micromouse should be slower in making turns than in going straight. The above idea of using different weights on the distance recorded in each square to the goal square may also reduce possible paths after the flood algorithm is executed.



(a) (b)

Figure 8 (a) Solving the maze via the flood algorithm if the distance recorded in each cell is the distance to the goal square, (b) square indices of the maze.

When the goal square and the shortest paths from the start square to the goal square are found, the shortest paths can be furthermore optimized such that the micromouse can run in diagonal instead of consecutive 90 degree turns to reduce even more the run time from the start square to the goal square. Figure 9 shows such 3 possible paths with diagonal routes and 45 degree turns.

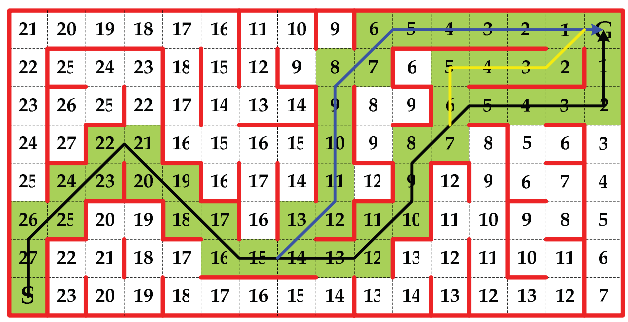


Figure 9 Using diagonal runs to optimize given shortest paths

To speed up the learning process, the maze solving algorithms described above are implemented as a simulation program which is shouwn in figure 10. The input information for maze solving algorithms is the maze wall configurations. The algorithms will then generated distance values from any square in the maze to the goal square. These values will then be used to find out the optimal route for a micromouse to go from the start square to the goal square. The user interface shown in figure 10 is convenient for students not only to define various mazes, but also to debug their codes for the algorithms.

C. Motion control algorithms

The results of the maze solving algorithm can then be used in the motion control algorithm to drive the micromouse as fast as possible from the start point to the goal. Although the optimal path with diagonal segments can be drawn by using lines (see figure 9), the trajectory for the micromouse should be smooth enough such that it won't skid due to centrifugal force when making turns.

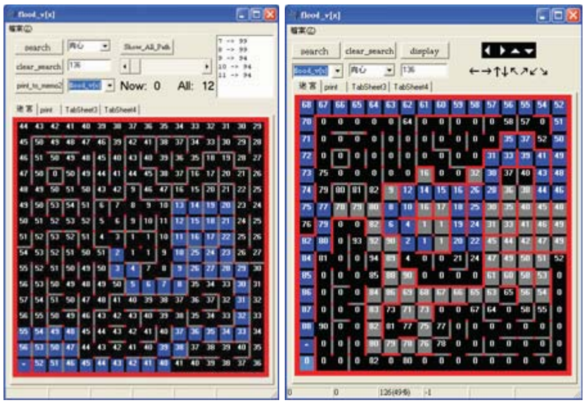

Figure 10 User interface of the maze-solving program

Therefore, smooth trajectory patterns for the micromouse when making 45, 90, 135 degree turns, and making U and V turns shown in figure 11 should be stored in the firmware of the micromouse. The stored information for these smooth trajectories includes the diameter of wheels, start and end positions, and the speed profiles for both wheels. The diameter of the wheel is necessary because the firmware can only track the steps of motors, and the distance traveled is also related to the diameter of wheels.

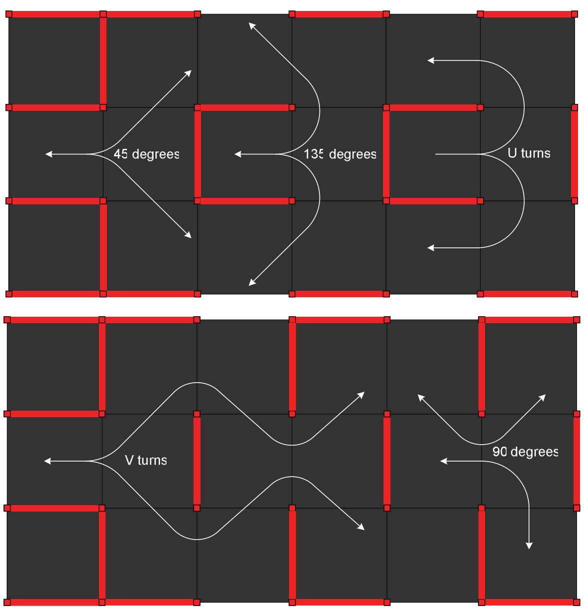

Figure 11 Smooth trajectory patterns for micromouse to make 45, 90, 135 degree, U and V turns.

The approximate mathematical equations proposed in [17] can be applied to find out the position of the micromouse in the maze:

$$v_L(k) = \pi D \times \frac{p_L(k)}{T_s \times p_C},\ v_R(k) = \pi D \times \frac{p_R(k)}{T_s \times p_C}, \quad (2.a)$$

$$v(k) = \frac{v_L(k) + v_R(k)}{2},\ \omega(k) = \frac{v_R(k) - v_L(k)}{L}, \quad (2.b)$$

$$x(k+1) = x(k) + T_s v \cos(\theta(k)), \quad (2.c)$$

$$y(k+1) = y(k) + T_s v \sin(\theta(k)), \quad (2.d)$$

$$\theta(k+1) = \theta(k) + T_s \omega(k+1), \quad (2.e)$$

where D, $p_L(k)$, $p_R(k)$, p_C, $v(k)$, $v_L(k)$, $v_R(k)$, $\omega(k)$, L, $x(k)$, $y(k)$, $\theta(k)$, and T_s stand for the diameter of the wheel, the pulse counts of left wheel at the kth sampling interval, the pulse counts of right wheel at the kth sampling interval, the pulse counts of the stepper motor to run a round, the velocity of the micromouse at the kth sampling interval, the velocity of left wheel, the velocity of the right wheel, the angular velocity of the micromouse, the distance between the wheels, the x, y coordinate of the midpoint between the wheels, the orientation angle of the micromouse, and the sampling interval for the digital control algorithm, respectively. The formula in (2) is accurate enough if the sampling interval is sufficiently small.

Although stepper motors are used in the micromouse proposed in this paper, the same pulse commands for the two stepper motors can not guarantee that the micromouse will go in a straight line. This is because the load conditions and the friction forces for the two wheels are eventually not the same. Moreover, the 45, 90, 135, 180 degree turns based on the pulse commands, circumferences of the wheels, and the distance between the wheels also need to be corrected due to measurement errors. To make the micromouse run smoothly in a given maze, there are three types of errors which need to be corrected based on the optical sensors installed on the micromouse. They are 1) longitudinal error, 2) lateral error, and 3) alignment error, which are shown in figure 12.

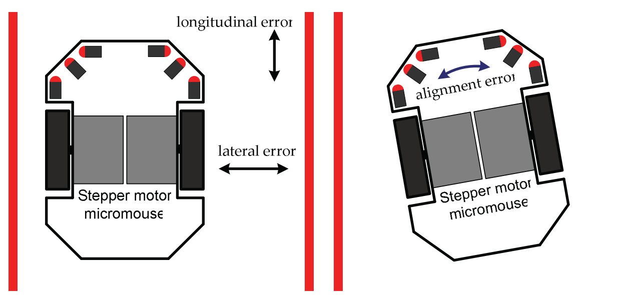

Figure 12 Error sources for a micromouse in a given maze

The alignment and lateral errors of the micromouse can be corrected by using either the pulse commands or the infrared sensor readings. The longitudinal error can be corrected if the pole position of the maze can be detected when the micromouse runs in a given maze. This is shown in figure 13. Because the initial position and the orientation angle θ of the micromouse are all set to 0, these calculation errors should also be corrected based on the infrared sensor readings. Diagonal straight line motion can be corrected by using the readings of forward-looking optical sensors, such that the micromouse would not hit the posts or corners alongside the path.

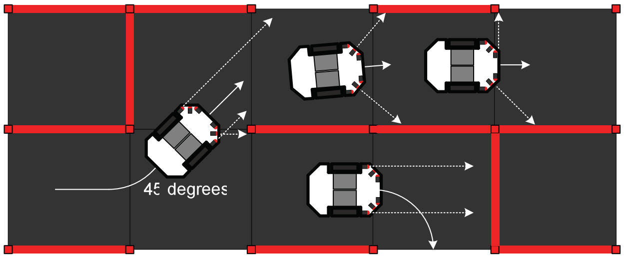

Figure 13 The strategies that a micromouse can use in correcting the longitudinal, lateral, and alignment errors

D. Workshops for vocational high school teachers and students

The joint effort described in this paper is also used to encourage vocational high school teachers and students to learn implementation skills of intelligent mobile robots. Figure 14 shows the free workshops financially supported by Ministry of Education. Lecturers include students, teachers of Lunghwa University of Science and Technology, and technicians from local microcontroller manufacturers. Although most of the students are teaching assistants, there are indeed some students who are proficient enough acting as lecturers. Moreover, every one of them who joins the workshop can bring back not only the intelligent mobile robots, but also the IDEs.

(a)

(b)

Figure 14 Free workshops of (a) line-following robots, and (b) micromouse for vocational high school students

IV. CONTESTS FOR INTELLIGENT MOBILE ROBOTS

To see how well students integrate all the skills learned in the hands on laboratory in implementing line-following robots and micromice, contests (see figure 15) were held after they finished their intelligent mobile robots. Students are also encouraged to join national contests [4]. It is interesting to note that the racing contest did motivate the students to strive to learn the knowledge and skills necessary to make intelligent mobile robots. For example, one group of students in line following robots tried changing the distance between consecutive optical sensors and obtained better results in predicting the line position. They even made a new line-following robot (shown in figure 16) which could run at a maximum speed of 1.2m/s. This is a competitive design to those devised by Cook [13].

(a)

(b)

Figure 15 Contests for (a) line-following robots, and (b) micromouse.

V. QUESTIONNAIRE FEEDBACK

A survey was conducted in a hands-on laboratory for line following robots. It can be seen from Table 1 that the feedback on the questionnaires from the students was quite positive. The majority of the students (78%) agreed that they were motivated to learn those skills and theories, and were satisfied (90%) with the organization of the laboratory. The feedback also shows that the project-based laboratory was more appealing than an earlier conventional laboratory. However, there are three students who thought that the cost is still too high for them, which is partly due to the fact that most of the department's students are economically disadvantaged.

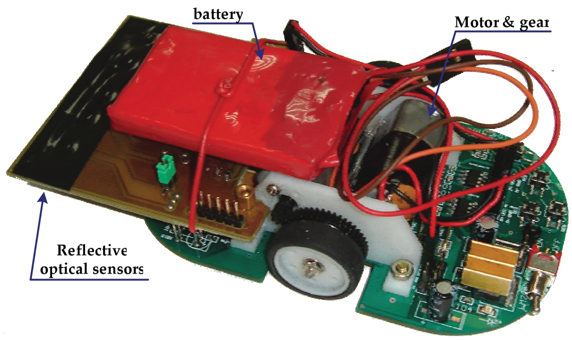

Figure 16 The new line-following robot devised by students

Table 1. The average scores of the survey for the hands-on laboratory

Questions	Average
The hands-on laboratory can effectively help me learn hardware circuit and programming implementation skills.	**4.06 (1-5)**
The contests held after the mobile robots are finished interest me a lot and encourage me to learn more about the necessary skills and theories.	**3.91 (1-5)**
It is more interesting to me to make the robot from scratch in both hardware and software, because each step is explained in detail.	**4.15 (1-5)**
I am willing to pay the money to own the mobile robot.	**3.52 (1-5)**
I am satisfied with the project-based hands-on laboratory.	**4.50 (1-5)**

VI. CONCLUSIONS

The joint effort of Lunghwa University and local microcontroller manufacturers to redesign course contents and learning platforms, to host free workshops for vocational high school teachers and students, and to hold national contests for intelligent mobile robots are described in this paper. The effort was also appreciated and financially supported by the Ministry of Education. The local microcontroller manufacturers support not only free chips and IDEs, but also technicians to help teach in workshops. The effort is seen to effectively motivate students in classes and workshops to learn actively the intelligent mobile robots.

ACKNOWLEDGMENT(S)

The authors would like to thank National Science Council for its financial support under grant NSC 98-2511-S-262 -002.

Cybertech: Robotic Competition and Subject

Learning Mechatronics from a practical point of view

Pablo García-Robledo, Patricia García-Borrás, Ramón Galán
Universidad Politécnica de Madrid Madrid, Spain 28006
Email: (pgrobledo,patriciagb)@etsii.upm.es; ramon.galan@upm.es

Abstract—**This paper describes a subject and contest held in Universidad Politécnica de Madrid. This contest offers the students the opportunity of developing one or more robots so they can put into practice all their knowledge on electronic and mechanical systems. As a subject, all the students can attend a course in which they learn the basics on mobile robots. As a contest, it encourages all participants to improve their designs so they can win important prizes.**

Cybertech; robot; contest; subject; bull; fighting

I. INTRODUCTION

Robotic Competitions for undergraduate students are very popular nowadays. It has been demonstrated that this is a good method to involve the students in working teams and a way of teaching how real components work [1][2][3].

There are different contests all around the world where students develop different kind of robots for educational purposes, like Fire-Fighting [4], Robocup Junior [5] or Hispabot [6]. But other competitions are focused on reinforcing the research efforts on different areas, like RoboCup Soccer Competition [7] and RoboCup Rescue [8].

All these competitions have something in common, the participants must show a working robot which can perform the task and they compete with the others to demonstrate that their prototype is the best. This makes the participants try to do their best and consequently the results are better.

The Universidad Politécnica de Madrid has several engineering competitions, one of them is Cybertech. The Cybertech competition started on 2001 with only 96 students and has increased this amount until 2008 with 140 students. Cybertech is yearly held at Industrial Engineer Faculty. Any UPM student can participate in the contest and attend the subject, no matter what faculty he/she is studying at.

Cybertech is a contest and subject made for and by students. It is coordinated by one professor at the Industrial Engineer Faculty and organized by last year undergraduate students and postgraduate students.

The students are grouped into teams of four or five people to design and build one or various robots. They can decide what event they are going to take part. Participants also have to prepare an oral presentation of their projects.

There are several challenges in Cybertech: Line-Followers, Maze, Bull-Fighting, Solar Racers and RoboSim. These challenges are widely explained in section 2.

The competition usually takes places around April. Section 3 shows how the contest is organized.

The contest is also an elective subject for the UPM students. This subject represents six free election ECTS credits. The subject is related on section 4.

On section 5, there is a description of the material given and recommended to the participants. Teams with students registered in the subject are given the Arduino microcontroller so they can follow the coursework.

Section 6 shows the amount of participants in each Cybertech edition and the influence of different milestones in the number of students.

Last section explains some improvements for the upcoming years in the contest and subject.

II. THE CHALLENGES

A. Line-Followers

The most popular event in Cybertech is the line-followers. For this event, participants must build a robot that follows a black line over a white background.

This event has several difficulties in the robot's path. First

Figure 1. Line Followers Track.

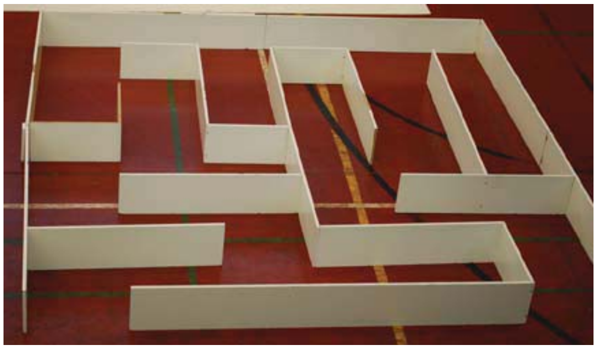

Figure 2. Maze.

of all, the robots must be capable of turning corners, which means in most cases that the sensors will lose the path. In second place, there are forks where the shortest path is marked so the robots can decide to take this way instead of the longer one.

The contest consists of three different trials. First of all, participants compete against each other trying to take as little time as possible to complete a path. There are two symmetric paths so participants can play two at a time.

The second trial is based on car races. This time four or more participants, depending on the amount of them, compete at the same time in a track with two parallel paths as seen in Fig. 1. The robots must be capable of overtaking one each other in case of collision. The semifinal and final trials bring the best participants face to face in a track similar to the previous one but with fixed obstacles they must overtake.

B. Maze

In this case, participants must do a robot capable of solving a maze. These robots usually are the smaller ones and use distance sensors to detect the walls.

The maze, as seen on Fig. 2, is made of white wood and can be changed by the organization.

In the first trial, participants know the maze map one day before the contest. In this case, they can think what the best

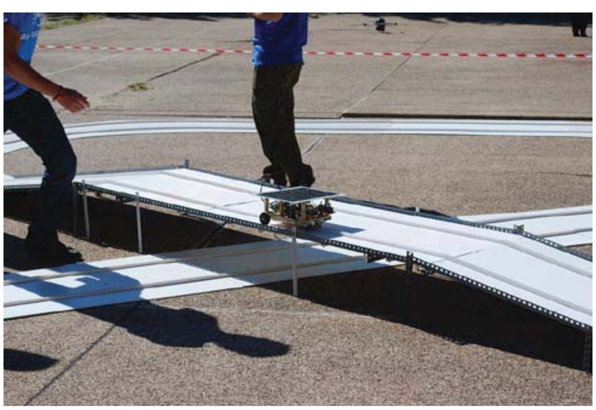

Figure 3. Solar Track

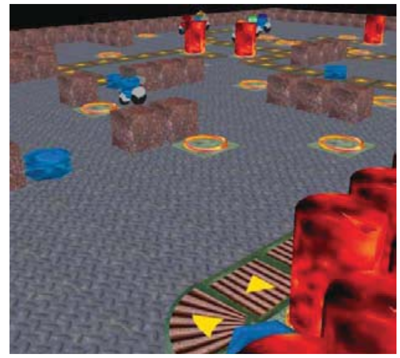

Figure 4. RoboSim Maze

strategy to solve the maze is.

Next trial's plane is given once the first trial is finished so they have little time to prepare their robots.

In the final, participants don't know how the maze is, so the robots must take their own decisions. These kinds of trials makes it unadvisable to program the map in the robot so it knows the maze. Participants usually have to research in common ways of solving mazes, which is an important part of the subject.

C. Solar Racers

One of the most important things that an engineer must take into account is that it is essential to know and improve new sources of energy.

In this event participants must develop a car which can move only by using solar energy. The cars must be capable of going up a slope and moving under a shade (Fig. 3.), but the amount of stored energy is restricted.

For this challenge the participants mainly develop the electronic power system and the chassis with motors. The car doesn't need to turn because there's a rail in the floor so the designers can concentrate in the power problems.

D. RoboSim

In this event the robots are virtually simulated in computers and participants must develop a computer program to control the robot.

Participants' program connects to the main server where a maze is held. This program must act as a robot in the maze, where there are different kinds of challenges and obstacles like fire or slippery ground as seen on Fig. 4. In each round all participants play at the same time and the one that gets first to the target earns extra points.

E. Bull Fighting

The Bull Fighting event makes the difference between Cybertech and any other robot contests. For years, participants had to fight against a bull given by the organization [9] but this was real hard to beat.

Figure 5. Bull Fighting.

Nowadays the participants develop both the bull robot and the bullfighter in the same robot (Fig. 5.). The bull robot has two pins in the front so it can attack the bullfighter, which has a balloon around itself.

The contest is as easy as trying to survive for several minutes the bull continuous attacks. It is also appreciated that the bullfighter gets near the bull instead of running ahead. As in real bullfights, the public will show white handkerchiefs at the end and the more they show, more points will earn the bullfighter.

III. CYBERTECH AS A CONTEST

As a contest, Cybertech is open to any UPM student who wants to participate and it is not needed to attend the subject. This makes Cybertech a really interesting event for the UPM as different faculties can try to win the contest. Nowadays there are students from Industrial Engineer, Computer Science, Aeronautical Engineer, Telecommunication Engineer and even, Agronomist Engineering participating in the contest as good as the Erasmus students. The contest normally takes place on Spring and lasts for two days. During the first day most of the events are held so on the second day only the participants who attend to semifinals and finals must come. It is done this way because the contest days are common school days so the participants must attend their lectures.

A. Cybertech International Contest

On 2008 there was a Cybertech International Contest in cooperation with BEST (Board of European Students of Technology) [12]. During one week 44 students from 20 European countries prepared robots for the bullfighting event. The students were grouped in teams of four people so each member in the team had different skills. The course's last day there was a competition between the teams to determine which one had done best.

IV. CYBERTECH AS A SUBJECT

There are two kinds of participants in Cybertech: the ones who only want to participate in the contest and the ones who are registered in the subject. These latter must attend a coursework that consists of four workshops.

A. Workshops

The workshops give the student a general idea about mobile robots. Each one of them takes almost four hours. The workshops are focused on how to develop a mobile robot for one or several challenges. During these workshops the students don't develop their prototypes; this must be something they do on their own so they can use their imagination.

During the first workshop, the students are introduced into several theoretical aspects of the subject such as microcontrollers, power supplies and how to program the controller. One of the most important things the students learn during this workshop is to solder electronic elements in PCB. They have to solder a motor control board which will be used in other workshops to control DC motors and in their final prototype.

The second workshop is focused on programming the microcontroller. Most students in Cybertech have never programmed before in C language, and none of them have programmed a microcontroller. It is then compulsory to explain how they can interact with the input/output signals.

Third workshop tries to give the students an overall idea on working with digital sensors and switches as well as how to control a DC motor. They must learn some common schematics to use sensors and how to filter the rebounds on the switch signal via hardware or software.

Fourth and final workshop is meant to introduce the students in the use of analog sensors. This can be a very wide field of study so they are only told how to use a specific sensor and how to measure the analog value in the microcontroller.

B. Tutorships

Once the students complete the workshops a tutor is assigned to each team. Usually a tutor has up to five groups of people during the year. The students must talk to their tutor regularly and tell him how they make progress. The tutor must answer all the questions the team could ask and depending on their knowledge he must encourage them to research more accurate solutions to their problems. When the team is made up of second degree people it is enough for them to achieve a

Figure 6. Workshop.

Figure 7. Team presenting their prototype.

working robot, but for last degrees it is common to ask them for better prototypes.

C. Presentations

All teams including a registered student in the subject must present their work in public. The presentation can't last for more than ten minutes and they must explain the main mechanical and electronic parts of their design.

As the presentations are done months before the contest, the teams are encouraged to present their robots as the best robots ever. It is also a way to make the teams work on their designs soon before the contest and consequently there are few last time prototypes in the exams.

D. Conferences

To improve the students' knowledge on robot systems, Cybertech organizes several conferences on different subjects each year. As an example, on 2008 there were three conferences on art and the relation with robots. During the conferences, severeral people showed how they could transform old computers and mechatronics into different sculptures or music instruments. In fact, we were glad to invite Carlos Corpa who showed how he and a Computer Science professor developed the poet robot PaCo. It was on 2005 when the most recalled conference was given by the Spanish astronaut Pedro Duque, who explained how different robots worked in the space. Since then, all the conferences are strongly recommended between the students, demonstrating how people are always interested in robots.

E. Exams and grades

Prior to the contest the teams have an exam in order to verify their prototypes. These exams usually are small events as the ones in the contest in which the participants must show that their robots are good enough to participate in the real events. The final grades are calculated as seen on equation (1). The most important result is the position in the contest (C), if a team wins the any of the events they are given top marks, but it is only needed to attend to obtain five points out of ten. The exam (E) and the presentations (P) have equal weights. Finally, the tutor (T) can give different grades to each team member depending on their work.

$$G = 0.5C + 0.2E + 0.2P + 0.1T \qquad (1)$$

V. THE ROBOTS

All the robots must be autonomous and no bigger than an A4 paper sheet in area (less than 30x20 cm). It can't also weight more than five kilograms. It is absolutely forbidden to use a commercial robot in the competition, so all the robots must be hand made by the students. Fig. 8 shows several robots developed for the Line Followers Challenge.

The only exception to these rules is the bullfighters. These robots are made with a commercial base given by the organization which includes a PIC microcontroller and several distance sensors.

All teams including any student registered in the subject are given a set of material so they can attend the workshops. The following explains all the components.

A. Arduino

The microcontroller used in Cybertech is Arduino Duemilanove [10]. This controller is very cheap and enough for the purposes of the subject and contest.

To control a couple of DC motors the set includes a commercial Motor Shield [11] for Arduino Duemilanove. This shield can handle up to two DC motors. The shield is unsoldered out of the box so the students must solder all the parts in the first workshop.

B. Sensors

The students are free to choose the sensors they want to use, but the organization gives them a CNY70 which can distinguish between black and white over flat platforms. These sensors are analog sensors so they can use them to practice with analog and sensors and then they learn how to turn it into digital information with a simple inverter.

The other sensor that is recommended but not given to the

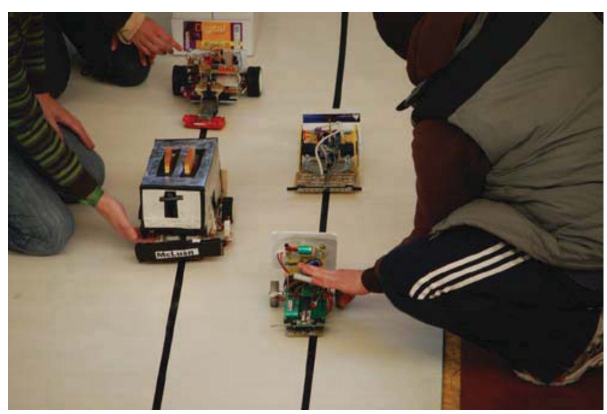

Figure 8. Line Followers Robots examples.

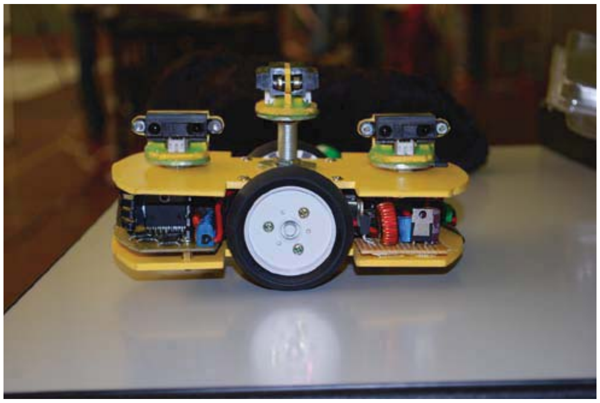

Figure 9. Robot developed for the maze event.

students is the GP2D12. This distance sensor uses IR and provides an analogical signal to measure the proximity of the objects. This can be very useful for line following participants so they can overtake without touching the opponent's car.

These sensor are widely used for the Maze event, for example, the robot shown on Fig. 9. has six distance sensors on it to detect the surrounding walls.

C. Others

The set of materials also includes different components as switches, leds, resistors and potentiometers. All this material is very useful during the lessons so the students can try different schematics and the interaction between the parts and the microcontroller.

VI. PARTICIPANTS

Since 2001Cybertech has had a lot of participants. Until 2005 there was no course related to the contest and, since then, the amount of participants has increased until 2008. The inclusion of the course resulted in the improvement of the prototypes and therefore a lot of rules had to be changed. As an example, the inclusion of obstacles in the line followers' track was done on 2006, making it impossible to win if the robots can't overtake them.

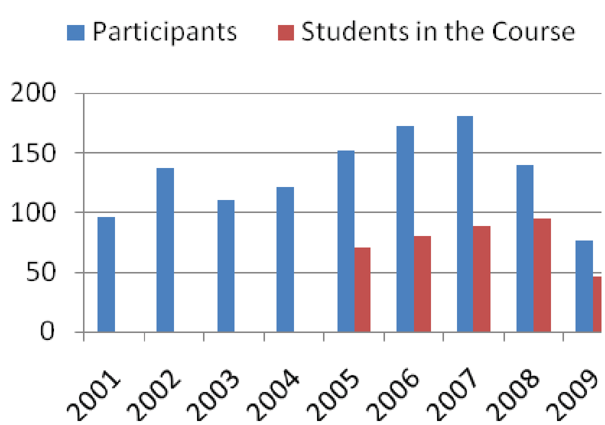

Figure 10. Number of Participant in Cybertech.

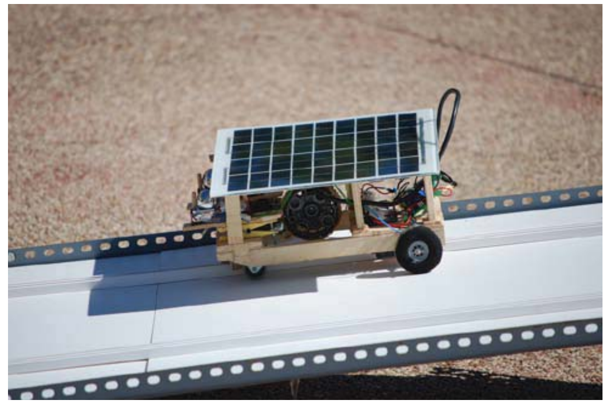

Figure 11. Solar Robot.

During 2009, for reasons beyond the organization responsibility, it was impossible to organize the contest until January so the amount of participants decreased considerably due to the few time to register.

The number of participants showed in Fig. 10 means that Cybertech is one of the most crowded subjects in Universidad Politecnica de Madrid. Every year there are more students from different faculties interested in participating and lately other universities from Spain has asked if it is possible for them to take part in the contest.

VII. UPCOMING EDITIONS

Right now Cybertech is preparing the 2010 contest and subject. On its tenth birthday the organization is willing to introduce several changes that will improve both the subject and the contest.

First of all, we are planning on an inheritance program so the teams that year after year participate in the contest will change the older members with new students. These teams are normally groups of people that registered in the subject when they were in the second degree and kept participating in the contest every year, improving their robots. It is our interest that when someone in the team refuses to participate in the next edition, the team can choose between several young applicants the new member of the group. These applicants should write a letter of motivation introducing themselves, explaining why they want to become the new team member and highlighting their skills.

On the second hand, the RoboSim event will be replaced with a Soccer League. This contest is based on the RoboCup Soccer Simulator [14] and it is intended to form groups that will be able to participate in the real RoboCup contest.

The reason why Cybertech is taking this decision is that we want it to be not only a Universidad Politecnica de Madrid contest, but a way to get to the big robot competitions that are held over the world as seen on section I.

VIII. CONCLUSIONS

Cybertech is a great opportunity for all UPM students. The participants have the chance to apply all the knowledge

Figure 12. RoboCup Soccer Simulator. [13]

acquired in their studies and to learn things that only the experience can teach.

Most of the participants undertake this kind of project for the first time in their lives and learn the importance of coordination between the team members, as good as to research solutions for real problems.

From 2010, the students that choose to participate in the Soccer League will probably have the opportunity to attend to the real RoboCup competition, as long as they prove their programs to be good enough for the contest. This is a great opportunity that will surely become Cybertech's best appeal.

Cybertech is also a chance for the students in the organization to learn several administrative tasks like how to organize a coursework. They also learn how important it is to obtain the funds needed to organize the events.

In future editions of the contest, it is possible that there will be an international event. It is the organization will to have a contest with as many foreign universities as possible participating in the bull fighter's arena.

ACKNOWLEDGEMENT

Cybertech has been funded by Sociedad de Amigos de la Escuela, Universidad Politécnica de Madrid and Caja de Ingenieros. The organization wants to thank their support.

Abstract. **There are two unsolved problems in the field of virtual learning environments: a set of new types of assessment is required for learning management systems (LMSs), and there is a need for a way to assess lifelong adaptive competencies. Proposed solutions to these problems need to preserve the interoperability, reusability, efficiency and abstract modeling already present in LMSs. This paper introduces a competency assessment data model (CADM) being developed as part of adaptive evaluation engine architecture (AEEA). AEEA is designed to solve the above-mentioned problems while fulfilling all quality requirements. The CADM is described with a data centric model using XML for each assessment scenario.**

Keywords: Competencies, Adaptive Assessment; Competency Assessment Process; New Assessment Types; Virtual Learning Environment.

I. INTRODUCTION

IMS question and test interoperability (IMS-QTI) [1] is an open technical e-learning specification to support the interoperability of systems and the reusability of assessment resources. Items and testing can be expressed and interchanged using IMS-QTI assessment. IMS learning design (IMS-LD) [2] is a specification for a meta-language which enables the modeling of learning processes, and is designed to express many different pedagogies. The activities to develop in a learning design can be expressed with IMS-LD.

In order to support new types of assessment in an e-learning process while preserving interoperability, reusability, efficiency and abstract modeling, new models to extend the current e-assessment specifications are required. In [3] and [4] a UML model is proposed to extend and combine IMS-QTI and IMS-LD specifications. [5] - [8] show how an outcome variable of a QTI test can be coupled to an IMS-LD property, and how assessment application tools can be integrated with IMS-LD as services. [9] and [10] propose the creation of a new layer over IMS-QTI and IMS-LD data, thereby establishing a new specification by building a high-level assessment process modeling meta-language. The LAMS project [11] is another kind of proposal based on IMS-LD and IMS-QTI specifications, but a totally new specification is being built to support a whole range of possibilities in e-assessment.

The development of lifelong competencies is a global tendency that uses the e-learning process to eliminate space and time barriers. This is the background against which new pedagogical models supported by new assessment process models are needed.

These two ideas were taken into account in [12] when adaptive evaluation engine architecture (AEEA) was proposed. AEEA is a competency-based adaptive assessment process for to judge the competencies of learners in a virtual learning environment. The process is supported by extensions for educational specifications and for integral user modeling. In order to implement AEEA, four data models must be integrated: a competency data model [13] and [14], a user model [15] [16] [17] [18], a competency assessment learning design model [19], and a competency assessment data model (CADM). The design of a CADM, which includes the entire data model for e-assessment scenarios proposed in AEEA (formative peer assessment, formative teacher assessment, self assessment and summative assessment), is presented in this paper. It is described with a data centric model using XML for each assessment scenario.

The assessment items metadata and the test metadata are based primordially on the IMS-QTI specification and complemented with XML data on the appraised competencies.

The paper is structured as follows: in Section 2 the relationship between competencies and e-assessment is described. In Section 3 an AEEA overview is presented. In Section 4 a competency data model, user model and competency assessment learning design are explained. In Section 5 the new competency assessment data model is proposed. In Section 6 conclusions and proposals for future work are laid out.

II. COMPETENCIES AND E-ASSESSMENT

Competency acquisition is the process through which people engage in activities or solve everyday problems in a professional or work context, through the joint exercise of three types of knowledge: know-how, knowing how to learn and knowing how to be, accompanied by critical awareness and the taking of responsibility for actions undertaken [20].

Competencies based on a virtual learning process join theory and practice, contextualize training, guide the organization of content and activities, promote comprehensive education (the three types of knowledge) and establish mechanisms for rigorous ongoing assessment based on performance in problematic situations in the relevant context (discipline, social, scientific, etc.). To address a competency acquisition process, LMSs need to transform their learning design and assessment methods.

To carry out a competency acquisition process the traditional summative assessment provided by an LMS must be complemented with other types of assessment. Formative assessment, self assessment, peer assessment and 360-degree feedback might all be considered. This information is stored within a portfolio assessment to obtain an all-round measurement of the level of competency acquisition.

- Assessment can be considered *formative* when the feedback from learning activities is used to adapt the teaching to meet the learner's needs or to encourage students to take control of their own learning.
- *Self assessment* is where students make judgments about their own work. Students critique their work and form judgments about its strengths and weaknesses.
- *Peer assessment* is student assessment of other students' work, both formative and summative.
- In e-learning *360-degree feedback* refers to feedback that comes from all the different actors around the student. The name refers to the 360 degrees in a circle, with the student at the center of the circle. Feedback is provided by subordinates (e.g., where the student is leader of a team), peers, and teachers. It also includes self assessment and, in some cases, feedback from external sources. Fig. 1 shows the relationships between participants in 360-degree feedback in e-learning.
- *Portfolio assessment* provides evidence of the learning process as an active demonstration of knowledge. It is used to evaluate learning processes and learning outcomes, as well as to encourage student involvement in their assessment, their interaction with other students, teachers, parents and the larger community.

During a course each type of assessment produces at least one outcome variable linked with some assessed competence. The set of outcome variables allows student classification. Based on this classification, an adaptive decision is made about changing the path and resources for students in their learning design. Fig. 2 shows the proposed competency acquisition run time process

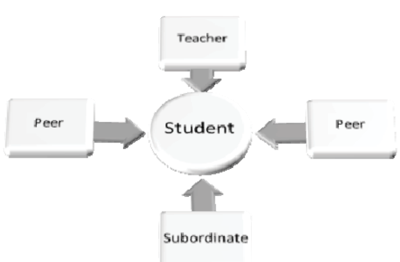

Figure 1. 360-degree feedback in e-learning

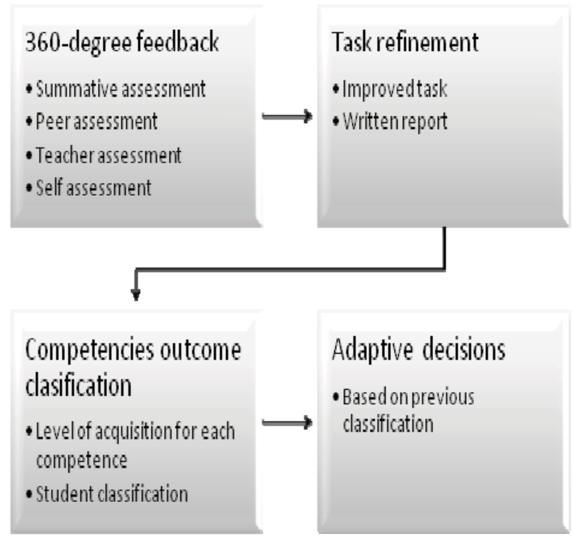

Figure 2. Competency acquisition run time process

III. AN AEEA PROPOSAL OVERVIEW

The main aims of AEEA [12] are: 1) to create an adaptive assessment structure in the learning design based on a definition of the competence element; 2) to build repositories of assessment items and tests with additional meta-information about the competencies assessed; 3) to build different, new, assessment engine software tools integrated within an LMS; and 4) to define a set of rules to drive learning design adaptations aimed at producing an adaptive competency e-assessment process.

AEEA is composed of two packages: an *Author Assessment Package* to support design time process steps and a *Monitoring Assessment Package* to support the run time process steps.

The first package proposed in AEEA, the *Author Assessment Package* (Fig. 3), covers the first three steps of an e-assessment process at the design stage:

- *Competency Assessment Plan Design*: to select the sequence of appropriate assessment types to demonstrate students' competencies; to construct and define decision rules and assessment policies for adaptation.
- *Items Construction*: to prepare items of evaluation in different assessment authoring software tools.
- *Tests Construction*: to build units of assessment for each type of assessment proposed in the assessment plan. The unit must assure the type and value of the expected response in the plan.

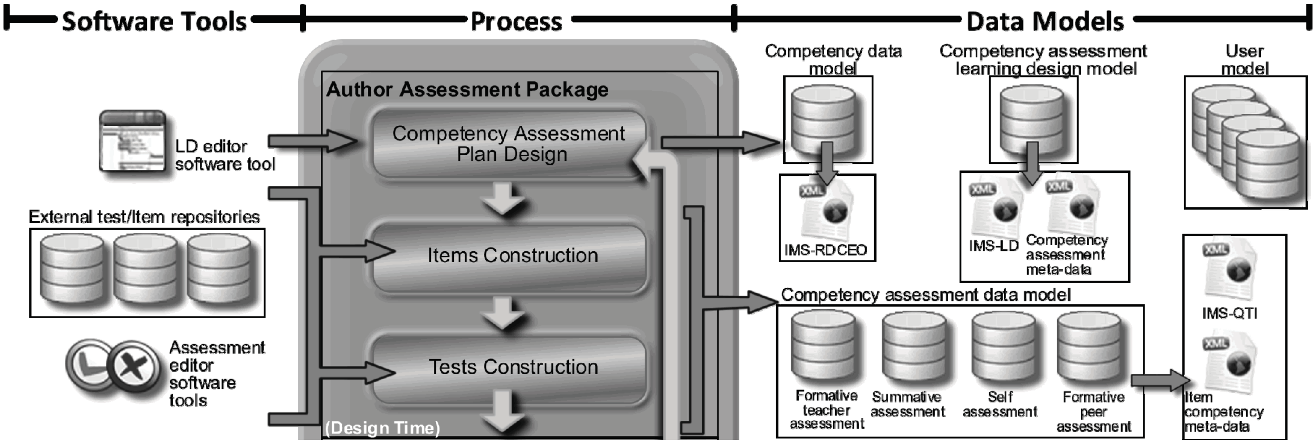

Figure 3. The Author Assessment Package of AEEA

Four data models are required for the implementation of the *Author Assessment Package*:

- *Competency data model:* this is a data model to describe the hierarchy of competencies, their characteristics and relations. Its basic specification is IMS-RDCEO [21].
- *User model:* this is a data model to describe a system user's relevant data, such as demographic information, learning style, background, etc. The basic specifications are IMS-LIP [22], IMS-AccLIP [23], and ISO-PNP [24].
- *Competency assessment learning design model*: this is a data model to describe the assessment plan and its adaptive rules. The basic specification is IMS- LD [2].
- *Competency assessment data model (CADM)*: this is a data model to describe e-assessment scenarios (formative peer assessment, formative teacher assessment, self assessment and summative assessment.) and students' results.

Three kinds of software tools are required for the *Author Assessment Package:*

- An *LD editor software tool* is used to configure the LD assessment plan where outcome variables of QTI can be coupled to LD properties.
- *Assessment editor software tools* are used to design assessment items and tests.
- *External test/item repositories* are used to store assessment items and tests.

In the *competency assessment plan design* step, an *LD editor software tool* is used to configure the *competency assessment learning design*. The *competency data model* and the *user model* are also set up inside this step.

In the *item construction* and *test construction* steps *assessment editor software tools* are used to define and to recover assessment item and test metadata from the *CADM* data model stored in the *external test/item repositories*.

IV. COMPETENCY DATA MODEL , USER MODEL AND COMPETENCIES ASSESSMENT LEARNING DESIGN

Some of the data models needed for AEEA were built by the BCDS research group before or parallel with development of the CADM.

The *competency data model* [13] [14] describes the elements of information that can be used to specify how a specific competence can be defined, developed and monitored in an LMS. The model was constructed through the analysis of different competency models and based on curricular design theories.

IMS reusable definition of competencies and educational objectives (IMS-RDCEO) is the language used to represent and exchange competency definitions. In order to implement the model proposed, a service for competency definition [25] [26] [27].was developed in dotLRN, a well-known open virtual learning environment

With a different research purpose, a complete *user model* has been developed [15] [16] [17] [18]. This model takes into account several different user characteristics and constructs a profile for each user.

The learning style profile is an enriched abstraction of Felder's categorization and is inferred through the application of his index of learning styles [28] to users. From the 44 questions in the Felder and Silverman approach considered as input, the user model is constructed as described elsewhere [29].

Two types of competency are inferred for the competency profile by analyzing the user's interactions within a number of LMS tools. Collaborative competencies are defined by analyzing the user's behavior in tools such as forums, chat rooms and e-mails. For specific competencies, three levels – novice, average and expert – are considered. These levels are related to one or more of Bloom's objectives [30].

The growing interest in mobile and ubiquitous systems has attracted researchers' attention to other dimensions of the access device profile, such as user location, physical environment, social context, and affective state. Our approach

[31] considers a number of characteristics of the user access device, in particular hardware features such as screen size and the capacity to show images, colors, and to reproduce sounds. It also considers software characteristics such as the mime types supported, character codification, availability of java and browse capacity such as the possibility of using frames, tables, java applets, and java script.

We have developed a number of projects to determine any special needs our users may have, such as learning difficulties and sensorial limitations.

The competency assessment learning design model [19] is achieved by inputting the user modeling and learning process specification.

So far, we have developed learning designs (LDs) in a deterministic way, using a competency definition and learning object metadata. The learning design generated is a cognitive but not a specific assessment design.

However, our ultimate aim is to enrich our work through the use of different retrieval algorithms and thereby increase the complexity and the specified level of LD generation and to facilitate the teacher's design task.

V. COMPETENCY ASSESSMENT DATA MODEL (CADM)

Learning management systems usually have a standard package for summative assessment. The CADM proposal therefore focuses on the development of data models for the other three types of assessment (formative peer assessment, formative teacher assessment and self assessment).

XML schemas describe, with a high level of abstraction, the structure of and restrictions on the contents of XML documents in a very precise way, beyond the syntactical rules of XML [32]. Different XML schemas are proposed in a CADM to provide the extensibility, interoperability, reusability; efficiency and abstract modeling required for the new data model. These XML schemas become an extension of the IMS-QTI specification used for summative assessment.

For each new assessment scenario, a CADM proposes two XML schemas, the first to represent assessment items and the second to represent tests. The scenarios and schemas are explained below. The schemas are shown as tables (for space reasons) emphasizing their most significant elements.

A. Schemas for formative peer assessment

Formative peer assessment (FPA) can be developed in three modalities: *individual,* when students complete their assignments alone and other students on the course peer review their work; *intra-group,* when the students work on a collaborative task in groups and each member is judged by the others; and *inter-group,* when the students on a course are divided into subgroups to carry out a task and the peer review of one group is performed by another. FPA schemas need to allow for data modalities to be set up.

The actors in this scenario are the teachers who direct protocol evaluation as e-moderators, the peer reviewers and the learners. FPA schemas need to allow for grants to be set up for these participants.

[33] suggests that to be successful, the peer evaluation process should first involve students in a discussion of the rating scale and the construction of the evaluation form. After this, the peer review can be done. As a final step, learners make changes to their work and write a report justifying the changes accepted and those rejected. This means FPA schemas should allow a rating scale to be set up and assessment items on the evaluation form to be enabled or disabled. [34] declares that peer forms must contain rich, detailed, qualitative feedback information about strengths and weaknesses, and not merely a mark or a grade. The schemas should also allow rating data and comments about strengths and weaknesses to be saved. Rating data are defined using a rubric to score the quality characteristics of the evaluation items.

Table I presents the characterization of the elements and sub-elements of the schema for FPA items and Table II presents the characterization of the elements and sub-elements of the FPA test schema.

B. Schemas for formative teacher assessment

Formative teacher assessment (FTA) must take place for all tasks on which students are assessed, so it could be carried out for individual or collaborative tasks. Assessment items represent quality characteristics linked with a level of competence acquisition. A rubric score is stored for each assessment item.

Table III shows the characterization of the elements and sub-elements of a schema of TFA items and Table IV shows the characterization of the elements and sub elements of a TFA test schema.

C. Schemas for self assessment

Students take a short test to assess their interests, skills, abilities and competencies in every task. Assessment items are linked with competencies and qualified with a general rubric score.

Table V shows the characterization of the elements and sub-elements of the item schema. Table VI presents the characterization of the elements and sub elements of the test schema.

TABLE I. ELEMENTS OF THE SCHEMA FOR FPA ITEMS

<quality_characteristic> <title> <description> <competence_knowledge> <competence_context> </quality_characteristic >	This describes a quality characteristic that can be evaluated in a student's work. Each quality characteristic is linked with a competence.

TABLE II. ELEMENTS OF FPA TEST SCHEMA

<modality> <type></type> <number reviews> <anonymous> </modality>	This describes the type of modality, number of peer reviews and a Boolean element to say whether the learner can know their peer reviewers or if the evaluations are to be anonymous.
<outcomes> <outcome> <name> <value> <competence-id> </outcome> </outcomes>	This describes the outcomes of the assessment. Each outcome is linked with a competence.
<grants> <teacher></teacher> <peer></peer> <learner></learner> </grants>	This describes each actor's or user's grants at the FPA interfaces. It determines whether a user can insert new items or areas of assessment, vote on items to include in the form, make a review or read results.
<rating scale> <min-value> <max-value> <number categories> </rating scale>	This describes the rubric score applied to assessment items. The rubric score is defined with the minimun value, the pass value, the maximun value, and the number of categories.
<items> <item> <id></id> <path></path> <weighting> <grade></grade> <item> </items>	This describes the set of items linked with an FPA test. The items are quality characteristics evaluated with a scoring rubric and a percentage weighting.
<strengths> <comment> <peer-reviewer-id> <notes> </comment> </ strengths >	This describes the reviewer's comments regarding strengths in the evaluated work.
<weaknesses> <comment> <peer-reviewer-id> <notes> </comment> </weaknesses>	This describes the reviewer's comments regarding weaknessess in the evaluated work.

TABLE III. ELEMENTS OF A SCHEMA OF FTA ITEMS

<quality_characteristic> <title> <description> <competence_knowledge> <competence_context> <rubric1-info></ rubric1-info> <rubric2-info></ rubric2-info> <rubric3-info></ rubric3-info> <rubric4-info></ rubric4-info> </quality_characteristic >	This describes a quality characteristic that can be evaluated in a student's work. Each quality characteristic is linked with a competence. The description of the rubric score scale is saved within the item.

TABLE IV. ELEMENTS OF A FTA TEST SCHEMA

<task> <type></type> <name></name> <task-id></task-id> </task>	This describes general data on the task: type of task (individual or collaborative), name and task identifier.
<outcomes> <outcome> <name> <value> <competence-id> </outcome> </outcomes>	This describes the outcomes of the assessment. Each outcome is linked with a competence.
<grants> <teacher></teacher> <learner></learner> </grants>	This describes the grants for each actor or user at the interfaces of TFA. It permits defining if a user can insert new items or areas of assessment, vote on items to include in the form, review or read results.
<items> <item> <id></id> <path></path> <weighting> <grade></grade> <item> </items>	This describes the set of items linked with a FTA test. The items are quality characteristics which are evaluated with a rubric score and a weighting.
<strengths> <comment> <teacher-id> <notes> </comment> </ strengths >	This describes the teacher's comments about strengths in the evaluated work.
<weaknesses> <comment> <teacher-id> <notes> </comment> </weaknesses>	This describes teacher's comments about weaknessess in the evaluated work.

TABLE V. ELEMENTS OF SELF ASSESSMET ITEM SCHEMA

<quality_characteristic> <title> <description> <competence_knowledge> <competence_context> </quality_characteristic >	This describes a quality characteristic that can be evaluated in a student's work. Each quality characteristic is linked with a competency. The description of the rubric score scale is saved within the item.

TABLE VI. ELEMENTS OF SELF ASSESSMET TEST SCHEMA

<task> <type></type> <name></name> <task-id></task-id> </task>	This describes general data on the task: type of task (individual or collaborative), name and task identifier.
<outcomes> <outcome> <name> <value> <competence-id> </outcome> </outcomes>	This describes the outcomes of the assessment. Each outcome is linked with a competency.
<grants> <teacher></teacher> <learner></learner> </grants>	This describes the grants for each actor or user at the interfaces. It permits defining if a user can insert new items or areas of assessment, vote on items to include in the form, review or read results.
<rating scale> <min-value> <max-value> <number categories> <rubric1-info></ rubric1-info> <rubric2-info></ rubric2-info> … <rubricN-info></ rubricN-info> </rating scale>	This describes the rubric score applied to assessment items. The rubric score is defined with a minimun value, a maximun value, the number of categories and their descriptions.
<items> <item> <id></id> <path></path> <weighting> <grade></grade> <item> </items>	This describes the set of items linked with the test. The items are quality characteristics evaluated with a rubric score and a weighting.
<strengths> <comment> </comment> </ strengths >	This describes students' own comments about strengths in the evaluated work.
<weaknesses> <comment> </comment> </weaknesses>	Ths describes students' own comments about weaknessess in the evaluated work.
<findings> <comment> </comment> </findings>	This describes students' own comments about findings in the evaluated work.

VI. CONCLUSIONS AND FUTURE WORK

Assessments play a significant role in the competence acquisition process and there is a clear need to run interoperable and adaptive competence assessment tests in LMSs. The traditional summative assessment of LMSs must be accompanied by other types of assessment. Metadata about assessed competencies must be defined and monitored throughout the e-learning process, and therefore the competency data model, learning design and assessment must work together.

In this paper a competency assessment data model is proposed as part of AEEA implementation. Three new types of model are proposed (schemas for formative peer assessment, formative teacher assessment and self assessment) as an extension of the IMS-QTI specification. Competency data are introduced in assessment items and test metadata. Other research is integrated to implement the author assessment package of AEEA.

Our work is now focused on the first package of AEEA implementation, in particular on developing assessment editor software tools, the integration of a competency data model with competency learning design and a CADM, and also on preparing assessment items in different repositories.

For the future, we plan to implement assessment software tools such as dotLRN and Moodle services and provide proof of the design-time architecture.

On Education Quality Control Issues for Sino-France Hybrid Engineer Diploma

Jin JIANG, Ling ZHAO, Jinwu QIAN, *IEEE Member*
Sino-European School of Technology of Shanghai University, 200444, Shanghai, China

Abstract—**Quality control in higher education is a complex social key project fostered by the Chinese government. As a sino-foreign cooperation school in engineering, we are focusing more intensively on quality control in higher engineering education. Sino-European School of Technology of Shanghai University (UTSEUS) was established by Shanghai University in cooperation with University of Technology Network (France) in 2006. Dual-campus education program has been introduced to UTSEUS ever since: two years of campus life in China, and the next two years in France. Challenges on the program designs, the teaching modes, the teaching strategies, teaching quality control and teaching collaboration have been updated accordingly concerning the different educational systems we have in China and that in France. With monitoring the dual-campus engineering education, several approaches have been introduced to the quality control of higher engineering education in UTSEUS.**

Keywords- quality control, Sino-European cooperation, dual-campus teaching, teaching assessment system.

I. INTRODUCTION

With our knowledge broadening continuously in the ever-changing 21st century, the problems that we are dealing with have also become ever more complex.

Driven by the economic globalization, the world's need for engineers with an international background is accelerating in the multinational enterprises (MNE). To answer the call of the times, we feel the urge to nurture our engineering majors with a global and innovative mind, which is also the trend of internationalization of higher engineering education in China. In 2006, UTSEUS was officially established by Shanghai University (SHU) with University of Technology Network (UT) of France—University of Technology at Compiegne, at Troyes and at Belfort (UTC, UTT and UTBM). Accordingly, preeminent professors and courses were introduced to UTSEUS from France in order to answer the call of globalization.

It is widely known that engineering education is shifting itself from mere technology education to research education. Teaching method patterns in Shanghai University are in the transition from instructional-based to research-based. Through the study of the model and experience employed by the UT groups, the practice on teaching modes, teaching strategies, teaching quality control and teaching collaboration in dual-campus engineering education system utilized by UTSEUS has been implemented. This paper is to discuss how to manage the quality control in higher engineering education and what UTSEUS has accomplished so far in this field.

II. QUALITY CONTROL IN HIGH INTERNATIONAL ENGINEERING EDUCATION

More and more universities have realized that mastering the techniques is not enough for the engineers of 21st century. It can be a niche for them to comprehend corporate management and the social culture as well.

Our engineering majors should be able to design and practice with a global and innovative mind. International engineering education with a dual-campus system is popular worldwide. Therefore, it is important to find effective approaches to control the educational quality under such system, which is the preoccupation and priority for our international engineering school to design a appropriate program.

Considering the massive and growing market yearning for engineers with an international background, the universities need to adjust their teaching methods. Nevertheless, what key characteristics should such an engineer possess?

In 2001, the United States National Academy of Engineering (NAE) and the United States Natural Science Foundation (NSF) co-sponsored the "2020 Engineer" program. By the end of 2004, the program issued its 1st official report on "2020 Engineer: The vision of engineering development in the new century"; in 2005 summer, they released the 2nd formal report on "Training of Engineers in 2020: engineering education to adapt to the new century" These reports analyze the engineering practice, the technical, social, professional, international backgrounds and etc, which describe in detail the expectations and characteristics of the future engineers.

Engineers in year 2020 should have analyzing capability, practical experiences, creativity, communication skills, business and management expertise, leadership, ethical consciousness, and life-long learning desire. The report describes a qualified engineer for our teachers, employers and students.[1]

With the continuous development of higher engineering education, the traditional mentoring educational model has been replaced and the elite training model has also been diluted. Nowadays, the higher engineering education is available to larger population of students. Meanwhile, the need of the enterprises for elite professionals is on the rise. Considering all the previous aspects, higher engineering education and its reform must be monitored in light of quality control with its evolving management models and tools.

In the traditional method, quality control is to "discover talents and enable them to maintain excellence".[2] Faced with such massive demand of professional engineers, we feel it our responsibility to cultivate the qualified engineers that will meet the need of the industry and ensure every step in the teaching process with the quality control system. Numerous research projects on Quality Management in Education (QMIE) have been carried out by those prestigious universities renowned in engineering, such as the "CSE model" by UCLA (University of California, Los Angeles). But it is difficult for a school with dual-campus system to control the quality in education via the traditional approaches. It is beneficial for us to learn from the industry in order to update our approaches of quality control. Total Quality Management (TQM) is the most intensive means in quality control. TQM system is based on the information integration technology, takes combination between quality control and quality management as main principle, and fulfills enterprise's long-term operating strategies finally.[3] And thus, it can be an appropriate quality control approach in international engineering education.

According to the essence of every TQM approach, we can find the corresponding approaches in quality control at different stages of the quantitative management in education, which includes control of pre-teaching design, teaching process control, and teaching quality assessment.

III. Control of each teaching phase

A. Control of pre-teaching design

During the stage of pre-teaching design, the priority is to design the appropriate teaching program and curriculum planning.

Teaching program is the blueprint in assisting the achievement of the basic goals and specifications of education. The gist is the implementation of program with specifications of monitoring and evaluation in quality of education. Therefore, it is ideal to have a team of experts to monitor the quality of design and practice of the teaching program.

The evaluation of the programs in the University of Massachusetts presents a type of quality control in terms of teaching design. They put forward several points concerning quality control of the programs as follows: (1) How does the professional guide the content of programs; (2) Does teaching scheme meet with contemporary needs; (3) Whether the structure of the programs is logical, sequential, and coherent. How about the field operations, test operations, seminars or other large-scale operations and so forth help students acquire and integrated what they learned? (4) Does programs really enable students properly to prepare further study or employment?[4]

At UTSEUS, four majors are tailored with their own teaching programs respectively. Given the four-year program, it is urgent for us to adjust the program to meet the growing need from the market and retain the quality as well. Having carried out a survey in a large scale with the assistance of the cooperative school in Shanghai University and the prior four-year experience, we feel even more confident in reforming the program of mechanics to start with. Since the undergraduates with engineering backgrounds are popular amongst the enterprises, the teaching program has been reformed or changed according to these needs. With the two-year reform in teaching program of mechanics, our students not only have more access to practical training, but also refresh their understanding with the major.

Curriculum planning is the detailed part of the teaching program, which should be designed by specialists as well.

In the process of designing the teaching program and the curriculum planning, the first step of TQM is fulfilled. The criterion of education quality control is confirmed. Accordingly, the top-down structure for TQM can be devised with the criterion.

B. Control of teaching process

With the dual-campus system, the students in UTSEUS first spend three to four years studying in China, and then, they can choose to study another two years and a half in France in order to attain the engineering diploma or two more years to gain a master degree there instead. Due to the different educational systems between the two countries, divergent teaching processes are therefore lied between the Chinese and French professors. The cooperation courses in UTSEUS will be helpful to students to adapt to the model of engineering education in France. On that account, in UTSEUS, there are approximately 17 courses taught by French and Chinese teachers in the whole learning package .

Considering the two nations' different teaching models, it is important to find more effective approaches to practice quality control in education during the teaching process. By analyzing the four-year practice in UTSEUS, it is clear that the people are the key factors in quality control in such teaching model. As it is emphasized in TQM that everyone in an organization should support and participate in the quality control procedure which is carried out in the organization. The first step of quality control in teaching process is to have all the teachers and students realize the importance of implementing TQM in the teaching process. If each teacher participates in the quality control of the teaching process, it will be a good opportunity to form a standard procedure for cooperation course in dual-campus.

French professors are not able to carry out their long-term teaching plans in UTSEUS because of the short-semester practice in the Shanghai University. As a result, a team of more experienced French professors are formed. The courses taught by them are thus carried out. The question is, how to assure the quality of teaching process with such a team? First of all, we have an experienced French professor to be the head of the teaching team. He will find and organize his teaching team. The object and the quality of the course depend on his design. In order to keep the teaching process effective, the teaching team is composed of several French professors and one to two Chinese professors. It is also the team head's responsibility to keep all the team members communicating effectively and efficiently. According to the different teaching methods and teaching concepts between the Chinese professors and the French professors, the division of teaching part of Chinese and French professors will be well planned approximately one year prior to the commencement of the course. Although each professor teaches one part of the course during the teaching process, the joint content is designed and monitored by the team head. This structure of teaching team and course design is practicable in the teaching process of the dual-campus, which can also sustain the teaching quality on an average level.

Then how to improve the quality of such course? We need the help from our students and advanced information techniques. Considering the characteristics of teaching in dual-campus, we designed a platform called "open-course-ware" to assist the teaching team to improve teaching quality. On such platform, students can present his problem and put forward his suggestion to the teaching team. It will help the head teacher of the team adjust the course to benefit the students in time. Then there will be good effect at the end of the teaching process. Of course, the effect of the course will be measured by a evaluation survey. The traditional evaluation on teachers is replaced with the evaluation on courses. The results of course evaluation are the reference to the academy and the teachers.

There are still a lot of courses only taught by our Chinese teachers in UTSEUS. These courses are within the framework of teaching managements in Shanghai University. Experienced professors in Shanghai University will evaluate the teaching process of specified course occasionally and submit their opinion by reports. The same evaluation standards are applied to the courses taught by Chinese teachers.

Therefore the teaching process quality control in dual-campus should focus on the approaches of motivating both teachers and students. The teachers should design an efficient method to organize the course. And it is important for them to teach with an open manner and positive attitude.

C. *Evaluation of teaching quality*

We can evaluate the quality of teaching by two methods: evaluation of students and evaluation of curricula.

a) Evaluation of Students

The evaluation of students can also reflect the quality of our education. Our purpose is to develop high quality engineering, so our evaluation of students must be suitable to this purpose. By traditional method, we evaluate students by their absolute score in the examination. It may reflect how many contents students have mastered and how well they master the knowledge. But its reflect-function depends on that the exam is normative, rational and has reasonable difficulty. Moreover, the absolute score can not reflect the student's location in the course. Students may focuses on refining results excessively. This is not the characteristics of a high quality engineer.

In UTSEUS, we have introduced European Credit Transfer System (ECTS), which is a relative score evaluation system, to reform the traditional evaluation. Through using ECTS, we can efficiently overcome the disadvantages brought by the absolute score system. It will help us to encourage students to compete healthily, promote them to improve their studies continuously and let them develop their self-learning ability.

Based on using both absolute score and ECTS, we adopt an all-round evaluation model to evaluate the students' academic situation. In reference to the absolute score and ECTS of students, we establish a mode of communication called "assessment conference". In this conference, we analyze students' learning comprehensively, assess their academic achievement and pay more attention to their development in the future. And the most important focus we consider is the trends of students' learning.

With four-year practicing, 63% of our first students have finished their 3-year studies in UTSEUS and gone to France for their studies for Engineering Diploma.

b) Evaluation of Curricula

Evaluation of teaching at universities is traditionally realized in terms of student ratings. Curriculum evaluation is rarely done in a systematic manner. More often, the emphasis is placed on a particular aspect, which is only of little help in terms of modifying education. Christine Spiel introduces five phase of evaluation to be considered and contrasting results to others. The first and the concentrated phase is the baseline evaluation. Especially, while a course is under reformation, the evaluations of it should primarily focus on new curricula by contrasting it to traditional ones. [5]

UTSEUS has learned the experience and method from UT groups, and established our own method evaluation of curricula. With traditional evaluation, students will give a course or a teacher a grade to evaluate its teaching quality. Considering our own characteristics, we have a teaching group working on the course, it's not reasonable to value one teachers on one course. So we concentrated on the course itself. We have the students to fill a form, which is about the course, including teaching method, teaching content, and the detailed feeling about the course by students, etc. With the result of this form, we can learn the general information about the quality of this course. By collecting the information and suggestion given by students, we can analyze the reformation of the course and suggest the teaching group to adjust the teaching method. By means of evaluation, several courses have improved its teaching effect obviously, and our cooperating colleagues will be much more glad to teach and do reform in UTSEUS.

IV. ADVANCED INFORMATION TECHNIQUES

A. *System Architecture*

An online education assessment system is under development. The system was initially designed as PHP + MySQL architecture, but due to the database of UTSEUS is not a completely independent system, which relies on the raw score provided by Registry office and basic personal information provided by student's affair office of Shanghai University. In order to share the public information platforms of the campus and reduce the maintenance cost of infrastructure of data and database server, the database was migrated to the Microsoft SQL Server solution.

There are views and stored procedures running on the SQL server for complex computing tasks, reducing the data exchange between database and application server to improve network performance and reducing the complexity of application development, applications and end users to focus on aesthetic interaction and a clear presentation of data.

A flash library named as “The Open Flash Chart” is being delivered by LGPL. It can be a graphical front-end display of statistical data. The database statistical data is read by PHP and the OFC class library transfer output data into a JSON (JavaScript Object Notation) format, sent to the open-flash-chart.swf object, it can draw a lot of kinds of charts on-line output.

A Moodle site is set to provide e-learning services in UTSEUS. The Moodle system is an open source software based on PHP. The low layer libraries of Moodle are well developed, it includes classes and functions covered database abstract and User managements. The base codes can be reused in new software development. The applications integrated in moodle seamlessly with the benefits of mature user authorities and privileges mechanisms. By modify some core codes of Moodle we made it fit the education activities of UTSEUS well.

B. Applications Oriented to Quality Control

Figure1 is a transcript of a student in UTSEUS, a self-developed program convert a Shanghai University Score System to the ECTS and GPA system. On this page, a GPA performance chart is given to show the trend of a specified student, progress or retrogress.

Figure.1 Transcripts

Figure2 is Zoom of GPA performance chart. The green dot-line is semester GPA, the red dot-line is final GPA and the blue dot-line is French course GPA.

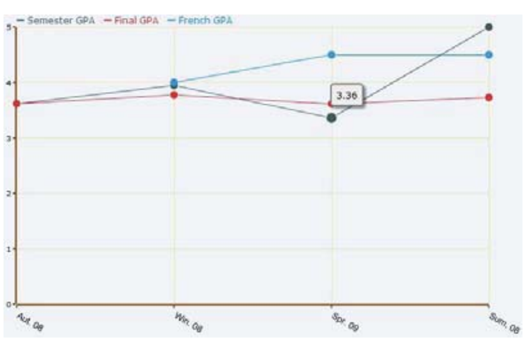

Figure.2 Zoom of GPA performance charts

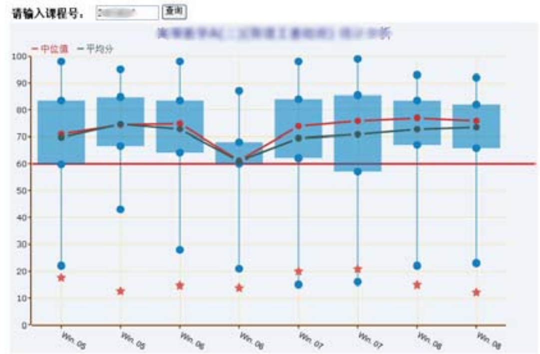

Figure.3 Box Plot for course quality analysis

Box plot, also known as box-line diagrams, is a box and two line segments graphics indicated by five eigenvectors which include maximum, minimum, median and two quartiles. "Single course quality analysis map", highest point of each box is a specific the highest score of the exam when a semester is over, the next point is the student who in the top quarter, the third point is the score in the top three quarters, the lowest point is the lowest score(except 0)of the test (lots of reasons not directly associated with learning level cause 0 point such as absence of test, cheating, so 0 point is not included in statistics), the red dot is the median value that means the score of half ranked score of the exam. The box is the distribution of the middle half ranked score. Box plot graph characterizes the distribution of results, in general, a large dispersion implying a no good quality of education. Formula for the overall standard deviation formula is as follows

$$\sigma=\sqrt{\frac{\sum_{i=1}^{n}(x_i-\bar{x})^2}{n}}$$

The standard deviation can be more precise to describe a number of discrete levels of data, and its unit is the same as the input data; The asterisks in lower part of the chart is the standard deviation of the exam results. Visual comparison in a box plot diagram, with a large polymerization there’s a small standard deviation, and on the contrary with a small polymerization there’s a large standard deviation. The second box-plot reflects the desired result of a exam (Calculus of winter semester in 2005) with high average and low dispersion; the sixth box-plot (exam result of Calculus in winter semester, 2005) indicates poor quality of teaching with even the box of middle ranks crossing the pass line and the difference of the highest score to the lowest is large and the overall dispersion is large. When the mouse moves onto each box, the teacher’s name and related information will be shown in a float label.

Figure 4 is a final GPA of all grades in subparagraph (>= 3 and< 2.5) percentage of charts, dashed line for the French course GPA. Figure.5 is a specific semester GPA for all grades compared, each column is a grade. The information system gives these charts automatically. Statistics and data mining is an emerging field, new methods and new techniques emerging, In future research, more statistics and analysis of score will be integrated into the system.

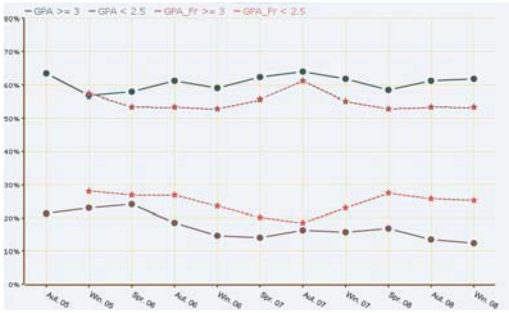

Figure.4 A specific grade divided by the cumulative semester GPA Analysis

Figure.5 A specific sub-semester GPA for all grades compared

To analyze the relationship of studying in China and in France, Pearson correlation coefficient is introduced. For the score data are continuous and approximately normally distributed, fit the condition of Pearson coefficient. The result is the Pearson coefficient is around 0.4~0.5. The significance is 0.01 that means the result is acceptable.

V. CONCLUSION

The quality of engineering education is the most important support for an engineering school. As a sino-european engineering school, we have the duty to do well in quality control of our engineering education. Since there are so many aspects in the quality control of education, the first thing we try to do is to design a schedule and blueprint to guide our efforts in this job. As is said above, we have some successful experience in evaluation of students and curricula. It's time to synthesize the evaluation method to integrate into a general system. It's a long-term work to design a perfect culture program. But we have to determine our standard about the evaluation of the program, and then we can do a good job in designing and reforming the culture program. On above topic, we do the quality control on the whole procedure of teaching and have got successful experience in evaluation stage. In the future, the teaching process quality control may be the second emphasis to improve. While we have the clear and determined goals (programs) of education, we should do the quality control in teaching process (including teaching method, teaching standard, etc.), and when the course finished we can use the evaluation of students and curricula as a feedback system to our quality control system.

Statistics and data mining is an emerging field, with new methods and new techniques emerging. In our future research, more statistics and analysis of score will be integrated into the system.

ACKNOWLEDGMENT

This research is jointly Sponsored by the Educational Quality Program from Shanghai Education Commission (Education Highland Project).

***Abstract*. - This is a report intended to describe a research about assessment of learning activities done in a virtual forum. Student's messages in the forum as a whole were considered as analysis unit. It was employed a content analysis technique to identify characteristics involved in the messages. Categories and indicators for analysis were defined from the Community of Inquire Model, adapted specifically for mathematics courses. Examples selected as a guide for learning activities assessment are shown, in terms of number and type of participation, as well as result from linear correlation analysis between numbers of participations to each category.**

***Keywords*.- Inquiry community, social, didactic and cognitive categories.**

I. Introduction

Interaction in virtual forums has been studied by several researchers. They have analysed different aspects of interaction [1, 2, 3, 8, 10, 12, 14]. To consider knowledge construction caused by students interacting in forums is a methodology for making inferences by sistematically and objectively identifying defined characteristics in the messages. Van Diijk analysis [12] includes considering the quality of language employed, beliefs that arise in social interaction. Everyone's contribution bears an own meaning and must be considered individually.

A remarkable method is the codification method proponed by Henri [8]. Accordingly, there must be distinction between participation and interaction categories, because number of participations is not a valid indicator to verify quality of interaction. Anderson, Garrison and Rourke [1, 5, 11] have developed the Community of Inquire Model to analyze interactions and learning processes in virtual forums, which is consistent with the constructivist proposal for learning.

II. Community Of Inquire Model

For this model it is supposed that the learning process is integrated by three central components: Social, didactic and cognitive dimensions.

Social dimension is defined as student's skill to communicate social and emotionally into the learning community by means of messages; with those messages students build personal relationships, settles affective communication and develops social ties, and so there is an environment necessary for the group to feel safe for open communication and behold around common goals.

Didactic dimension deals with designing, facilitating and guiding social and cognitive processes, intended to achieve meaningful learning [1].

This dimension can be seen in the forum as messages between teacher and students to accomplish the course goals, which means to decide about resources, programs, study guides, methodology, contents, discourse, activities and deadlines. As course designer, the teacher inherits a key role, but it must be taking into account that in a course with constructivist approach responsibility is not exclusive for her/him.

According to Anderson [1], contributions to this category may surge from anyone collaborating to implement the didactic role.

Cognitive dimension. Garrison [7] defines cognitive dimension as the level to which students are able to construct and confirm meanings through reflection and dialogue within an inquiry community.

This dimension is based on critical thinking which could be understood as a process, as well as a result. As a product it refers to acquiring deep and meaningful understanding, which is perceptible in the different assignments elaborated by students. As a process it is considered that critical thinking acquisition may be enhanced by understanding how it is accomplished.

It is important that in this research the term "category" instead of " dimension" or "presence", as used by Marcelo [10] and Anderson [1], correspondingly.

III. Methodology

The need for original indicators was perceptible when first trying to categorize the messages put into the forum, according to the definitions made by those authors and found several situations not included in. Therefore it was generated a first set of original indicators, to try a new scale to categorize messages submitted to the forum.

Considering this new scale, indicators were redefined, in a way that the new set of indicators was suitable for two consecutive categorizations that produced same results. For each indicator, significant samples of text were collected.

The content of each message submitted to the forum was analyzed according to the previously defined indicators. When there were found one or more indicators, then it were considered that the message contained a collaboration of the type of the indicator and so it was counted. A message might include only one category indicators or two or three categories simultaneously.

IV. RESULTS

An important part of the study was adapting the Community of Inquire Model to the specific characteristics of the selected course. In Tables 1, 2 and 3 defined indicators for each category are shown, as well as significant samples of text, taken as guiding examples in the categorization (Note: Phrases in tables 1, 2, 3 are taken literally from messages submitted by students to the virtual forum. S.A., V.C., C.T. and J.C. are the initials of students' names).

TABLE I. INDICATORS TO CATEGORIZE, AND EXAMPLES OF SOCIAL CATEGORY

Social Indicators	Examples
Expressions about emotions, feelings and moods.	"Welcome fellows, I'm happy to work with you" "… I feel stressed because S.A. does assignments pertaining to future and gets parts that do not belong to him"
Jokes, irony, sarcasm or mockery expressions.	"You can't stand against women. I agree with you!!! (Just kidding!!!!)"
Comments about aspects not related to the course, as everyday life, personal communications.	"My computer is in trouble and I'm working in a public facility" "Do you know when are we having the i.d.'s to obtain books from the UDG library?"
Support, appreciation, recognition, grateful, displeasure and apology expressions.	"If is there any question from the assignment that you consider that I may help you, I'll do it with pleasure". "I'm sorry, I faced problems with my computer"
Comments not related to course contents.	"If you don't notice until now, we are the only team that has send assignments to the folder in the platform." "You may purchase online the Pita Ruiz book at Santa Fe book store"
References to other classmates' messages or assignments.	"... that is why V.C. says: We first rewrite..." "The J.C.'s answer may help to solve the problem." "...on exercise 1 I agree with J.C...."
Using classmates' first name to address them.	"C.T., I already have checked the exercises you send."
References to the Group, using expressions as we, ours, our Group, classmates.	"...we have to put together our parts to conform just one document for the assignment..." "My fellows, my proposal is..."
Etiquette of Communications, greetings, welcomes, farewells, etc.	"Hi everyone" "Please install..." "Greetings"

TABLE II. CATEGORIZATION INDICATORS AND EXAMPES OF DIDACTIC CATEGORY

Didactic Indicators	Examples
References to program, work methodology, assessment criteria and deadlines to submit assignments.	"To sustain your messages and answers you must define and interpret the concepts involved..." "Write formulas with the equation editor" "The limit to deliver assignments 1 and 2 is the 19.02.07."
References to platform, or available resources.	"Please install the Skype program..." "...how do you put the vertical line in the augmented matrix when in the program...?" "Please consult the study guide …"
Agreement or disagreement expressions about assignment of activities.	"Hi, I agree." "I don´t agree with that …I told you I was to do exercise 1"
Expressions to direct dialogs and activities to achieve course objectives and learning construction.	"Hi Partners: What is the strongest argument to solve an equation system?" "It's necessary further work for assignments 1 and 2 because there are several failures..." "In problems … matrices are second degree and in …,third degree, therefore it would be convenient distribute them so that you every one receive a problem from each first and second parts"
References to contents, tutoring and questioning.	"In general, the number of transpositions depends of …" "What's the use of permutations parity and product of substitutions?" "Te concepts permutation and substitution are basic for learning the concept of determinant."
Requests and judgment expressions about own or other's work.	"Excellent answers." "Your explanation is quite complicated". "...in order to clarify your conclusion it would be good to indicate that parameters ann and b are different of 0."
References to additional information sources.	"The teacher put in the home page some tips … so we can put in just one format the assignment" "see examples in the adjunct file" "... it was consulted in the editorial Alianza book, and the researcher familiar matrices..."
Comments about development and completion of assignments.	"I'm sending you what I have done about assignment 2..." "... yesterday I didn't send the assignment, but for sure I'll send it today." "...I suggest putting in the platform the drafts of your shares for the assignments..."

TABLE III. CATEGORIZATION INDICATORS AND EXAMPLES OF COGNITIVE CATEGORY Y

Cognitive Indicators	Examples
References to the problem, indicating what is known and asking about unknowns.	"I solved 5.1 and found the X substitution, from knowing that the substitution product is associative for any finite number of substitutions. I'd like to know if you found another method..." "I have calculated the range of matrix 2.1 from the maximum order of its minors different from 0. Is it valid? Or it has to be done by calculating the number of no-null rows of the scaled matrix from the given matrix"
Expressions about difficulties to problem understanding, and confusion.	"Regarding problems from exercise 2, I don't know how to verify the solutions..." "I can't finish exercise 1.3..." "I don't understand exercise 3.3."
Comments to share and explain problem solving strategies.	"...watch how I did exercise 2.3. I'll try to explain to you with words. You begin with the first number of the row..." "A general comment is that your solutions are correct and well founded by deduction, but there are some alternative solutions..."
Agreement or disagreement expressions about assignments.	"...I considered that is a correct answer, but the deduction is not" "Juan Carlos told me that ... Is it true? I think ..." "Are you sure that is the correct answer? How can you probe it?"
References to information gathering and/or teacher and students suggestions	"...thanks for the observation, with that I finish exercise 1.3," "Considering the exercise 1.1 that our partner C.T. has solved, I noticed that I have missed to locate..." "It was useful for me to see the way you deduce the requested equation, in fact it's easier than the one I used."

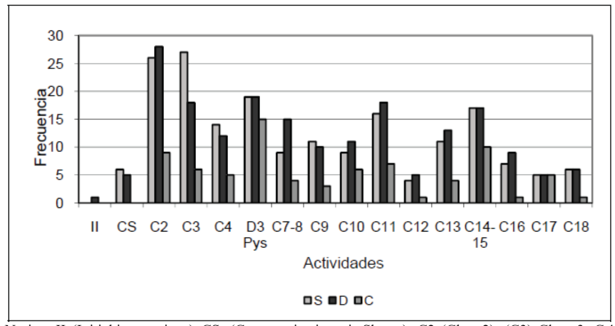
At the virtual forum participated eight students and a teacher, all of whom submitted 321 messages; when using Content Analysis with defined categories and indicators, there appeared 617 collaborations distributed as shown in Table 4. There is noted that the number of collaborations is close to two times the number of messages; this relationship shows how most messages include more than one category (Note: Teacher collaborations are included in distribution by categories).

TABLE IV. DISTRIBUTION OF CONTRIBUTIONS TO VIRTUAL FORUM IN CATEGORIES

Description	Frequency	%
Contributions to forum	617	100.00
Teacher contributions	174	28.20
Students contributions	443	71.80
Contributions to social category	252	40.84
Contributions to didactic category	269	43.60
Contributions to didactic category	96	15.56

Data of Table 4 show that the number of collaborations of each category is different. The number of collaborations of social category (S) and didactic (D) are similar (252 and 269 respectively), while the cognitive category (C) just had 96 contributions. This distribution seems reasonable for it corresponds to collaborations submitted to virtual forums where students and tutors direct their learning process through debating course contents [1].

It was observed that the amount of participations corresponding to each category was different for each learning activity, this suggest a variation for each category along the development of the course (Fig. 1).



Notice: II (Initial instructions), CS, (Communication via Skype), C2 (Class 2), (C3) Class 3, C4 (Class 4), D3 Pys (Discussion 3. Permutations and substitutions), C7-8 (Class 7-8), C9 (Class 9), C10 (Class 10), C11 (Class 11), C12 (Class 12), C13 (Class 13), C14-15 (Class 14-15), C16 (Class 16), C17 (Class 17), C18 (Class 18).

Figure 1. Histogram to show the number of each type of participations in the activities indicated along the course.

Figure 1 shows also a trend towards a reduction in the number of participations as the course progress. Such trend is noticeable for each three categories. The reasons for this decrease are not the same, but it could be said that for this particular course, students communicated directly among themselves using skype as syncronous media, skiping the possibility for registering those communications.

In Figure 2 the corresponding rates of participations in the activities are presented graphically. It can be seen as the rate between the types of collaborations remained relatively constant in spite that, as previously stated, the number of participations decreased along the course.

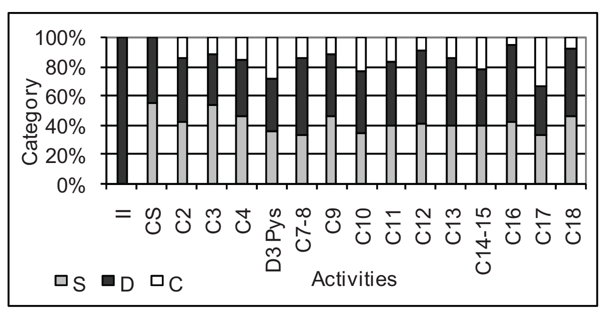


Figure 2. Rate between number of collaborations from each category in learning activities.

To de scribe the rea ltionship be tween the socia l a nd didactic collaborations a frecuency polygon is pre sented. In Figure 3 it ca n be appreciated t hat soc ial category prevails slightly over the didactic one in the first t hird of the course, and then it reverts for the rest of the course.

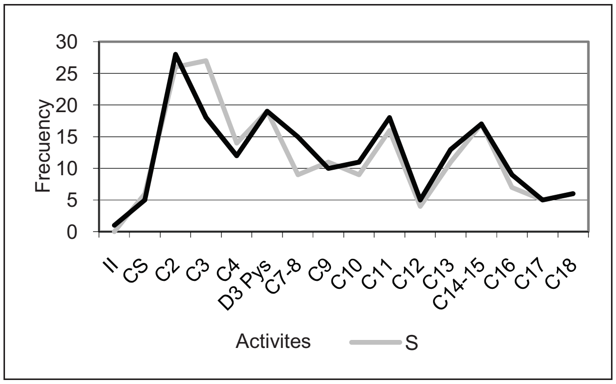

Figure 3. Rate between the number of collaborations from each category within the learning activities.

That slightly larger number of collaborations from social category with respect to the didactic one, may be devoted to the initial need for creating a community sense in order that students feel confident to participate. Once this environment is stablished there may be a slight decrease in the number of affective social collaborations and open comments, because social reinforcement is not needed as previously [13].

Regarding cognitive co llaborations i t c an be see n in figure 4 that the y appear until th ird activity (Cl ass 2), this occurs as th e fi rst and second a ctivities (In itial In structions and communication via Skype) were directed to describe the methodology to use and communication media.

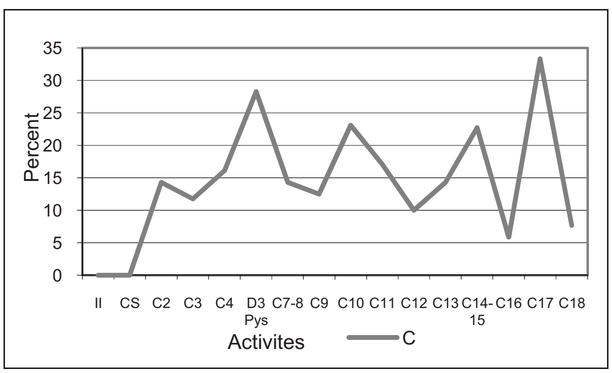

Figure 4. Percent of cognitive collaborations in course activities.

It ca n be seen in F igure 4 th at t he perc ent of cognitive collaborations alo ng the course cha nge fro m 3 to 33 %. It increased fro m 23 t o 33 % when it was in dicated in t he forum to c heck and co mment home work pr oducts, accordingly to provided indicators.

During sessions (Discuss ion 3, P ermutations an d substitutions, Class 1 0, Classes 14, 15 and 17) st udents had to assess their own product and those from their classmates, in order to indicate amendments.

This beha viour is congr uent w ith t hat d escribed by Garrison [7] rega rding how que stions or tasks proposed in the virtual forum influence t he type and level of cognitive activity of students.

The var iation in the rate of cognitive c ollaborations i n the forum als o agr ees w ith Ga rrison [7]. He st ated t hat cognitive activity is done in "research cycles" when students progress purp osedly from un derstanding the pro blem towards s uperior c ognitive le vels such as exploring, integrateing and application.

From t hese descr iptions, data m ake believe abo ut a plausible c orrelation between the n umber of ea ch ty pe of collaboration. For fur ther a nalysis i t w as con sidered t he frecuency st udents col aborate t o e ach c ategory. Usi ng this data i t was i nvestigated line al correlation between t he number of c ollaborations of e ach couple of ca tegories social-didactic, social-cognitive and didactic-cognitive.

Pearson coefficients for each case are shown i n Table 5. It can be seen that for all the cases there was a high positive linear correlation.

TABLE V. LINEAR CORRELATION BETWEEN THE NUMBER OF COLLABORATIONS TO THE CATEGORIES

Categories	Pearson's correlation coefficient r_{XY}	t_{table}	t_{cal}
Social-didactic 0.	9926	1.9432	20.0787
Social-cognitive 0.	8916	1.9432	4.8236
Didactic-cognitive 0.	9239	1.9432	5.9162

When usi ng th e t p robe f or ea ch correlation coefficient with $\alpha = 0.05$ and 6 fr eedom de grees, nul l h ypothesis H_0 were rejec ted, as they re flect that there is no e vidence of linear correlation for the number of collaborations from both categories considered ($H_0 : r = 0$ and $H_i : r > 0$).

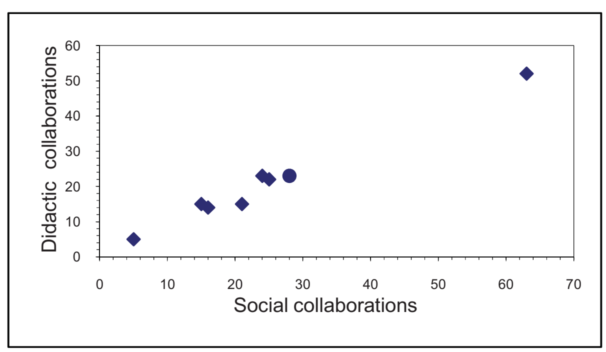

Figure 5. Linear correlation between social and didactic collaborations (r=0.9926).

Therefore it was stated that there is evidence of a linear relationship, meaningful statistically between the number of social and didactic collaborations (Fig. 5), social and cognitive (Fig. 6), as well as for didactic and cognitive collaborations (Fig. 7).

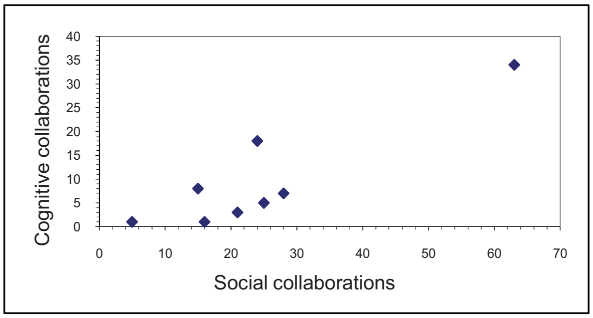

Figure 6. Linear correlation between social and cognitive collaborations (r=0.8916).

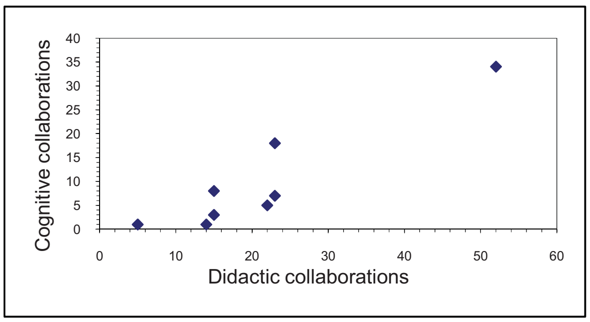

Figure 7. Linear correlation between didactic and cognitive collaborations (r=0.9239).

These results agree with those of Garrison [7] about how those three categories are highly related; how social and cognitive categories influence the didactic one, and how cognitive category in a virtual forum can be created and supported [4]. Garrison Anderson and Archer [4] suggest categories intertwine; they are not isolated from one another.

According to Garrison [7] a high positive correlation between the number of social and didactic collaborations may be explained for most social interchange are related to learning, common purposes and research.

Linear correlation between social and cognitive collaborations was previously recorded by Garrison, Anderson and Archer [6], they explain how ideas interchange, proposing solutions and comfort feeling to participate in discussions, expunge simultaneously social and cognitive sides.

High correlation between didactic and cognitive collaboration frequencies confirms as previously stated about how tutor questioning and tasks requested play an important role to develop the cognitive category.

Finally it can be said that result from using the statistic probe *t Student* indicate that social, didactic and cognitive categories are strongly related as described by Garrison [7].

V. Conclusion

From results it can be said that using this model was useful for studying the development of learning activities in the virtual forums. It could be convenient for designing future courses in similar contexts.

Data collected employing indicators defined for this research can be useful as an assessment instrument for student performance in the forum, besides, they are useful to assess the effect of learning activities designed to impulse knowledge building (cognitive category).

Frequency measurement of collaborations to each category was used to find and understand collaboration patterns, however this is not a quantitative research purposed for statistical inferences. But it was a first approach to understand and explain the complex development of online learning activities. From this perspective goals were accomplished.

Abstract— **In the last decade, universities and higher education institutes have become more and more interested in using computers to deliver their formative and summative assessments. Therefore, several computer-assisted-assessment systems have been developed. The variance in the application domains of e-assessment has a main influence on having different assessment systems in the same university. Since universities have different colleges and specializations based on their types and in order to deliver their assessment activities online, each college is developing or buying assessment system or tools based on its specializations and courses. This has caused some universities to have more than one computer-assisted-assessment system. In this paper, a service-oriented e-assessment system will be suggested to solve this problem. A service-oriented architecture for a generic and flexible assessment system will be provided with cross-domain use cases to show the flexibility of this architecture.**

Keywords- E-assessment, Modular assessment system, Assessment services, Service-oriented architecture for assessment, Middleware for tools interoperability.

I. Introduction

The breadth of the assessment field and it's richness of several application domains raise problems when it comes to develop tools to assess those application domains. Numerous commercial and academic assessment systems and tools are used to assess different application domains. The level of coordination between those systems and tools highly depends on the standards and specifications underpin them as well as the domain related activities. In e-assessment design and development, the new developed tools should have the ability to communicate and interact with the existing ones without further modifications. Such tools should not be tightly coupled to a specific assessment system. Rather than, they should be reusable and interoperable so that they can be used to extend other systems and tools.

In the world of Service-oriented Architectures (SOA), the new developed services hold great promise when they are interoperable and fit with existing tools' services. One promising area is to modularize e-assessment systems in a way of composing loosely coupled assessment tools together. Such composition requires: i) clear guidance represented by a well-formed *framework*; ii) *standards and specifications* that represents the whole process of assessment as well as the communication between the services and components; iii) *cross-domain requirements* analysis in order to define the specific requirements for each application domain (such as, educational editor in the mathematic domain); iv) *web services* that provide the cross-domain requirements and interact through well-defined interfaces.

The rest of this paper is organized as follows: Section 2 explores the different aspects for understanding the e-assessment domain. Section 3 suggests a Modular Assessment System for Modern Learning Settings (MASS) towards a generic and flexible assessment system. A SOA-based architecture for MASS is discussed in Section 4. Section 5 discusses how this SOA-based architecture can be mapped into system components as part of more detailed architecture. Problems and challenges for aggregating domain-based tools and services within MASS context are discussed as part of a suggested Middleware in section 6. Section 7 investigates the MASS suggested architecture using a persona-based use case. A conclusion and future work are provided in Section 8.

II. E-Assessment domain

Challenges that may face e-assessment development varies according to the level of assessment domain understanding. Bloom's described the assessment process based on the learning outcomes represented by levels of learning objectives [1]. Authors of [2] classified the learning assessment domain into four assessment types *summative, formative, diagnostic, and self-assessment.* Some others believe that there is a need to develop models for exploring and defining this domain [3]. For Instance, the Joint Information Systems Committee (JISC) has initiated a service-oriented based framework for e-learning called "e-Framework" [4]. Based on this framework JISC has presented an e-Framework Reference Model for Assessment (FREMA). FREMA represents an intensive guide for the assessment domain resources *standards, projects, people, organizations, software, services, and use cases.* FREMA structure is based on concept maps describing the ontology that has been used to model the assessment domain. [5].

Other researches described the assessment domain from different perspectives. As in [6] the requirements for what they called the 'Ultimate' assessment engine have been discussed. From this perspective, the assessment domain has been investigated as the possible requirements for the possible stakeholders and roles of the assessment system.

A different way of domain understanding has been discussed in [7]. In this research the authors investigated the e-assessment domain as a set of possible services. A Service-Oriented Framework for Assessment (SOFA) has been initiated as a set of layers: *User Agents, Assessment services, Common Services, and infrastructure resources*. In presenting this framework they provided people in the domain of e-assessment with a guide to understand the interactions between the domain users and the available resources as a set of services. They also stressed on the importance of designing those services to be standard-conform to avoid having a repository of useless services. Rather than, those services will be interoperable and useful for designing flexible assessment systems.

III. MODULAR ASSESSMENT SYSTEM FOR MODERN LEARNING SETTINGS (MASS)

Based on the highly demand for having a generic and flexible e-assessment system, MASS has been suggested. MASS is supposed to have: (a) *flexible design* to be used as a stand-alone system or to be easily extended by third-party tools. (b) *User-friendly interfaces* for both students and educators where a user interaction and online submission of solution and evaluation can be done. (c) Assessment environment for *various learning and assessment settings* which supports guided as well as self-directed learning. (d) *Management and (semi-)automatic support* over the entire assessment lifecycle (exercises creation, storage and compilation for assessments, as well as assessment performance, grading and feedback provision). (e) *Rubrics design* and implementation interfaces to allow the educators to design their own rubrics based on learning objectives to assess learners' performance against a set of criteria. (f) *Support of various educational objectives and subjects* by using various tools sets which for example enables automatic exercise generation or selection, automatic grading and feedback provision. (g) *Results analysis and feedback provision* (immediately or timely) of the current state of user knowledge and meta-cognitive skills for both educators and learners and also for adapting course activities and learning contents based on users' models. (h) *Standard-conform information and services* to be easily sharable, reusable and interoperable. This may include the tests' questions, answers and students' results, rather than any other required services. And finally, (i) *Security and privacy* where a secure logon of users based on pre-defined levels of access, and also users' authentication based on machine (domain users) or by usernames/passwords.

MASS is planned to be a SOA-based assessment system where different assessment tools can integrate with each other to assess different application domains. MASS highly depends on interoperable web services that can extend MASS's assessment native services (Authoring, Scheduling, Delivering, Scoring, and Reporting) to assess specialized kinds of assessment (e.g. Algebra assessment and Programming assessment) based on several application domains. Fig. 1, shows how cross-domain web services can be used to extend the core services provided by MASS. A Middleware layer has been added between the Application layer and the Application Domains one. This Middleware will be designed to handle the use of domain-based web services to extend MASSs' ones for specialized application domains. Moreover, it will be used to facilitate and tackle the problems and challenges of running external domain-based tools within the context of MASS.

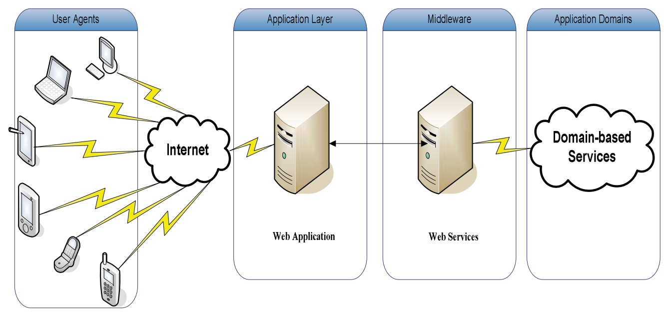

Figure 1. Cross-domain web services to extend MASS native services

IV. SOA-BASED ARCHITECTURE

As Shown in Fig. 2 a SOA-based architecture for MASS has been presented. This architecture consists of four main tiers: Client Application Tier, Business Tier, Service Tier, and Resource Tier.

A. Client Application Tier

The client application tier forms the front tier where the user agents interact with the system. Matters such as security and privacy of data and processes are handled in this tier. Furthermore, unauthorized user agents are prevented through this tier from accessing the system resources.

The **controller** of each client application must be capable of controlling the whole actions in this tier. The application processes and requests are passed by this controller to a special **interaction services** layer that communicate with the business tier using communication standards and technologies (such as Simple Object Access Protocol (SOAP), or XML-Remote Procedure Call (RPC)).

B. Business Tier

The whole business logic is taken place in this tier. In our case, the main MASS modules (Authoring, scheduling, delivering, and reporting) are part of this tier. For each module a set of core services are available in the service tier. Separating the business logic in a different tier fosters MASS to be more modular and flexible. Furthermore, this tier facilitates the update of the business logic in an easy and flexible manner. As in the client tier, this tier also has a controller and an interaction services to communicate with the service one.

C. Service Tier

In the world of SOA there are three main roles of interaction: *service provider, service registry, and service requestor.* Service providers are software agents that provide the service. They should **publish** a service description on a services registry. Service clients are software agents that **request** the execution of services. They should be able to **find** services descriptions on the services registry. The words in bold with the operation **bind** form the main operations in the SOA. During the bind operation the service requestor invokes a web service at run-time using the binding information in the requested service description to locate this service. This invocation has two main possible scenarios: the first one is direct invocation by the service requestor using the technical information in the service description located on the services registry. The second one is via a service discovery agency where the communication between the service requestor and the service provider goes through the services registry of the discovery agency. [8]. In the case of MASS the first scenario will take place where the invocation of the domain web services will be done directly through the services registry in the service tier.

In the server side there are two main operations:

- Service Registration: each service provider from the resources tier registers its web services through the **service provider interface** to the **service registry**. The service providers are normally domain related systems (such as algebra assessment system, programming assignment assessment tool…) that provide their business logic services (such as algebra marking, equation editor) as web services.
- Service Invocation: this operation is mainly handled by the **service request layer** where the requested service from the client application through the business tier modules is searched in the **core services** repository. If the service is not available in the core services repository then it will be searched in the new registered services in the **services registry.**

By using these two operations the requests from the client applications are answered. Once the business tier module (e.g. Authoring) uses a new registered web service from the **service registry** in the service tier, the service becomes available through that module **core services**. So the next time such web service is needed the module can directly use it from its **core services**.

D. Resource Tier

The resource tier contains the MASS infrastructure resources (such as MASS databases) as well as the domain related systems and tools. The domain related systems can be assessment related such as algebra assessment system or can be business related such as the Student Information System (SIS). For each of these systems and resources there are a set of web services they must provide. The more web services they provide the more flexible and generic MASS will be.

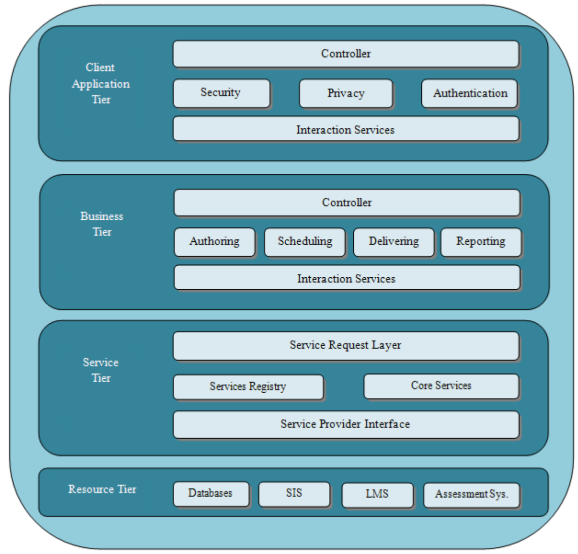

Figure 2. SOA-based Architecture for MASS

V. DETAILED ARCHETICTURE

The architecture presented in Fig. 2 is more conceptual than showing the real components of MASS. This section discusses a more detailed architecture where it explains how the SOA-based architecture layers are presented as system components and modules as well as it suggests architecture for the middleware layer. Moreover, it shows the assessment process represented by a set of core services for assessment and guided by the SOFA layers [7]. Some other common services such as authorization and authentication are also shown in this architecture. Fig. 3 demonstrates the more detailed architecture where it consists of four main layers: User Agents Layer, Application layer, Middleware Layer, and Application Domains Layer.

A. User Agents Layer

This layer represents the possible users of MASS. User agents can be native users (such as students, teachers, and administrators) or external users (such as related tools or LMSs). External users can be services requestor or provider. In case of a tool or a LMS is requesting a service from MASS, MASS should be flexible and interoperable to act like a service provider without rewriting code or system rebuilding. But if they providing services they will be part of the application domain layer and their services will be registered to the services registry in the middleware layer.

B. Application Layer

This layer represents the native components of MASS. All the assessment native services (Authoring, scheduling, delivering, analyzing or scoring, and reporting) and the common services (user management, authentication, authorization, security, and privacy) are parts of this layer. This layer can also be referred as the layer of MASS native services. Based on SOFA [7], the assessment services layer and the common services layer are mapped into modules. For instance, the assessment core services in this layer are represented by a set of main modules (Authoring, Scheduling, Delivering, Analyzing, and Reporting). The assessment process is explained using these modules by defining the main tasks of each module. As shown in the architecture of this Layer the assessment cycle starts with authoring assessments and ends with reporting. Adapting of the assessment process to achieve the learning goals is part of the analysis module. The adaptation process can suggest changes in the assessment process which may go back to the authoring services. All the communications between the assessment services are done through the services buss.

C. Middleware Layer

For the sake of generality and flexibility this layer has been added to the architecture. One of the main goals of MASS is to be flexible in order to work as a stand-alone system or to integrate with other systems and tools. This middleware forms as a run-time platform where the domain-based services (e.g. Domain-based Editor) will be registered in order to be used by MASS modules.

The domain-based services will be used to extend the services provided by MASS. As well as they will be used to integrate between MASS and other application domain systems and tools. For each new domain-based service the service provider should publish the service description on the middleware services registry. This description will be used by the MASS modules to bind the service to any possible service requestor. Moreover, a flexible design will be suggested for this layer fostering MASS to run domain-based tools as part of its context.

D. Application Domains Layer

This layer represents the systems and tools that are used in specialized application domains such as Algebra assessment and Programming assessment. For those systems and tools it is supposed that they provide their services as web services. These web services will be used to extend the MASS core services which gives MASS the ability to assess different application domains. MASS should be flexible to run those tools within its context without the need to build them from scratch. Next section discusses this challenge and suggests possible solution for that.

VI. MASS MIDDLEWARE

In order to have a flexible and generic e-assessment system the following aspects should be considered:

- Standards-conformation
- Learning Objects (LO) Interoperability
- Tools Interoperability
- User Interface Interoperability
- Web services management

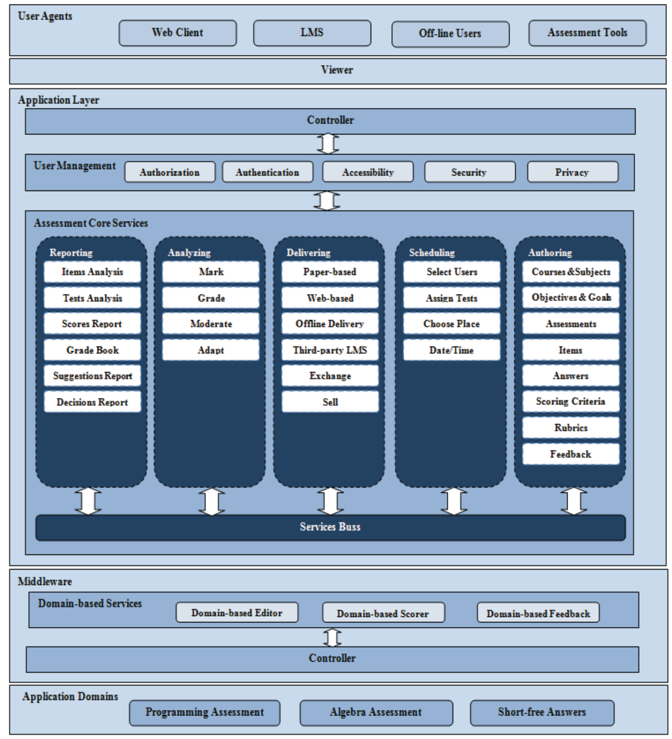

Figure 3. Detailed Architecture for MASS

In the context of e-assessment the term interoperability mainly refers to the ability of sharing Learning Objects (LO) between different assessment systems. For the sake of LOs interoperability, LOs should be standard-conform. Once they are standard-conform they can be easily shared between different standardized e-assessment systems [7]. Furthermore, these LOs can be re-used to construct new assessment activities without a need to build them from scratch. Some of the possible e-learning and e-assessment standards and specifications consortia are: The Instructional Management System Global Learning Consortium (IMS GLC) [9], Advanced Distributed Learning (ADL) [10], ADL Sharable Courseware Object Reference Model (SCORM) [11], The Aviation Industry CBT (Computer Based Training) Committee (AICC) [12], and IEEE Learning Technology Standardization Committee (IEEE LTSC) [13]. According to [14] almost all of these standards require the following aspects regarding LOs communication:

- *Launch:* the requirements for launching an LO in a web-based environment.
- *Application Programming Interface (API):* the interface of methods to be invoked by an LO to communicate with LMSs.
- *Data Model:* the dataset for the communication process.

According to [15] *interoperability* refers to "the ability of two or more software components to cooperate despite differences in languages, interface, and execution platform". Tools interoperability concerns the ability of aggregating third-party tools to cooperate with a LMS platform. Third-party tools can be used to extend the services provided by the core system with services for specialized application domains. One of the possible specifications for tools interoperability is the work provided by the IMS GLC. IMS GLC has provided an architecture for tools interoperability as web services. IMS Tools Interoperability Guidelines v1.0 has described this architecture as well as its main components [16]. The suggested architecture has introduced two main concepts:

- *Proxy Tool:* from its name this tool will be used by the LMS to communicate with the external tools. A standard mechanism for packaging this tool to be deployed to an LMS has been defined by the architecture. The proxy tool is meant to be environment-independent where it does not require specialized code. The proxy tool is entirely a *descriptor-based package* that describes the deployment, configuration, and runtime context.
- *Tools Interoperability Runtime (TIR):* is a set of services that have to be implemented to the hosting environment (MASS in our case and the application domains tools). The TIR facilitates the deployment, configuration, and launching of the proxy tool. This deployment, configuration, launch, and outcome services are in somehow similar to the launch, API, and data model discussed earlier.

The communication between the TIR/Proxy Tools is handled by a *core protocol* defined for this purpose. The core protocol is based upon the IMS General Web Services (GWS) specifications v1.0 [17] which utilize XML with WSDL for defining services and SOAP for the base transport protocol.

Since the communication between the third-party tools and the core system is performed as web services some kind of web services management is required. Matters such as services provision, services registration, services invocation, and security and accessibility should be taken into consideration. Special standards and specifications can be used to represent these web services descriptions. For instance the IMS General Web Services (GWS) specifications can be used where the WSDL/XSD created files are designed to comply with Web Service Interoperability (WS-I) Consortium Base Profile v1.1 [18].

A. Middleware Functionalities

Having that MASS is standard-conform and its LOs are authored with regarding to e-learning and e-assessment standards (e.g. IMS Questions and Test Interoperability (IMS-QTI) specifications [19]), the challenge of aggregating tools within MASS services is still there. In fact, designing MASS core services with respect to standards and specifications will not fix the problem of integrating third-party tools within MASS context. For instance, some of the services provided by the application domains tools such as cross-word puzzles in the domain of Natural Languages teaching and assessment are not covered by the available standards and specifications (e.g. IMS QTI). Another example could be the requirement for domain-based assessment tools or services such as services for scoring special types of assessment items (e.g. algebraic questions). Moreover, the need for third-party tools and services is not limited to the assessment types, rather than it exceeds that to the integration services between two systems such as e-assessment system and Student Information System (SIS).

As shown in [20] SCORM has a lack in its interoperability definition. Addressing the interoperability of content packaging and the interoperability of the Run-Time Environment (RTE) is not enough to have flexible tools interoperability. The author stressed on two other important concepts for improving content interoperability: *Standardized user interface controls, and open-source of a standardized SCORM API implementation.* Launching the content in the UI with a lack of standards causes different behaviors based on the properties of the web browser such as *width, height of the browser, resizing, area of launching within the browser.* LMS developers do not follow the same programming strategies SCORM supposing they are.

In order to tackle the fore mentioned problems and challenges the middleware has been added to MASS architecture. The middleware layer will form as a platform on which aggregating runtime interoperable tools will take place. Furthermore, the registration of the domain-based web services will be handled by this middleware through well-formed interface to a service registry. The later on binding of these services to the service requestor (MASS User Agent) is also done by this middleware. Designing this middleware in a flexible way will foster MASS to be more and more flexible.

B. Middleware Architecture

Fig. 4 shows the main components of MASS middleware as well as the required services and communication patterns with the Application Domains Tools. This architecture is highly designed based on the architecture provided by the IMS Tools Interoperability Guidelines. Based on these guidelines the following steps will take place in the deployment of the Proxy Tool:

1. *Tool developer creates Proxy Tool deployment package. The deployment package is an archive contains a manifest and Proxy Tool's deployment descriptor.*
2. *MASS administrator deploys Proxy Tool deployment package to the MASS container.*
3. *MASS TIRs deployment service loads the Proxy Tool, thus creating a Proxy Tool Definition within MASS (during which validation of the deployment profile occurs, including a validation of profiles like security, outcome, user and delivery context asserted by the Proxy Tool deployment descriptor. MASS administrator can choose to not deploy the Proxy Tool if it does not support the required profiles).*
4. *MASS Administrator configures the Proxy Tool for use within an Institution by updating its definition appropriately with MASS data model.*

5. *An instructor or course designer utilizes the Proxy Tool definition to create a Proxy Tool Instance within a delivery context (course). The instance inherits the full base configuration and is additionally customized by the instructor/designer for launch from within the specific delivery context.*
6. *A learner in the course of a learning session is presented with the Proxy Tool instance (as a Learning Object or as part of one) and subsequently launches the Proxy Tool by selecting the URL provided by the MASS's user interface.*
7. *Tool's TIR validates and accepts launch in collaboration with the MASS's TIR which directs the user to the Tool's user interface, e.g., a redirect to a Tool specific URL.*
8. *Learner uses the Tool and in doing so potentially generates an outcome.*
9. *Tools' TIR sends the outcome to the MASS's TIR at the end of a learner's interaction with the Tool.*

A possible enhancement for this procedure could be the registering of the Tool's service after the end of step 9 in the services registry located in the MASS middleware. The Tool's Service description as well as the service endpoint represented by the service URL can be published to the service registry so that in future requests the service will be directly provided to the learner or to the instructor user interface.

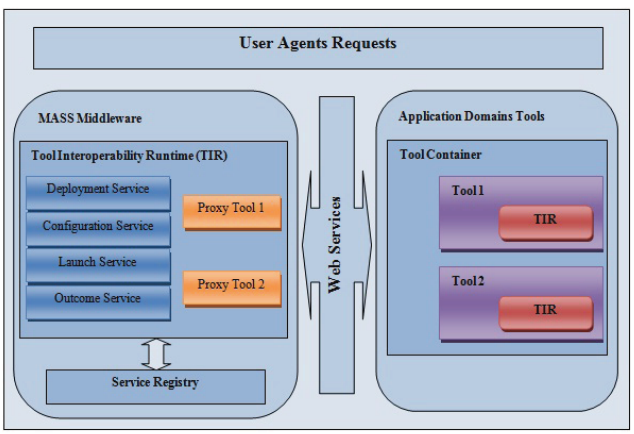

Figure 4. The cooperation between MASS modules and Application Domains' Tools through MASS Middleware

As shown in this architecture the Tool Interoperability Runtime services are:

- *Deployment Service*: The main function of this service is to interpret and load the Proxy Tool definition into the host TIR via its deployment descriptor. Thus this service is also expected to perform validation of the Proxy Tool settings in order to ensure correctness of and compatibility with the MASS's TIR.

- *Configuration Service*: The main function of this service is to manage the runtime settings of the Proxy Tool in order to provide the proper set of the same response for/during any given launch context.

- *Launch Service*: This service provides two main services, depending upon the context:

    - *Proxy Tool Host*: Performs all the functions related to launch of a Proxy Tool, including generating the relevant Proxy Tool launch message, utilizing the appropriate security profile, etc.

    - *Tool*: Exposed as a web service (Proxy Tool 1 and 2) that accepts launch messages from the MASS's TIR, understands the security profile used therein and responds back to the MASS's TIR using the Proxy Tool core protocol as to the status of the launch.

- *Outcome Service*: This service provides two main services, depending upon the context:

    - *Tool*: A web service client that generates outcome messages from the Tool's TIR conforming to a specific outcome profile type, for a given interaction of a user with the Proxy Tool/Tool, including utilizing the appropriate security profile.

    - *Proxy Tool Host*: Exposed as a web service that accepts outcome messages from the Tool's TIR, understands the security profile used therein and responds back to the Tool TIR using the Proxy Tool core protocol as to the status of the outcome processing.

VII. USE CASE

In order to investigate the eligibility of MASS suggested architecture, this section will discuss a use case of a programming course for beginners lecturer based on the following persona:

Persona, Jordi
Jordi is a lecturer at a department of computer science. One of his courses is "Programming for Beginners". For each semester a number of at least 500 students are attending this course from different departments and colleges. His department is using MASS to manage their online-assessments.

Scenario
"*I am using a programming assessment tool with simple functionalities of code-peer-review and feedback. This tool allows the annotation of code examples from students by tutors. Then the students have to annotate their pre-annotated examples. The students' annotations are compared with the tutors' ones and a valuable feedback is*

provided. I want this tool to be integrated with MASS in order to allow the only registered students in the course to upload their assignments to MASS and then those assignments will be used by the code-peer-review tool within the environment of MASS. ”

Based on this persona and scenario the following procedure will take place to integrate the code-peer-review tool with MASS:

1. Jordi registers to MASS users as a lecturer which will allow him to create the course of “Programming for Beginners”.
2. The students register as MASS users with the role students and request participation-confirm from Jordi to participate in the course.
3. After accepting students, Jordi creates a new assessment activity with type assignment using the Authoring module of MASS. As this assignment is using an external tool Jordi has to ask MASS administrator to integrate the tool with MASS resources.
4. Assuming that this tool has a Proxy Tool Deployment Package, the administrator deploys this package to the MASS container. MASS TIRs deployment service loads the Proxy Tool, thus creating a Proxy Tool Definition within MASS. If not the administrator has to ask the Tool developer/ Supplier to provide a Proxy Tool Deployment Package.
5. The administrator configures the Proxy Tool to fit with MASS data model and grants a privilege for Jordi over it. After that this tool will appear in the resources of the Authoring module used by Jordi to create the assignment activity.
6. Jordi utilizes the Proxy Tool definition from the Authoring Module resources to create a Proxy Tool Instance within the assignment (delivery context). The instance inherits the full base configuration and is additionally customized by Jordi using the Authoring module of MASS for launch from within the assignment.
7. Students who are participating in the assignment activity will launch the Proxy Tool by selecting the URL provided by the MASS’s assignment user interface.
8. The code-peer-review tool's TIR validates and accepts launch in collaboration with the MASS’s TIR which directs the student to the tool's user interface.
9. Students use the tool and in doing so potentially generate an outcome.
10. The code-peer-review tool's TIR sends the outcome to the MASS's TIR at the end of a student's interaction with the tool.
11. The outcome is passed to the MASS modules for further processing for instance to the Reporting module to provide feedback about the student-tool interaction.

VIII. CONCLUSIONS AND FUTURE WORK

According to the breadth and depth of the assessment application domains, several academic and commercial assessment tools and systems have developed. Some of these assessment tools and systems are limited to specific application domains. Moreover, they are not carefully designed to be standard-conform as well as they barely coordinate to other tools and systems in different application domains of assessment. This has caused universities and higher education institutes to have more than assessment tool. Managing several assessment tools are money and time consuming as well as requires extra resources. Tackling such problems and challenges by having a generic and flexible assessment system is a great challenge. Aggregating tools from different assessment application-domains in order to have a single flexible and generic assessment system requires: *Framework* for domain systems and tools development guidance; following *Standards and Specifications* that will help developers in producing their systems and tools; *Cross-domain requirements;* and *Web services* achieving those requirements.

A Modular Assessment system for Modern learning Settings (MASS) has been suggested as a generic and flexible e-assessment system. For the sake of flexibility and generality a SOA-based architecture for MASS has been designed. The design of this architecture is done with the guidance of the SOFA framework for assessment. The SOA-based architecture has been mapped into a more detailed architecture with a clear view of MASS components and modules. The detailed architecture has four main layers of: User Agents Layer, Application layer, Middleware Layer, and Application Domains Layer.

General and flexible assessment systems are capable to share their components with other systems. Therefore, MASS should be standard-conform in order to easily share its components. Following standards lacks a clear view of how to develop interoperable assessment tools. This lack has caused by having different standards and specifications (such as SCORM RTE, IMS TI) that have been published to support developers for developing interoperable assessment tools with weak definition for the interoperability process. For instance, in the case of SCORM RTE the standard explained how content packages conforming to SCORM standards can be shared between tools during their run-time but, it did not carefully explained launching this content in the user interface [20]. In order to facilitate tools interoperability during MASS runtime, the middleware layer has been suggested. The Middleware layer will form as a platform for tools runtime interoperability as well as for content sharing. Moreover, the middleware architecture is supposed to facilitate the domain-based web services registration to MASS. Those web services will be used to extend the capabilities of MASS native services assessing different specialized application domains.

For future work, the first prototype of MASS will be developed. A set of application-domains tools will be selected to extend MASS services. The first prototype side-by-side with the selected third-party tools will be used to evaluate the suggested architecture of MASS.

Abstract— **It is well known by the educational community that active learning has a greater impact on the effectiveness of the learning process than other methods. It has long been recognized that the most effective learning techniques involve direct, purposeful learning experiences, such as hands-on or field experiences. In particular, computer-controlled models have been a useful aid in teaching programming, Artificial Intelligence and Robotics concepts. This paper describes our experience using LEGO Mindstorms® in three different scenarios: an elementary course on Programming, an advanced-level course on Artificial Intelligence and a third first-level course on Robotics. Our focus in those experiments is not on whether using LEGO kits is better than other methods to learn a programming language, AI algorithms or Robotics, but rather on introducing how this mixture of collaboration, competition and peer learning in a laboratory environment helps the students to increase their motivation and improve their professional skills such as problem solving, team work and leadership.**

Keywords: Active learning; LEGO Mindstorms; learning experiences, engineering courses, evaluation; assessment; surveys; empirical results; Java programming.

I. INTRODUCTION

After years of compelling research on the field, it is commonly agreed that the most effective learning methods involve direct, purposeful learning experiences, such as hands-on or field experiences. This fact is illustrated, for instance, by Dale's cone (Fig. 1), where passive learning would cover those activities that people can learn from, but not generally as effectively as active learning, which would include those activities that boost our learning experience.

Furthermore, active learning is even more required in technical studies (such as engineering), in which obviously concepts studied in class must be put into practice in different scenarios so that the students fully understand the fundamentals and also acquire the necessary competencies to apply them to solve real-world problems. Markets demand that professionals are mastered not only in a specific knowledge domain, but also in professional skills [2],[3], such as leadership, team work, autonomous and collaborative learning and management of increasing amount of information in short periods of time.

On the other hand, the European Higher Education Area (EHEA) [4] is investing a huge effort to foster the conversion of former ways of teaching into a modern type of learning. This new learning paradigm must be student-focused, holistic and comprehensive, helpful and encouraging, promoting autonomy and proactiveness, able to increase the student's motivation and disposition towards the course and thus improving the outcomes of the learning process. Apart from the competences specific to their curriculum, the integral vision of the learning experience is assumed to produce better qualified professionals. These professionals must have high added-value essential transversal (non-technical) competences that achieve the highest probability of success whether in current or further studies or their professional life. Team-work, communication skills and critical analysis are essential outcomes.

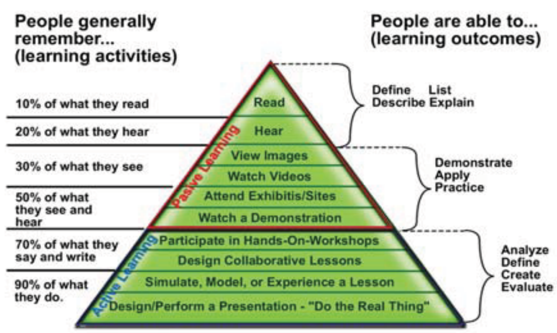

Fig. 1: Dale's cone [1] (released under a Creative Commons License)

This paper describes a series of experiments using LEGO Mindstorms® [5],[6] that have been carried out since 2005 in several scenarios involving a variety of student groups and course levels.

The purpose here is not to discuss the appropriateness or disadvantages of using those kits to teach technical topics, but rather to show how they increase motivation and improve professional skills. Activities that involve a mixture of real-world application of technical concepts, collaboration, competition and peer learning in a laboratory environment, achieve excellent outcomes in terms of students' motivation and development of transversal skills, and also improve their disposition towards hard tasks and their perception of the learning process quality. A critical analysis of how the methodology affects the learning experience is done, considering both subjective and objective results.

This work was partially supported by Learn3 (Plan Nacional de I+D+I, TIN2008-05163/TSI) and by Universidad Carlos III de Madrid (UC3M) on different calls for Experiences on Teaching Innovation.

We first review, in the background section, some previous experiences using LEGO kits in different environments. Then we place our work in context defining our goals with the introduction of Robotics in the different experiences. Then we discuss about our results and findings and how to use them in other context in future work. Finally we conclude about the usefulness of our experiences to improve motivation and develop professional skills.

II. BACKGROUND

Some studies [7] mention some of the conditions under which people learn properly, such as: what they learn is personally meaningful to them, what they learn is challenging and they accept the challenge, what they learn is appropriate for their developmental level, they can learn in their own way, have choices, and feel in control, they use what they already know as they construct new knowledge, they have opportunities for social interaction, and they receive helpful feedback. Projects using LEGO Mindstorms® have been proved as a good vehicle for implementing these concepts.

A. LEGO Mindstorms®

LEGO Mindstorms® [6] is a Robotics kit originally developed by MIT for building programmable robots. It combines standard LEGO blocks and LEGO Technic pieces (such as gears, axles and beams) [5] for its structure and a programmable brick and components (such as electric motors, sensors, etc.) for its control center (Fig. 2). The first generation of LEGO Mindstorms® was released in 1998 and was built around a brick known as the RCX. It contained an 8-bit 16MHz microcontroller with 32KB RAM. Programs written in one of several available programming languages are created on a computer and sent to the brick using an infrared (IR) interface. In addition to the IR port, there were 3 sensor input ports and 3 output ports (usable for motors and lamps) and an LCD that can display the battery level, the status of the input/output ports and which program is selected or running.

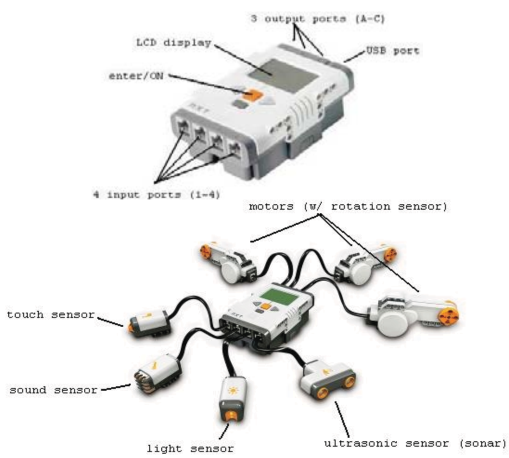

Fig. 2: Brick, sensors and actuators of the NXT kit

In July 2006, LEGO Mindstorms® NXT replaced the first-generation RCX. The new brick includes one main 32-bit 48MHz processor with 64KB RAM and 256KB Flash, and a second 8-bit processor for controlling an extended set of sensors and actuators. The brick also includes 4 sensor input and 3 actuator output ports, all of them with a digital I2C interface using a pseudo RJ12 connector. The IR interface is substituted by an USB and a Bluetooth port. The basic NXT kit consists of 519 Technic pieces, 3 servo motors, 4 sensors (ultrasonic, sound, touch, and light), 7 wires, a USB cable, a USB Bluetooth dongle, and the NXT brick. There also exist expansion kits that provide with more different building pieces and other types of sensors.

Initially the LEGO-supplied programming languages were RCX Code (assembly) and ROBOLAB (a graphical language). However, the enormous popularization of these kits led to the creation of new alternatives by the community, mainly as open source new firmware or virtual machines, supporting modern programming languages such as C/C++ and Java. For NXT, currently there exist over 30 alternatives including the Official Mindstorms SDK (Visual Basic, Visual C++, MindScript and LASM), the original ROBOLAB graphical language, leJOS (Java), NBC (assembly), NXC (C-like language), RobotC (C), GCC (GNU Compiler for C/C++, Fortran, Java, Ada, etc.), Ruby, Python, MATLAB, etc.

In general, the programming environment is simple enough to be learnt by the students easily. Thus, they can construct robots that perform complex tasks in a very short time. This combination of versatility and simplicity, together with its motivating potential, makes LEGO Mindstorms® a powerful help in a variety of learning scenarios.

B. Related work

Innovative teachers are continually looking for creative ideas, both to get their ideas across and to hold the interest of their students. With this purpose, LEGO have been widely used in different contexts with different objectives.

Fagin [8] and Schumacher [9] (2001) were among the first to introduce LEGO Mindstorms® in basic programming courses. Fagin used Ada language to teach basic control sentences (sequential, iteration or selection) and Schumacher used Java to teach fundamental computer programming concepts and introduce the concepts of autonomous vehicles, embedded computer systems and simulation. Barnes [10] (2002) also used Java and pointed out the usefulness of physical models to teach event-driven programming and the physical limitations of LEGO brick to achieve a good object oriented programming style. Wright and Gilder [11] (2003) explored the use of LEGO Mindstorms® in more advanced courses to design interdisciplinary senior projects to better prepare graduating students for their careers as engineers. His work covers robotics, algorithm state machine design, assembly programming language and compiler design concepts

All these previous work describe experiences with few students per course. Cliburn [12] (2006) reviews previous experiences and deploys a more ambitious one using LEGO Mindstorms® in 5 different courses during several years. As a conclusion of his work, Cliburn identifies three principles to consider to successfully designing these kinds of experiences. First, the project and the programming interface should support the objectives of the course and be relatively straight forward to learn. Second, the group size should be small to ensure that all students develop the required programming skills. The third principle is that students should be given time in class for building the robot. More recently, Jipping [13] introduced LEGO robots to teach Java bytecode (2007) and Talaga [14] (2009) to teach Artificial Intelligence (AI). LEGO was not only used to teach programming skills in different languages or AI techniques but also it has been used to develop professional skills [12] such as the experience proposed by McGoldrich [15] to improve peer learning or Barak's experience [7] to develop problem solving skills. All these studies reveal that using LEGO Mindstorms® in enriched collaborative learning environments has positive impact on student performance and motivation in most of the courses.

Comparing our work with previous work in this area, our main contribution is that our experience is not a punctual pilot one, but rather several courses in different context during a long period of time. We describe our experiences, like previous studies, but we also provide empirical data that support our conclusions gathered from different methods (direct observation, interviews, surveys, etc.). We also tackle the challenge set by previous work that suggests the need to collect data on how the student perceives this type of learning and research on how informal learning takes place in collaborative and competitive environments. Our findings are independent of age, cultural heritage and personal interest of the students.

III. OUR EXPERIENCE USING LEGO MINDSTORMS®

Based on those previous experiences about the benefits of using LEGO to improve students' motivation, we decided to organize a workshop that consisted of a competition where the goal was to build robots that participated in different challenges. The competition was a team-league that took place in different sessions. Each of these sessions presented challenges of increasing difficulty covering different aspects of programming, robotics and AI algorithms. The duration of the session, the difficult of the challenge and the main issues involved (programming, robotics or AI) was based on the context of the course. Work was done in teams of 3-5 students.

This was in 2005 as part of an advanced level course on AI (experience I, 33 students). The experience was so successful that we decided to carry out a more ambitious project introducing LEGO kits as an optional activity for students in an elementary course in programming (experience II, 127 students), in 2006. Most of the data analyzed in this paper was collected in this second experience. We finally had the opportunity to carry out a third similar experience in an introductory course in Robotics (experience III, 24 students).

A. Experience I: AI Course

1) Context

Our first experience with LEGO kits started in 2005, when they were introduced in a course called Intelligence in Communication Networks (ICN) [16] (first semester, fifth year, Telecommunication Engineering). Students learn the fundamentals of AI, the impact of intelligent behaviours in information systems and the areas where these technologies may bring the most significant advances. The course is elective and involves around 45 hours/semester. Sessions with LEGO typically take place during 6 sessions within regular classes (9 hours in all). These activities have the same impact on the final grade as other assignments. The experience began in 2005-2006 and was so successful that it has been repeated annually until the present. We started with 7 RCX kits but we switched to NXT kits two years later, when 20 new kits were acquired.

2) Objectives

The introduction of LEGO kits in this course was partly motivated by a significant decrease in the number of students enrolled in the course during the academic year 2005-2006, when the average of 50 students enrolled per year abruptly decreased to 33. Despite other causes (such a general decrease in the number of students at university), we think that it was necessary to introduce new lab sessions in the laboratories that motivate students while practicing their newly acquired knowledge on AI applied to Robotics.

3) Challenges

Different AI techniques, among the topics explained during the course lectures, have to be applied to solve the different challenges, such as problem solving or kNN (k-Nearest Neighbour algorithm). This way students can develop and experiment these techniques applied in a real working system. Our experience shows that at the end of each session practically all teams were able to develop a robot that meets the specifications stated in the challenge.

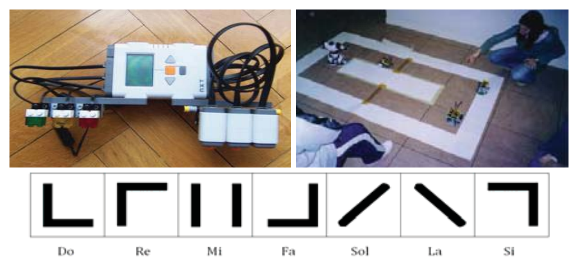

Fig. 3: Challenges in ICN course

In addition to an introductory session, three main challenges are posed to the students (Fig. 3):

- **Rock, paper, scissors**: Build a smart robot able to play that game. The purpose is to illustrate that most times an intelligent behaviour can be implemented with common-sense rules.
- **Escape from maze**: Build a robot able to run away from a maze. This task needs more advanced planning and solution search techniques.
- **Artificial vision:** Build a robot able to recognize and classify images. In this case, the aim is to implement a classifier using any of the studied techniques.

4) Methods and Results

The mixture of robotics, competition and collaboration reveals itself a powerful combination for learning AI. The students were highly motivated for this kind of lab sessions. The initial objective to increase the number of students enrolled in the course was reached as it can be seen in Fig. 4.

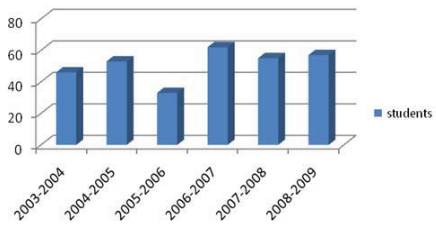

Fig. 4: Evolution of number of students enrolled in ICN course

As a collateral result, a significant increase in the number of Master's Thesis (Fig. 5) was achieved.

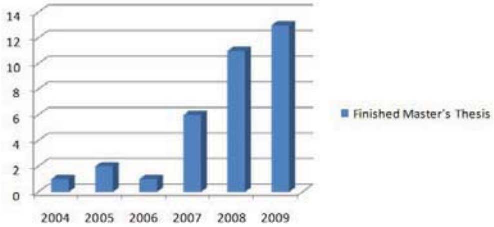

Fig. 5: Finished Master's Thesis supervised by the authors

This increase was mainly due to students who had been enrolled in ICN course, particularly in thesis about topics related with ICN contents, as shown in Fig. 6.

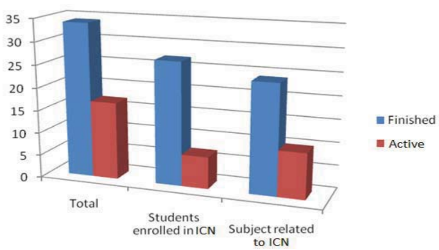

Fig. 6: Master's Thesis supervised by the authors related to ICN course

Annual teaching evaluation surveys show that the main reasons for choosing the course are the appealing syllabus and express recommendation from students of previous years. Although the relatively high passing rate could also influence the choice, we think that it doesn't constitute a key factor as this rate is similar to other subjects.

B. Experience II: Programming Course

1) Context

After this first successful experience in the first semester, LEGO kits were also introduced in four different introductory programming courses [17] taught in first year of different degrees, as an optional workshop at the beginning of the second semester, named Robot.IT![1] [18]. The experience began in 2006 with a pilot group of 127 students enrolled in these different degrees. The distribution of students by degree, in that academic year was the one shown in Fig. 7.

[1] IT stands for *Ingeniería Telemática*, our Department.

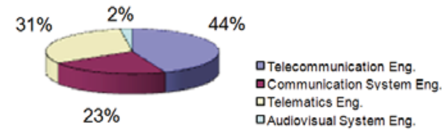

Fig. 7: Distribution of students by degree (2005-2006)

In this case, the workshop deployment has a significantly higher management cost than in the first experience, mainly due to the high number of participants. For this reason, the workshop is not organized on an annual basis but once every two years, giving the opportunity to join to students who enrolled in the subject that year and the year before.

2) Objectives

Programming courses during the second semester deal with algorithms and data structures (stacks, queues, trees, etc.). Students enrolled in these courses have previously received teaching during the first semester, on basic programming structures and object-oriented programming concepts. In general, results achieved by students during the first semester usually are not very good, and many students leave the course even before lectures start in the second semester. After the disappointing first semester results, it was necessary to influence student motivation to increase attendance of students enrolled in lectures and labs during the second semester.

The decision to introduce LEGO kits in those courses was largely motivated by the success achieved on our previous experience. Our main goal was to stretch the motivation gap between the first and second semester and to get student excited again about learning programming. To reach this goal we provide a different and enriched competitive and collaborative learning environment that fosters general interest in programming and illustrates the usefulness of programming in computer controlled physical models. Aside from the programming aspects, this environment also provides nice illustrations of two fundamental concepts that are often associated with Java: bytecode portability and the programmability of small devices as we mentioned above.

Our objective was not to improve student performance in courses, since the contents taught in the workshop had no direct relationship with those seen in class. For this reason the workshop was optional and has no impact in the final grade. The workshop takes place during 3 sessions outside regular classes with a total duration of 9 hours (3 hours per session).

During the workshop a teacher and a set of teaching assistants (typically two per session) help teams to resolve any doubt or technical problems. Teaching assistants are students chosen from among the course participants who have volunteered for this work. The teaching assistants have a short preparatory session with the teacher before the start of the workshop where they are trained in the tasks to be performed and the difficulties that arise in each session to be able to support their peers.

Finally, the large number of students involved in this second experience allows us to take some measures in order to evaluate the real impact of the workshop on student motivation and asses the methodology used during the experience. Issues related with the duration of each session, the number of sessions, the worst and the best aspects of the workshop, etc. were measured.

3) Challenges

Three challenges were posed to the students:

- **Robot Sumo Fight**: Build a robot that plays an all-against-all sumo tournament, pushing all the opponents out of the game area. This is a basic challenge to learn about light sensors and practice loops and conditionals.
- **Robot Recycler**: Build a robot able to find as many soft-drink cans as possible, pushing them out of the game field in one minute. This challenge involves several sensors and, optionally, advanced search strategies based on an ultrasonic (sonar) sensor.
- **Line Tracker**: Build a robot that can follow a path, a black line on a white surface, in the shortest time. This is a typical example of a non-trivial rule-based system.

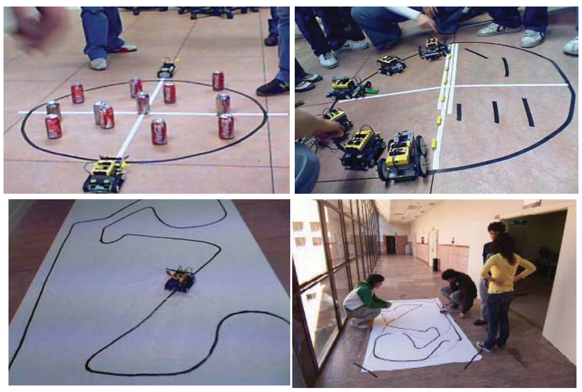

Fig. 8: Robot.IT! workshop

4) Methods and Results

A 40-question survey was designed to calibrate and improve some issues related to the **learning design** of the workshop, gather student opinion about the workshop **contents**, evaluate the impact in student motivation, evaluate **student's perception about his/her own learning**, evaluate the student's opinion about **using LEGO Mindstorms® in other courses**, evaluate their opinion about the **integration of workshop results in their grades**, and other questions (not related with this paper) about schedule, distribution of students by sex, how they knew about the workshop, opinion about the blog, etc. Survey has answered by 98 out of 127 participants and some conclusions can be drawn on each issue.

a) Results about the learning design of the workshop

- **Schedule**. Students agree with the session length (Question 19). 59% would keep as they are (3 hours), 37% increase in 1 or 2 hours. Only 4% of respondents would reduce the length of the sessions. Most people (82%) think that the difficulty of the challenges is adequate for the available time (Q20, Fig. 9). As each session was an independent challenge, we conclude that 3 hours is an appropriate time to address each of the challenges. In general, students are highly motivated, and despite the fact that the workshop involves about 9 hours (3 hours per challenge), takes place outside usual teaching hours and has no impact on the grades, surprisingly, most students (65%) would prefer to increase the number of sessions (Q18).

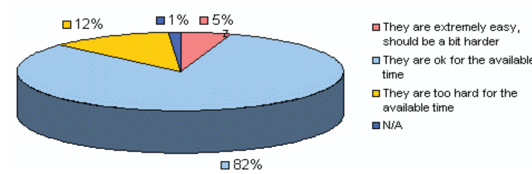

Fig 9: What do you think about difficulty of challenges? (Q20)

- **Groups**. When we asked students for the optimal group size (Q21), 59% would support increasing the group size to 4 people, 36% would keep the current suggested size (3) and only 5% which would reduce it. Despite students' opinion, our experience shows that the optimal size of groups is 3 persons because the pressure on the three members is just to keep everybody working. Increasing the pressure is likely to not complete the challenge and if the pressure decreases, there is a risk that some members do not work enough and the rest have time to absorb his work.
- **Teaching assistants**. Students highly value the presence of teaching assistants in class to support them during the session (Q23). 80% consider them a great help to overcome the challenges. Regarding whether they prefer to deal with the teaching assistants or teachers (Q24, Fig. 10), 61% prefer the teaching assistants because they are students and their relationship is closer. After the experience 30% of students would enrol as a teaching assistant in future editions.

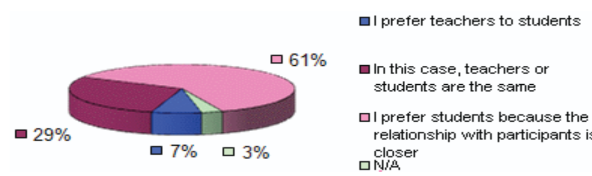

Fig.10. Do you prefer teacher or assistant support? (Q24)

- **Competition**. Most of the students (74%) consider the competition among groups highly motivating (Q30, Fig. 11). and 95% of the students agree in the importance of the competition factor in the workshop.

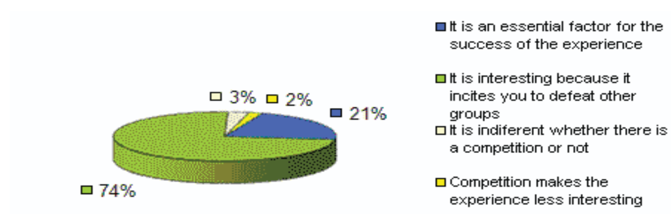

Fig.11. What do you think about the competition among groups? (Q30)

- **Preparatory work**. In order to analyze if preparatory work was necessary, we asked the students if previous lessons would have been interesting to improve the experience (Q16). Most students (56%) said it was not necessary since they could learn by themselves. 30% considered interesting to receive a previous lab class and 12% a previous lecture.

- **Students' preparatory work**. As previously mentioned, documentation for each challenge was provided at least a week in advance, and students were suggested to review it. When the students were asked if they prepared the sessions in advance (Q28, Fig. 12), most people (64%) answered negatively, and 60% said that they spent no time in preparing the sessions (Q29, Fig. 13). Despite the poor students' previous work, all the teams reach the challenges goal at the end of each session. We think that this lack of commitment from students is also because the workshop was conducted outside school hours and had no impact on their grades. When we asked what it would have happened if the workshop was a course for itself (Q31), students said they would have studied how to program the robot (62%), how to build the robot (5%), or the strategy to win the challenge (32%).

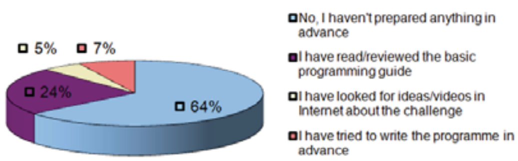

Fig. 12: Have you prepared the sessions in advance? (Q28)

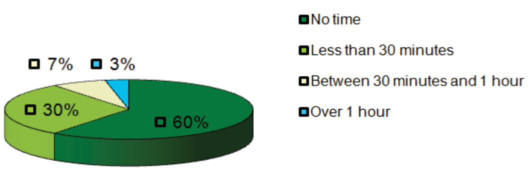

Fig. 13: How long have you prepared the session in advance? (Q29)

b) Results about content

- **Preferences**. When we asked participants which tasks they liked most (Q12), almost half of students (45%) responded that all of them in general, 26% preferred the work related to building the robot, 22% chose the hardware and software strategy design to solve the challenge, and only 7% preferred programming tasks. On the other hand, when they were asked for the most unpleasant tasks, half of the students (50%) answered that all of them in general, 25% dislike to write the control program, 11% to build the robot and 10% to design the strategy. We conclude that there is not a very marked preference for one kind of task with respect the others. 45-50% of the students do not manifest any preference. One of the most disliking tasks is programming in Java (25%) because it is one of most difficult task for them, as will be seen later.

- **Difficulties**. Tasks that are more difficult for students (Q14) are related to the integration and testing of the robot (43%) but these are not the ones they dislike. The next task by difficulty level would be programming (35%) and building the robot (17%). Although programming is considered by the students as one of the most difficult (35%) and disliking (25%) task, it is also considered the most important factor to win the challenge (53%) followed by good luck (30%) and building a mechanically good robot (13%).

- **Documentation**. Most of the students (55%) think that the documentation could be improved introducing more code examples (Q22). This issue has been solved in subsequent editions.

c) Impact of the workshop in student's motivation

- **Reasons to enrol**. When students were asked about why they took part in the activity (Q9), the two main reasons were to learn something about robotics (53%) and as a recreational activity (36%).

- **Subjects involved in workshop**. After the experience, students showed more interested in Robotics (Q37). 58% wanted to study more about this topic. Also they showed more interest in Java (Q38): 56% think that they liked programming more, and 44% kept the same opinion than before the workshop.

- **Overall opinion**. The general opinion about the experience was very good (Q10, Fig. 14) and 100% would recommend the experience to a friend (Q11). To calibrate their interest in the workshop, they were asked, as a kind of joke, what their response would have been if they would have had to pay to get better prizes (Q40). Surprisingly they would pay from the workshop. Most of the students (45%) would have participated for 3 €, 17% for 1€ and 23% for 5€.

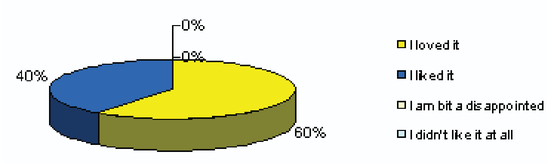

Fig.14: What is your opinion about the experience? (Q10)

d) Perception of the student about their own learning

- **Previous knowledge**. Only 5% has previous knowledge about LEGO kits (Q6), the rest (95%) had no knowledge before starting the activity. Regarding their self-perceived knowledge of Java (Q7), although all of them have a previous course in Java during first semester, in general (58%) their previous knowledge was not very high.

- **Knowledge about robotics**. 98% of the students say that they have increased their knowledge about Robotics. 58% also say that, as a result of the experience, they are more interested in Robotics than before (Q37).

- **Knowledge about Java**. Their perception of learning Java is lower than learning Robotics (Q35). 47% of the students answer that they have learnt about Java, but surprisingly, within this group, 32% felt that concepts learnt were not useful in their degree. In fact, we anticipated these results, because the content of the workshop was not directly related with the content of the programming course as it was mentioned before. Then students were asked about what they would change in the workshop so as to be able to learn more Java (Q36). Only 6% think you cannot learn Java using LEGO. The rest report that it could be useful to have a lecture explaining useful programming techniques (41%), others prefer to have more difficult challenges that need advanced techniques (24%), and finally others chose to have the same challenges, but forcing certain programming techniques (28%).

e) Integrating the workshop in their grades

When students were asked about their opinion if they have to grade the experience (Q31), 10% thought that it should be based on the ranking of the competition, 32% of the people report that the grades should be based on the quality of the robot and the degree of fulfilment of the challenge requirements, 45% thought that there should be a balance among those criteria and only a 18% report that the grades should be based on the evaluation of the robot by the teachers.

f) Using LEGO Mindstorms in other courses

After the workshop, most of the students (94%) report they would like to have some workshops like this in their studies (Q33). In this group, 29% would like to integrate this experience regardless of evaluation criteria, but 65% think that the evaluation criteria have to take into account not only the results of the competition but also the quality of the robot and the fulfilment of the challenges.

C. Experience III: Course on Robotics

1) Context

In the third experience, LEGO kits were specifically used in the context of a course on Robotics, included in the list of BEST summer courses. The Board of European Students of Technology (BEST) [19] is a non-profit organization that provides communication, co-operation and exchange possibilities for students all over Europe. BEST organizes different activities where students from member universities get the opportunity to increase their international experience, establish contacts, improve their English and have fun. Each course is attended by 20-30 engineering students. Participants attend lectures given by the university's teaching staff or by experts from companies. At the end of the course, students take an exam, designed to evaluate the participants' success. The title of the course was "My robot, my lovie and me" [20], took place in June 2009 and involved 24 participating students of different European countries, along with around 10 Spanish members of the organizing local committee.

2) Objectives

The decision to introduce LEGO kits in this context was motivated because it provides a different environment in which some concepts about engineering are learnt in an environment that promotes social interaction. As the course was specifically the LEGO workshop, we had the opportunity to assess the concepts taught during the sessions, without interaction of other elements such as lectures or other laboratory practice.

3) Challenges

Five challenges (Fig. 15) were posed to the students:

- **The chilling cable car**: Build a cable car able to pull itself along a string, as fast as possible.
- **The risky can recycler**: The same as the Robot Recycler challenge in experience II.
- **The impassible robot rumble**: The same as the Robot Sumo challenge in experience II.
- **The fearless cowboy**: Similar to the Line Tracker in experience II, with a higher difficulty level involving harder curves, tunnels, ramps and any sort of obstacles.
- **The grand death race**: Similar to the previous one but introducing crossovers, thus forcing robots to use more sensors to deal with this issue.

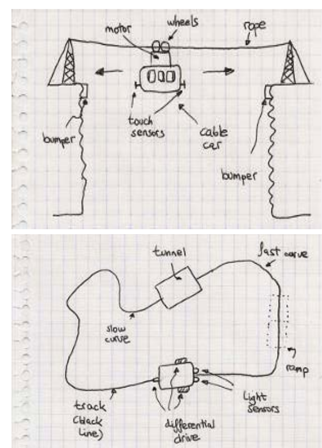

Fig. 15: "My robot, my lovie and me" challenges

4) Methods and Results

To calibrate the impact of the learning experience, an exam was carried out at the end of the course. The exam had 10 questions. Questions from 1 to 5 were about robot components and their behaviour in different situations. Questions from 6 to 10 were about programming the robot behaviour. In both cases with increasing difficulty of the first to the last question of each block. The results are shown in Fig. 16.

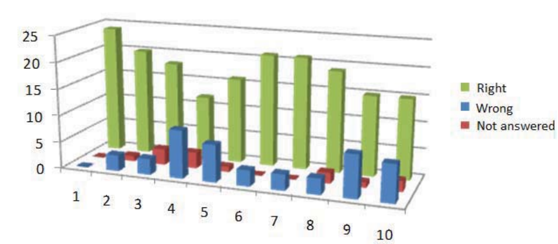

Fig. 16: Exam results in BEST Course

Student performance is high in both cases but noticeable a slight decrease in the number of questions answered correctly at the end of each block coinciding with the increase of difficulty in questions as shown in Fig. 16.

D. Informal learning and workflow

One of the most important results of these ongoing experiences developed over the last five years has been the observations gathered by the teachers and the teaching assistants who supervised the workshop. This information was directly collected by the authors during the sessions and through subsequent interviews to different participants. These observations provide valuable information on how informal learning takes place during the sessions.

One of the findings was that the workflow of the students was the same regardless of age, gender, country of origin or course level into which they were enrolled. It is also independent of the subject they were related to, whether the course was mandatory or voluntary, the result of the activity was or was not part of the final grade and even whether participants knew or didn't know each other before starting the workshop and groups formed spontaneously or as directed by the teacher. Typically the workflow was the following:

- **Understanding the goal and collecting information**. Students attend the teacher introduction and read information about the challenge (description, rules and hints). This information was available from one week before the session but students usually didn't review the material until they were directly challenged in the workshop as shown in Fig. 12 and Fig. 13.
- **Brainstorming and planning**. Then, they planned to outline the characteristics of the robot (large, small, light, heavy, number of sensors and actuators) and the general strategy.
- **Organization and division of roles**. Normally, and usually before finishing the previous stage, the students, trying to be efficient due to the pressure of the competition, begin to distribute the work among them, both explicitly (sometimes they reach an agreement on how to share out the work) or implicitly (sometimes it just happens naturally). It has been observed that there is a general tendency for women to handle more of the tasks associated with building the robot and men related to programming the brick, although this issue has to be further analyzed based on actual objective evidences.
- **Solving problems**. When first problems for each role appear, this is the typical sequence to solve them: 1) Ask team partners with other roles; 2) Review extra documentation (tutorials on building and programming robots using LEGO kits); 3) Ask teaching assistants or teacher(s); 4) Ask students in other teams with the same role.

  Some groups prefer to interact with other students rather than with the teacher, so they first ask the teaching assistants. However, the teacher usually gives a more effective technical help (especially in hard challenges), so some groups directly make this choice. In any case, we are not able to draw any conclusion because the choice can be simply based on availability (usually there is just one teacher and several teaching assistants).

  After the first round of questions, steps 3 and 4 changes the order and finally the sequence is 4 and then 3. This is because normally teaching assistants and teachers are in high demand and are slow to respond and therefore they finally prefer to ask students in other teams with the same role and similar tasks. In most cases, interacting with other teams is enough to solve the problem, and only in very specific cases the teacher support is essentially necessary, for example when the group is severely delayed with respect to others. In this phase, the main flow of information is among students in different teams with the same role, what we would call "meeting of experts".

  At this point, it is worth to notice that, although students provide information to other teams, there is no plagiarism because this help gives them clues to solve their problems, but does not provide them with the whole information that they have used because, after all, this is a competition.
- **Integration tasks**. When different roles advance in their task, they need greater interaction with teammates to integrate all efforts in the same direction because there are strategic decisions that heavily rely on work done by other members. In this stage of the work, there is an important flow of information among teammates who begin to learn about the tasks assigned to other members of their own team.
- **Testing**. Even though the students have tested their work in previous stages, during individual work, in this phase all the teammates work together to build the final result. In this stage the students learn a lot about the work developed by other teammates and all team members work together.
- **Improving performance** to be the better. At this stage, students inspect the robots developed by other teams in great detail and learn the best strategic decisions to integrate them in their own robots.

The mixture of collaborative and peer learning with a competitive environment have been proved to be a great tool to improve motivation and meaningful learning in our students.

When the students were asked about the methodology used during the session they are not always aware of the workflow followed, but the information collected by other sources shows that was the same in all experiments despite the different contexts in which they have occurred.

IV. Discussion

From the very beginning, we didn't think about these experiences as one-off events but instead as ongoing activities that we planned to repeat with a certain periodicity. In fact, once that the initial investment both in LEGO kits and accompanying material (such as sticky tape, ropes, game fields for the challenges, bridges or ramps for the track, etc.) and also in the preparation of teaching material (such as the descriptions of the challenges, the fundamentals of Robotics or AI techniques, tutorials, programming guides, hints, etc.), each new edition is less demanding and the effort for carrying it out is mainly limited to the time for arrangements (lab reservation, software installation), some cheap consumables and, obviously the teacher's attendance to the different sessions.

Specifically, experience I involving ICN course will be repeated on a yearly-basis during each academic year, at least while the current study plan is active. As shown in the result section, students' satisfaction is very high as proved by the annual course evaluation surveys and the increasing number of enrolled students, so it turns out to be a motivating factor.

Regarding experience II, Robot.IT! will continue to be a biannual activity. Here the requirements are considerably harder than in the first case, mainly because of organizational issues (for instance, sessions take place out of normal teaching hours, so we have to deal with the short availability of laboratories and constraints in student timetables) and also because they involve a high number of students.

The survey gives many details about technical issues to maximize success when carrying out activities involving LEGO kits. The results reveal that the optimum team size is three members; the session length of about 3 hours, the number of challenges depending on the available time, the difficult of the challenges proposed is adequate to the students' level of knowledge. Also the study shows that students prefer autonomous and peer learning and they prefer to be technically supported by other students than by the teachers, because the relationship with them is closer. Competition and social interaction are key issues that contribute to increase the student's motivation. Although the experience is fully satisfactory for students and increases their motivation to learn programming, the experience can be substantially improved by stretching the gap between the contents of the workshop and the content of programming courses. Our next steps will be oriented in that direction as we explain in the next section.

Finally, experience III is the least regular one, and whether there will be or not some new editions will depend on factors that are out of our direct control. However, developed materials and ideas can be easily reused in the other experiences.

To sum up, these experiences have illustrated that the participation in workshops as a form of active learning (Fig. 1) is highly motivating for students and contributes significantly to reinforce transversal skills (autonomous learning, problem solving and team work) learnt with this experience.

V. FUTURE WORK

There is still much room for improvement and there are still many new ideas to put into practice in the different scenarios.

From our point of view, in the case of experience I, the problem is that AI courses usually comprise a wide and compartmentalized syllabus covering many techniques and applications in different areas (though very briefly in some cases) that has to be taught (and learnt) in a few hours and by means of a limited short number of exercises. Interest in sessions using LEGO kits is not discussed, as students themselves think, but are in fact quite isolated. We find out that students sometimes have certain difficulties to reinforce those basic concepts or even learn them. In consequence, a major drawback of such didactic approach is that students focus on 3 or 4 topics from the entire course contents. Although deep learning of those topics is probably ensured, learning of the rest of the contents is also probably much more superficial. To overcome this limitation, the schedule has been yearly rearranged to solve some of these problems (mainly eliminating the less interesting topics for engineering students).

In another work, we proposed the application of peer review methodology [20] as a complement to the project-based learning approach in order to allow students to explore in depth other topics besides the one developed in their own projects. Preliminary results are promising, but these conclusions still have to be further studied in detail.

Regarding experience II, we want to strengthen the links among concepts introduced in the programming courses and the ones that students have to put into practice when they are programming their robots during the workshop. Our idea is to make a higher effort to improve the teaching process. First, we are interested in reviewing essential programming concepts such as different types of loops (for, while, do, until), the usage of conditionals (both isolated or inside a loop), the meaning of variables to represent a given state of an automaton, inclusion of arrays, etc. Then we would like to introduce advanced programming concepts, such as multitasking or event-oriented programming, which appear quite naturally during the challenges. In addition, we would like to give the participants and overview of advanced extra concepts related to engineering and Robotics (such as dynamic sensor calibration, basic driving techniques, degrees of liberty of a system, etc.) and/or AI techniques (such as search strategies for problem solving, rule systems, simple machine learning algorithms, etc.). We also will force the interchange of roles among team members in during each session to improve the learning of different skills.

In general, we have to catch the student attention to the workshop. Despite its attractiveness, the workshop is elective and competes against all other courses (compulsory, more important, failed from previous years...). Apart from the workshop contents themselves, there are probably many influential factors, for instance, their timetable or the academic calendar, which have to be considered globally as a whole.

Regarding experience III, no significant changes are planned to be introduced in eventual future editions of the course. However, the promotion of the course will be improved and lessons learnt from these experiences will be introduced.

In addition, a recurrent topic for us is how to foster the development of transverse abilities in students. Lacks in some basic competences are detected in students, such as idea communication, oral or written expression, critical analysis, self confidence, etc. Although this is more a continuous holistic process and the impact of these experiences is very hard to evaluate, we are interested in promoting those competences, so our plans include the incorporation of psychologists or educationists so as to research on this topic.

Finally one of the most important challenges for future editions of these courses is to integrate the conclusions drawn on how informal learning takes place during LEGO Mindstorms® workshop and introduce them in the lectures. To do this, we plan to propose enriched learning experiences, with weekly challenges to be solved by teams of three members. We will try to promote competition among teams and role interchange inside each team. We also provide material for autonomous learning and promote experts meeting among members of different teams with the same role to improve the learning, and integration meetings among members of the same team to fix relationship among concepts.

VI. Conclusions

In this paper, we have described our experience using LEGO Mindstorms® in different context in a period of five years. The originality of our study in relation to previous work is the length of the experience, the fact that it has been performed simultaneously in different contexts and the focus on the way in which informal learning takes place in these competitive and collaborative environments. We also provide a description of challenges, technical issues, parameters and references to implement this experience using LEGO. In addition, we provide the workflow description and list some lessons learnt about informal learning in order to enrich other learning environments not directly related with LEGO Robots.

We have shown the impact of using LEGO workshop in student motivation (Fig. 4). There was a 73% growth in the number of students enrolled in ICN (from 33 in 2005-2006 to an average of 57 students per class in subsequent years) as a result of introduce LEGO Mindstorms® in this course. 71% of the Master's Thesis supervised by the authors was directly related with ICN course (Fig. 5 and Fig. 6). All students surveyed (100%) would recommend a workshop like this and 94% would include similar experiences in other career courses. Measures about the benefits of competitive, collaborative and peer learning as they are perceived by the students have been taken. 74% of the students consider competition among groups a key issue to increase motivation (Fig. 11), 80% consider that teacher assistants are a great help to overcome the challenges proposed and 61% prefer asking other students rather than the teacher because their relationship is closer with them (Fig. 10).

Based on with the data collected during these experiences, we also calibrate some issues like the optimum group size, session length and number of challenges. We expect that the information provided by our experience can be useful to other groups interested in using LEGO Mindstorms® to promote active learning in their classes and maximize the success of their experiences.

Acknowledgments

Thanks to our colleagues Raquel M. Crespo and Jesús Arias for their help in supporting and promoting these experiences. Thanks to Universidad Carlos III de Madrid for its support on the following calls for Experiences on Teaching Innovation: "Active Programming learning using low-cost robots as a motivating factor" (III call, 2005-2006), "And now, what? Development of professional skills and competences" (IV call, 2006-2007) and "Using new technologies in teaching practices to improve teacher-student interaction" (VI call, 2008-2009)

Competencies for Informatics Systems and Modeling

Results of Qualitative Content Analysis of Expert Interviews

Abstract— **This article presents the first results of expert interviews conducted within the project MoKoM funded by the German Research Foundation (DFG). These are intended to refine our first theoretically derived competence model comprising competencies in the domains of informatics systems and modeling. In this context, the question arises, which software engineering workflows could be relevant for software engineering education at secondary schools and which are also adequate in professional contexts. Furthermore, it will be exemplarily shown which competence aspects have been added to the theoretical model and how to advance it in an empirical manner.**

General Issues in Engineering Education, Pedagogies, Modeling Competencies, System Comprehension, Active Learning

I. MOTIVATION

This article describes the methodical strategy to develop a competence model for informatics systems and modeling especially conducting and analyzing expert interviews within the project "Measurement Procedure for Informatics in Secondary Education (MoKoM)" funded by the German Research Foundation (DFG) [1]. Also, first exemplary results of the content analysis of the expert interviews are presented. Due to these results refinements on the theoretically derived model were accomplished. The article gives an outline of an exemplary analysis of 17 interview transcripts. The main focus is on the refinements of the theoretically derived competency model which could be obtained due to the results of the content analysis. Our temporary competence model was derived by means of theoretical and rational considerations. That means that curricula and expert papers treating informatics modeling and system comprehension were taken into account. However, a restriction on exclusively theoretically derived competencies would risk that the reference of competencies to complex requirements in real situations is neglected or disregarded. For this reason, an additional step is necessary in order to determine competencies more reliably, that is, ensuring an empirical access to determinate the relevant competencies. Conducting expert interviews within which the Critical Incident Technique was deployed, representing an appropriate empirical approach in order to detect the relevant competencies which belong to the two domains informatics modeling and system comprehension.

II. THEORETICALLY DERIVED COMPETENCE MODEL

In the following, the four competency dimensions of the informatics modeling and informatics comprehension model are presented.

K1. Basic Competencies

- K1.1 System Application
- K1.2 System Comprehension
- K1.3 System Development
    - K1.3.1 Business Modeling
    - K1.3.2 Requirements
    - K1.3.3 Analysis & Design
    - K1.3.4 Implementation
    - K1.3.5 Test
    - K1.3.6 Deployment

Figure 1. Competence Dimension K1 Basic Competencies

They form the fundamental framework of our theoretically derived competence model.

K2. Informatics views

- K2.1 External view
    - K2.1.1 Expectations of Systems' Behavior
    - K2.1.2 Informatics Literacy & Professional Practice
    - K2.1.3 Usability
- K2.2 Internal view
    - K2.2.1 Layered Architectures
    - K2.2.2 Net-Centric Computing
    - K2.2.3 Systems of Patterns
    - K2.2.4 Algorithms & Data Structures
    - K2.2.5 Fundamental Ideas of Computer Science
    - K2.2.6 Graphical Representations
    - K2.2.7 Languages (Programming & Modeling)
    - K2.2.8 Computational Thinking (imperative, functional, logical, object-oriented)

Figure 2. Competence Dimension K2 Informatics views

All competence dimensions were theoretically based on international syllabi and curricula with high reputation, e.g., the

"Computing Curriculum 2001" of ACM and IEEE [2], "Model Curriculum for K-12 Computer Science" of the ACM [3]. These sources gave us a lot of inspiration and concrete advice for the structuring of our competence model. We also analyzed competence frameworks with high reputation, e.g., "The European Qualifications Framework (EQF)" of the European Union [4], "Definition and Selection of Competencies (DeSeCo)" of the OECD [5]. But none of these competence frameworks are really appropriate for education in the field of computer science.

The competence component K1.2 *System comprehension* was theoretically based on "Development of Competencies with Informatics Systems" [6]. The competence component K1.3 *System development* was theoretically derived from the process workflows of the Rational Unified Process (RUP) [7]. Each dimension comprises different competency components which characterize in more detail the requirements within the two mentioned informatics domains. According to Weinert´s notion of competency [8], competencies encompass both cognitive and non-cognitive skills and abilities.

K3. Complexity

K3.1 Number of Components of Informatics Systems
K3.2 Level of Net-Centric Computing
K3.3 Stand-alone Systems vs. Distributed Systems
K3.4 Level of Human-Computer Interaction

Figure 3. Competence Dimension K3 Complexity

Whereas the first two dimensions K1 *Basic Competencies* (see Figure 1) and K2 *Informatics views* (see Figure 2) are targeted on cognitive aspects with regard to the two domains, the fourth dimension K4 *Non-Cognitive Skills* (see Figure 4) includes attitudes, motivational, volitional and social skills which are of crucial importance for managing high demands and solving informatics problems in complex situations.

K4. Non-Cognitive Skills

K4.1 Attitudes
- K4.1.1 Perception & Anticipation of Informatics Systems
- K4.1.2 Expectations for Informatics Literacy & Professional Practice

K4.2 Social-Communicative Skills
- K4.2.1 Cooperation & Teamwork
- K4.2.2 Empathy: Change of Perspectives & Roles (User, Developer)

K4.3 Motivational and Volitional Skills
- K4.3.1 Openness to new Ideas & new Requirements
- K4.3.2 Learning Motivation
- K4.3.3 Commitment

Figure 4. Competence Dimension K4 Non-Cognitive Skills

The third dimension K3 *Complexity* (see Figure 3) is chosen in order to obtain a graduation of competencies which correspond to different levels of learners' skills. Also for this reason the first two dimensions are additionally graduated according to following taxonomic levels: (1) Knowledge, (2) Transfer and (3) Evaluation.

III. Examples of Qualitative Content Analysis of Expert Interviews

A. *Procedure of Conducting and Analysing the Expert Interviews*

In a first step of the empirical procedure the expert interviews were conducted. 30 experts on informatics, with a division in three equal groups were interviewed: experts in the domain of didactics of informatics, computer scientists and expert informatics teachers. This sample configuration was chosen in order to reveal the widest possible range of informatics and didactics expertise. The interview was based on a structured questionnaire manual and included questions concerning the expert status of the interviewees and several scenarios concerning application, testing, modifying and developing of informatics systems resp. software. Altogether 12 scenarios were used in the interview. To limit the duration of the interviews to an appropriate length each interviewee was only interviewed to four scenarios. Each interview lasted about 60 to 90 minutes. The interview included the following steps: (1) Welcoming the interviewee and introducing the underlying notion of competency and the interview technique (critical incident technique), (2) Presenting each scenario to the interviewee and encouraging him or her to give details of his/her intimate proceedings and approaches to solve the presented informatics problem, (3) Asking the interviewee to evaluate the four hypothetical scenarios with regard to their representativeness (with reference to rating scales).

The expert interviews were transcribed in full and analyzed by means of qualitative content analysis according to Mayring [9]. The main objective of qualitative content analysis is to reduce the large text material to a manageable size in such a manner that important information is not wasted. *Summarizing, explicating and structuring* are the main techniques of qualitative content analysis. The first technique enables to compress extensive proportions to text material. Deploying the second technique additional text material is brought to those passages in the text which need further explanation. The third technique means that a certain structure is extracted systematically from the text material. In our case this structure was brought to the text material in the form of our category system which belongs to our theoretical competency model. Analyzing the interview transcripts, all three techniques were applied. They do not mutually exclude one another, but rather complement each other well. At first, meaning units (i.e. textual elements containing relevant information concerning competencies) were systematically extracted. In the next step, it was investigated if the gathered meaning units could be matched to the competency categories of our model.

B. *Informatics Systems*

In Section B, we focus on K1.2 S*ystem comprehension* and its relations to other competence dimensions through concentration on a typical scenario "testing of unknown software (developed by others)". This scenario and its questions will be introduced to the interviewees as follows.

Scenario: "*You are asked by a colleague to test his software, which was developed to solve configuration problems, e.g., to set up a new car or a new computer.*"

Question 1: *"What is your strategy of testing to solve this problem? Which aspects do you have to bear in mind?"*

Question 2: *"Which cognitive skills are required for such a software exploration?"*

Question 2.1: *"Which informatics views are important for this task?"*

Question 2.2: *"Which complexity would you assign to this task?"*

Question 3: *"Are there any attitudes or social communicative and cooperative skills which are necessary to accomplish this?"*

Question 4: *"Which differences of competence levels would you expect between novices and experts?"*

Question 5: *"Could you imagine a potential pupil's procedure to solve this problem?"*

Question 6: *"Which obstacles would pupils have to cope with?"*

This scenario was interpreted through qualitative content analysis. Out of 26 interviews, eight experts were asked about such a scenario. The first results of the qualitative content analysis have to be structured according to the dimensions of the competence model. Relations between the competence components and meaning units in the interview have to be found and described (matching).

For this we use the following expressions: Answer plus number of competence component followed by the original statement of the expert (if necessary shortened). If the expert discovered a competence component, which is underestimated, this leads us to an additional answer. If the experts delivered a recommendation how to foster this needed competence component, then we add a more sophisticated description of the situation.

Firstly, K1.2 has to be proved. Therefore, a key question of the analysis process is how the experts support the assumption that testing of unknown software delivers an approach to informatics systems comprehension. The following three answers are examples of this proof of our assumptions:

Answer K1.2 (system comprehension): *"Then you need to understand fundamental mechanisms or relations or concepts, correctness of software, termination, knowledge about software ergonomics"*.

Answer K1.2 (system comprehension): *"I need a kind of model-view on the informatics system to explain the system's reactions that could be surprising. That means I need a model of processes behind the GUI"*.

Answer K1.2 (system comprehension): *"I will use my increasing system comprehension to plan the input-output relations."* The experts recommend for learners an unexpected exploration with non-systematical testing, which will fail for sure, followed by the successful systematic strategies of testing. But this should not be misunderstood as a guide line for school lessons.

The more experienced the experts were in the field of school informatics, the easier we could match their meaning units with the components of the theoretically founded competence model. This could be a hint that the competence model is not close enough related to the practice of software development. To remove doubts we trust on the evaluation of the next version of the competence model through the method of expert rating. Until then, we take this as an indicator that the rough structure of the theoretically founded competence model is appropriate.

To illustrate this, we give one example to each competence component beginning with the competence dimension K2 *Informatics views*:

Answer K2.1.1 (expectations of systems‘ behavior): *"You are not able to cope with a certain input mask if you don't know which input is expected."*

Answer K2.1.3 (usability): *"All parts of a Graphical User Interface have to be tested."*

Answer K2.1.4 (functional view): *"When the functionality and reliability of the informatics system was systematically tested, then we evaluate the other aspects of the quality of the software." (*new competence component; see Section IV/A*)*

Answer K2.2.8 (computational thinking): *"You have to learn which programming style is most appropriate for the given class of tasks. An important obstacle for this selection is the boundary of one and only one well-known programming style."*

The experts mention the handicap of the first and only successful problem solving strategy, e.g. a specific programming style. This phenomenon leads to failure, if one is matching a problem to an inappropriate problem solving strategy. A solution is a broad range of informatics strategies. The first successful informatics paradigm learned by a developer (student) is mostly applied even if it is not the best fitting solution.

Answer K4.1 (perception & anticipation of informatics systems): *"For the task of systematic testing perseverance and accuracy are indispensable for success."*

In turn, through the success you can improve your ability in accuracy and perseverance.

Answer K4.1.2 (expectations for informatics literacy & professional practice): *"A software engineer is responsible for the safety of humans and has to avoid any danger to life and limb."*

Answer K4.1.2 (expectations for informatics literacy & professional practice): *"Sensitization of pupils with respect to quality of software and responsibility."*

Answer K4.2 (social-communicative skills): *"One has to communicate with customers."*

Answer K4.2 (social-communicative skills): *"There is a serious contradiction between the competence of problem solving and the social-communicative competencies."*

It is necessary to supervise the development of social-communicative competencies, since they are not fostered as a side-effect of informatics problem solving. The task of systematic testing gives the opportunity to gain non-cognitive competencies on a higher level when the learner presents his results to other learners e.g. the explanation of use cases, the presentation of test results including the visualization of large data collections.

Answer K4.2.2 (empathy: change of perspectives & roles): *"When we test software of others, we have to learn to criticize in a fair and sensitive way."*

To foster empathy, systematic testing delivers the opportunity of mutual peer reviewing, i.e. each person has to give constructive criticism, handle criticism of others and not to insult others in a careless way while criticizing.

Answer K4.3 (motivational and volitional skills): *"This process leads to deep satisfaction with your own work and after a long period to a positive attitude towards high quality of software."*

From K1.2 to K4.3, the content analysis has shown 14 especially illuminating results in the form of support with refinements of the theoretically derived competence model. This leads us to the conclusion that the decision for this research method was very successful. The set of data allows a new version of the competence model influenced by the empirical studies (see Section IV / A).

C. Informatics Modeling

A typical scenario for K1.3 *System Development* in the expert interviews is the development of a software project or to pass a particular workflow within the software development process. In the following one exemplary scenario "Merchandise Management System" will be introduced.

Scenario "Merchandise Management System":

"You are asked to develop a software based merchandise management system for a small school kiosk.

Question 1: *"What is your course of action to solve this task? Which software engineering workflows do you have to pass?"*

Question 2*: "Which graphical models would you apply?"*

Question 2.1: *"Which informatics views are important for this task?"*

Question 2.2: *"Which complexity would you assign to this task?"*

Question 3*: "Which cognitive skills are required to develop such a software system?"*

Question 4: *"Could you imagine a potential pupil's procedure to solve this problem?"*

Question 5: *"Which attitudes, social communicative skills and motivational aspects are necessary to solve this problem?"*

In this connection, meaning units have to be derived from the interviewees' answers to *Question 1-5*. Furthermore potential relations between meaning units and components of the theoretically derived competency model have to be investigated.

Many interviewees stressed that K1.3 *System development* is an important ICT related competency and learners have to pass the workflows of professional software engineering processes.

Answer K1.3 (system development): *"We have to run through the workflows of the waterfall model."*

Answer K1.3 (system development) *"We have to pass the workflows of professional software development processes."*

The following interviewees' utterances accentuate specific software development workflows (K1.3.1 – 1.3.5) and competencies which could be allocated to them.

The K1.3.2 *Requirements* was mentioned five times. In this interrelation it was declared that learners have to be able to analyze use cases and to specify functional requirements.

Answer 1.3.2 (requirements): *"Analyze use cases to gain information about the way the system is used."*

Answer 1.3.2 (requirements): *"Specify functional requirements."*

The K1.3.3 *Analysis & Design* was mentioned by a large number of interviewees. It was stated that K1.3.3 *Analysis & Design* are processes which obey many iterations. In order to gain additional information to refine the theoretically based competency model it was expedient to subdivide these utterances to *Analysis* and *Design*. Nevertheless these workflows are strongly interwoven and will be mostly passed within several iterations [7, p. 2].

Answer K1.3.3 (analysis & design): *"Analysis Workflow has to be passed."*

Answer K1.3.3 (analysis & design): *"Object-oriented-Analysis has to be run through."*

Answer K1.3.3 (analysis & design): *"Within Analysis Workflow, learners have to envision the problem/task".*

Concerning the *Design* the interviewees mentioned that learners have to choose appropriate concepts and to develop their own conception to design an informatics system.

Answer K1.3.3 (analysis & design): *"Learners have to get familiar with several design-techniques."*

Answer K1.3.3 (analysis & design): *"Learners have to be enabled to choose an appropriate concept to design an informatics system."*

Answer K1.3.3 (analysis & design): *"They have to be able to derive potential program modules and tasks."*

Answer K1.3.3 (analysis & design): *"After all learners must get to know how to develop an own conception for designing the software."*

Irrespective of a potential distinction between *Analysis* and *Design* the interviewees listed several UML modeling techniques. This shows that learners have to be able to choose appropriate modeling techniques with respect to the actual software iteration.

Answer K1.3.3 (analysis & design): *"Learners have to apply UML-diagrams"*

Answer K1.3.3 (analysis & design): *"Develop class diagrams."*

Answer K1.3.3 (analysis & design): *"Identify potential classes."*

Answer K1.3.3 (analysis & design): *"Identify and allocate constituent parts of a class diagram, i.e. attributes, methods, associations and inheritance."*

Answer K1.3.3 (analysis & design): *"Applying state charts."*

Answer K1.3.3 (analysis & design): *"Applying deployment diagrams."*

The K1.3.4 *Implementation* was mentioned four times. In this context it was stressed that learners should be enabled to understand algorithms and to become familiar to an (Object-oriented-) programming language

Answer K1.3.4 (implementation): *"Understanding algorithms (recursive algorithms in particular)."*

Answer K1.3.4 (implementation)*: "We have to learn how to implement programs in a specific programming language and to cope with syntax errors."*

Answer K1.3.4 (implementation): *"Becoming familiar to Object-oriented-Programming."*

Answer K1.3.4 (implementation): *"Understanding the distinction between class-/object- attributes and –methods. "*

As mentioned in chapter A it is important to foster K4.2 *Social Communicative Skills* within informatics problem solving processes. Passing the *Implementation* offers the opportunity to develop software in teams.

Answer K4.2 (social-communicative skills): *"Programming in teams"*

In addition the interviewees mentioned that learners have to be able to integrate software modules (worked out by teams) into a comprehensive software system. Although the following meaning units could be allocated to the K1.3.4 *Implementation,* this might give advice to supplement the theoretically derived competence model by adding the component K1.3.6 *Deployment*.

Answer K1.3.4 (implementation): *"Synchronizing modules developed in teams."*

Answer K1.3.4 (implementation): *"Assembling modules developed in teams."*

Additionally it was stated that learners are faced with informatics system of a different grade of completion. Consequently the following meaning units might give us advice how to supplement the competency dimension K3 *Complexity of an Informatics System*.

Answer K1.3.4 (implementation): *"Learners must be able to develop software from the scratch."*

Answer K1.3.4 (implementation): *"Learners have to be enabled to get involved in an already existing informatics system and to re-engineer it."*

Answer K1.3.4 (implementation): *"They have to learn to analyze interfaces of an existing informatics system."*

The relevance of the K1.3.5 *Test* was declared by three interviewees.

Answer K1.3.5 (test): *"Testing and justifying the product's quality by comparing it to the (functional) requirements."*

Moreover the interviewees mentioned some well-established software testing procedures:

Answer K1.3.5 (test): *"Performing Blackbox-Testing."*

Answer K1.3.5 (test): *"Performing Whitebox-Testing."*

Answer K1.3.5 (test): *"Performing Regression-Testing."*

In summary this chapter illustrates several meaning units, which were derived from the interviewees' answers. These were structured with respect to the subcomponents of K1.2 *System Development*. According to this assignment of meaning units to the competence components (K1.2.1-K1.2.5), chapter IV-B will show how to refine the theoretically derived competency model, i.e. illustrating components which have to be justified, pointing out components which seem to be appropriate, showing interrelations to other competency dimensions and lining out components to supplement the model.

IV. Empirically Refined Competence Model

A. Informatics System

In this paragraph we discuss the consequences of the content analysis (see Section III / B). The competence component K1.2 *System comprehension* has to be refined with two sub components, K1.2.1 *Requirements* and K1.2.2 *Test* (see Figure 5). The following examples will illustrate this:

Answer K1.2.1 (requirements): *"You have to compare the real system's behavior with the definition of its requirements."*

K1. Basic Competencies

K1.1 System Application
K1.2 System Comprehension
  K1.2.1 Requirements
  K1.2.2 Test
K1.3 System Development
  K1.3.1 Business Modeling
  K1.3.2 Requirements
  K1.3.3 Analysis & Design
  K1.3.4 Implementation
  K1.3.5 Test
  K1.3.6 Deployment

Figure 5. New Competence Dimension K1 Basic Competencies

Answer K1.2.2 (test): Systematic testing is mentioned by all experts. This should be learned through strategies (blackbox testing, whitebox testing), manuals and tools of testing.

The competence dimension K2 seems to be very important. A criterion for the success of problem solving is the selection of the most appropriate informatics strategy related to theoretical foundations and practical tools. Denning defines views as "The five windows of computing mechanics" [10, p 17]. Therefore, a change is recommended between different solution strategies of problem solving. Several experts stress the meaning of this relation. Informatics should not be reduced to programming. Therefore, we assume that this competence dimension is incomplete if only a static sequence of K2.1 *External view* and K2.2 *Internal view* with their facets is considered and we insert a new component, K2.3 *Change of views*.

Also the competence component K2.1 *External view* needs refinement, but only with one new sub component, K2.1.4 *Functional view* (see Figure 6), including input- output relations and state diagrams.

Answer K2.1.4 (functional view): *"In my opinion the view on the whole system has to be called functional view. This is connected with the analysis of input-output relations and designing and understanding of state diagrams. "*

For the competence dimension K3 we discovered a special situation. The competence components which we used, e.g., a "count of components", are not mentioned by any expert. But new competence components like combinatorial complexity and the complexity measures, time and space, are stressed very often. This leads us to the decision to insert two components, K3.5 *Combinatorial complexity* and K3.6 *Measures of complexity: time and space* (see Figure 7). Maybe we will later skip the unsuccessful components. It is too early to finalize this decision.

Answer K3.5 (combinatorial complexity): *"It is clear that we have to cope with the combinatorial complexity of 10^{10} solutions in the process of systematical testing."*

Answer K3.6 (measures of complexity: time and space): *"To characterize the quality of the software we should use runtime performance (including efficiency) and memory requirements to evaluate an informatics system, which lead us to the complexity measures, time and space."*

Furthermore, the scalability of problem solving strategies is related to the complexity of informatics systems. We found an impressive number of experts' statements, which connect scalability with the competence dimension K2 *Informatics views*. But in an unexpected way, the experts did not mention the role of scalability in the context of *Question 2.2* on the assigned complexity. We took all pro and contra arguments into consideration and came to the conclusion that it is necessary to put scalability into the competence model as new competence component, K3.7 *Scalability*, with strong connection to the other complexity factors.

To summarize the most important results of empirical evaluation line A (Informatics systems), in the following two paragraphs we focus on a deeper discussion of K2.3 *Change of view* (see Figure 6) and K3.7 *Scalability* (see Figure 7). Both results could be seen as a bridge between the empirical evaluation lines A and B (Informatics modeling).

K2.3 Change of view: In the particular research on system comprehension (during the last four years) we developed a successful strategy of changes of views from *observable behavior* (S_A) to *internal structure* (S_B) without focus on *construction of a concrete realization* (S_C). The main advantage is the change of view from *observable behavior* (S_A) to *combination of behavior and internal structure* (S_{AB}) and then to *combination of internal structure and construction of a concrete realization* (S_{BC}) and then to *combination of behavior and construction of a concrete realization* (S_{AC}). "The learners are able to explain, why a certain internal structure has been chosen with respect to the intended behavior of the informatics system." [11, p. 7]. Further research results are two important connections, firstly between static and dynamic properties of informatics systems and secondly between exploration and development of informatics systems. On our way from a theoretically established competence model to an empirically proved one, the change of view effects also the networked thinking in different ways: networking of fundamental ideas of informatics, networking of informatics sub systems, networking of successful patterns of informatics, such as object-oriented design patterns and architectural patterns. Surprisingly this opens an approach to informatics competencies not only connected with modeling and programming but to exploration of informatics systems.

K2. Informatics views

K2.1 External view
- K2.1.1 Expectations of Systems' Behavior
- K2.1.2 Informatics Literacy & Professional Practice
- K2.1.3 Usability
- K2.1.4 Functional View

K2.2 Internal view
- K2.2.1 Layered Architectures
- K2.2.2 Net-Centric Computing
- K2.2.3 Systems of Patterns
- K2.2.4 Algorithms & Data Structures
- K2.2.5 Fundamental Ideas of Computer Science
- K2.2.6 Graphical Representations
- K2.2.7 Languages (Programming & Modeling)
- K2.2.8 Computational Thinking (imperative, functional, logical, object-oriented)

K2.3 Change of View

Figure 6. New Competence Dimension K2 Informatics views

K3.7 Scalability: Here we face the problem that most research results target on informatics modeling. We will refer to selected examples: In Informatics complexity of a problem resp. task plays an important role. Depending on the size of input n, how many resources, represented by the function f(n) are necessary to process a program on a machine. Resources may be the necessary time and space, the number accesses to the data bases etc. Some standard algorithms deliver good results for a small input size, but for a large input size they deliver bad results or no solution in a given time boundary. Therefore, the criterion scalability can be used to decide, which solution (system, algorithm, process) should be applied to different problem sets.

K3. Complexity

K3.1 Number of Components of Informatics Systems
K3.2 Level of Net-Centric Computing
K3.3 Stand-alone Systems vs. Distributed Systems
K3.4 Level of Human-Computer Interaction
K3.5 Combinatorial Complexity
K3.6 Measures of Complexity: Time & Space
K3.7 Scalability

Figure 7. New Competence Dimension K2 Informatics views

There are nearly no publications for the influence of scalability of system comprehension. One example would be to find an efficient search strategy in relation to the expected search space. This means, you should not use the same strategy for searching key words in a finite text and for application of a web based search engine assuming a huge amount of candidates in the solution set. This leads us to heuristic solution strategies. Furthermore, scalability is an evaluation criterion for the range of application of a given informatics systems or tool.

The application of the empirical method Critical Incident Technique and content analysis established seven new competence components with respect to a scenario on system comprehension:

- K1.2.1 *Requirements,*
- K1.2.2 *Test,*
- K2.1.4 *Functional view,*
- K2.3 *Change of view,*
- K3.5 *Combinatorial complexity,*
- K3.6 *Measures of complexity: time and space,*
- K3.7 *Scalability.*

The same empirical method allows removing competence components. But to be one the safe side, we decided that we use the second empirical method, expert rating, to prove the agreement of the experts with the now more completed competence model. And after this research phase, it is easier to discover redundancies and removable components. This means, we can merge different components if necessary, in case of redundancies.

B. Informatics Modeling

The component K1.3 *System development* is an important part of the competency model, because it covers essential processes and competencies to develop an informatics system. Nevertheless the analyses of the expert interviews have shown the need to refine this component.

In this connection no interviewee stressed the K1.3.1 *Business modeling* or competencies which could be explicitly allocated to it. Hence this competency component has to be justified by taking further interviews and expert ratings into account or regarded as not be relevant for system development at least on secondary level.

K1.3.2 *Requirements* was mentioned several times and seems to be appropriate at this stage of work.

K1.3.3 *Analysis & design* was stressed by many interviewees. Nevertheless there are a lot of meaning units derived from the interviewee's utterances, which could be explicitly allocated to analysis or to design. Consequently it seems to be serviceable to split K1.3.3 *Analysis & design* into these separated workflows in order to categorize competencies more precisely. As mentioned before these workflows are interwoven and will be passed within several iterations [7, p. 2]. Irrespectively the analysis of the interviewee's utterances has shown that learners have to be fostered to choose serviceable modeling techniques and an appropriate course of action with respect to the actual iteration of the software engineering process (abbreviation: *sequencing pattern*). Fostering this kind of competency enables learners to restructure knowledge in multiple ways according to changing situational demands [12] and constitutes a precondition for situational learning. The application of different modeling techniques requires static views as well as dynamic views, e.g., class diagrams to support the static view and state diagrams for the dynamic view. To foster appropriate modeling competencies, K2.3 *Change of views* is inevitable.

Additionally, adding "Sequencing pattern*"* could be another purposeful refinement of the competency model. Furthermore, the selection of appropriate modeling techniques according to the actual stage of development of the software engineering process represents the appliance of scalable informatics problem solving strategies. Hence, K3.7 *Scalability* seems to be interwoven with other complexity factors of an informatics system and justifies the supplementation of K3 *Complexity* once more. Choosing expedient modeling techniques also comprises the appliance of several UML diagrams. This competence facet could be assigned to K1.3.3 *Analysis & Design* as well as to K2.2.6 *Graphical representations* and illustrates the linkage between K1 *Basic competencies* and K2 *Informatics views*.

As illustrated in chapter III / C K1.2.4 *Implementation* is an essential workflow within software engineering processes. The illustrated meaning units show its interrelation to other dimensions of the competency model. In this connection *understanding of algorithms* can also be assigned to K2.2.4 *Algorithms & data structures* and constitutes an important internal view on an informatics system. In addition to K1.2.4 *Implementation,* object-oriented programming can also be allocated to K2.2.7 *Languages (programming & modeling)*. These interrelations illustrate the linkage between K1 *Basic competencies* and K2 *Informatics views*. Furthermore the interviewees mentioned that learners have to be fostered to develop an informatics system from the scratch and to re-engineer an already existing informatics system, i.e. analyzing interfaces or integrating new program modules into a comprehensive system. These different approaches might illustrate the handling with informatics systems of a different grade of completion. Hence, “grade of completion” might be an appropriate competency component to describe informatics systems of varying complexity. Consequently this competency component might be useful to supplement K3 *Complexity*.

In addition to the interviewee’s utterances concerning the system’s completion many interviewees declared expressly that learners have to be enabled to synchronize and to assemble program modules (developed by teams) in order to integrate them into a comprehensive informatics system. Accordingly it seems to be expedient to supplement K1.3.2 *Requirements* to the competency model. Additionally synchronizing and assembling program modules demands K4.2 *Social-communicative skills*. In this context workgroups have to agree to common interfaces for instance. This fact shows, that K1 *Basic competencies* is also related to K4 *Non-cognitive skills*.

K1.3.5 *Test* was also mentioned by many interviewees and seems to be appropriate as a constituent part of the competency model.

The application of the empirical method Critical Incident Technique and content analysis established two new competence components with respect to a scenario on system development:

- K2.3 *Change of view,*
- K3.7 *Scalability.*

This chapter focuses the empirical refinements of the theoretically based competency component K1.3 *System development*. In this context almost any of the subcomponents (K1.3.1-K1.3.5) seem to be appropriate. Furthermore there are several interrelations between the competency dimensions (K1 to K2, K3, K4). In addition, it has shown to be serviceable to add new components to the theoretical model. Particularly adding “Sequencing pattern” indicates that informatics modeling covers competencies to consciously select problem solving strategies according to the respective context the learners are faced. The supplementation of “Deployment” shows that modules worked out by working groups have to be consolidated in an expedient manner. Consequently it is inevitable to foster K4.2 *Social-communicative skills* explicitly and they should not be treated as negligibility.

V. Conclusions

As highlights of this article we summarize two research results, which will influence our further work in a specific way. These are *Scalability* and *Change of view*.

Scalability was found through the different research perspectives, informatics systems and informatics modeling. One important conclusion in Section IV / A was the criterion scalability can be used to decide, which solution should be applied to different problem sets. Another important conclusion in Section IV / B was that the context specific selection of modeling techniques represents the application of scalable informatics problem solving strategies. For the reader it is obvious that the person who is faced with an informatics system plays different roles, firstly as an explorer of informatics systems, secondly as a developer of such systems. It would be possible to describe both phenomena with different expressions to distinguish these aspects of scalability. But we decided to combine the two conclusions in one more abstract competence component K3.7 *Scalability*, because both aspects constitute the appropriate problem solving strategy.

In the same way we found change of view through the different research perspectives, informatics systems and informatics modeling. The research perspective on informatics systems delivers the next conclusion; the change of view affects the networked thinking in different ways. The analogue conclusion from the perspective of informatics modeling leads to K2.3 *Change of views*, which is inevitable to consciously use different modeling techniques.

This article presented first exemplary results of an empirical approach to determine competencies with reference to the domains *Informatics System Comprehension* and *Informatics Modeling*. The described results suggest that refinements and supplements to the theoretically derived competence model can be accomplished. On the basis of 17 from a total of 30 interview transcripts, it has been shown how the interviews were conducted and analyzed. Furthermore, it has been demonstrated how the results were applied to prove the theoretically derived competence model and to refine and supplement the model.

The described empirical procedure to complement the theoretical model is nevertheless restricted: One methodological restriction includes that the relevant competence requirements cannot be actuated comprehensively by the used scenarios. So it is important that the scenarios contain at least typical and representative tasks and problems to solve. This was evaluated by the represenativeness ratings of the experts. Furthermore, the actions described by the informatics experts might not necessarily mirror their actual behavior in those scenarios because they could describe idealized actions to solve the problems in the scenarios. On this issue, the different orientations of expertise of the interviewees serve as a corrective to some extent. The deployment of the qualitative content analysis took place adhering to comprehensible, methodical rules and principles. Nevertheless, qualitative analyses include inevitably interpretative processes which might restrict the objectivity, reliability and validity of the described analyses.

So it is necessary to prove the resulting competence model in further empirical research steps focussing on the content and criteria validity of the model. In a first step informatics experts with different backgrounds of expertise shall evaluate the relevance, difficulty, representativeness and differentiation of the determined competencies to prove the content validity of the model. The analysis of the criteria validity of the model is focussed on the following question: Do the determined competencies describe the requirements of successful acting in a sufficient manner? In order to answer this question, instruments to measure the different facets of the competence model and the criteria behavior have to be developed. Based on these measurements, then the correlations between the levels of competence on the one hand and the successful problem solving behavior as criteria on the other hand can be interpreted as criteria validity indicators of the competence model.

Abstract—**This paper describes an experiment conducted in Brazil in teaching an undergraduate database course to Computer Engineering and Computer Science students at the University of Campinas (UNICAMP). The experiment has introduced advanced (graduate-level) material in this introductory course, showing students how to integrate course material into several other subjects. The ultimate goal is to engage students in a richer learning environment, enhance motivation, broadening their horizons, and showing them how to solve problems in other fields by looking at a problem from distinct angles.**

This work was conducted within a binational research project involving UNICAMP/Brazil and Jacobs University/Germany.

Keywords- computer science education; multi-disciplinary teaching; non-standard databases; raster databases

I. Introduction and Motivation

Computer Engineering (CE) and Computer Science (CS) courses are seeing a progressive drop in student enrollment in several countries – see, e.g., the annual CRA report [1]. Given the pressing need for qualified manpower in this area, universities all over the world are updating their curricula, or introducing new course modalities, to attract a wider spectrum of candidates. Furthermore, traditional subjects are being restructured to show students how to apply what they learn to new domains.

The University of Campinas (UNICAMP, Brazil) is not an exception to this activity. It is one of the country's foremost universities. Undergraduate computer science courses have been introduced in 1969, making them oldest in the country. The UNICAMP computing courses are consistently rated among the country's top five courses (out of roughly 2,000 computing courses).

Besides being responsible for two undergraduate curriculae (in Computer Science and one modality of Computer Engineering) and the graduate program in Computer Science, the Institute of Computing is also responsible for the basic education in computing for the entire university. This increases its responsibility in keeping its courses up-to-date and tailoring them to specific needs (e.g., for Arts or Biology students). Hence, the contents of computing courses go through frequent updates as part of the university's policy of training high-level professionals.

This paper describes results of applying one such modification, in an experiment which was conducted during the first semester of 2009. The experiment concerns teaching database management systems to second year CS and CE majors.

The main goal of this experiment was to introduce a new way of looking at databases, showing students how they could combine what they were learning during this course with what they had seen in other subjects, so that they could solve problems in other sciences. As an experimental platform the rasdaman system [2][3][4] was adopted. This is an open source database system geared towards the management of multi-dimensional raster data, i.e., arrays in a programming sense. Rasdaman allows students to query different kinds of scientific data stored and managed by a database management system; in our case, this is PostgreSQL [5]. With its raster query language, rasql, rasdaman smoothly extends the retrieval capabilities of SQL to multi-dimensional sensor, image, and statistics data as they appear in manifold variations in the earth and life sciences and beyond, such as astronomy.

The paper discusses our findings on extending classical database teaching with a non-standard, but SQL-like retrieval language which allows performing visual query experiments in domains appealing to "techies". Discussion is based on tests applied during the course and a questionnaire filled by the students. These findings point at the interest of motivating basic computing courses with multidisciplinary material from other disciplines. They also show that it is possible to adapt graduate level subjects to an undergraduate course. This not only helps those who are interested in pursuing graduate work, but also shows students the need for first learning the basics, so that afterwards they can understand advanced topics.

The remainder of this paper is organized as follows. Section II briefly presents the contents of a basic database course, and comments on how it is being taught at UNICAMP. Section III discusses advanced material used in our experiment, usually considered at graduate level. Section IV presents rasdaman, the retrieval tool used here. Section V follows on this by comment-

This project is sponsored by CNPq (Brasil) and DFG (Germany) and partially supported by grants from Brazilian funding agencies CAPES and FAPESP.

ing on the exercises applied, and analyzing the results. Section VI covers some related work. Section VII concludes the paper.

II. Teaching Database Systems to undergraduate CS students

A. *Basic course material*

Traditionally, basic database management courses cover two complementary aspects: modeling and design, centered on creating a database from a given set of user requirements; and internals of database systems, covering issues such as query optimization, transaction processing and storage structures. These two aspects are often treated in separate courses, the first emphasizing user-related problems, and the second systems implementation issues.

These subjects are usually considered as part of the core of Computing curricula – e.g., [6] – being taught within not only Computer Science and Computer Engineering programs, but also in MIS-related programs [7]. However, in spite of the immediate application of what they learn in this course, students are seldom able to generalize the concepts.

This is, of course, not a problem particular to database teaching, but rather concerns the way courses are often taught in the credit-based system. One way to approach this problem is to introduce projects to be solved by teams [8]. This approach, sometimes called "Project-based learning", is common to many engineering and technological courses, helping students to learn to work together, an essential skill for all professionals. In particular, in database courses, students are given a problem and have to solve it by designing and constructing a database, and subsequently develop an information system on top of this database, accessible by "end-users".

This requires several basic computing skills, such as requirement analysis, programming and designing data structures. For this reason, database courses should never be offered in the first year of study of CS or CE majors.

B. *Teaching databases – connecting with other courses*

The approach of teaching databases separately from the users' and from the system's point of view gives lecturers and students more time for each subject. On the other hand, students find it difficult to connect the two views. Thus, at UNICAMP, we have designed a basic course that combines both aspects. Students may afterwards take additional credits on advanced topics.

The first author has been teaching database-related topics for over 24 years at UNICAMP, striving to connect course content with other courses [8]. This approach is based on showing students that they can use material covered in databases as a means to partially reviewing other courses they have taken, as well as a preview of other courses.

Course material and exercises are divided into user-related and systems-related. Each topic is introduced with examples and motivation from other topics, always reminding students that subjects cannot be considered in isolation. Table 1 summarizes this approach. Column 1 enumerates a few basic course subjects, and Column 2 indicates courses in which related subjects are taught. The first three lines are mostly user-related concerns, and the SQL language is used as an entry point to systems issues, which are covered in the last four columns.

C. *Barriers to overcome – bringing the curriculum up to date*

Like in any other CS subject, there is a need to combine two sometimes conflicting goals – to cover the necessary basic material, and introduce advances and state of the art questions to prepare students for their professional life.

Our experiment, discussed from now on, combined these goals. As will be seen, we introduced advanced graduate material in the introductory database course – namely, non-standard queries and applications. To further motivate students and enhance learning, we used a raster query engine so that they had a practical, hands-on experience of visually interesting material.

III. New paradigms – non-standard queries and applications

Databases are omnipresent in industry, science, and government, hence there is a plethora of practical examples just waiting to be exploited for teaching. Still, in today's classrooms the prevailing scenarios center around business applications or academic administration ("students – teachers – courses"). However, our observation is that at least Computer Science and Engineering students typically have a high technical/scientific affinity and feel much less enthusiastic about administrative and business scenarios. Hence, scientific use cases bear a significant motivation potential for this audience.

TABLE I. Relating database and other subjects

Course Subject	Other courses
Database modeling and design Requirement elicitation	Software engineering Interface design
Map conceptual to logical levels (e.g, ER to relational) Normalization	Algorithm design Logics
Formal query languages SQL basics	Compilers Logics Interface design
Query optimization	Compilers Operating systems Software engineering
Transaction management	Operating systems Algorithm design Distributed systems
Concurrency control Recovery mechanisms	Operating systems Distributed systems Algorithm analysis
I/O and data structures	Algorithm analysis Computer networks

An additional shortcoming is the lack of appealing visual effects – generally, a database course is perceived much less exciting than, e.g., computer graphics and visualization. Typically, visualization in databases is only addressed when it comes to a condensed presentation of query results to support human grasping of properties embedded in large data sets [10]. Taking advantage of a truly visual semantics normally is not addressed; even multimedia databases aim at extracting semantic information from images to later on query only alphanumeric data, but not the images themselves.

Aside from motivational reasons, exposing students to non-classical data and query models bears a value because it widens the horizon and avoids hardwiring the equation

“databases ≡ SQL”

in the students’ brains. Addressing XML databases is one possible counter measure, but these are not necessarily exciting in terms of visual presentation and use case scenarios either.

Our approach attempts to leverage the benefits of truly visual information for database education. In this approach, it does not matter whether students later on in their professional lives deal with such kind of data and query models – the driving forces in this experiment are (i) student motivation through visual experiences with scientific semantics and (ii) extending the students’ horizon beyond “classical” SQL.

To this end, we chose scientific sensor, image, and statistics data as our target. Most often, when sampled or generated from simulations, these come as raster data of some specific dimension and cell (“pixel”, “voxel”) type. In the earth sciences, for example, we find 1-D sensor time series, 2-D satellite images, 3-D x/y/t image time series and x/y/z exploration data, as well as 4-D x/y/z/t climate and ocean simulation data. Queries on them can rely on use case scenarios which are practically motivated, related to hi-tech appealing to students, and lead to query results that can immediately be verified visually. Actually, this work to some extent is a spin-off from ongoing standardization activities by the German partners where, for the Open GeoSpatial Consortium (OGC) Web Coverage Processing Service (WCPS) standard developed by Jacobs University; a demonstration site with a hands-on sandbox has been established at [10].

At the same time, the information category of raster data is so generic that use cases can be found in many domains beyond geographic applications. Other areas include topics as diverse as diverse human brain imaging, gene expression analysis, radio astronomy and cosmological simulations, and even psychology (where our current research addresses quantitative emotion analysis).

IV. RASQL OVERVIEW

The conceptual model of rasdaman centers around the notion of an n-D array (in the programming language sense) which can be of any dimension, spatial extent, and array cell type. Arrays are functions f:$D \rightarrow V$ from some domain D, which is a subset of d-dimensional Euclidean space $\mathbf{Z}^d$, into some value set V. A rasdaman database can be conceived as a set of tables where each table contains a single array-valued attribute, augmented with a system-generated object identifier suitable for foreign key references (Figure 1).

The rasdaman query language, rasql, offers an algebra-based query language [4] which extends standard SQL92 with declarative MDD operators suitable for a wide range of signal processing, imaging, and statistical operations. Server-based query evaluation relies on extensive logical and physical optimisation and a streamlined array storage manager [3]. Fro a teaching perspective, therefore, all conventional (i.e.: known from SQL) query language principles can be found and discussed.

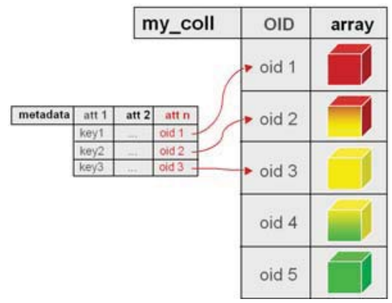

Figure 1. The rasdaman conceptual array model

A. *Raster Retrieval*

We introduce rasql only briefly, with a walk-through guided by didactics rather than by completeness; see [1] for a more comprehensive and formal treatment.

Like SQL, a query returns a set of items (in this case: either arrays or, for summarization queries, scalars). *Subsetting* of arrays includes *trimming* (rectangular cutouts) and *slicing* (extraction of lower-dimensional sub-arrays). The following query retrieves a 2000x3000 cutout from every Landsat satellite image in collection `LandsatImages`:

```
SELECT ls[ 1001:3000, 1001:4000 ]
FROM   LandsatImages AS ls
```

This works for any number of dimensions, and also allows wildcards to refer to the array boundaries. Let us assume that `ClimateCubes` contains 4-D cubes with time being the first dimension. The following query, then, extracts a 3-D spatial volume at time step 1020:

```
SELECT cc[ 1020, *:*, *:*, *:* ]
FROM   ClimateCubes AS cc
```

For each operation available on the raster cell type, a corresponding so-called *induced operation* is provided which applies the base operation to all cells of an array simultaneously. Both unary operations (e.g., record access, cast operations, or constant multiplication for contrast enhancement) and binary operations (e.g., masking an image) can be induced. An example is "*Band 3 of all Landsat images, with intensity reduced by a factor of 2*":

```
SELECT (char) (ls.band3 / 2)
FROM   LandsatImages AS ls
```

Not only arithmetic, but also boolean operators can be induced. Figure 2 (left) shows the three visible bands of a satellite view on the South Spanish coast. The query below masks out all non-green pixels from this image; the boolean result of the parenthesis expression is interpreted as 0 or 1, resp., so that a *false* value maps to black and a *true* value retains the original color value:

```
SELECT (    ls.green > 130
        AND ls.red   < 110
        AND ls.blue  < 140
       ) * ls
FROM   LandsatImages AS ls
```

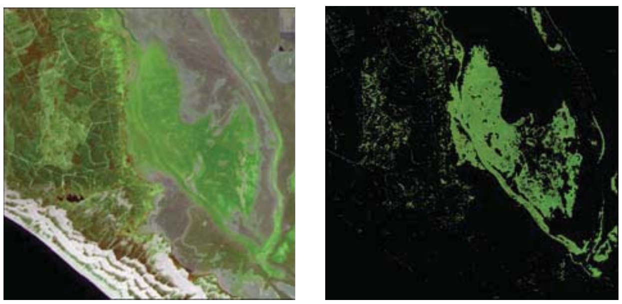

Figure 2. Landsat scene (left) and green detection (right)

In general, array expressions can be used in the `SELECT` part of a query and, if the outermost expression result type is boolean, also in the `WHERE` part. Therefore, we need a means to ”collapse” raster-valued expressions, such as induced comparisons, into scalar boolean values. This is accomplished through so-called *condensers* which summarize over the array values, representing the counterpart to SQL aggregation. Based on a higher-order generalized construct the usual aggregates are defined, such as *count*, *average*, *min*, *max*, *all*, and existence quantifiers. For example, the following query retrieves the “*percentage of green area per region in Landsat scenes*”.

```
SELECT   count_cells( ls.green > 127 and r )
       / count_cells( ls and r )
FROM   LandsatImages AS ls, Regions as r
```

The `MARRAY` operator constructs a new array with some given extent and a contents determined by a scalar expression used to assign a value into each raster cell position. To this end, it defines locally scoped cell coordinate iteration variables. For example, a 256x256 checker-board array can be defined as

```
MARRAY x IN [0:255], y IN [0:255]
VALUES mod( x + y, 2 )
```

In practice, `MARRAY` frequently appears in conjunction with condensers. The following example illustrates this, deriving a histogram from 16-bit brain scans of unknown dimension:

```
SELECT MARRAY n IN [0:16535]
       VALUES count_cells(b) = n
FROM   BrainScans AS b
```

Advanced applications of this pattern include filter kernels, general convolutions, up to the Fast Fourier Transform. Interesting parallels also can be found to the relational GROUP BY / HAVING clause. A theoretical analysis of the expressiveness and complexity of array indexing expressions is given in [4].

In contrast to alphanumeric query results which can be readily printed, raster results need to be encoded for display. The following query delivers spectral band 3 from all Landsat images, encoded in JPEG:

```
SELECT jpeg( ls.band3 )
FROM   LandsatImages AS ls
```

B. *Storage and Processing*

The storage model adopted by rasdaman is based on multidimensional *tiling*, i.e., a user-definable decomposition into rectangular sub-arrays of suitable size (Figure 3). Tiles are stored as BLOBs (binary large objects, i.e.: linearized byte arrays) in a standard relational database system, such as PostgreSQL.

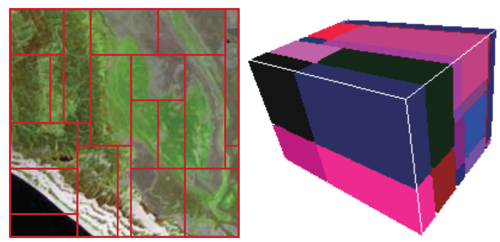

Figure 3. Sample 2-D and 3-D tiling

Query processing relies on *tile streaming*: operator tree nodes read data tile by tile, process them, and pass on result tiles to the next higher node. This way, arrays of unlimited size can be processed without limitations imposed by server main memory. See [3] for further details.

C. *Front-End Tools*

For the purpose of our experiment, two tools have been provided. *Rview* is a graphical-interactive tool which allows submitting queries typed into a text window, retrieving result sets, and visualizing them in various ways, including 1-D charts, 2-D tables and images, and 3-D animations. The *rasql* tool allows submitting queries via command line and store results in files or, alternatively, output them directly to the console. Especially the latter feature, in combination with an ASCII output format, allows inspecting particular data values in detail and with Unix tools well known to the students at this stage.

V. EXPERIMENT EVALUATION

In order to describe the experiment, we first situate the database course in the CS and CE curriculum and next discuss the students’ academic and work profile.

The experiment of reorganizing the database course was conducted during 4 months (from March to June 2009) in a 90-hour undergraduate introductory database course. This course is organized in 6 hours per week, of which 2 are for hands-on exercises and the other 4 dedicated to theoretical classes.

In the first semester of 2009, this course was offered to a class of 65 students in the evening. The Institute of Computing offers both day and night computing courses. The night course offers a bachelors degree in Computer Science; the day course offers a degree in Computer Engineering. The contents of most computing related courses are the same, though CE has many more credits to cover engineering requirements. In particular, the database course is offered on the fourth or fifth semester of both degrees, and students have already taken courses on programming, data structures and operating systems.

Academically, day and night students are very similar – university entrance examinations are very competitive at UNICAMP, and are conducted on a country-wide basis. Every year, acceptance rate for CE and CS is between 20:1 and 25:1 (though in the beginning of the nineties the competition was as high as 35:1). Hence, only very good students are accepted in our courses.

On the other hand, the profile of students who take night classes is very different from those in day classes. First, most students are employed, and even though in the same age range as day students (e.g., between 18 and 23) they are usually more mature and take their course work more serious. Second, they have a more practical mindset, in the sense that they are always looking for ways to apply what they are learning to solve problems they are facing in their jobs. Finally, since courses take place from 7 to 11 PM every day, plus Saturday mornings, lecturers have to work hard to keep students interested. In this sense, rasdaman exercises were a big success – the students had never experimented with such a system, or worked with such examples (at work or school) and were noticeably motivated by the new kind of exercises. This was also indicated in their answers to the questionnaire – all said they would be willing to participate in similar rasdaman experiments in the future (last question of the questionnaire).

The course material was reorganized in three stages. Eight percent of the 90 hours allotted to the course were occupied exclusively by introducing rasdaman – roughly, 3 hours of theoretical issues and 4 hours of hands-on exercises. Additional hours of graduate level material were also taught, to provide the theoretical basis on non-standard database management issues and multi-dimensional data. From the start, students were told that the course would be "different", i.e., that besides covering the required material they would use a new kind of database system, and that they would be experimenting with novel applications.

First, students were introduced to the basics of database management systems. This was accompanied by motivation on how database systems are needed (and profit from) other subjects, such as VLSI design, climate modeling and astronomy. Here, the notion of raster data structures was also introduced, preparing the ground for the use of rasdaman.

This first half of the course comprised the subjects involving user-related external issues (i.e., database design and querying formalism, see Section II). Each subject was accompanied by practical exercises. Students also had to develop a set of small database applications (in PostgreSQL [5]), to familiarize themselves with database creation and query specification.

Next, students were presented with the internals of database management systems, especially query optimization and transaction management. At the same time, additional material was presented, covering rasdaman basics [3]. First, there was an introduction to the rasql language, showing how it supported queries to raster data. Basic database material seen in the first half of the course was revisited during this stage, showing how it could be used to solve problems in scientific data handling - e.g., in environmental control, image analysis in health studies and in biodiversity. This was accompanied by hands-on exercises on examples of rasql.

Finally, they were introduced to rasdaman architecture, which was compared with the architecture of standard DBMS. For instance, they were shown how query processing in rasdaman was just an instance of DBMS query processing, with adaptations to support vectors and matrices. Further experimentation on rasql was introduced at this stage.

Each exercise was followed by challenges, e.g., asking the students to pose variations of an initial problem. Exercises grew in complexity, starting with simple one-dimensional data handling to processing movies and data cubes (e.g., of geological data, or temperature time series). The tasks to which the students were exposed included the following challenges:

Challenge 1: What is the difference in terms of the result structure of these two queries?

```
SELECT b                  SELECT avg_cells(b)>10
FROM   BrainScans AS b    FROM   BrainScans AS b
WHERE  avg_cells(b)>10
```

The first query obviously would return a subset of the stored images while the second one would return one scalar boolean value per image. Result visualization made the students aware of the data structures generated during query evaluation and allowed them to visually compare the results.

Challenge 2: Generate an array as shown in Figure 4.

A possible answer is this query:

```
SELECT MARRAY x IN [0:10],
              y IN [0:10]
       VALUES (y > x)
FROM   rgb
```

This shows how coordinate positions can influence a cell's value through index arithmetics and, at the same time, highlights one of SQL's issues: no result can be delivered without indicating a table, even if this table is not used for the result.

Challenge 3: Generate the result shown in Figure 5 (right) for a given circle center (x0/y0) and radius (r).

	0	1	2	3	4	5	6	7	8	9	10
0	0	0	0	0	0	0	0	0	0	0	0
1	1	0	0	0	0	0	0	0	0	0	0
2	1	1	0	0	0	0	0	0	0	0	0
3	1	1	1	0	0	0	0	0	0	0	0
4	1	1	1	1	0	0	0	0	0	0	0
5	1	1	1	1	1	0	0	0	0	0	0
6	1	1	1	1	1	1	0	0	0	0	0
7	1	1	1	1	1	1	1	0	0	0	0
8	1	1	1	1	1	1	1	1	0	0	0
9	1	1	1	1	1	1	1	1	1	0	0
10	1	1	1	1	1	1	1	1	1	1	0

Figure 4. Task input for generating given data patterns

Figure 5. Extracting geometrically defined areas

The expected answer is a query like this one:

```
SELECT rgb *
       MARRAY x IN [0:199],
              y IN [0:199]
       VALUES (sq(x-x0) + sq(y-y0) < sq(r))
FROM   rgb
```

During this part of the classes, several students suggested the use of rasdaman to help teach calculus and linear algebra. They proposed examples of its use in such classes, and were excited at being able to connect the contents of a database course with the more theoretical subjects they had seen the previous year.

Handling images and movies was also another source of interest. Several of them were familiar with movie editing tools, but never from a purely mathematical point of view. Though all were aware of images as 2D and movies as 3D objects, they had never practiced slicing and dicing frames – especially using a database framework. Details on course material for the rasdaman classes appear in [13].

As we all know, hands-on exercises are the most efficient form of learning. However, students mostly see such exercises as a means to practice course material, and are seldom able to see how courses can interconnect. Here, they not only experienced working with a database. To solve the exercises, they had to recall (and thus make the mental links to) notions in linear algebra, boolean algebra, calculus and physics. For instance, in the questionnaires one student commented that for the first time he understood how equations work in practice.

The appendix shows the questionnaire filled by the students. In the original questionnaire, all questions were accompanied by answer options (e.g. "YES, explain why"; "NO, explain why not"). These options have been omitted for the sake of brevity, and only the questions have been included.

All students said they had never seen any database system that was similar to rasdaman – including those that said they had already worked with maps, but never with multidimensional raster data management. They all said the classes were interesting, and 90% would be willing to participate in further exercises. Most said that this system could be used in other courses (examples cited included mathematics, physics, operating systems and image processing). Half of the respondents said that there should have been more of the internals covered, so they could understand "how it works".

Twenty percent of the respondents said that they thought this kind of topic should be left to advanced undergraduate courses. Interestingly enough, those who gave this opinion work as database administrators or database programmers. Thus, they looked at the course from an immediate, vocational view (which is not the main focus in UNICAMP teaching approach).

One of the course's exams also contained one question on rasdaman, asking students to describe its main characteristics and functionality. The idea was not to check whether they knew rasql syntax, but to see how they would describe the system's capabilities. Twenty percent of the students did not answer this question (a few said they had not gone to the hands-on classes). The majority correctly identified the possibility of managing raster data, with examples of what they had seen in class.

VI. RELATED WORK

This section discusses related work in teaching databases and in introducing multidisciplinarity in CS courses.

Curricular issues in computing are now treated in terms of Grand Challenges by joint ACM and IEEE education committees [14]. One of the problems is that computers and computing basics are used in all domains, and there is a need for approaching subjects at distinct levels of complexity and for all kinds of majors – from the Arts and Humanities to Engineering. One consequence of this ubiquity is that CS and CE majors now have to think in a multidisciplinary context, applying what they learn to problems in other domains. However, this requires major curricular modifications, and (re)training lecturers to teach traditional subjects establishing links with other areas.

Multidisciplinarity is being moreover seen as a solution to another problem afflicting CS and CE degree-offering programs – the decrease in student enrollment and the number of drop-outs. This second problem has given rise to the appearance of many new degrees – e.g., [15] – and to new ways of teaching computing, often emphasizing human and social aspects [16]. Multidisciplinary teaching has been established as one of the priorities of the Brazilian Computer Society as a prerequisite to training the future generations of professionals and researchers [17]. Our experiment in teaching databases has gone in this direction, showing students how to deal with problems arising in other domains by working with database concepts.

Within this multidisciplinary context, data management is seen as a primary concern, for professionals and researchers alike. If Computer Science is considered to be the "third pillar" of scientific research (along with the pillars of theory and experimentation), then data concerns the fourth one [18]. As exemplified in Section II, subjects covered in database courses can be linked to several other computing subjects. Moreover, as practiced in our course experiments, database-related issues can be used to support the solution of problems in other disciplines. For this reason, database courses present a very good starting point for implementing curriculum modifications.

Given this role of databases in curricular content, there have been many proposals for teaching this subject (e.g., [7], [8], [19], [20], [21], [22]). However, as mentioned by [19], educators face a dilemma when it comes to database education.

Indeed, database concepts have continued to expand, with the creation of many specialized database systems. Moreover, advanced topics of ten years ago have now become basic topics in many situations, especially with the advent of the Web. The latter is forcing computing courses to adapt to this new environment. Database projects have migrated from stand-alone applications to distributed Web-based platforms, which has been the case in our experiment, too –in the use of both PostgreSQL and rasdaman.

The survey conducted by [7] also points out in this direction – database courses are now adapting to cover scalability, and the need to accommodate Web-based skills. Advanced topics are also proposed by [19][21][22]. While [19] introduces advanced topics in a second course, and [21] and [22] propose a suite of courses to accommodate topics, we introduced multi-dimensional data management (a graduate subject) in the first basic course. Students were motivated by this change, though those who work with database systems were more concerned with the immediate application of course content to their daily jobs, and thus did not see the usefulness of learning advanced material in a first course.

Finally, other authors stress specific points of curricular issues involving databases. Some, like [23] or [24], emphasize the need for treating data security as a concern of all that deal with data management [22], or the importance of basics such as transaction management [24] to provide students with a solid conceptual basis for subsequent studies. Others, like [25], see database courses as a way to help non-majors in collaborative learning. In his findings, a database project immerses students in the solution of real-life problems, thereby better motivating the learning experience. Like [24], we stress basic principles and mechanisms, to subsequently show how they can be instantiated in other situations. Like [25], we consider projects to be a good platform to enhance collaboration. The latter was also observed during the rasdaman exercises: since they required remembering subjects from linear algebra and mathematics, several students would get together to solve the exercises. Security, on the other hand, is just mentioned in UNICAMP's course, being covered in advanced topics. However, it could well be introduced as part of a broader problem – that of ethics, nowadays a part of CS curricula.

Finally, it must be stressed that there is no such thing as "one size fits all". While this refers to the discussion in [26] of issues in teaching an introductory CS course, we firmly believe there are domain-specific requirements that cannot be accommodated in a single course. Moreover, student background and expectations have to be taken into account. Thus, our experiment can be replicated only in similar environments – i.e., for students taking CS or CE degrees which require a solid background in mathematics, plus data structures and programming. In particular, such courses will have to take the evolution of data structures into consideration. This is the point stressed by [27], showing how data structures are evolving to consider advanced access methods and parallelism. Computing education must continue to enforce basics, while at the same time emphasizing new kinds of computational thinking.

VII. CONCLUSIONS AND ONGOING WORK

This paper discusses an experiment in teaching database management basics at the undergraduate level by combining standard course material with advanced topics. Besides working on traditional exercises with database tables, students had to practice handling and querying scientific raster data. Exercises were motivated by problems found in other disciplines, especially geography, biodiversity, and physics.

The results of this experiment, analyzed both in course exams and via a questionnaire applied after the course, indicate that it was successful in several ways. First, students' motivation in practical exercises was enhanced. Second, they became interested in browsing Web sources for additional material, connected with other (non business-oriented) uses of database systems. Finally, all students gave very high grades to the usefulness and interest of the exercises with multi-dimensional raster data.

The latter findings are particularly interesting since this was an undergraduate night course in which 90% of the students already work in IT-related jobs (e.g., as programmers or systems analysts). Since exercises relied on data from scientific domains, we did not expect that students would rate them as highly useful, considering that they do not directly relate to their jobs. However, comments on the questionnaire say that they relate usefulness to (a) having learnt new concepts, (b) having understood that database systems are not limited to tuple-oriented transactions, and (c) having discovered that a database system can be used to practice other subjects, such as computational geometry or linear algebra.

We intend to extend this experiment to other semesters to obtain a broader basis on which we can build a more solid exercise base. This will require, moreover, preparation of more concise data sets so that students can conduct several small experiments in a single class on subsets of the same data, and compare results.

Additionally, we will carry out the same experiment at the German university involved to get a broader basis for evaluating our results.

Another extension is to use the same approach in other courses. The first author is adapting some of the material used to teach an introductory CS course to Arts students, in 2010. In this case, the emphasis will be on examples for handling multimedia, and rasdaman will be used as a tool, but not a system to learn database concepts.

APPENDIX: QUESTIONNAIRE

This appendix contains the questionnaire handed out to the students in both classes to obtain feedback on our approach.

This questionnaire on the classes you had about rasdaman is important for the planning of future offerings of the subject. It will also be used as a basis for a scientific paper. A summary of the main results will be sent to all respondents. Thank you for your collaboration.

Please answer all the questions. In doubt, answer "I have no opinion about this subject". Always answer in the space below the question. You can write as much as you want.

1. This kind of use of databases and DBMSs was new to you, or had you already seen something similar? If not new, please explain.

2. Were the classes on rasdaman useful in your training? Give an example of what you learnt towards this goal.

3. What were the highlights of the classes? And the main shortcomings?

4. Were there some topics that you think should have been covered?

5. Was the time alloted to cover the material adequate (3 classes – approximately 8 hours)? If not, how many hours would you recommend? [Why]

6. Was the number and type of classes adequate (1 theoretical class, 2 hands-on classes)? If not, what would you recommend? [Why]

7. Was the material used appropriate (PDF slides)? If not, what else should have been provided?

8. Do you think the material of these classes could also be presented in other courses? If yes, give an example.

9. Would you recommend we give these classes for the next offerings of the database course? [Why]

10. In an interval from 1 (minimum) to 5 (maximum), which grade would you assign to the rasdaman classes, considering the entire experiment (content, methodology, material)?

11. Would you like to participate in other activities using the same software?

Engineers and their practice: a case study.

***Abstract*— There has been a growing awareness of the need for models of engineering practice in recent years and the publication of The New Production of Knowledge [1] by Gibbons led to considerable attention being focused on two distinct modes of knowledge production: Mode 1 associated with a traditional academic discipline-based approach and the more recently-emerged Mode 2, a problem-focused process more common in the entrepreneurial sphere.**

The case-study reported here originally set out to use Gibbons' models to characterize the work of a group of Portuguese engineering researchers over a 15-year period. The study employs a qualitative methodology and narrative approach to characterize practice within this group of engineers so as to look for appropriate lessons that can be applied to engineering education to better prepare future professionals.

Analysis of the information gathered during the study has caused us to question our original model of engineering practice and leads us to the conclusion that the Unifying Model recently proposed by Trevelyan [2] could represent a better fit to characterize the activities of this group and would suggest a need to gather empirical data on engineering practice.

Keywords*: *Model, engineering practice, knowledge production, case study

I. INTRODUCTION

Engineering design often tends to be addressed in engineering schools from a post-positivist perspective. This approach arguably produces professionals best prepared for the classic industrial age when processes were more stable and durable than they are today or will be tomorrow. With globalization and the development of new communication technologies the production of knowledge has naturally moved from a linear, explanations-oriented model to one which revolves around networked innovation in a solutions-oriented world and in general we can say that the practice of engineering design in industry and academia have been getting closer. The publication of The New Production of Knowledge by Gibbons et al in 1994 [1] led to considerable attention being focussed on two distinct models of knowledge production, identified by these authors as Mode 1 (associated with a traditional academic discipline-based approach) and the more recently-emerged Mode 2 (a context-driven and problem-focused process more common in the entrepreneurial sphere). The differences between these two approaches as recently characterized by Figueiredo and Cunha [3] are summarized as follows:

TABLE I. PARAMETERS ASSOCIATED WITH GIBBONS' MODES 1 AND 2 OF KNOWLEDGE PRODUCTION

	Mode 1	**Mode 2**
Context	academic, scientific	economic and social applications
Innovation	linear	problems are set and solved in the context of application
Community	disciplinary, homogeneous teams, university based	transdisciplinary; networked; heterogeneous actors
Orientation	explanation, incremental	solution focussed
Method	repeatability is important	repeatability not vital (there may be secrecy/copyright issues)
Quality assurance	peer-review is central	context dependent: may involve peer-review; customer satisfaction
Definition of success	scientific excellence	efficiency; satisfy multiple stakeholders: commercial success

It is often assumed in the literature that engineering design is at the heart of engineering education and is what distinguishes it from other scientific areas within higher education [2]. However, although the practice of engineering design in academia and industry have tended to converge towards a Mode 2 approach, as yet there is relatively little evidence that this has been accompanied by corresponding developments in the engineering education. Jorgensen [4] argues that educational reforms have tended to focus on the development of Mode 1 model leading to a "crisis in engineering design" with "new professional groups taking over the core and more radical design tasks in companies" and he claims that "this change seems to reduce the classical engineering design departments to focus on incremental innovations and maintaining the existing products and production lines." He suggests there is a need for a re-thinking as to the "missing elements in engineering teaching" so as to prepare future professionals to face the challenges arising from contemporary technological innovation. To better understand the practice of today's engineers and its implications for education it was decided to focus initially on one national company.

In 2009 the US-based consultancy firm, Strategos, polled 186 CEOs and senior figures in leading Portuguese companies to gather data on which international and national firms they considered to be the most innovative [5]. The national company with the highest vote was YDreams, a recent startup which was created in 2000 when a group of engineers from a successful university research department at a Lisbon university felt the need to move from a university to an entrepreneurial context. YDreams has since had considerable national and international success in the areas of interactive spaces.

The authors decided to begin a pilot-study of the YDreams team to trace their historical development and see what lessons could usefully be drawn for engineering education by studying the knowledge production and practice of such an innovative organization. The key engineers in this startup were originally part of a successful university research department at the New University of Lisbon throughout the 90's in the field of environmental engineering and IT. Their Environmental Systems Analysis Group (GASA) was known for its pioneering work in a field that has since become dominated by Google Maps. In 2000, frustrated by the limitations encountered within the academic system, they effectively set aside the projects they had been working on and dedicated themselves to an entrepreneurial start-up. Their YDreams Company has since come to enjoy considerable international success in the interactive space and ubiquitous computing sectors (http://www.ydreams.com/).

A. Research questions

Is the Gibbons Mode 1, Mode 2 model appropriate to characterise the engineering practice of this group of engineers?

What can we learn about engineering practice in an innovative startup company by interviewing key players in its history?

II. METHODOLOGY

The initial methodology chosen employed what Cresswell refers to as an exploratory qualitative design [6]. This methodological approach has been used successfully in social science research for some years and has more recently also come to be adopted in engineering education research, usually as a prelude to quantitative methods within a mixed-methods methodology [7].

Accordingly, Gibbon's Mode 1 and 2 Model of knowledge production (and engineering design) were used as a basis for interviews with two of the founders of the firm and the narrative data obtained was analysed qualitatively, guided by the work of Czarniawska on narrative research methods [8].

Separate lightly-structured interviews were carried out with two senior members of the group involved in both phases: António Câmara, CEO of YDreams and former head of the GASA group and Edmundo Nobre, YDreams administrator (CFO) and co-founder. The interviewees were previously sent a brief summary of the intended case-study, which included Table 1, and invited to relate their experiences in individual interviews; they were not given specific questions to answer but rather encouraged to relate their practice in the context of the GASA research group and contrast this with their current activity in the entrepreneurial context of YDreams.

The interview transcripts were then analysed for material relevant to the Mode 1 and 2 parameters and organised under the relevant headings set out below. Subsequently a bracketing process [6] was applied to these first extracts and the transcripts were scanned for additional references to engineering practice. This produced two further observations and these are included in the Discussion section.

All extracts quoted in the paper were translated from the original Portuguese transcripts and subsequently checked for accuracy with the interviewees.

III. RESULTS

The interview data has been structured here using the Mode 1 and 2 parameters. The corresponding characterisations are summarised in the boxes at the beginning of each section with Mode 1 on the left in each case.

The narrative information relating to the university context is set out first and after that the same organizational structure is employed for the extracts describing the entrepreneurial context.

A. University Context: GASA

1) Context

academic, scientific	*economic and social applications*

António Câmara (AC): Well, we were engineers but we were doing work that was engineering/science where we were essentially emulating the approach of the physical sciences, and not really engineering as such.

(Edmundo Nobre) EN: Environmental engineers have always had a wide-ranging approach by the nature of their very general training.

AC: University groups tend to follow the logic of academia and academic publication and we had a lot of people working on theories of interaction in a way largely oriented to emulating the sciences rather than developing products. We were creating new worlds but following an existing academic model.

2) Innovation

linear	*problems are set and solved in the context of application*

AC: For example, Conservation International, which has Harrison Ford as its vice-chair, was looking for a visualization system to represent the impact of forest fires on Amazonia and resulting climate change. We submitted a proposal based on our visualization models whereas MIT Media Lab presented a demonstration created by the people who had done the special effects for the film Titanic. The difference being that they already had an operational prototype, a finished product, while we had only a complex model. So, obviously, Conservation International chose them and this episode really got us thinking, made me alter my own perspective quite radically and made me realize that however good our work was technically, we were never going to get very far in today's world using an academic approach.

So while our thinking was "ride the wave", Media Lab was aiming to "put man on the moon" and in the university context it was extremely difficult to create any kind of multidisciplinary laboratory like they had, almost impossible in fact, because there were all kinds of barriers stemming from the fact that we worked within academic disciplines. So, when we worked in the Environment Department we were expected to be dedicating ourselves to working on the environment, even if we were able to come up with something useful for automobiles ....

3) Community

disciplinary, homogeneous teams	*transdisciplinary; networked; heterogeneous actors*

AC: It was basically research work and recognition came from other researchers. In other words, our community was that of investigators the world over within our area.

EN: We were always in contact with the best work going on internationally and made a point of encouraging our graduates to go to work at the top research centers. They in turn often stayed on and tended to cite our work which gave us more visibility.

AC: Then at a certain stage we came up against other communities, ones like MIT, not the traditional scientific community, who were leaders in the field and this was something of a shock for us.

4) Orientation

explanation, incremental	*solution focussed*

AC: At GASA it was basically the kind of scholarly approach to which the majority of university courses here aspire; which means that they were very much built around knowledge, scientific knowledge, stabilized knowledge.

EN: We had the first virtual reality lab in Portugal, created for Expo 98 in Lisbon, complete with a set of instruments that were groundbreaking in world terms at that time in the area of over land navigation. We were the first country to have this infrastructure set up but it dwindled out, because policy-wise its value wasn't recognized. It was an over-ambitious project, probably ahead of its time, and like so many other breakthroughs within universities because there isn't an entrepreneurial or commercial perspective then things get bogged down and bit by bit come to a halt.

5) Method

repeatability is important	*repeatability not vital*

EN: Our objective at that time was to produce papers whereas we came to see that at other centres like MIT the object was more to produce enterprises and so they had an applied research approach and received a lot of financial support from industry.

Now MIT had funding to buy super-computers whereas we here could only invest in people, people who were capable of developing powerful algorithms which allowed us to overcome our less advanced hardware and what we achieved was certainly on a par with the best we saw at international level.

6) Quality assurance

peer-review is central	*context dependent: may involve peer-review; customer satisfaction*

AC: We were, of course, very aware of ISI indexing (…) and getting our work accepted for major conferences which are extremely competitive, with an acceptance rate of around 3%.

7) Definition of success

scientific excellence	*efficiency; satisfy multiple stakeholder, commercial success*

AC: What we basically wanted was to achieve worldwide recognition within the academic milieu through papers, articles and later books.

B. Entrepreneurial Context: Ydreams

1) Context

academic, scientific	economic and social applications

AC: I realized that to be competitive with the top laboratories in our field we would need to have professional level management, accounts, public relations … in short to have an enterprise-like structure.

EN: We had come to the conclusion that if we couldn't do what we aimed to do within the academic system then we would have to do it on the outside; so basically we went ahead and set up the company.

EN: When we first set up YDreams, the wide-ranging background of our team stood us in good stead. Now this transdisciplinary approach has paid off and in fact we have people who originally trained as environmental engineers holding down key positions in accounts, programming and project management.

Whereas in our GASA days we used to play around with ideas and ask "OK, how could we get this on the market?" now it was more in a case of "OK, how can what we do that will be important for the market?"

2) Innovation

linear	problems are set and solved in the context of application

EN: We have our R&D section, YLabs, which has a variety of functions and these include:

assisting in developing the technological infrastructure for the company itself

short-term research focused mainly on product development for our clients

long-term research which is looking to identify future paradigm shifts so that we can be right there when things are happening. In this respect, I would give the example of our work on interactive spaces which up to now has been entirely in the digital domain but as this sector has become successively more the province of large international competitors, we have to be agile and so we have been working on the application of recent innovations in materials sciences and bubble-jet technology to apply our knowhow to the development of novel interactive spaces in the physical domain.

3) Community

disciplinary, homogeneous teams	transdisciplinary; networked; heterogeneous actors

AC: Now I would say that our community is completely different: we do what we do so as to satisfy two groups of people: our clients and our investors.

4) Orientation

explanation, incremental	solution focussed

EN: We set out to adapt our practice from the GASA days to create a structure which was much more dedicated to industry, with a strong focus on applied research, one which would in turn be supported by industry. Our focus was to be on the real world products rather than on publications. We aim to be a cutting edge company.

5) Method

repeatability is important	repeatability not vital

AC: Now it really feels like we are doing engineering design and that we have left the world of classic research. One consequence of this is that now when we produce something new our first priority is to take out a patent and if we have time afterwards we may write it up in a paper. So this changes the dissemination process quite radically.

In the company we have continued to carry out research, the difference being that now we are very much more in the Man on the Moon mould. Now we really want to create products and the objective of all our research, pure or applied, is precisely product-focused. We are not at all interested in repeatability – we want to be unique, that's what it's all about!

6) Quality assurance

peer-review is central	context dependent: may involve peer-review; customer satisfaction

AC: So we are creating intellectual property, very important to appeal to clients and this has been fundamental in attracting investors in the various phases the company has gone through. To be competitive we have to bring value to the market.

7) Definition of success

scientific excellence	efficiency; satisfy multiple stakeholders; commercial success

EN: We originally wanted to leave academia and conquer the world! Success for us has two dimensions: obviously we want to become millionaires (laughs) but on the other hand we would like to be a company which helps give Portugal a strong international technological presence on a par with, say, what Nokia has in Finland. That is a company which altered their national panorama and we would like to think we could one day make a similar claim, that is to really make the difference between what Portugal is today and what it could achieve tomorrow – help to create a technology driven nation.

IV. Discussion

The data presented suggest that, although the Mode 1 and 2 characterizations can be seen as useful here to characterize in a broad sense the knowledge production activity of the group of engineers in question and to help us accompany what seems to have been a significant phase change in the work of the group, they should not be seen as an either/or way of describing the real-world activity involved.

In addition, having bracketed the previous extracts, a rereading of the interview transcripts threw up some additional comments, which led us to rethink our original model of engineering practice and reexamine our concept of what engineers actually do:

EN: Right now, I recall off the top of my head that our head of Quality, head of Research, head of Software, our top programmer and the account managers of our best accounts all come from an environmental engineering background and this pluridisciplinarity, the capacity to handle a broad sweep of areas is very valuable in a company like ours. These roles involve heading up teams where skills of dealing with both a range of multidisciplinary projects and with their commercial aspects are vital. Obviously when we get to the execution, programming, design and so on then we will call upon our specialized people for these very specific functions.

AC: What worries me is that engineering courses in our national universities don't have a tacit curriculum like you

can find at top international institutions: our graduates have the technical skill; they can solve problems but are not good at explaining them. One feels they were well trained in problem-solving but at the expense of important skills like analyzing, communicating and debating which contribute to the kind of structured thinking we need.

Noting that a significant number of engineers in the company were in posts of responsibility outside conventional engineering domains and that the CEO identifies communication skills as a priority for success, has lead us to see limitations in our original model of engineering practice which was based around engineering design and knowledge production and encouraged us to look for alternatives, particularly for models based on an empirical approach. Although the vast majority of literature on engineering practice tends to view it in terms of design or technical problem-solving [9, 10, 11, 12, 13] such models are rarely based on empirical studies analyzing what engineers do.

A model proposed by James Trevelyan of the University of Western Australia in 2009 does however address these issues [3]. The Unifying Model of Engineering Practice sees engineering as social system involving a sequence of steps common to most engineering activities and which are enclosed within a scaffold that continually guides the implementation steps towards the intended objectives. The scaffold in turn involves continual interaction between all the participants, including the client, financiers, engineers, contractors, suppliers, production and service delivery workers, technicians, regulators, government agencies, local community and special interest groups. This model grew from a longitudinal study of engineering graduates in Australia [14, 15] which showed that the majority spent less than 30% of their working time on specialized problem-solving and technical coordination emerged as the most frequently mentioned activity. The study found that graduates asked to estimate time spent on different aspects of their work estimated that nearly 60% of their time is spent interacting with other people, including working face to face, meetings, correspondence, reports and working with human-readable data in information systems and this finding would tend to give weight to Antonio Câmara's comment on the importance of communication skills.

V. Conclusion

To quote Trevelyan: "Engineering works. It could work better, however, with improvements in education and an identity in which the social and technical embrace each other with equal prominence." [3] Accordingly it is important to have empirical data on the activity of engineers in successful companies so as to achieve a good alignment between engineering education and the needs of future engineers and their employers.

Our current research, carried out in collaboration with the University of Western Australia, involves empirical data collection from engineers in YDreams and other firms considered innovative in the Portuguese context to see to what extent the Australian data and the Unifying Model are relevant to the southern European context and how this model can help adapt engineering education to the needs of tomorrow.

***Abstract*—Related to the notion of derivative of a function, its application to function optimization is an interesting and illustrative problem for Engineering students. In the present work, we develop an application of the derivative concept to optimize the filtering of a colour image. This implies to optimize the value of the filter parameter to maximize performance. We propose to maximize the quality of the filtered image represented by the *Peak Signal to Noise Ratio* (PSNR), which is a function of the filter parameter. The optimal value for the parameter is obtained by means of an algorithm based on the approximation of the derivative of the PSNR function so that finally the optimum filtered image is obtained.**

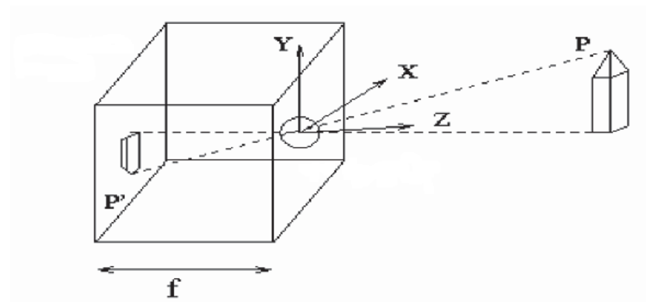
I. Introduction

Applications of calculus of maxima of one variable functions, presented to Engineering students, usually consists on finding the zeroes of a derivative which is expressed in terms of elementary functions. In some cases the numerical point of view of the calculus of this derivative is also considered. However, it is quite difficult to show a real and interesting application where the derivative plays a crucial role. In this paper we will see that the problem of optimizing an image by using colour image filtering can be reduced to the calculus of the maximum of a certain function called the *Peak Signal to Noise Ratio*.

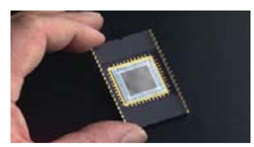
In Section II we will show some preliminaries about image acquisition and representation. Some basic notions about image filtering are also presented. The utility of fuzzy logic is introduced for filtering design. Section III describes the optimization algorithm based on the approximation of derivatives. Section IV shows simulation results, and conclusions are provided in Section V.

II. Preliminaries

An image is a $2D$ representation of the objects in a $3D$ scene which is obtained by projection of the $3D$ objects on an image plane. In digital cameras, this projection is obtained according to the pinhole camera model [1]-[3] (see Figure 1(a)): the objects, represented in a $3D$ space, are projected through a center of projection on the $2D$ image plane. The center of projection corresponds to the camera optics and the image plane is physically represented as a Charge Coupled



(a)



(b)

Fig. 1. (a) Scheme of the pinhole camera model: The object P, represented in the (X, Y, Z) space, is projected through the center of projection (camera optics) on the image plane (CCD) as the object P'. (b) A CCD sensor.

Device (CCD) sensor which captures the input radiation. The CCD sensor (see Figure 1(b)) comprises an array of $M \times N$ single light sensors. This implies that the acquired digital image is also an array of $M \times N$ single elements called *pixels* (from picture elements). In digital colour images, each pixel represents a single colour of the image. Colours are commonly represented in computers using the Red-Green-Blue (RGB) colour space. This colour space follows an additive model so that any colour is obtained by appropriately mixing the three primaries: Red, Green and Blue. Thus, each colour image pixel is associated with a tern of RGB values which represents the appropriate quantity of each primary colour that should be mixed to obtain the colour stored in that pixel.

Digital image acquisition process can be affected by many different factors able to degrade the quality of the image. For instance, deficient illumination conditions or CCD sensor malfunctions may introduce irregularities in the image also known as (Gaussian) *noise*. Other factors able to affect the

(a) (b)

Fig. 2. (a) Ideal noise-free image, (b) image corrupted with (Gaussian) noise.

image quality are, among others, transmission errors or storage faults. Figure 2 shows an ideal noise-free image and the same image contaminated with noise.

The presence of these irregularities, or noise, is not desired mainly for two reasons: (i) the perceptual image quality is lower, which is critical from the user standpoint, and (ii) the presence of noise is an important drawback for many tools of computer image analysis. Therefore, many techniques to reduce image noise have been developed in the recent years [2], [3]. Classical techniques to approach this problem are based on a linear approach. The Arithmetic Mean Filter (AMF) and the Gaussian Filter (GF) use an average operation among each pixel and its neighbours pixels [2], [3]. These methods are able to reduce image noise but they blur edges and details in the image too much. To solve this, a series of nonlinear methods were developed [2], [3],[4]-[8]. In general, these techniques are based on detecting image edges and details and smooth them less than the rest of image regions. In particular, the techniques in [5]-[8] propose to average each image pixel with only its neighbour pixels which are similar to it. Since it is difficult to differentiate between similar and non-similar pixels in a crisp way, it is more appropriate to assign a degree of similarity. The Fuzzy Bilateral Filter (FBF) [8] that we use in this work, employs fuzzy logic to assign this degree of similarity. According to fuzzy logic, the degree of similarity between two pixels is a value in $[0, 1]$ that represents in which degree two pixels are similar, where 1 means total similarity (equality) and 0 total dissimilarity. Since Lofti A. Zadeh introduced the theory of fuzzy sets in 1965, it has become a well-known area of study in the last decades. Fuzzy logic constitutes a generalization of the classical set theory which represents a gradual transition between the classical notions of outside and inside of a set. Fuzzy logic has been successfully employed in many engineering problems and many related research topics as, for instance, fuzzy topology and fuzzy metrics [9]-[13], are still active.

In most adaptive nonlinear filters, and also in the case of the FBF [8] that we use here, the smoothing capability can be tuned by modifying the values of their parameters. Thus, appropriate tuning is needed to achieve optimal performance. In this paper, we illustrate how derivatives can be used to find an appropriate setting of the λ parameter in the FBF filter. For a detail descrption of this filter, we refer the interested reader to [8]. For the purpose of this work, we just focus on the fact that the performance of the filtering process (output image quality) can be seen as a function of λ. Therefore, we propose to optimize the image quality measure represented by the *Peak Signal to Noise Ratio* (PSNR), which is a function of this parameter. The optimal value for the parameter is obtained by means of an algorithm based on the approximation of the derivative of the PSNR function so that finally the optimum filtered image is obtained.

III. Optimization algorithm description

The quality of a filtered image can be measured with several functions. In this case we will use the *Peak Signal to Noise Ratio* (PSNR) which, since the quality of the filtered image depends on λ, we define as a function of λ as follows:

$$PSNR(\lambda) = 20 \log \left(\frac{255}{\sqrt{\frac{1}{NMQ} \sum_{i \in \mathbf{F}} ||\mathbf{F}^o_{\mathbf{i}} - \mathbf{F}^\lambda_{\mathbf{i}}||^2}} \right) \quad (1)$$

where M, N are the image dimensions, $|| \cdot ||^2$ denotes the square of the Euclidean norm, $\mathbf{F}^o$ is the original noise-free image, and $\mathbf{F}^\lambda$ is the filtered image obtained after applying the FBF, respectively.

As mentioned above, we seek for the value of λ that achieve the optimum PSNR performance. To find it, we apply the following algorithm: First, we take an initial λ_0 for λ as a rough approximation to the optimum. For the current approximation to the optimum, λ_n, we approximate the derivative of $PSNR(\lambda_n)$ as

$$D(\lambda_n) = \frac{PSNR(\lambda_n + \delta) - PSNR(\lambda_n - \delta)}{2 \cdot \delta}, \quad (2)$$

where, $\delta > 0$. Now, we check whether the actual approximation to the optimum is already good enough: if $|D(\lambda_n)| < \epsilon > 0$, then the derivative at λ_n is small enough to conclude that it is very close to the optimum, and the method stops. Otherwise, we find the next approximation to the optimum λ_{n+1} from the previous λ_n as

$$\lambda_{n+1} = \lambda_n + \alpha D(\lambda_n), \quad (3)$$

where $\alpha > 0$ is called the learning parameter whose importance will be commented in Section 3, and the above procedure is repeated. Notice that, according to Eq. (5), the sign of $D(\lambda_n)$ indicates the direction in which the optimum is located and the *speed* in which the algorithm advances towards it is proportional to $|D(\lambda_n)|$.

IV. Simulation Examples

To illustrate the use of the derivative in the identification of the optimum λ for the FBF, the corrupted image of Lenna in Figure 2 (b) will be used. Figure 3 presents the PSNR computed for the image and the complete range of λ values.

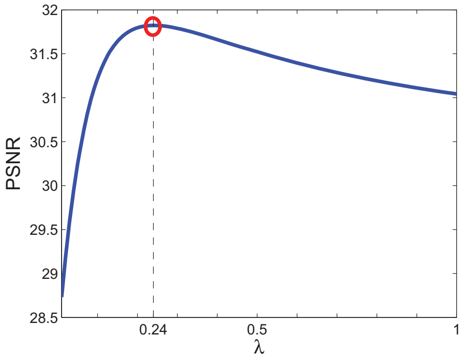


Fig. 3. PSNR curve for the complete range of λ values in the corrupted image of Lenna in Figure 2 (b).

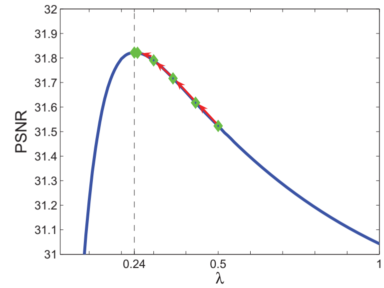

(a)

(b) PSNR = 31.80

Fig. 4. Optimization for initial point $\lambda = 0.5$ and $\delta = 0.01$, $\alpha = 0.05$ and $\epsilon = 0.1$: a) optimization steps, b) optimum filtered image.

This figure shows that the optimum filtering performance is attained for $\lambda = 0.24$. To compute this PSNR curve, it was necessary to filter the Lenna image one hundred times - from $\lambda = 0.01$ to $\lambda = 1$ in steps of 0.01. This is a valid but computational overwhelming method to obtain the optimum parameter. Furthermore, we only obtain the optimum with a certain accuracy which depends on the step used. To improve the accuracy we need to reduce the step, which in turn means to increase the number of times the image needs to be filtered. For instance, to reduce the accuracy in one order, it is necessary to increase by 10 the number of times the complete image is filtered.

An alternative to the extensive computation used to obtain Figure 3 is the derivative-based -or gradient-based- optimization treated in this paper. Let us illustrate the use of this method with an example. The optimization will be started from the central value $\lambda = 0.5$. The optimization parameters are $\delta = 0.01$, $\epsilon = 0.1$ and $\alpha = 0.05$. The evolution of the optimization is depicted in Figure 4(a). We arrive to the optimum filtering the image only 12 times - the number of approximations of the derivative (6) times the 2 applications of the filter per approximation (2 according to Eq. (2)). Furthermore, by reducing ϵ, the accuracy of the optimum can be improved with only a few more runs. The optimum filtered image attained is shown in Figure 4(b).

The convenient choice of the optimization parameters is of paramount importance to ensure convergence to the optimum. We have already commented that ϵ controls the accuracy achieved in the identification of the optimum. In this paper, we are considering the noise-free optimization case, so that we assume that the function to optimize -the PSNR curve- is free of measurement noise. If this is not the case, ϵ should be high enough so that it exceeds the noise level in the derivative estimation.

The three parameters, δ, α and ϵ, have interrelated effects. For the sake of easy understanding, the influence of the choice of δ and α will be discussed separately, varying the parameters one at a time while maintaining the other fixed. Let us run the optimization for δ values equally distanced in the logarithmic scale over [0.001, 1] and for fixed values of $\alpha = 0.05$ and $\epsilon = 0.1$. The results are presented in Table I. The lower the value of δ, the better the derivative estimation. This is again assuming the PSNR function to optimize is free of measurement noise - it is well known that derivative estimations are highly affected by noise. Since the derivative is more accurately estimated for low δ values, the optimization arrives to higher values of PSNR. Also, we can see that the value of δ is related to the number of points or λ values in the optimization where the derivative is estimated. The higher the value of δ, the lower the number of points. Notice that if δ is too high, the optimization algorithm may not converge to the optimum. The changes observed in the optimization method due to the use of different values of δ can be easily explained in simple geometric terms. If the current value of λ is far from the optimum, high δ values result in derivative estimations of high magnitude. Therefore, the optimization is speeded up and the number of points evaluated are reduced. If otherwise λ is close to the optimum, the optimum may be included in the interval $[\lambda-\delta, \lambda+\delta]$ where the derivative is estimated. If this is the case, the magnitude of the derivative is underestimated. The higher the value of δ, the higher the interval where this occurs and the further to the optimum we may converge.

Let us run the optimization for α values equally distanced in the logarithmic scale over [0.005, 5] and for fixed values of $\delta = 0.01$ and $\epsilon = 0.1$. The results are presented in Table II. We can see that the value of parameter α is especially important for the optimization. The optimization may easily diverge if the parameter is made too high. Nonetheless, for very low values of α, the number of points where the derivative has to be estimated is much increased. For instance, for $\alpha =$

δ	# points	Attained PSNR
$1 \cdot 10^{-3}$	8	31.822
$3.26 \cdot 10^{-3}$	6	31.822
$1 \cdot 10^{-2}$	6	31.822
$3.26 \cdot 10^{-2}$	6	31.822
$1 \cdot 10^{-1}$	5	31.815
$3.26 \cdot 10^{-1}$	4	31.634
1	∞	Divergence

TABLE I
RESULTS FOR DIFFERENT VALUES OF δ AND $\alpha = 0.05$ AND $\epsilon = 0.1$ WITH STARTING POINT $\lambda = 0.5$.

α	# points	Attained PSNR
$5 \cdot 10^{-3}$	55	31.822
$1.58 \cdot 10^{-2}$	18	31.822
$5 \cdot 10^{-2}$	6	31.822
$1.58 \cdot 10^{-1}$	29	31.822
$5 \cdot 10^{-1}$	∞	Divergence
1.58	∞	Divergence
5	∞	Divergence

TABLE II
RESULTS FOR DIFFERENT VALUES OF α AND $\delta = 0.01$ AND $\epsilon = 0.1$ WITH STARTING POINT $\lambda = 0.5$.

$5 \cdot 10^{-3}$, 55 derivative estimations were needed to arrive to the optimum. This means that the Lenna image had to be filtered 110 times, 10 times more than for computing Figure 3. The best α value, so that the algorithm converge to the optimum in the lowest number of points, depends very much on the initial point - initial λ value. As a general rule, α should be set high enough for a fast exploration while not too high to avoid divergence.

V. CONCLUSION

The use of real applications of Mathematics motivates the learning process of students in several ways. In particular, most mathematical notions can be explained by use of different models. In this work we have presented a simulation model which will allow the students to relate the notion of derivative of a function and one of its applications which is optimization problems. By the simulation process described in this paper, the students will approximate the optimal value of the parameter in a function and, moreover, they will really see how appropriate is the result of this algorithm since the visualization of the output images by using a filter technique will allow the students to search for better results. This application can be used in a first semester of Calculus either as a guided practice or as an accessible research project for advanced students.
